*a) Benefits:* Improved accuracy: By clustering data first, XGBoost can make more accurate predictions within each group.

Discovering Hidden Patterns: Clustering can reveal hidden patterns that were not visible in the raw data, allowing XGBoost to make better-informed predictions.

*b) Challenges:* Choosing the right number of clusters: Deciding how many clusters to use in K-Means can be difficult and may require testing different values to find the best result.

Increased computational complexity: Combining K-Means and XGBoost can be computationally expensive, especially for large datasets, as it requires running both clustering and multiple model training processes.

Combining K-Means with XGBoost is an effective strategy to improve predictions in complex and heterogeneous data sets. K-Means helps to organise the data and uncover hidden patterns, while XGBoost uses this information to make more accurate predictions. This approach is particularly useful in domains such as marketing, healthcare, and finance, where segmenting data can lead to more targeted and effective models.

## E. Clustering with K-Means

K-Means clustering was employed to group the data into 80 clusters. During the experimentation phase, several different values for the number of clusters to determine the optimal configuration for the data. Through this process, it became clear that 80 clusters offered the best balance between maintaining a manageable level of complexity and achieving a high level of classification accuracy. Therefore, after careful consideration and testing, 80 clusters were chosen as the ideal number, as they effectively captured the nuances in the data while optimizing the overall performance of the model. This thorough approach is one of the main reasons for settling on 80 clusters. Each cluster was analyzed for the percentage of obese students, leading to the classification of clusters into risk levels (high, medium, low). The data was then annotated with these risk levels.

Risk Level Classification (Obesity Risk Level (ORL)):

$$ORL \begin{cases} \text{High Risk} & \text{if Percentage of Obese Students} \geq 70\% \\ \text{Medium Risk} & \text{if } 40\% \leq \text{Percentage of Obese Students} < 70\% \\ \text{Low Risk} & \text{if Percentage of Obese Students} < 40\% \end{cases}$$

The classification of risk level based on the percentage of obese students is designed to reflect the severity of the health issue and highlight the influence of surrounding factors on obesity rates. Here is why it is divided in this way:

High Risk (70%): When the percentage of obese students is very high (greater than or equal to 70%), it indicates a severe issue, suggesting that the surrounding factors—such as those studied in this research, including parental weight and height, neighborhood safety, monthly income, and psychological factors—have a significant impact on individuals, potentially leading to a higher likelihood of obesity. In this case, these factors seem to play a major role in shaping the health outcomes of students.

Medium Risk ($40\% \leq x < 70\%$): At this level, the obesity rate is moderate, indicating that surrounding factors still have a considerable influence on students. This means that while not as severe as in the "high-risk" category, these environmental, social, and psychological factors still contribute to obesity, but perhaps to a lesser extent. Therefore, it is essential to address these factors to prevent further escalation.

Low Risk (<40%): When the percentage of obese students is below 40%, it suggests that the impact of surrounding factors is relatively less significant in leading to obesity. However, preventive action is still crucial, as factors such as parental characteristics, neighborhood conditions, and psychological well-being can still play a role in maintaining or reducing obesity rates over time.

To conclude, the higher the percentage of obese children in each risk category, the greater the influence of surrounding factors, such as those explored in this study, on individuals, potentially leading to obesity. This classification underscores the need for targeted interventions addressing these factors to mitigate obesity rates at different risk levels.

## F. Modelling with XGBoost

After that, the XGBoost algorithm is applied to train the model in the dataset. XGBoost is one of the most powerful machine learning algorithms and is based on the Gradient Boosting technique to progressively build multiple trees. Each tree corrects the errors made by the previous ones and, through this iterative process, the accuracy of the predictions improves with every new tree added to the model.

## G. Steps to Analyse and Classify Student Obesity Risk

This section provides a structured overview of the process used to analyze student data to identify and classify risk levels for obesity. The workflow includes data loading, preprocessing, exploratory analysis, data balancing, and the application of the K-Means clustering algorithm, culminating in user-specific obesity risk assessment.

*1)* These steps cover the entire process from data loading to user-specific risk assessment.

*a)* Data Loading and Exploration:

- Load Data: Import data from a CSV file and examine the structure, including data types and missing values.

- Exploration: Review the dataset to understand its composition and identify potential issues such as missing or incorrect values.

*b)* Data Processing and Transformation:

- Text to Numeric Conversion: Convert text data into a numerical format for easier processing.
- Data cleaning: Remove unnecessary data points and create new relevant features.

*c)* Exploratory Analysis:

- Correlation Analysis: Compute and display the correlation matrix between features to identify relationships between variables.
- Outlier Detection: Use the interquartile range (IQR) method to detect outliers in numerical features.
- Box plot: Visualize the distribution of numerical data and identify outliers.
- Bar plot: Plot categorical data such as gender and the presence of obesity to understand distributions.

*d)* Data Balancing:

- Apply SMOTE (Synthetic Minority Over-sampling Technique): Balance the dataset by increasing the number of samples in underrepresented categories.
- Post-SMOTE Analysis: Display the dataset distribution after applying SMOTE to ensure balance.

*e)* Clustering of K-Means:

- Cluster Formation: Apply the K-Means algorithm with 80 clusters to the weighted data of 694 samples. Through experimentation, 80 was determined to be the optimal number of clusters.
- Obesity Percentage Calculation: Calculate the percentage of obese students within each cluster and determine the corresponding risk levels.

*f)* Report and Analyze Results:

- Summary: Provide a detailed summary of the number of obese students and their percentages at different risk levels.
- Cluster Classification: Classify the clusters into predefined risk levels (High, Medium, Low) and display the data accordingly.

*g)* User-Specific Risk Assessment:

- Data input: Collect input data from the user.
- Risk Level Determination: Based on user input, classify your risk level of obesity using the K-Means model.

The objective of this process is to thoroughly analyze student data to uncover obesity patterns and identify risk levels. This involves examining various factors, such as birth date, sex, and other characteristics. By applying K-Means clustering, students are grouped based on similar characteristics, allowing us to better understand obesity trends and provide actionable insights for intervention.

*2) Apply XGBoost:* Once the data have been clustered, the next step is to develop a predictive model using the XGBoost algorithm. XGBoost is known for its high performance, making it ideal for handling large datasets and complex relationships.

*a) Data Preparation:*

Input data: Use the clustered data from the K-Means algorithm. The data, now organised into clusters, helps to reveal deeper relationships and structures.

*b) Model Training:*

Train XGBoost: Train the XGBoost model on the clustered dataset, feeding the input features and their corresponding target labels to learn patterns and predict results.

*c) Hyperparameter Tuning:*

Optimise model: Improve the performance of the model by fine-tuning key hyperparameters such as the learning rate, maximum depth, and number of estimators. This can be done using methods such as grid search or random search.

*d) Model Evaluation:*

Performance metrics: Evaluate the model using metrics such as precision, precision, recall, and F1 score to determine how well the model predicts obesity risk levels.

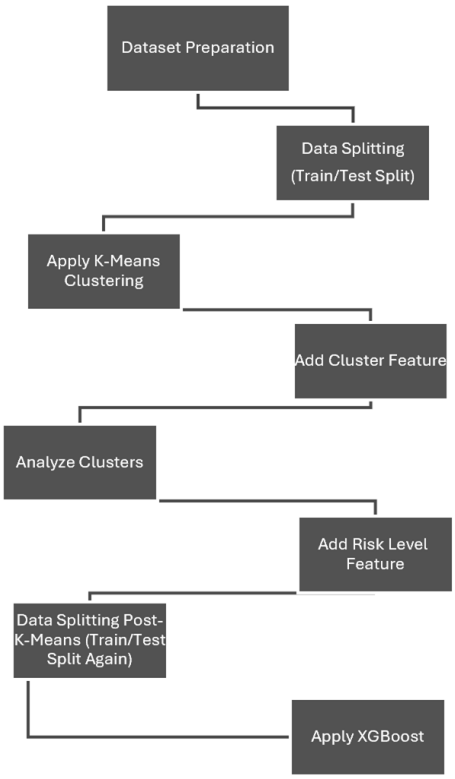

Fig. 3. Flowchart of the analysis process using K-Means and XGBoost.

As shown in Fig. 3, the process of applying K-Means clustering followed by XGBoost in the analysis of obesity risk. The flowchart highlights key steps such as data preparation, clustering, risk level classification, and finally, the use of XGBoost to build a robust predictive model. The diagram provides a clear view of how clustering is integrated with predictive modelling to assess the risks of obesity in students.

## IV. Experiments and Results

The primary objective of this analysis was to determine whether it is possible to predict childhood obesity based on environmental factors. The study aims to explore the relationship between a child's environment and the probability of obesity by applying machine learning models such as K- Means for clustering and XGBoost for predictive modelling.

### A. Overview of the Dataset

The dataset used for this study comprised 411 identified students, including 15 key variables related to both the child's physical characteristics and environmental factors. After applying SMOTE to balance the dataset, the number of samples increased to 694. The dataset includes the following key variables:

Mother's Weight (M_Weight), Mother's Height (M_Height), Father's Weight (F_Weight), Father's Height (F_Height), Appearance self-assessment (appearance_self), Body pride (body_pride), Neighborhood safety for jogging (neighborhood_jog_safe), Neighborhood safety for biking (neighborhood_bike_safe), Family's monthly income (family_income), Gender, Birthday, Obese Student (Obese_Student)

### B. Applied Models

The analysis involved the use of two main models:

*1)* K-Means for clustering students based on similarities in their features.

*2)* XGBoost for building predictive models based on the generated clusters.

### C. Performance Metrics

The XGBoost model was evaluated based on several performance metrics that provided insight into its effectiveness in predicting obesity risk. The model achieved the following metrics: As seen in Table II, the performance metrics for the obesity classification model are outlined, including Precision, Recall, F1-score, and Support for both non-obese (Class 0.0) and obese (Class 1.0) categories. These metrics provide a detailed evaluation of the model's ability to accurately classify obesity.

TABLE II. Performance Metrics for Obesity Classification Model

| Class | Precision | Recall | F1-score | Support |
|---|---|---|---|---|
| 0 (Not Obese) | 0.93 | 0.85 | 0.89 | 118 |
| 1 (Obese) | 0.82 | 0.92 | 0.87 | 91 |

As seen in Table III, the macro and weighted average performance metrics of the obesity classification model are presented. The model achieves a macro average precision of 0.88, recall of 0.89, and an F1-score of 0.88. Similarly, the weighted averages show strong performance, with precision at 0.89, recall at 0.88, and an F1-score of 0.88. The overall accuracy of the model is 88.04%, reflecting its reliability in predicting obesity across the data set.

These results indicate strong performance across all metrics, validating the model's ability to accurately predict childhood obesity based on environmental factors.

TABLE III. Overall Performance Metrics for Obesity Classification Model

| Metric | Value |
|---|---|
| Macro Average Precision | 0.88 |
| Macro Average Recall | 0.89 |
| Macro Average F1-score | 0.88 |
| Weighted Average Precision | 0.89 |
| Weighted Average Recall | 0.88 |
| Weighted Average F1-score | 0.88 |
| Overall Accuracy | 88.04% |

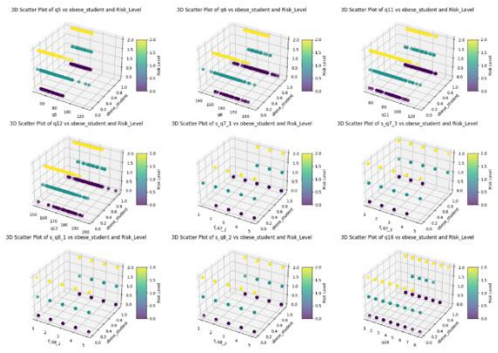

Fig. 4. 3D scatter plots showing the relationship between various characteristics, obesity, and risk levels.

The results of the analysis are supported by 3D scatter plots as seen in the Fig. 4. These graphs visually demonstrate the relationship between different characteristics such as parental weight, neighborhood safety, and child's risk of obesity. The color-coded risk levels (purple, teal, yellow) highlight distinct clusters where, environmental factors align with the likelihood of obesity. This representation makes it easier to identify how certain characteristics influence the risk levels.

### D. Risk Level Categorisation

As seen in Table IV, the clusters are categorized by their risk levels based on the proportion of obese individuals in each group. The table includes the cluster number, the number of obese individuals, the percentage of obese individuals, and the associated risk level. Clusters with a higher percentage of obesity are classified as high-risk, while those with lower percentages are categorized as 'medium risk' or 'low risk.' This classification helps identify obesity prevalence within different clusters, providing insight into the varying levels of risk across the groups.

This section provides a detailed breakdown of obesity rates among children, classified into high-, medium-, and low-risk clusters. Each row in the table represents a cluster, detailing the number of obese children, the percentage of obese children within that cluster, and the associated risk level.

*1) High risk:* Clusters in the high-risk category exhibit a significantly high percentage of obese children. Key points include:

Clusters 18, 62, and 41 show a 100% obesity rate, indicating that all children in these clusters are classified as obese. Clusters 14 and 25 demonstrate high obesity rates of 92.86% and 84.62%,

respectively. The lowest percentage within this category is 70% (Cluster 40), which still indicates a substantial proportion of obese children. These findings suggest that in high-risk groups, most children are obese, with some groups having all children classified as obese.

TABLE IV. ALL RISK LEVELS CLUSTERS

| Cluster | Number_of_Obese | Percentage_of_Obese | Risk_Level |
|---|---|---|---|
| 18 | 12 | 100 | high risk |
| 62 | 3 | 100 | high risk |
| 41 | 5 | 100 | high risk |
| 35 | 6 | 100 | high risk |
| 14 | 13 | 92.86 | high risk |
| … | … | … | … |
| 22 | 10 | 66.67 | medium risk |
| 15 | 6 | 66.67 | medium risk |
| 78 | 4 | 66.67 | medium risk |
| 7 | 8 | 66.67 | medium risk |
| … | … | … | … |
| 58 | 1 | 12.5 | low risk |
| 21 | 0 | 0 | low risk |
| 67 | 0 | 0 | low risk |
| 24 | 0 | 0 | low risk |
| … | … | … | … |

*2) Medium risk:* Clusters in the medium-risk category have lower obesity rates compared to high-risk clusters, but the rates are still significant:

Clusters 22, 15, and 78 show an obesity rate of 66.67%, which means that approximately two-thirds of the children in these clusters are obese. Clusters such as 68 and 65 show obesity rates of around 64.29% and 62.50%, respectively. The lowest obesity rate within this category is 42.86% (Clusters 13, 77, and 27).

This category indicates a moderate level of obesity, with a substantial proportion of children classified as obese, though less prevalent than in the high-risk clusters.

*3) Low Risk:* In the low-risk category, obesity rates are significantly lower:

Clusters such as 45, 16, and 73 show a 33.33% obesity rate, which means that only one-third of the children in these clusters are obese. Some clusters, such as Cluster 79, have an obesity rate as low as 15.38%. Several clusters (eg, clusters 21, 67, and 24) show a 0% obesity rate, indicating that there are no obese children in these clusters. These clusters display minimal levels of obesity, and many clusters having no children classified as obese at all.

### *E. Obesity by Risk Levels*

As seen in Table V, the summary of obesity by risk levels provides an overview of the number of obese individuals, total individuals, and the percentage of obese individuals within each risk category. The high-risk group exhibits the highest percentage of obese individuals, at 80.63%, followed by the medium-risk group at 56.16%, and the low-risk group at 12.18%.

TABLE V. OBESITY SUMMARY BY RISK LEVEL

| Risk_Level | Number_of_Obese | Total_Number | Percentage_of_Obese |
|---|---|---|---|
| high-risk | 204 | 253 | 80.63 |
| medium risk | 114 | 203 | 56.16 |
| low risk | 29 | 238 | 12.18 |

This summary highlights the varying prevalence of obesity at different risk levels, with obesity rates much higher in high-risk groups compared to medium and low-risk groups.

The results confirmed the initial hypothesis that a child's surrounding environment plays a significant role in their likelihood of becoming obese. Factors such as parental weight, neighborhood safety, and socioeconomic status (as indicated by family income) were found to be closely related to obesity risk levels. This finding is consistent with previous research, confirming the importance of these environmental influences on childhood obesity.

The results were generally consistent with previous studies, which also emphasized the role of environmental and familial factors in determining the risk of obesity. However, the integration of machine learning techniques, such as K-Means and XGBoost, provided a more refined predictive model with high precision in this study.

## V. DISCUSSION

The purpose of this chapter is to interpret and discuss the results obtained from the analysis of childhood obesity based on environmental factors. By applying machine learning techniques such as K-Means for clustering and XGBoost for predictive modelling, this study aimed to uncover patterns and relationships between various factors that influence childhood obesity. The discussion section will evaluate the performance of these models, explore the significance of key findings, and highlight areas for further improvement and future research.

### *A. Model Performance*

The models showed strong performance, especially in terms of precision, recall, and F1 scores. The XGBoost model, in particular, was highly effective in predicting obesity risks, achieving an overall accuracy of 88.04%. These findings align with existing research, reinforcing the efficacy of machine learning techniques in predicting childhood obesity based on environmental factors.

### *B. Insights from the Study*

The experiment confirmed that various factors, such as parental weight, neighborhood safety, and family income, significantly impact childhood obesity. The models provided valuable information on these relationships. However, there are other important factors, such as duration of sleep, medical conditions, and diet patterns that could further refine the predictions of obesity if included in future research. Despite

promising results, including an accuracy of 88.04%, it is important to consider that there are other factors that influence obesity that were not included in this study. For example, factors such as sleep duration, medical conditions, and eating patterns may play a significant role in determining the risk of obesity among children. These factors could have substantial impacts on the results we obtained and may contribute to improving accuracy if considered in future models. Therefore, it is recommended that future research incorporates a broader range of relevant factors and variables, including dietary patterns, to provide a more comprehensive and accurate assessment of the risk of obesity. Additionally, including more diverse data can help improve model performance and offer deeper insights into the factors that influence obesity.

### C. Recommendations for Future Research

Future research should incorporate a broader range of variables, including diet patterns, sleep habits, and medical conditions, to provide a more comprehensive assessment of the risk of obesity. Furthermore, collecting more diverse data could enhance model performance and provide deeper insights into the factors influencing childhood obesity.

## VI. Summary and Key Findings

### A. Study Approach and Methodology

The research addressed the challenges of childhood obesity using machine learning models, specifically XGBoost for prediction and K-Means Clustering to categorize students based on risk levels. The study began with an extensive review of the literature to understand the current state of research in this field, followed by a comparison of different machine learning approaches. This provided the foundation for selecting and implementing the models that were ultimately used.

### B. Results

Through the application of K-Means Clustering, students were classified into different groups based on their risk of obesity. This clustering method offered valuable information on how various factors, such as socioeconomic status, parental characteristics, and neighborhood conditions, influence a child's likelihood of developing obesity. The clusters created a framework that allowed for a deeper analysis of the risk levels.

Once the clusters were established, XGBoost was applied to predict the risk of obesity with high precision. The model achieved an accuracy of 88.04%, demonstrating its effectiveness in handling the dataset and providing reliable predictions for childhood obesity based on the characteristics extracted from the clustering process. The combination of these techniques proved to be a powerful approach for predictive modelling in this domain.

### C. Broader Implications

These findings highlight the potential of machine learning techniques to advance our understanding of childhood obesity. The success of XGBoost in predicting risk of obesity offers a strong foundation for further research and development. In particular, these methods could be refined to support early interventions, potentially reducing the prevalence of childhood obesity by targeting high-risk groups more effectively.

### D. Conclusion

In summary, this study provides a compelling case for the application of machine learning in health-related fields, specifically in understanding and predicting childhood obesity. The results achieved, especially the accuracy of classification and prediction, suggest that machine learning can play a vital role in future research and public health interventions aimed at combating childhood obesity. Future studies can build on this by incorporating more variables or experimenting with alternative algorithms to improve prediction accuracy and develop targeted intervention solutions.

# Industry 4.0 for SMEs: Exploring Operationalization Barriers and Smart Manufacturing with UKSSL and APO Optimization

Meeravali Shaik[1], Piyush Kumar Pareek[2]
Research Scholar, Nitte Meenakshi Institute of Technology, Visvesvaraya Technological University, Belagavi-590018, India
Assistant Professor, Sreenidhi Institute of Science and Technology, Ghatkesar, Hyderabad-501301[1]
Research Supervisor, Nitte Meenakshi Institute of Technology, Visvesvaraya Technological University, Belagavi-590018[2]

***Abstract*—The research aimed to find out why SMEs have a hard time adopting smart manufacturing, what makes smart manufacturing operational, and if only large companies can afford to take advantage of technological opportunities. It used a knowledge-based semi-supervised framework named Unsupervised Knowledge-based Multi-Layer Perceptron (UKMLP), which has two parts: a contrast learning algorithm that takes the unlabeled dataset and uses it to extract feature representations, and a UKMLP that uses that representation to classify the input data using the limited labelled dataset. Next, an artificial protozoa optimizer (APO) makes the necessary adjustments. This research is based on the hypothesis that large companies may be able to exploit Small and Medium-sized Enterprises (SMEs) to their detriment in cyber-physical production systems, thus cutting them out of the market. Secondary data analysis, which involved evaluating and analyzing data that had already been collected, was crucial in accomplishing the research purpose. Since big companies are usually the center of attention in these discussions, the necessity to delve into this subject stems from the reality that SMEs have a higher research need. The results confirmed the importance of Industry 4.00 in industrial production, particularly with regard to the smart process planning offered by algorithms for virtual simulation and deep learning. The report also covered the various connection choices available to SMEs in order to improve business productivity through the use of autonomous robotic technology and machine intelligence. This research suggests that a substantial value-added opportunity may lie in the way Industry 4.0 interacts with the economic organization of companies.**

## I. INTRODUCTION

Because data and the interactions among data cases reveal insights into software and service quality, as well as the dynamics of software creation and evolution, data plays a crucial role in contemporary software development [1-2]. There is a treasure trove of information regarding the development and evolution of a project in Software Engineering (SE) data, including code bases, changes, mailing lists, forum discussion, and bug/issue reports [3]. Automated SE methods and tools have come a long way since their inception, but most of them have concentrated on automating the creation, storage, and management of data that is specific to a single SE task, rather than helping with human experience-based decision-making or increasing productivity across all SE tasks [4]. The aforementioned methodologies and tools for software project decision-making, particularly in the face of uncertainty and that are unable to disclose the hidden linkages among different types of data or the data's deep semantics [5]. Thanks to the advancements in Machine Learning (ML) and Deep Learning (DL) algorithms, ML/DL models can now be trained to systematically evaluate and integrate data from big data software repositories, as to find patterns and new information clusters [6-7]. This paves the way for more thorough and organized information and decision-making frameworks [9] by improving comprehension of the data's deep semantics and interconnections via the use of statistical and probabilistic procedures [8]. Insightful and useful information regarding software systems and projects can be automatically uncovered by ML/DL approaches by analyzing and crosslinking the abundant data found in software repositories, something that cannot be accomplished just by practitioners' intuition and expertise [10]. The use of ML approaches in the automation of SE processes has also been driven by the exponential growth in the volume and difficulty of SE data.

The widespread use of ML/DL for data representation and analysis stems from the fact that many SE problems can be expressed as data analysis (learning) tasks [11]. These tasks include classification, ranking, regression, and generation, where the aims are to classify data instances into predefined categories, induce rankings over data instances, assign real values to data instances, and generate (usually brief) natural language descriptions as outputs [12–13]. As an example, it is natural to cast binary defect prediction as a classification job. This task involves predicting whether new instances of code regions (such as files, modifications, and methods) include faults. Ranking tasks can be applied to software crowdsourcing activities such as code search, defect localization, bug assignment, pull requests, requirements, reports, test case prioritization, and recommendations [14]. Software engineering (SE) researchers also use continuous data with regression models to approximation (1) software development effort [15], (2) software defect count and bug fixing time, (3) configurable software performance, (4) energy consumption, and (5) software reliability, a conditional probability problem. As a last step, certain activities have been reformed as generation tasks. One of them is code summarization, which

involves providing a high-level, plain language description of the code. Another is the development of code artifacts, such as code comments.

To get the feature map out of datasets without labels, to use a contrastive learning model here [30]. In the next step, to build a model besides train it with a small dataset of labels. When tested on several classification datasets, the proposed framework UKSSL outperforms other state-of-the-art algorithms while utilizing a smaller dataset. In order to enhance the classification accuracy, the study work employs the APO model to refine the parameters of the proposed model. Here is a rundown of the remaining research: Section II lists relevant literature; Section III gives a brief overview of the proposed technique; Section IV analyses the results; and Section V attractions conclusions.

## II. Related Work

Data privacy and algorithmic bias are two of the ethical issues that Kedi et al., [17] has explored in addition to the technical difficulties of applying machine learning, which include algorithm complexity, system integration, and data quality. To also talk about the limits that are unique to SMEs, such as limited resources and a lack of technical knowledge. The future is bright for new technologies like reinforcement learning and deep learning, and there will be helpful suggestions for SMEs on how to make the most of these developments. In order to achieve long-term success and a leg up in the digital economy, the conclusion stresses the need of using machine learning.

For the Chinese market, Liu et al. [18] constructed 34 stock price determinants and then used Bayesian optimization to train four models: RF, DNN, GBDT, besides Adaboost. These models are then used to predict the closing prices of innovative SMEs that too relisted the following day. This study covers the period from July 22, 2019, to September 10, 2021 and uses 78,708 samples from 337 SMEs listed on the STAR market. Based on the experimental results, the Random Forest (RF) and Deep Neural Network (DNN) models [16] outperformed the Gradient Boosting Decision Tree (GBDT) and Adaptive Boosting (AdaBoost) models in terms of the evaluation metrics: Coefficient of Determination ($R^2$), Root Mean Square Error (RMSE), Mean Absolute Percentage Error (MAPE), and Directional Accuracy (DA), thereby demonstrating superior prediction performance.

In order to enhance manufacturing processes, particularly for SMEs, Cruz et al. [19] propose a methodology for incorporating a completely automated procedure that uses automated machine learning algorithm. The approach is based on using the created models as objective functions of a non-dominated sorting genetic procedure that uses reference points. This sorting algorithm then produces production processes that are pareto-optimal based on preferences. A small manufacturing enterprise's production process data was used to execute and evaluate the technique, which resulted in very accurate models for the indicators that to be analyzed. In comparison to the results achieved using the conventional trial-and-error approach that focused solely on productivity, step of the suggested methodology was able to raise manufacturing process productivity by 3.19% and decrease defect rate by 2.15%.

In order to boost teamwork among SMEs promote innovation, and drive economic development, Wang, & Zhang [20] suggested using the XGBoost procedure in conjunction with IoT data. Internet of Things (IoT) and machine learning's part in fostering long-term economic growth in specific areas. In today's cutthroat business environment, staying ahead of the curve requires constant technological innovation. This article takes a look at how geography and environmental factors have affected economic development in different parts of China. Through performance evaluation, it contributes to regional economic success by focusing on SME coupling and coordination. Integrating IoT devices gives SMEs access the real-time data, which allows them to get profound insights into production, supply networks, and consumer behavior. At the same time, the XGBoost algorithm evaluates the data effectively and finds useful insights. The data from 11 provinces along the Yangtze River economic belt shows that between 2015 and 2020, Jiangsu Province will have the best regional innovation performance. The practical outcomes, supported by datasets that combine data from these provinces, demonstrate the promise of this strategy driven by the Internet of Things and XGBoost. With an astounding accuracy rate of 91.7%, this research highlights how effective this integrated strategy is in optimizing SME processes, outperforming rival machine learning techniques RF, and LR. It also calculates the ranking of the innovation environment, the mean value. Across 30 provinces in China, the average innovation degree was 0.1624.

SMEs are an important part of most economies' job markets, and Litvinenco has [21] focused on assessing their credit risk. The regulator claims that there is a lack of practical application of ML approaches, even though these methods can improve capital requirements assessments and open up financial services to this segment. One possible explanation is that financial firms are compelled to utilize simpler models due to the total complexity of explainability and interpretability. The benefits of these techniques are not always obvious, which is another factor. This research suggests a decision tree/logistic regression hybrid model to solve the complexity issue. With interpretability complexity on par with logistic regression, this model outperforms Random Forest and XGBoost. Their purpose is to differentiate a model's misclassifications based on their capital significance and to give an idea of the total capital supplies that a model is capable of producing. By comparing the models using these and other generally used measures, the financial institutions are able to make a better-informed judgment on which model would best satisfy their objectives?

Using authorized invoice data from 425 SMEs in Chongqing, Huang et al., [22] has concentrated on company performance statistics. In order to understand the feature contribution of a particular output, a prediction classifier was built using logistic regression, random forest, support vector machine, and soft voting ensemble learning methods. This classifier was then merged with the SHAP value. Consequently, our study demonstrated a robust association between the extracted characteristics and future defaults, paving the way for the prediction of companies' financial success.

To address the issue of SMEs' unbalanced in SCF using deep learning (DRL), Zhang et al., [23] proposed a new method they term DRL-Risk. To propose an instance-based account, taking into account the actual damage caused SMEs, and formulates the ICRP process. To then suggest a decision-policy deep duelling neural network for predicting SMEs' credit risk. The DRL-Risk method can use deep reinforcement learning to focus on SMEs that are most likely to incur large losses financially. The experimental results show that when compared to the baseline approaches in recall, G-mean, and financial loss, the DRL-Risk methodology may greatly improve the performance of predicting the credit risk of SMEs in SCF.

## III. Proposed Methodology

### A. Data Collection

Although the organization has a production management information system, it does not have much of a presence on the Internet. In the absence of a comprehensive digital strategy, the company is contemplating the implementation of autonomous production processes, sensor networks for the Internet of Things, and predictive maintenance systems. It can take part in the flow of information between suppliers and customers to some extent.

The use of straightforward economic software facilitates interaction with other branches of governmental administration. Data becomes more important to a software-controlled, dynamic Internet presence. Supply besides demand chain info flows, such as collaborative virtual archives, real-time big data, are being considered as part of an overall digital strategy.

To fully understand how SMEs engage with cyber-physical smart factories, cognitive automation, and Industry 4.0 wireless networks, it is necessary to first address SMEs after a quick overview of the concept. According to the European Commission, the number of employees and revenue are the main requirements for qualifying SMEs.

These requirements are provided in Table I. Certain businesses are the only ones that must meet these standards [24]. Companies are considered small if they have less than 50 workers and yearly sales of up to €10 million, and medium-sized if they have less than 250 employees and yearly to €50m million, meaning they have a balance sheet of up to €43 million.

Table I shows that there are several ways in which businesses can be assessed for their preparedness for this undertaking. These range from strategy and organization to smart factories, manufactured commodities, decision-making processes driven by big data, and human resources [25]. In the methodical approach of secondary analysis, the research questions are formed initially, and then the dataset is located and evaluated in great detail. Consequently, the primary objective of determine which obstacles hinder European SMEs the most when it comes to implementing Industry 4.0. Researchers drew on a variety of secondary data sources—including peer-review the academic articles, books, government records, and company annual reports—to compile the information needed to complete the study.

TABLE I Categorization of SMEs

| Company Category | Turnover | Staff Headcount | Balance Sheet Total |
|---|---|---|---|
| Medium-sized | ≤€50 m | <250 | ≤€43 m |
| Small | ≤€10 m | <50 | ≤€10 m |
| Micro | ≤€2 m | <10 | ≤€2 m |

A variety of screening and quality evaluation methods were used in the analysis, including data from the European Commission, the Organisation for Economic Co-operation and Development (OECD), and tools such as Distiller Systematic Review (DistillerSR), Mixed Methods Appraisal Tool (MMAT), Risk of Bias in Systematic Reviews (ROBIS), and the Systematic Review Data Repository (SRDR).The SME Alliance's secondary data analysis was also used to perform the research. The following scientific procedures to be employed to data: i) the analytical technique that breaks down a large research problem into smaller ones in order to better understand it. In this study, the used: (i) analysis, which involved searching domestic and foreign literature in the designated research area for relevant information; (ii) synthesis, which involved processing and combining previously acquired knowledge; and (iii) comparison, which involved finding a knowledge, phenomena, or objects in order to learn more about the studied issue. (iv) the investigating strategy that was employed to discover more about the current issue. This method was utilized in this study to interpret the results of the analyses. Its purpose is to draw theoretical conclusions about the research problem based on the examined knowledge, which is prearranged dependencies. Comparative analysis was also a part of the investigation. Of the 268 companies surveyed in Germany, 56.5% did not fully comply with the requirements for implementing Industry 4.0 [26]. For the novice level 1 implementation approach, 20% of respondents are just somewhat prepared. Table II shows that just 0.3% met all five requirements at the exceptional level of execution.

To find out how ready companies are for Industry 4.0, a poll was run. Fifteen hundred chief executive officers (CXOs) from nineteen different nations took part. While 20% of chief executive officers said their companies are ready for a new business model, only 14% said to "extremely confident" in their ability to answer the problems of Industry 4.00. Despite the need for significant changes, 84% of educate their personnel and only 25% thought their employees to completely incorporate Industry 4.0. Less than one-fifth of people who took the survey felt adequately ready for intelligent and autonomous technologies. On a 15-year time frame, Fig. 1 shows the amount of SMEs in the EU [27]. The proliferation of these firms is plain to see.

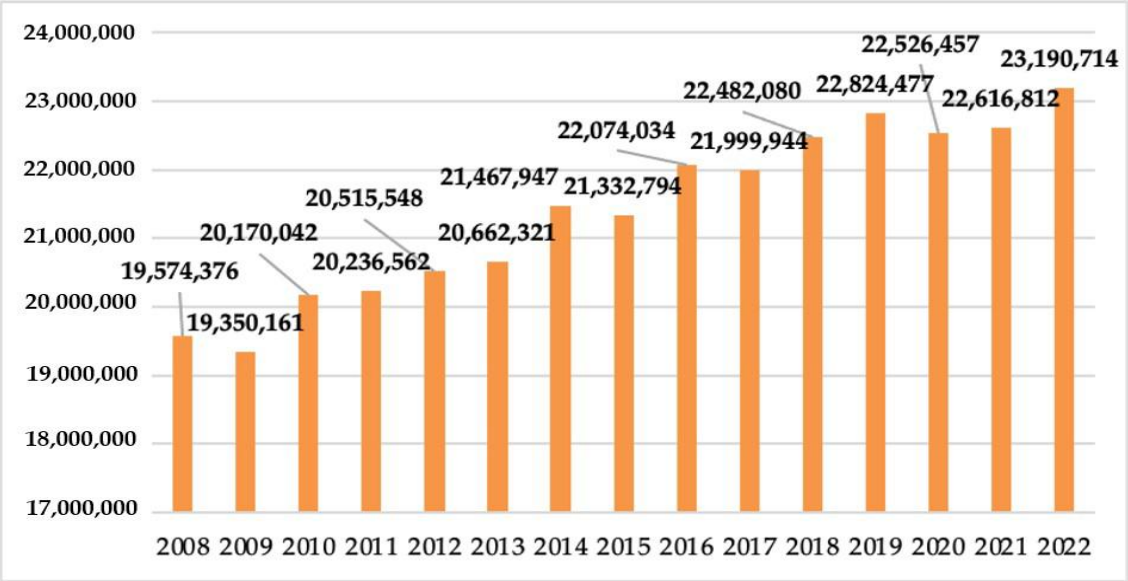

Fig. 1. Sum of SMEs in the European Union (EU27) from 2008 to 2022. Basis: Authors' gathering [27].

Nearly 23 million people called them home in 2022. The first step for SMEs is to automate their administrative and marketing processes. The hardest part of starting a business is often the first step. Strong technological complementarities might encourage future adoption after an initial shift to digital know-how. Many small and medium-sized enterprises (SMEs) depend on external systems, assistance, and guidance to accomplish these and other digital technology goals. There are financial considerations as they need to make up for a lack of internal capacity, thus this is done. Take digital platforms like e-commerce marketplaces and social networks as an example. They provide a great chance to improve some activities while keeping costs down, including data analytics and business intelligence services. To a similar extent, SMEs manage digital security risks by using external consultants or incorporating security-by-design into their digital services. Knowledge marketplaces provide AI solutions, and cloud-based software as a service allows them to skip the introduction of new AI systems. Autonomous mobile robots use cloud computing, image recognition, smart manufacturing, and real-time monitoring. The use of data analytics, imaging and sensing tools, and virtual reality simulations are all components of digital twin-driven smart manufacturing. In smart industrial settings, collaborative autonomous systems use cloud computing analytics, mobile robotic equipment, and tools for acquiring and analyzing images.

When it comes to digital disparities, technical complementarities might make things worse as bigger and better-informed companies can afford to use more sophisticated digital strategies. Enterprise CRM production process integration, and data analytics are all examples of more advanced technologies that highlight the gap between SMEs and larger companies.

It is necessary to high the benefits and drawbacks of Industry 4.0 technologies before assessing implementation hurdles. The irregularities in the deployment of Industry 4.0 must be described and characterized correctly. While there are certainly obstacles to overcome before big data-driven technologies can be completely utilized, industrial artificial intelligence can enhance production capabilities and productivity, leading to higher profitability. Rapid and configurable operations, including storage cost savings, allow for 10-30% cheaper costs in mass manufacturing, which is the greatest advantage of implementing Industry 4.0. Another perk is the possibility of a ten to thirty percent drop in logistics and quality control costs.

Worker output, environmental impact, and overall efficiency can all benefit from more effective use of energy and natural resources, which can boost productivity by 15–20%. Consequently, the manufactured goods may be made and delivered to clients faster. Industry 4.0 encourages steady economic expansion by highlighting state-of-the-art industrial manufacturing methods. There are ever-changing tests that SMEs face while trying to embrace Industry 4.0. Given the interconnected nature of the factors that slow down or speed up the adoption of new technology, this study will also evaluate the potential benefits of using the suggested deep learning model to help SMEs overcome implementation hurdles.

TABLE II STAGES OF IMPLEMENTATION

| Level | Designation |
|---|---|
| 0 | Expert |
| 1 | Top Performer |
| 2 | Intermediate |
| 3 | Experienced |
| 4 | Top Performer |
| 5 | Intermediate |

### B. Contrastive Learning of Visual Representations

In order to forecast the output of data, the study makes use of deep learning. $E(\bullet)$ is the symbol for the encoder, which is able to transform the data into two representations, r′ and r″, by removing any semantic information. The Vision Transformer

(ViT) [28] is a source of inspiration for our light encoder construction LTrans in our framework. It gets pictures r′ and r″ as Eq. (1) shows, where the yield r′ ∈ $R^d$ is created layer.

$$r' = e(i') \tag{1}$$

To change the input of the standard Transformer—a 1D embeddings—into a series of 2D flattened patches with dimensions N × P2 • C, instead of the data being reshaped from H × W × C. The original data's height and width are indicated by the H and W in this case. The size of the C stands for the number of channels. Each data patch's resolution, denoted as P2, and the total number of patches are determined by Eq. (2).

$$N_{patch} = (HW \vee P)^2 \tag{2}$$

To first flatten the patches using the original data shaper, then project them into D dimensions using a linear projection with trainable parameters. In Eq. (3), we can see the linear projection, with ip standing for the 2D patches that are flattened from the initial data set i. An i_class is a unique token for a categorization. This is very much like the BERT [CLS] token [29]. Patch embeddings are the results of this projection. The position embeddings are put to use, $e_{position}$ to maintain the data regarding the positions. To generate position embeddings using typical learnable 1D methods, then combine them embeddings to form the final embedded patches E_0. Afterwards, the LTrans is fed embedded patch data.

$$E_0 = e_{position} + \left[i_{class}; i_p^1 e; i_p^2 e; \ldots; i_p^N e\right], e \in R^{(P^2.C)\times D}, e_{position} \in R^{(N+1)\times D} \tag{3}$$

To add a normalization every component and a residual both component to LTrans, which comprises of MLP blocks. A large number of academics are interested in incorporating multi-head attention into their models. To be more specific, let's pretend to have an input sequence$x \in R^{N\times D}$. To calculate sum over each charge V in the input arrangement x, as Eq. (4) shows. The sights of attention $Attention_{mn}$ are found by comparing the query representations of two elements in the arrangement and their pairwise similarity. $Q^m$ and key $K^n$, as Eq. (5) shows. Lastly, $Sa$ is calculated by the Eq. (6).

$$[Q, K, V] = xU_{QKV}, U_{QKV} \in R^{D\times 3D_h} \tag{4}$$

$$Attention = softmax\frac{QK^T}{\sqrt{D_h}}, Attention \in R^{N\times N} \tag{5}$$

$$Sa(x) = AttentionV \tag{6}$$

The outputs of k self-attention procedures are projected together by multi-head self-attention (MSA), as demonstrated in Eq. (7).

$$MSA(x) = [Sa_1(x); Sa_2(x); , \ldots Sa_k(x)]U_{QKV}, U_{QKV} \in R^{k.D_h\times D} \tag{7}$$

Two completely linked layers with GELU non-linearity make up the MLP chunks in the LTrans. In Eq. (8) and Eq. (9), the full Ltrans procedure is detailed.

$$x_l' = MSA\big(Norm(x_{l-1})\big) + x_{l-1}, l = 1 \ldots L \tag{8}$$

$$x_l = MLP\big(Norm(x_l')\big) + x_l', l = 1, \ldots, L \tag{9}$$

Projection head $p(\cdot)$may transpose the illustration r to a different feature interplanetary z using a tiny non-linear multi-layer perceptron neural network. The ғ is a non-linear ReLU function, as seen in Eq. (10). The $W^{(1)}$ is encoder $e(\cdot)$, and the $W^{(2)}$ is weight projection head $p(\cdot)$.

$$z = p(r) = W^{(2)}\sigma\big(W^{(1)}r\big) \tag{10}$$

Our final model is the result of combining the four parts listed above. This algorithm determines to have size N, constant τ, encoder e, projection head p, and data expansion module A. pass the data into the encoder $e(\cdot)$ and projection head $p(\cdot)$. After that, to do the pairwise similarity and calculate the encoder $e(\cdot)$ besides forecast head $p(\cdot)$. Finally, to produce a network$e(\cdot)$, then head. To will use this encoder $e(\cdot)$in order to create the unlabeled dataset's foundational data representations, and then feed that knowledge into our model so it can perform the classification task.

- Underlying Knowledge Based Multi-Layer Perceptron Classifier (UKMLP)

With the help of the restricted labelled data, the UKMLP attempts to refine the feature representation learnt by the aforementioned model. Here, to take a page out of transfer learning's playbook by enhancing the traditional classifier's architecture. Specifically, to add 12 hidden layers, with the following configuration: three layers of 256 layers of 512 neurons connected, two layers of 1024 connected, and three layers of 256 neurons connected. The three components of the design are the input layer, two hidden layers, and the output layer. After receiving input from model up top, the underlying knowledge is passed on to the buried layers. The output layer's neuron counts changes depending on the dataset's classes. As shown in Eq. (11) it adheres to a rectified linear activation for every hidden layer. If x is less than zero, the ReLU function returns zero as an output; otherwise, it returns the input value.

$$f(x) = max(0, x) \tag{11}$$

The UKMLP loss function, multi-class entropy, is illustrated in equation (12). Here, yˆ vector y containing the actual class label, is a one-hot representing the predicted class probabilities for all C classes, and the natural logarithm is represented by the log.

$$L(y\hat{}, y) = -\sum_{i=1}^{C} \quad y_i log(y\hat{}_i) \tag{12}$$

- Fine-tuning using Artificial protozoa optimizer

Here to present the APO algorithm, which is used to fine-tune the UKMLP model's parameters using its mathematical models that mimic protozoa.

*1) Mathematical models*: This section presents the algorithm that can be used to solve the minimization problem. For metaheuristic algorithms, the solution set representation is crucial. Each protozoan in our suggested method occupies a certain location inside the solution set, which is represented by $dim$ variables.

*2) Foraging*: When studying protozoa foraging behavior, to took both internal and extrinsic influences into account. The protozoa's feeding habits are an example of an internal factor,

whereas species collisions and competing behaviors are examples of external variables.

*3) Autotrophic mode*: In order to sustain themselves, protozoans can use chloroplasts to make carbs. The protozoan will relocate to a spot with lo To r light intensity if it is exposed to very bright light. When it's in a dimly lit area, the inverse is true. Taking into consideration the light levels surrounding the *j*th protozoan is suitable will move to the site of the *j*th protozoan. Our mathematical model for mode is as follows:

$$X_i^{new} = X_i + f. \quad (13)$$

$$X_i = \left[x_i^1, x_i^2, \dots, x_i^{dim}\right] X_i = sort(X_i) \quad (14)$$

$$f = rand.\left(1 + cos\left(\frac{iter}{iter_{max}}.\pi\right)\right) \quad (15)$$

$$np_{max} = \left[\frac{ps-1}{2}\right] \quad (16)$$

$$w_a = e^{-} \quad (17)$$

$$M_f[d_i] = \{1, if\, d_i is \in randperm\left(dim, \left[dim.\frac{i}{ps}\right]\right)\ 0, otherwise \quad (18)$$

where $X_i^{new}$ and $X_i$ denote the efficient position, besides original site of the $i$th protozoan, respectively. $X_j$ is the randomly designated *j*th protozoan. $X_{k-}$ Represents a randomly selected protozoan in the $k$th paired than $i$. Precisely, if $X_i$ is $X_1$, $X_{k-}$ is also set as $X_1$. $X_{k+}$ denotes a haphazardly s $k$th paired neighbor, besides its rank directory is greater than $i$. Particularly, if $X_i$ is $X_{ps}$, $X_{k+}$ is also set to $X_{ps}$, where $ps$ is the population size. $f$ represents a foraging factor and $rand$ denotes a random number in the distribution. $iter$ besides $iter_{max}$respectively. $np$ indicates the number of neighbor pairs among the external factors and $npmax$ is the maximum charge of $np$. $w_a$ is mode and $eps(2.2204e-16)$ is a significantly small sum. $\odot$ denotes the Hadamard product. $M_f$ is a size of $(1 \times dim)$, where every element is 0 or 1. $d_i$ index $d_i \in \{1,2, \dots, dim\}$.

- Heterotrophic style

A protozoan can get its nourishment by soaking up organic stuff when it's dark. With the expectation that $X_{near}$ is close by and has plenty of food, the protozoan will go there. This mathematical model is proposed for the heterotrophic mode.

$$X_i^{new} = X_i + f\left(X_{near} - X_i + \frac{1}{np}.\sum_{k=1}^{np} w_h.(X_{i-k} - X_{i+k})\right)\odot M_f \quad (19)$$

$$X_{near} = \left(1 \pm Rand.\left(1 - \frac{iter}{iter_{max}}\right)\right)\odot X_i \quad (20)$$

$$w_h = e^{-\left|\frac{f(X_{i-k})}{f(X_{i+k})+eps}\right|} \quad (21)$$

In order to sustain themselves, protozoans can use chloroplasts to make carbs. The protozoan will relocate to a spot with light intensity if it is exposed to very bright light. When it's in a dimly lit area, the inverse is true. Taking into consideration the light levels surrounding the *j*th protozoan is suitable will move to the site of the *j*th protozoan. Our mathematical model for mode is as follows:

$$X_i^{new} = X_i + f. \quad (13)$$

$$X_i = \left[x_i^1, x_i^2, \dots, x_i^{dim}\right] X_i = sort(X_i) \quad (14)$$

$$f = rand.\left(1 + cos\left(\frac{iter}{iter_{max}}.\pi\right)\right) \quad (15)$$

$$np_{max} = \left[\frac{ps-1}{2}\right] \quad (16)$$

$$w_a = e^{-} \quad (17)$$

$$M_f[d_i] = \{1, if\, d_i is \in randperm\left(dim, \left[dim.\frac{i}{ps}\right]\right)\ 0, otherwise \quad (18)$$

where $X_i^{new}$ and $X_i$ denote the efficient position, besides original site of the $i$th protozoan, respectively. $X_j$ is the randomly designated *j*th protozoan. $X_{k-}$ Represents a randomly selected protozoan in the $k$th paired than $i$. Precisely, if $X_i$ is $X_1$, $X_{k-}$ is also set as $X_1$. $X_{k+}$ denotes a haphazardly s $k$th paired neighbor, besides its rank directory is greater than $i$. Particularly, if $X_i$ is $X_{ps}$, $X_{k+}$ is also set to $X_{ps}$, where $ps$ is the population size. $f$ represents a foraging factor and $rand$ denotes a random number in the distribution. $iter$ besides $iter_{max}$respectively. $np$ indicates the number of neighbor pairs among the external factors and $npmax$ is the maximum charge of $np$. $w_a$ is mode and $eps(2.2204e-16)$ is a significantly small sum. $\odot$ denotes the Hadamard product. $M_f$ is a size of $(1 \times dim)$, where every element is 0 or 1. $d_i$ index $d_i \in \{1,2, \dots, dim\}$.

- Heterotrophic style

A protozoan can get its nourishment by soaking up organic stuff when it's dark. With the expectation that $X_{near}$ is close by and has plenty of food, the protozoan will go there. This mathematical model is proposed for the heterotrophic mode.

$$X_i^{new} = X_i + f\left(X_{near} - X_i + \frac{1}{np}.\sum_{k=1}^{np} w_h.(X_{i-k} - X_{i+k})\right)\odot M_f \quad (19)$$

$$X_{near} = \left(1 \pm Rand.\left(1 - \frac{iter}{iter_{max}}\right)\right)\odot X_i \quad (20)$$

$$w_h = e^{-\left|\frac{f(X_{i-k})}{f(X_{i+k})+eps}\right|} \quad (21)$$

$$Rand = [rand_1, rand_2, \dots, rand_{dim}] \quad (22)$$

where $X_{near}$ is a nearby site, and ''±'' implies that $Xnear$ can be in dissimilar instructions from the $i$th protozoan. $X_{i-k}$ denotes the $(i-k)$th protozoan the $k$th paired index is $i-k$. Specifically, if $X_i$ is $X_1$, $X_{i-k}$ is also set to $X_1$. $X_{i+k}$ represents the $(i+k)$th protozoan designated from the $k$th paired index is $i+k$. Particularly, if $X_i$ is $X_{ps}$, $X_{i+k}$ is also set to $X_{ps}$. $w_h$ is factor in the heterotrophic mode. $Rand$ is elements in the [0,1] intermission as given in Eq. (22).

where $X_{near}$ is a nearby site, and ''±'' implies that $Xnear$ can be in dissimilar instructions from the $i$th protozoan. $X_{i-k}$ denotes the $(i-k)$th protozoan the $k$th paired index is $i-k$. Specifically, if $X_i$ is $X_1$, $X_{i-k}$ is also set to $X_1$. $X_{i+k}$ represents the $(i+k)$th protozoan designated from the $k$th paired index is $i+k$. Particularly, if $X_i$ is $X_{ps}$, $X_{i+k}$ is also set to $X_{ps}$. $w_h$ is factor in the heterotrophic mode. $Rand$ is elements in the [0,1] intermission.

*4) Dormancy*: As a defense mechanism against harsh environments, protozoans can go into a dormant state when threatened. In order to keep the number of protozoa constant, they replace dormant protozoans with newly created ones. The following is the mathematical model of dormancy:

$$X_i^{new} = X_{min} + Rand \odot (X_{max} - X_{min}) \quad (23)$$

$$X_{min} = [lb_1, lb_2, \dots, lb_{dim}]\ X_{max} = [ub_1, ub_2, \dots, ub_{dim}] \quad (24)$$

where $X_{min}$ and $X_{max}$ represent the vectors, respectively. $lb_{di}$ and $ub_{di}$ indicate the of the $di$th variable, correspondingly.

*5) Reproduction*: When protozoa are mature and in good health, they reproduce asexually by a process called binary fission. This kind of reproduction should theoretically result in the protozoan dividing into two females that are genetically identical. To able this behavior by creating an identical protozoan and then taking perturbation into account. How about this for a mathematical model of reproduction:

$$X_i^{new} = X_i \pm rand.\left(X_{min} + Rand \odot (X_{max} - X_{min})\right) \odot M_r \quad (25)$$

$$M_r[d_i] = \{1, if\, d_i is \in randperm(dim, [dim.rand])\ 0, otherwise \quad (26)$$

where ''±'' implies alarm forward besides reverse. $Mr$ is vector in replica procedure, whose size is $(1 \times dim)$, besides each element is 0 or 1.

*6) Algorithm*: Here are the specifics of the APO. Here are the parameters that are involved in integrating all the mathematical models:

$$pf = pf_{max}.rand \quad (27)$$

$$p_{ah} = \frac{1}{2}.\left(1 + cos\left(\frac{iter}{iter_{max}}.\pi\right)\right) \quad (28)$$

$$p_{ar} = \frac{1}{2}.\left(1 + cos\left(1 - \frac{i}{ps}.\pi\right)\right) \quad (29)$$

where $pf$ is a quantity fraction of latency besides reproduction in protozoa populace and $pf_{max}$ is the maximum charge of $pf$. $p_{ah}$ designates the likelihoods of heterotrophic behaviors, and $p_{dr}$ designates the likelihoods of dormancy besides imitation.

Note that the projected APO has limits: $np$ (sum of neighbor pairs) and $pf_{max}$ (maximum proportion fraction).

## IV. Results and Discussion

An NVIDIA TESLA P100 GPU with 16 GB of RAM and a XEON CPU of 13 GB RAM are used to execute the experiments in the study. The model's hyper-parameters are defined as follows: epochs=200, batch size=500, learning rate=0.01, projection dimension=64. Keras is used to implement the code with scikit-learn. Compare the proposed model to current methods using a variety of metrics in Table III, which displays the results of the validation analysis.

TABLE III Comparative Analysis of Proposed Model with Existing Models

| Model | MAPE | MSE | RMSE | R2 |
|---|---|---|---|---|
| DBN | 41.6 | 0.021 | 0.144 | 0.776 |
| CNN | 39.29 | 0.020 | 0.132 | 0.805 |
| LSTM | 52.99 | 0.019 | 0.245 | 0.735 |
| Proposed model | 29.95 | 0.013 | 0.116 | 0.905 |

Table III and Fig. 2 presents a comparative investigation of the planned model against existing models (DBN, CNN, and LSTM) using presentation metrics such as MAPE, MSE, RMSE, besides $R^2$. The proposed model shows the best performance with the lowest MAPE of 29.95, significantly outperforming DBN (41.6), CNN (39.29), and LSTM (52.99). For MSE, the proposed model also achieves the lowest value at 0.013, compared to DBN (0.021), CNN (0.020), and LSTM (0.019). In terms of RMSE, the projected model exhibits the smallest error at 0.116, while DBN, CNN, and LSTM have values of 0.144, 0.132, besides 0.245, correspondingly. Finally, the $R^2$ charge of the projected model is the uppermost at 0.905, indicating superior predictive accuracy compared to DBN (0.776), CNN (0.805), and LSTM (0.735). Overall, the proposed model significantly outperforms existing models across all metrics.

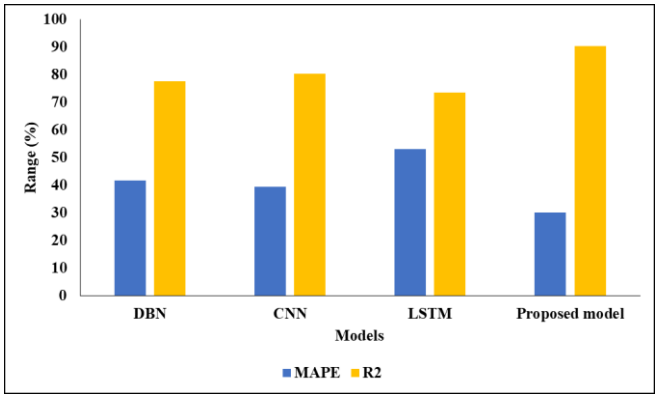

Fig. 2. Visual representation of proposed model.

TABLE IV ERROR ANALYSIS OF DIFFERENT MODELS

| Metric | Algorithm | | | | |
|---|---|---|---|---|---|
| | Proposed | LSTM | RNN | CNN | DBN |
| R2 | 0.98 | 0.96 | 0.956 | 0.94 | 0.93 |
| Mean Squared Error (MSE) | 0.0065 | 0.042 | 0.037 | 0.036 | 0.0325 |
| Root Mean Squared Error (RMSE) | 0.0803 | 0.095 | 0.091 | 0.099 | 0.108 |
| Mean Absolute Percentage Error (MAPE) | 0.0702 | 0.0966 | 0.086 | 0.089 | 0.0938 |
| Mean Absolute Error (MAE) | 0.0567 | 0.0634 | 0.0648 | 0.0743 | 0.1305 |

*1)* Comparative Analysis of Proposed model on error analysis

The error analysis of various algorithms is tested and results are averaged in Table IV.

In the analysis of R2, the existing ML and DL models are tested and achieved nearly 93% to 95%, where LSTM achieved 96% and proposed model achieved 98%. This is because the research work uses the optimizer for fine-tuning the parameters of the proposed model and existing models uses the manual learning rate and leads to high computational complexity. The existing DBN achieved 0.03 of MSE and 0.108 of RMSE, where RNN achieved 0.037 of MSE and 0.091 of RMSE and leads to high computational complexity issues than proposed model. The MAE of proposed model has only 0.0567 and the existing ML and DL achieved nearly 0.064 to 0.074 of MAE leads to increase the chance of error rate in detecting process. From the analysis, it is clearly shown that the proposed model achieved better performance than existing models such as DBN, CNN, RNN and LSTM models.

*2)* Experimental analysis of the proposed model on different iterations

Table V and VI presents the experimental analysis of proposed model on different iterations by considering with and without APO optimizer.

The performance of the proposed model was evaluated in terms of error metrics, including R-squared (R2), Mean Squared Error (MSE), Root Mean Squared Error (RMSE), Mean Absolute Percentage Error (MAPE), and Mean Absolute Error (MAE), across multiple iterations. The results were analyzed both without optimization and with the APO optimizer. Table V presents the error analysis of the proposed model across 10 iterations without optimization. The average R2 value achieved is 0.9950, indicating strong predictive performance. However, the other error metrics show fluctuations across different iterations. Notably, iteration 2 exhibits a lower R2 value (0.9893) and higher error values (MSE = 0.0312, RMSE = 0.1766, MAPE = 0.0255, and MAE = 0.1263), suggesting reduced accuracy in that particular run. Conversely, iteration 10 records a higher R2 value (0.9979) and lower MSE (0.0056), RMSE (0.0748), MAPE (0.0097), and MAE (0.0559), indicating more stable performance. The inconsistency in error values suggests that without optimization, the model exhibits variability in prediction accuracy across iterations.

TABLE V ERROR ANALYSIS OF PROPOSED MODEL ON DIFFERENT ITERATIONS

| **Number of iterations** | Proposed with various iteration without optimization | | | | |
|---|---|---|---|---|---|
| | **R2** | **MSE** | **RMSE** | **MAPE** | **MAE** |
| 1 | 0.9981 | 0.0052 | 0.0721 | 0.0099 | 0.0529 |
| 2 | 0.9893 | 0.0312 | 0.1766 | 0.0255 | 0.1263 |
| 3 | 0.9975 | 0.0066 | 0.0815 | 0.0095 | 0.0501 |
| 4 | 0.9927 | 0.0212 | 0.1456 | 0.0216 | 0.1101 |
| 5 | 0.9928 | 0.0211 | 0.1454 | 0.0210 | 0.1090 |
| 6 | 0.9977 | 0.0060 | 0.0777 | 0.0100 | 0.0560 |
| 7 | 0.9934 | 0.0194 | 0.1391 | 0.0207 | 0.1055 |
| 8 | 0.9978 | 0.0060 | 0.0772 | 0.0096 | 0.0529 |
| 9 | 0.9926 | 0.0216 | 0.1471 | 0.0219 | 0.1110 |
| 10 | 0.9979 | 0.0056 | 0.0748 | 0.0097 | 0.0559 |
| Average | 0.9950 | 0.0144 | 0.1137 | 0.0159 | 0.0830 |

TABLE VI ANALYSIS OF PROPOSED MODEL IN TERMS OF ERROR RATE WITH APO OPTIMIZER

| Number of iterations | various iteration with optimization | | | | |
|---|---|---|---|---|---|
| | R2 | MSE | RMSE | MAPE | MAE |
| 1 | 0.9981 | 0.0048 | 0.0690 | 0.0078 | 0.0460 |
| 2 | 0.9970 | 0.0054 | 0.0738 | 0.0097 | 0.0608 |
| 3 | 0.9973 | 0.0072 | 0.0849 | 0.0115 | 0.0616 |
| 4 | 0.9986 | 0.0032 | 0.0567 | 0.0100 | 0.0517 |
| 5 | 0.9975 | 0.0069 | 0.0828 | 0.0135 | 0.0697 |
| 6 | 0.9992 | 0.0029 | 0.0541 | 0.0088 | 0.0510 |
| 7 | 0.9992 | 0.0016 | 0.0399 | 0.0053 | 0.0338 |
| 8 | 0.9975 | 0.0071 | 0.0843 | 0.0133 | 0.0689 |
| 9 | 0.9983 | 0.0041 | 0.0638 | 0.0123 | 0.0596 |
| 10 | 0.9960 | 0.0114 | 0.1069 | 0.0164 | 0.0858 |
| Average | 0.9978 | 0.0055 | 0.0716 | 0.0109 | 0.0589 |

Table VI presents the performance of the model when optimized using the APO optimizer. The results indicate a notable improvement in performance. The average R2 value increases to 0.9978, demonstrating enhanced model reliability. Additionally, the error values significantly decrease, with MSE dropping to 0.0055, RMSE to 0.0716, MAPE to 0.0109, and MAE to 0.0589. The lowest MSE value (0.0016) and RMSE value (0.0399) occur in iteration 7, corresponding to an exceptionally high R2 value of 0.9992, signifying excellent model accuracy. The highest error values are observed in iteration 10 (MSE = 0.0114, RMSE = 0.1069, MAPE = 0.0164, MAE = 0.0858), yet these values remain significantly lower compared to the non-optimized model.

A comparison between the two approaches clearly demonstrates the advantage of using the APO optimizer. The reduction in error values across all metrics indicates that the optimization process successfully enhances model accuracy and stability. Notably, APO optimization effectively minimizes variations in model performance, ensuring consistency across iterations. The improvement in R2 values confirms that the optimized model maintains a stronger correlation between predictions and actual values, leading to more reliable outcomes.

## V. CONCLUSION

This study identified lack of capital and skilled workforce as the primary barriers preventing European SMEs from adopting Industry 4.0 technologies. Successful implementation depends not only on financial resources but also on strong leadership, strategic planning, and continuous skill development. The proposed model can guide SMEs in prioritizing digitalization steps and securing support through training and funding schemes. Importantly, Industry 4.0 is not exclusive to large firms—SMEs, with proper planning and resources, can also participate effectively. Future work will focus on developing cost-efficient AI-based training platforms to upskill SME workforces in Industry 4.0 technologies. Integration of real-time data from SME pilot implementations can further validate the UKSSL framework. Research can also explore decentralized financing models to ease capital constraints. Additionally, collaborative innovation hubs may support knowledge sharing and reduce adoption barriers.

***Abstract*—This study addresses the low production efficiency in manufacturing enterprises caused by the diversification of order products, small batches, and frequent production changeovers. Focusing on minimizing the makespan, this study establishes a Flexible Job-Shop Scheduling Problem (FJSP) model incorporating machine setup and workpiece transportation times, and proposes an improved sparrow search algorithm to effectively solve the problem. Based on the sparrow search algorithm, this study proposes a novel location update strategy that expands the search direction in each dimension and strengthens each individual's local search capability. In addition, a critical-path-based neighborhood search strategy is introduced to enhance individual search efficiency, and an earliest completion time priority rule is employed during population initialization to further improve solution quality. Several experiments are conducted to validate the effectiveness of the improved strategy, and the results are compared with those obtained using the particle swarm optimization and gray wolf optimization algorithms to demonstrate the efficiency of the proposed model and algorithm. The improved sparrow search algorithm can effectively generate feasible solutions for large-scale problems, provide practical manufacturing scheduling schemes, and enhance the production efficiency of manufacturing enterprises.**

***Keywords*—Flexible job shop scheduling; machine setup; transportation; sparrow search algorithm; earliest completion time priority***

## I. INTRODUCTION

The Flexible Job Shop Scheduling Problem (FJSP) is a key area in modern manufacturing. The growing complexity of market demands, such as product diversification, small-batch production, and frequent changeovers, has intensified the need to consider setup and transportation times in production scheduling. This makes FJSP research incorporating these factors, a critical academic focus.

Scholars have conducted extensive research on the flexible job shop scheduling problem under single constraints, either setup time or transportation time. Defersha et al.[1], investigated the flexible job shop scheduling problem considering worker-machine setup times and proposed an improved simulated annealing algorithm to solve it. Li et al.[2], proposed an improved artificial immune system algorithm to solve the flexible job shop scheduling problem considering setup scenarios. Peng et al.[3], investigated the multi-objective flexible job shop scheduling problem with job transportation time and learning effect constraints, and proposed a hybrid discrete multi-objective imperialist competitive algorithm to solve the model. Zhang Guohui et al. [4], examined the impact of machine installation, positioning, and other adjustment times on the flexible job shop scheduling problem, and proposed an improved genetic algorithm to solve the problem. Sadrzadeh [5], proposed a hybrid artificial immune-particle swarm optimization algorithm and validated its effectiveness through numerical experiments. Zhang et al.[6], designed a genetic algorithm with a tabu search procedure to solve the flexible job shop scheduling problem with transportation constraints and limited processing times. The aforementioned scholars have proposed various algorithms to address the FJSP with either setup or transportation times separately considered. However, these studies have overlooked the interactions among processing, setup, and transportation times. Setup times affect the start time of processing tasks, whereas processing times determine the start time of transportation tasks. The combined effects of setup and transportation times result in varying machine waiting times. Therefore, flexible job shop scheduling problem that simultaneously incorporates setup and transportation times is more consistent with real-world production scenarios.

For the flexible job shop scheduling problem that incorporates both setup and transportation times, An et al.[7], proposed a hybrid multi-objective evolutionary algorithm based on a Pareto elite storage strategy, aiming at minimizing the makespan, total delay, total production cost, and total energy consumption. Li et al.[8], simultaneously optimized energy consumption and makespan, employing an improved Jaya algorithm to solve the problem. Zhang et al.[9], proposed an effective heuristic algorithm to minimize the makespan and total energy consumption. Sun et al.[10], developed a hybrid multi-objective evolutionary algorithm aimed at minimizing makespan, total workload, critical machine workload, and penalties for early or late completion. Rossi [11], investigated the flexible job shop scheduling problem incorporating both transportation and setup times, employing an ant colony algorithm enhanced with pheromone mechanisms. In summary, the primary approaches for solving the flexible job shop scheduling problem encompass exact algorithms based on mathematical programming, as well as intelligent evolutionary methods such as the Genetic Algorithm (GA) [12], Tabu Search

(TS) [13], Ant Colony Optimization (ACO) [14], and Particle Swarm Optimization (PSO) [15]. Traditional algorithms such as genetic algorithms and tabu search often encounter limitations when addressing these problems, including high dimensionality, slow convergence, and challenging parameter tuning. In 2020, Xue et al., proposed the Sparrow Search Algorithm (SSA) [16], a novel population-based intelligent optimization method characterized by simple principles, few parameters, and ease of implementation, and has been widely applied in various fields [17]. Although the SSA algorithm has also been applied to solve the FJSP, its application to the FJSP with simultaneous consideration of setup and transportation times remains relatively rare.

Based on the aforementioned background, this study incorporates the real production scenario of Dalian BL Technology Co., Ltd. and formulates an integer programming model for the flexible job shop scheduling problem, which considers both setup and transportation times, aiming to minimize the makespan. The effectiveness of the proposed algorithm is verified using the CPLEX solver. As the data scale increases, it becomes difficult for exact algorithms to solve the problem in a short time. This study introduces enhanced strategies, culminating in the design of an Improved Sparrow Search Algorithm (ISSA) to solve the problem. Finally, the effectiveness of these enhanced strategies and the efficiency of the ISSA algorithm are validated using the small-scale Kacem and medium-to-large-scale Brandimarte benchmark instances.

The remainder of this paper is organized as follows: Section II formulates the problem and constructs the mathematical model. Section III presents the encoding scheme and proposes the improved sparrow search algorithm. Computational experiments are conducted in Section IV, followed by results and discussions in Section V. Finally, conclusions are provided in Section VI.

## II. Problem Description and Model Construction

### A. Problem Description

Dalian BL Technology Co., Ltd. is a multi-sector, order-driven manufacturing enterprise. The orders they receive typically consist of small batches and a wide variety of parts. When processing different types of parts, the machines require adjustments such as changing tool heads and adjusting machine parameters. Additionally, when metal parts proceed to the next processing step, they often need to be transferred to different machines, and manual transport equipment is employed to move the parts. Building on this manufacturing scenario, the workshop scheduling problem can be formulated as a flexible job shop scheduling problem (FJSP) that incorporates both setup and transportation times, described as follows: there is a set of $n$ jobs, denoted by $J = \{J_1, J_2, \ldots, J_n\}$, and a set of $m$ machines, denoted by $M = \{M_1, M_2, \ldots, M_m\}$. Each job $J_i$ consists of $j$ operations, with the $j$ -th operation of job $J_i$ represented by $O_{ij}$. Each operation can be processed on one or more machines; however, each machine can process only one operation at a time. Once an operation starts on a machine, it cannot be interrupted. Operations within the same job must adhere to a prescribed sequence, whereas there are no sequencing constraints among operations from different jobs. At any given time, each job can be processed on only one machine. Before any machine can process a job, it must be adjusted by workers according to that job's characteristics; moreover, the machine requires re-adjustment when switching between jobs. When transferring a job's operation to a different machine, transport equipment is required to move the job.

The problem follows the standard constraints of the flexible job shop scheduling problem while additionally accounting for the effects of machine setup and transportation on the scheduling process. Based on real-world conditions and the scope of this research, the following constraints and assumptions are proposed:

- If a job is processed consecutively on the same machine, no transportation is required.
- If two or more consecutive operations on a machine belong to the same job, no setup time is required for the subsequent operation.
- Loading and unloading times are included in the overall transportation time.
- Human resources and transport equipment are sufficiently available and can respond in real-time.

### B. Scenario Analysis

In the actual manufacturing scenario, processing can begin only after setup is completed, thereby influencing the processing start time. Similarly, transportation can commence only once an operation finishes, affecting the start time of transportation. Furthermore, subsequent processing can begin only after the setup has been completed and the job has been transferred to the next machine. The combined effects of setup and transportation times influence the machine's waiting time. Consequently, setup, transportation, and processing times are interrelated.

Taking the extended Kacem 4×5 dataset as an example, if scheduling is carried out without accounting for setup and transportation times, the resulting plan is shown in Fig. 1(a). If this scheduling plan is applied directly in the workshop, a significant delay in the overall makespan will result, as illustrated in Fig. 1(b). However, after incorporating the effects of setup and transportation times on the makespan, the proposed model optimizes the scheduling plan, and the final outcome, depicted in Fig. 1(c), achieves a shorter makespan compared to the previous plan.

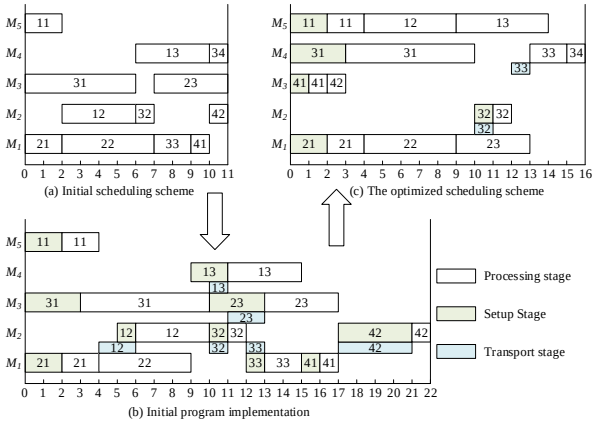

Fig. 1. Comparison of scheduling schemes

### C. Model Construction

The definitions of the model parameters are provided in Table I.

TABLE I. PARAMETERS OF FJSP MODEL WITH SETUP TIME AND TRANSPORTATION TIME

| Parameter | Definition |
|---|---|
| $J$ | Job set |
| $M$ | Machine set |
| $i, p$ | Job index |
| $J_i$ | A set of operations for job $i$ |
| $j, q$ | Operation index |
| $k, l$ | Machine index |
| $C_i$ | Completion time of job $i$ |
| $O_{ij}$ | Operation $j$ of job $i$ |
| $v_{ij}$ | Start transportation time of $O_{ij}$ |
| $u_{ij}$ | End transportation time of $O_{ij}$ |
| $s_{ij}$ | Start setup time of $O_{ij}$ |
| $Cmax$ | Maximum completion time |
| $e_{ij}$ | Ends setup time of $O_{ij}$ |
| $g_{ij}$ | Processing starts time of $O_{ij}$ |
| $h_{ij}$ | End processing time of $O_{ij}$ |
| $T_{ijk}$ | Processing time on machine $k$ of $O_{ij}$ |
| $P_{lk}$ | Transportation time from machine $l$ to $k$ |
| $W_{ijk}$ | Setup time on machine of $O_{ij}$ |
| $z_{ij}$ | For $O_{ij}$ 1 indicates that setup is required, 0 indicates that setup is not required |
| $x_{ijk}$ | For $O_{ij}$ 1 indicates that processing on machine $k$, 0 indicates not |
| $y_{ijkpq}$ | For$O_{ij}$ 1 indicates that processing before $O_{pq}$ on machine $k$, 0 indicates not |
| $L$ | A large positive number |
| $a$ | Virtual workpieces serve as start and end markers on the machine, helping to enforce tight-front and tight back constraints |

Based on the problem description, the model is constructed as follows:

$$mainCmax = maxC_i \tag{1}$$

$$h_{ij} \le v_{ij+1} \tag{2}$$

$$\sum_{k\in M} x_{ijk} = 1 \tag{3}$$

$$z_{ij} = \begin{cases} 1 \\ 1 - \sum_{k\in M}\sum_{p\in\{J_1,\dots,J_{j-1}\}} y_{ipkij} \end{cases} \tag{4}$$

$$h_{ij} = g_{ij} + \sum_{k\in M}\left(T_{ijk}\cdot x_{ijk}\right) \tag{5}$$

$$e_{ij} = s_{ij} + \sum_{k\in M}\left(W_{ijk}\cdot x_{ijk}\right)\cdot z_{ij} \tag{6}$$

$$u_{ij} = v_{ij} + \sum_{j,k\in M}\left(P_{ijk}\cdot x_{i(j-1)k}\right)\cdot x_{ijk} \tag{7}$$

$$h_{ij} \le s_{ij} + L\cdot\left(\sum_{k\in M} y_{ijkpq}\right) \tag{8}$$

$$\sum_{p\in J\cup\{a\},q\in J_p} y_{ijkpq} = x_{ijk} \tag{9}$$

$$\sum_{p\in J\cup\{a\},q\in J_p} y_{pqkij} = x_{ijk} \tag{10}$$

$$s_{ij} \le e_{ij} \le g_{ij} \le h_{ij} \le C_i \tag{11}$$

$$v_{ij} \le u_{ij} \le g_{ij} \le h_{ij} \le C_i \tag{12}$$

Eq. (2) stipulates those operations of the same job must be processed in sequence, and that transportation can commence only after the preceding operation is finished. Eq. (3) indicates that each process must be assigned to exactly one machine for processing. Eq. (4) indicates whether an operation requires setup. Eq. (5) represents the processing time constraints for the job. Eq. (6) represents the setup phase time constraints for the job. Eq. (7) represents the transportation phase time constraints for the job. Eq. (8) imposes timing constraints between adjacent operations and ensures that only one operation (whether setup or processing) can be performed on a machine at a time. Eq. (9) and Eq. (10) stipulate that if a job is being processed on a machine, there must be one preceding and one succeeding operation (including virtual operations). Eq. (11) and Eq. (12) represents the time constraints for each phase of the operation, requiring that the job must arrive at the machine and complete the setup before production begins. Additionally, the setup and transportation operations can occur independently.

## III. ALGORITHM DESIGN

The flexible job shop scheduling problem that considers both setup and transportation times, as investigated in this study, is an NP-hard problem. As the problem size grows, exact algorithms struggle to produce solutions within a short time. Considering the sparrow search algorithm's advantages—few parameters and ease of implementation—this study adopts and refines it to efficiently solve the aforementioned mixed-integer programming model.

### A. Encoding and Decoding

*1) In Flexible job shop scheduling research, encoding primarily addresses two aspects:* operation sequencing and machine selection. To address this challenge, a two-stage encoding scheme—operation sequence and machine sequence—is designed, as illustrated in Fig. 2.

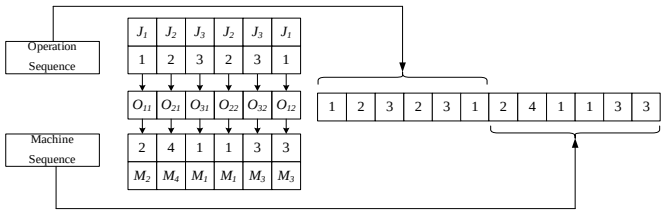

Fig. 2. An example of encoding.

*2) Operation Sequence (OS):* Each element in the sequence represents an operation for a job, and its position in the encoded sequence determines the order in which operations are performed. For example, if the OS sequence is1-2-1-3-2-3-1, it means the sequence of operations for these three jobs is $O_{11} - O_{21} - O_{12} - O_{31} - O_{22} - O_{32} - O_{13}$ .This encoding method

ensures the sequential constraints among multiple operations of each workpiece.

*3) Machine Sequence (MS): Each* element in the sequence represents a machine, specifying which machine processes the corresponding operation in the OS sequence. For example, if the MS sequence is 1-3-1-2-3-1-3, then $O_{11}$ is processed on machine $M_1$, and operation $O_{21}$ is processed on machine $M_3$.

By applying the Ranked Order Value (ROV) rule, one can map continuous individual vectors to discrete individual vectors. This process consists of two parts: encoding conversion for operation sequencing and encoding conversion for machine assignment. After decoding, one must evaluate the resulting machining scheme's quality and determine whether forward insertion of the workpiece is necessary.

- The operation sequence conversion steps are illustrated in Fig. 3.
- The machine encoding is mapped according to Eq. (13).

$$m_o = round\left(\frac{(\lambda+m)(m-1)}{2m} + 1\right) \quad (13)$$

The $o \in [1, d]$ represents the ordinal of the operation sequence, where $d$ is the total number of operations. The function, $round()$ performs rounding. The parameter $\lambda \in [-m, m]$ indicates that the coded position corresponds to the individual's location in continuous space. The variable $m$ denotes the total number of machines, and $m_o$ denotes the machine number selected for the corresponding operation $O_{ij}$.

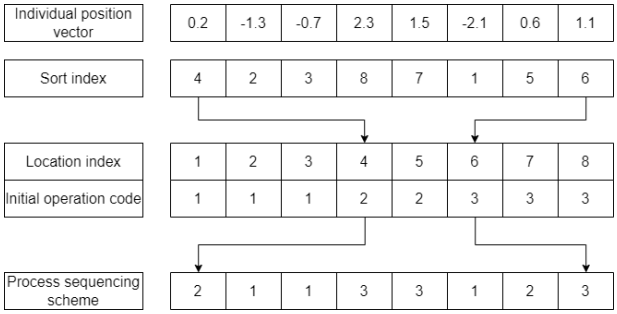

Fig. 3. ROV Mapping.

## B. Discoverers Location Update Strategy Optimization

An analysis of the discoverers' location update strategy in the sparrow population shows that when $R_2$ is lower than $ST$, the coefficient's range gradually shrinks from the initial [0,1] interval to roughly [0,1] as the number of iterations $i$ increases [16]. In particular, when $i$ is small, the coefficient is more l likely to be close to 1, thereby reducing the sparrow's range of activity in each dimension of the search space. Because finders constitute only a small fraction of the entire population, $i$ remains relatively small, causing the positional update factor to tend toward 1. To address this issue, if $R_2$ is less than ST, Eq. (14) can be used for the position update; otherwise, Eq. (15) is adopted.

$$X_{ij}^{t+1} = X_{ij}^{t} \cdot \left(2t + (-1)^t \cdot exp\left(\frac{-i}{a \cdot iter}\right)\right) \quad (14)$$

$$X_{ij}^{t+1} = X_{ij}^{t} + Q \cdot L \quad (15)$$

## C. Critical Path-Based Neighborhood Search

To further enhance the SSA algorithm's performance, a critical-path-based neighborhood search method is integrated into the basic SSA framework.

Processes located on the critical path often play a decisive role in determining the final quality of the overall scheduling scheme, as their completion times directly dictate the length of the entire production cycle. By adjusting these critical processes along with their adjacent operations, the algorithm explores additional solution spaces, thereby enhancing the potential to discover superior solutions. The procedure is as follows:

- Identify critical and non-critical operations;
- Randomly select one operation from the critical-operation set and one from the non-critical-operation set for swapping;
- New sequence feasibility check, the operation may be exchanged to the machine without processing capacity. The machine selection is carried out through the Earliest Completion Time First rule;
- Fitness calculation- Assign machines based on the workpiece coding sequence and machine coding, and perform forward insertion strategy to explore better results;
- Population update.

The pseudocode is as follows:

**Algorithm 1:** Critical path identification

```
Input: Operation Set
Begin:
    initialize CO
    for each operation O_ij:
        if h_ij = makespan then:
            put O_ij in CO
        end if
    end for
    while CO != null then:
        delete first operation O' of CO
        T = h_ij of O'
        for O_ij in Operation Set
            if h_ij = T then:
                put O_ij in CO
            end if
        end for
    end while
    return all marked operation
End
```

## D. Population Initialization

In the sparrow optimization algorithm, constructing the initial population is the first step, influencing the subsequent optimization process and outcomes. Although random initialization maintains the abundance and diversity of the population, the quality of individuals remains inconsistent. In

the initial phase of the algorithm, it may be difficult to quickly find a high-quality solution, requiring numerous iterations to gradually approach the optimal solution. This process raises the algorithm's computational cost and execution time. To enhance the algorithm's performance, this study employs random generation and ECT rule-based initialization to produce 50% of the population. The ECT rule dynamically calculates the completion time of each operation on every machine and assigns tasks to the machine with the earliest completion, thereby eliminating unreasonable machine selections during initialization and producing an initial solution that is both high in quality and diverse.

The pseudocode is as follows:

**Algorithm 2:** ECT rule

**Input:** Current operation ($O_{ij}$), process time on each machine ($T_{ijk}$), setup time on each machine ($W_{ijk}$), transportation time between $M_l$ (process$O_{ij-1}$) to current machine $M_k$($P_{lk}$)

**Begin:**
- **initialize** $t, p, w, completion\_time, et$
- **for** each machine$M_k$**:**
  - **If** $M_k$can process $O_{ij}$**then:**
    - $p = T_{ijk}, w = W_{ijk}$
    - **If** $O_{ij}$ is the first operation of the Job **or** the first operation on $M_k$ **or** $O_{ij}$ and $O_{pq}$ are from same job **then:**
      - $st = 0$
    - **end if**
    - **if** $O_{ij}$ is the first operation of the Job or $O_{ij-1}$ is processed on $M_k$ **then:**
      - $p = 0$
    - **else**
      - $p = P_{lk}$
    - **end if**
    - completion_time = $max(h_{ij-1} + tt, h_{pq} + w) + t$
    - **if** completion_time ≤ $et$ **then:**
      - mark current machine $M_k$ and update $et$
    - **end if**
  - **end if**
- **end for**
- **return** marked machine

**End**

## IV. Analysis of Numerical Experiments

This study performs an ablation experiment to validate both the effectiveness of the proposed algorithmic improvement strategy and the algorithm's overall efficiency. Additionally, small-scale and medium-to-large-scale experiments were conducted to further assess the algorithm's efficiency. The experiments were implemented in Java, running on an Intel(R) Core(TM) i5-7500 CPU @ 3.40GHz processor with 8GB RAM and the Windows 10 Professional operating system.

The experimental dataset consists of 15 newly created instances (MK01–MK10, Kacem01–Kacem05), which is generated by the small-scale Kacem dataset and the medium-scale Brandimarte dataset [18]. The commissioning time and shipping time are generated according to relevant strategies [19].

For the algorithm parameters, the population size exhibits a critical trade-off in optimization algorithms: an undersized population is prone to premature convergence to local optima, whereas an excessively large population imposes prohibitive computational overhead. Insufficient iteration cycles compromise convergence completeness while introducing substantial computational redundancy. The proportional allocation between discoverers and followers critically modulates the equilibrium between global exploration and local exploitation capacities within the algorithm framework. Through systematic orthogonal experimental design, the optimal parameter configuration was determined as follows: The population size was set to $N = 100$, the maximum number of iterations to $N\_iter = 400$, the discoverer proportion to $PD = 20\%$, and the vigilant proportion to $SD = 80\%$.

### A. Validation of the Improvement Strategy's Effectiveness

The Improved Sparrow Search Algorithm integrates three strategies into the standard algorithm: SSA1 denotes an optimized discoverer location update strategy, SSA2 represents population initialization via an ECT heuristic, and SSA3 adopts a critical-path-based neighborhood search strategy. This study designed eight sets of experiments to compare the strategies presented in TABLE II. The eight algorithms were each run independently ten times on the Brandimarte dataset, recording their best, average, and variance values, as well as the solution time.

TABLE II. Algorithm Comparison Strategy

| | SSA | SSA1 | SSA2 | SSA3 | SSA12 | SSA13 | SSA23 | SSA123 |
|---|---|---|---|---|---|---|---|---|
| Strategy 1 | ○ | ● | ○ | ○ | ● | ● | ○ | ● |
| Strategy 2 | ○ | ○ | ● | ○ | ● | ○ | ● | ● |
| Strategy 3 | ○ | ○ | ○ | ● | ○ | ● | ● | ● |

Note: ● indicates that the policy is applied; ○ indicates that the policy is not applied

*1) Analysis of the discoverer's location update strategy:* Strategy I modifies the parameters of the sparrow population's position update formula, increasing the step size and direction of the position update and enhancing the global search capability of the sparrow search algorithm to avoid local optima. In independent runs, the tenth solution comes closer to the optimum, showing reduced variance. As illustrated in Fig. 4(a), SSA1 outperforms SSA in variance across 12 of the 15 datasets, exhibiting a reduction of over 50% in Mk08 and Mk09. Fig. 4(b) to (d) presents comparative trials of the other groups incorporating Strategies II and III.

*2) Analysis of ECT rule strategies:* Among the four algorithms listed in Table II—SSA2, SSA12, SSA23, and SSA123—incorporate the finder location update strategy. To assess the impact of Strategy II, it is removed from these algorithms and compared with SSA, SSA1, SSA3, and SSA13. As a specific strategy, the ECT rule is tailored to the characteristics of this problem and is thus highly suited to the research in this chapter. The ECT rule quickly locates machines with shorter completion times, complementing the sparrow search algorithm. In conjunction with its global search

capability, this improves solution quality and efficiency. As shown in Fig. 5(a) to (d), when the effects of Strategies I and III are excluded, incorporating improved Strategy II yields superior solution quality. Since the sparrow algorithm relies on the current optimal solution when the sparrow population undergoes positional updating during the iterative process, high quality initial values can improve the solution quality. Results from ten independent experimental runs reveal a notable decrease in both the best and average values across all datasets, with a more pronounced effect on larger datasets. The quality of the initial population solution generated by the ECT rule and the random generation method is shown in Fig. 6(a), and the variance of the solution is shown in Fig. 6(b).

*3) Critical path-based neighborhood search strategy analysis:* Among the algorithms listed in Table II, SSA3, SSA13, SSA23, and SSA123 apply the location update strategy and culling Strategy II is compared with algorithms SSA, SSA1, SSA2, and SSA12. Incorporating Strategy III increases the solution time while reducing the average solution value. Since the processes on the critical path dictate the final completion time, each iteration later applies Strategy III to swap critical and non-critical processes. While this two-step operation of identifying and exchanging key processes increases computation time, it also enables a stronger local search capability. Fig. 7. (a) to (d) compares the effects of applying exclusion Strategies I and II and improvement strategy III on the algorithm's convergence performance. Incorporating Strategy III, clearly enhances the sparrow population's capacity for precise searching, leading to higher-quality solutions across iterations. The algorithm augmented by the improved Strategy III achieves an even better optimal solution.

### B. Small-Scale Experimental Validation Analysis

In the small-scale experiments, Java was used to invoke the CPLEX solver for comparison with the Improved Sparrow Search Algorithm. The solution results for the small-scale Kacem benchmark instances are presented in TABLE III. The Improved Sparrow Search Algorithm's solution time grows slowly as the problem size increases. Moreover, the difference between its objective function value and that of the exact solution via CPLEX remains small—specifically, the gap between the optimal solutions is only 1. However, from the kacem8-8 instance onwards, ISSA runs significantly faster than the solver, demonstrating the effectiveness of the Improved Sparrow Search Algorithm.

TABLE III. COMPARISON OF CPLEX AND ISSA ON KACEM DATA SET

| Dataset | CPLEX | | ISSA | |
|---|---|---|---|---|
| | $f$ | $t/s$ | $f$ | $t/s$ |
| kacem4-5 | 16 | 0.22 | 17 | 3.63 |
| kacem8-8 | 22 | 32.03 | 24 | 10.61 |
| kacem10-7 | 17 | 322.98 | 18 | 9.97 |
| kacem10-10 | 11 | 37.13 | 12 | 11.11 |
| kacem15-10 | 22 | 115200 | 23 | 35.59 |

### C. Analysis of Large-Scale Experimental Validation

TABLE IV. presents the experimental results of the Improved Sparrow Search Algorithm compared with the standard sparrow search algorithm, the standard gray wolf optimization algorithm, and the genetic algorithm. The experiment uses the Brandimarte dataset, running each set of algorithms independently ten times. The average value was taken as the solution for each algorithm, and the performance gap between the three algorithms and the best solution among them was also recorded. From Table IV, it can be observed that the Improved Sparrow Search Algorithm shows a significant improvement in all 15 instances, with a minimum improvement rate of 7.96% and an average improvement rate of 26.48%. Moreover, the optimal values obtained by ISSA are consistently better than those achieved by the gray wolf algorithm and the genetic algorithm. The enhanced position updating strategy strengthens the sparrow search algorithm's global search capability, helping it avoid local optima and consistently discover superior solutions across all the 15 algorithms. In all 15 test instances, the Improved Sparrow Search Algorithm achieves the optimal solution. $G_g$ denotes the gap between the optimal values of the GWO, GA, and ISSA solutions. The GWO algorithm's smallest gap is 9.0%, with an average gap of 33%. Meanwhile, when comparing the GA algorithm to ISSA, the smallest gap is 20.3%, and the average gap is 56%. These findings confirm that the ISSA algorithm developed in this study exhibits superior stability, convergence, and efficiency when solving FJSP problems involving setup and transportation times.

TABLE IV. COMPARISON OF ISSA, SSA, GWO AND GA

| Dataset | ISSA | SSA | | GWO | | GA | |
|---|---|---|---|---|---|---|---|
| | $f$ | $f$ | $G_g$ | $f$ | $G_g$ | $f$ | $G_g$ |
| Mk01 | 70.7 | 84 | 18.81% | 91.0 | 28.7% | 92.3 | 30.6% |
| Mk02 | 56.0 | 75 | 33.93% | 83.1 | 48.4% | 77.1 | 37.7% |
| Mk03 | 316.0 | 416 | 31.65% | 439.4 | 39.1% | 543.7 | 72.1% |
| Mk04 | 118.2 | 135 | 14.21% | 141.2 | 19.5% | 154.9 | 31.0% |
| Mk05 | 296.4 | 320 | 7.96% | 341.6 | 15.2% | 358.5 | 21.0% |
| Mk06 | 160.1 | 233 | 45.53% | 246.1 | 53.7% | 332.3 | 107.6% |
| Mk07 | 243.4 | 339 | 39.28% | 362.2 | 48.8% | 321.1 | 31.9% |
| Mk08 | 873.4 | 914 | 4.65% | 952.0 | 9.0% | 1050.6 | 20.3% |
| Mk09 | 596.2 | 720 | 20.76% | 754.4 | 26.5% | 1051.6 | 76.4% |
| Mk10 | 438.2 | 631 | 44.00% | 652.2 | 48.8% | 918.2 | 109.5% |
| Mk11 | 997.6 | 1113 | 11.57% | 1145.1 | 14.8% | 1221.8 | 22.5% |
| Mk12 | 830.0 | 963 | 16.02% | 1010.0 | 21.7% | 1090.7 | 31.4% |
| Mk13 | 737.5 | 1069 | 44.95% | 1081.9 | 46.7% | 1427.8 | 93.6% |
| Mk14 | 1037.2 | 1364 | 31.51% | 1408.6 | 35.8% | 1602.1 | 54.5% |
| Mk15 | 692.4 | 917 | 32.44% | 952.8 | 37.6% | 1407.0 | 103.2% |

## V. RESULTS AND DISCUSSION

Firstly, the experimental validation presented in Section IV demonstrates that Strategy I effectively improves the algorithm's stability with better variance performance, while Strategy II significantly improves the quality of initial solutions, thereby accelerating the optimization process and elevating solution quality. Additionally, Strategy III achieves considerable improvements in both convergence speed and solution quality, with only a marginal increase in computational complexity.

Secondly, experimental results on small-scale instances show that the proposed algorithm produces solutions comparable to those obtained by CPLEX solver, while exhibiting superior computational efficiency. For small-scale problems, our algorithm can effectively generate production

scheduling solutions. In large-scale experiments, the proposed algorithm outperforms other classical algorithms in terms of both solution accuracy and quality, demonstrating its effectiveness in solving flexible job shop scheduling problems that consider both setup and transportation times.

## VI. CONCLUSION

Frequent production changes seriously impact the productivity of discrete order-driven manufacturing enterprises. This study considers the machine commissioning time caused by production changeovers and the transportation time due to workpiece changeovers on processing machines. A mixed-integer programming model is formulated to minimize the makespan, and an Improved Sparrow Search Algorithm is proposed to solve it. Experimental comparisons with CPLEX, the Gray Wolf Algorithm, and the Genetic Algorithm confirm the algorithm's effectiveness and efficiency. The results demonstrate that the location updating strategy involving an expanded search direction, the ECT-based population initialization tailored to the problem, and the critical-path-based neighborhood search strategy proposed herein significantly enhance both solution efficiency and quality for the sparrow search algorithm. Future research could refine this study by incorporating employee resource constraints in machine commissioning and the operation of transport equipment to address more complex flexible job shop scenarios.

Future studies will advance this work by integrating machine-setup constraints and operator resource limitations for material-handling equipment, thereby refining the scheduling model to accommodate more complex scenarios in flexible job shop environments.

# A Hybrid Levy Arithmetic and Machine Learning-Based Intrusion Detection System for Software-Defined Internet of Things Environments

Wenpan SHI[1], Ning ZHANG[2]*
Department of Computer and Digital Law, Hebei Professional College of Political Science and Law, Shijiazhuang 050000, China[1]
Baoding Open University, Baoding 071000, China[2]

***Abstract*—The convergence of Software-Defined Networking (SDN) and the Internet of Things (IoT) has enabled a more adaptable framework for managing SDN-enabled IoT (SD-IoT) applications, but it also introduces significant cyber security risks. This study proposes a lightweight and explainable intrusion detection system (IDS) based on a hybrid Levy Arithmetic Algorithm (LAA) for SD-IoT environments. By integrating Levy randomization with the Arithmetic Optimization Algorithm (AOA), the LAA enhances feature selection efficiency while minimizing computational overhead. The model was evaluated using the NSL-KDD and UNSW-NB15 datasets. Experimental results demonstrate that the LAA outperformed baseline models, achieving up to 89.2% F1-score and 95.4% precision, while maintaining 100% detection of normal behaviors. These outcomes highlight the proposed system's potential for accurate and efficient detection of cyber-attacks in resource-constrained SD-IoT environments.**

***Keywords*—Intrusion detection; internet of things; software-defined; feature selection; levy arithmetic***

## I. Introduction

### A. Background

The Internet of Things (IoT) emerged from the rapid development of intelligent sensors recently and the need for device connectivity [1]. IoT presents broad opportunities in the healthcare, industrial, and supply chain industries, requiring robust stability, resilience, scalability, versatility, and control [2]. Moreover, IoT components have limits to their capabilities and contain embedded chips with various configurations. Traditional networks have become increasingly complex due to IoT-specific demands. Software-Defined IoT (SD-IoT) seeks to bring Software-Defined Networking (SDN) to the IoT by providing resource flexibility and network management for existing networks. SDN is considered a key technology to develop next-generation networks [3].

SDN transforms conventional Internet architecture via the separation of management and data layers [4]. Therefore, the management layer features more intelligence, programming, and innovation and accesses all SD-IoT components where resources and traffic can be efficiently managed. The security challenges associated with SD-IoT prevent its applications from being realized sooner. First of all, security concerns stem from the shared decision-making power of SD-IoT [5]. Attackers can quickly initiate and take over central controllers by conducting and applying malicious techniques and tactics like Denial of Service (DoS), Distributed DoS (DDoS), and malware, implement erroneous policies, and degrade network performance. Consequently, a security strategy must be a core part of the SD-IoT design to protect against cyber-attacks and maintain functionality [6].

### B. Problem Statement

A Network Intrusion Detection System (NIDS) is a tool developed to track and examine traffic on a network to identify threats, breaches, or illegal activities [7]. Signature-driven (also called misuse-focused or knowledge-based) and anomaly-based (also called behavior-based) methodologies are two primary methods for detecting intrusions into IoT systems [8]. It is possible to create a hybrid detection mechanism by combining both. However, this would require a lot of energy and resources to implement. Unlike anomaly-based systems that detect attacks based on traffic patterns, signature-driven systems classify traffic based on known threats. Existing and well-known attacks are well-protected by signature-based systems [9].

The rise of SD-IoT networks demands adaptive security mechanisms to address diverse cyber threats. While, commonly used, traditional methods like user authentication and encryption lack the flexibility to detect a wide range of evolving attacks in dynamic environments [10]. Intrusion Detection Systems (IDS), particularly those powered by machine learning, have proven effective in analyzing network traffic to identify attack patterns more accurately [11]. However, in resource-constrained SD-IoT systems, IDS models must be lightweight, analyzing only critical traffic features to maintain efficiency. Identifying these key attributes is a challenge. Moreover, ML-based IDS predictions are often tricky for cyber security experts to interpret, creating a need for Explainable Artificial Intelligence (XAI). XAI enhances transparency, allowing experts to understand and trust the decisions made by these models in cyber defense [12].

Applications such as geothermal energy extraction and underground mining increasingly rely on interconnected sensors and automated control systems for real-time monitoring and safety management. These cyber-physical environments, which include complex geological modeling and simulation efforts [13], are inherently vulnerable to cyber threats, thereby reinforcing the need for robust and lightweight intrusion detection systems in SD-IoT settings.

### C. Research Objectives

This study aims to address critical challenges in SD-IoT security by proposing an innovative solution for building a lightweight machine learning-based IDS. The main objective is to develop an efficient IDS by selecting an optimal subset of features, minimizing computational complexity, and conserving computing resources. The research introduces a novel feature selection method using the Levy-Arithmetic Algorithm (LAA), which applies the Levy flight random step theory to the Arithmetic Optimization Algorithm (AOA) to enhance search efficiency. Key contributions to this research include:

- Defining a security model for SD-IoT applications;
- Introducing a lightweight IDS using minimal features optimized by LAA;
- Training machine learning models such as Multi-Layer Perceptron, XGBoost, Random Forest, and Decision Tree on the selected features.

The remainder of the paper is structured as follows: Section II comprehensively reviews scholarly sources. Section III discusses the proposed method. Section IV presents the experimental setup and results. Section V outlines the primary outcomes, highlights the contributions, and suggests future research.

## II. Related Work

This section reviews the existing research on IDS for IoT deployments, listed in Table I. It highlights machine learning-based algorithms, feature selection techniques, and bio-inspired optimization algorithms for coping with resource constraints.

Rahman, et al. [14], proposed two approaches to overcome the limitations of centralized IDS for resource-limited endpoints: semi-distributed and decentralized. They used concurrent machine-learning algorithms to distribute the computing workload, with the semi-distributed scenario involving simultaneous modeling on the edge for feature selection and multiple classification layers. The decentralized scenario involved independent processes for feature selection and multi-layer perceptron classification, then amalgamated by a coordinated edge or fog for decision-making. The proposed approaches shows potential for detection accuracy equivalent to centralized IDS.

Forestiero [15], devised a technique for identifying irregularities in IoT using activity footprints. IoT2Vec, an embedding methodology, is used to depict devices and services using dense vectors. These vectors are allocated to mobile agents that adhere to an adapted bio-inspired paradigm. This approach facilitates intelligent global behavior derived from local movement rules recognized by all agents. A similarity rule facilitates each agent's selective application of movement rules, promoting automatic proximity among similar agents. The approach may detect solitary agents exhibiting anomalous behaviors, perhaps revealing intruders or malevolent users.

Li, et al. [16], used an Artificial Neural Network (ANN) to identify anomalous activity in a healthcare IoT system. The precision of recognition is significantly influenced by the characteristics inputted into the artificial neural network. Identifying relevant and distinctive aspects of network traffic is a critical and complex challenge due to its substantial influence on learning. The suggested approach utilizes the butterfly optimization algorithm to determine the ideal features for learning in an artificial neural network. The findings, achieving an accuracy of 92%, confirm the algorithm's efficacy in detecting discriminative aspects of traffic patterns. The suggested technique surpassed the performance of decision trees, support vector machines, and ant colony optimization used in prior research for the same objective.

TABLE I. Comparative Analysis of IDS Approaches for IoT Deployments

| Reference | Approach | Feature selection | Algorithm/model | Key findings |
|---|---|---|---|---|
| [14] | Semi-distributed and decentralized IDS approaches | Concurrent machine learning algorithms for workload distribution | Multi-layer Perceptron classification | Distributed IDS models show detection accuracy equivalent to centralized IDS. |
| [15] | Activity footprint analysis using IoT2Vec embedding | Bio-inspired selective movement rules | Mobile agents following adapted bio-inspired paradigms | The method detects anomalous behaviors by identifying isolated agents. |
| [16] | Anomaly detection in healthcare IoT | Butterfly optimization algorithm | Artificial neural network | Achieved 93.2% accuracy, outperforming decision trees, SVM, and ant colony optimization in feature selection. |
| [17] | Hybrid metaheuristic-deep learning for IoT intrusion detection | Harris hawk optimization and fractional derivative mutation | LSTM and GRU models | Outperformed other approaches in accuracy and efficiency on public datasets. |
| [18] | Detection of botnets using hybrid metaheuristics and machine learning | Modified firefly optimization | Hybrid CNN and quasi-recurrent neural network | Superior performance for botnet detection in cloud-based IoT systems. |
| [19] | IDS using variable searching pattern optimization for feature selection | Variable searching pattern optimization | Deep recurrent neural network | Achieved 96.1% accuracy, effectively identifying intrusions. |
| [20] | Hybrid IDS using grey wolf optimization and support vector machine | GWO for kernel function and parameter optimization | SVM with GWO | Outperformed other models in F-score, recall, precision, and accuracy on TON_IoT and NSL-KDD datasets. |

Sanju [17], presented a hybrid metaheuristic-deep learning methodology to improve the detection of intrusions in IoT systems. An enhanced metaheuristic approach using an ensemble of Recurrent Neural Networks (RNNs) is used to improve intrusion detection in IoT. Various attack kinds in IoT systems are discerned by using LSTM and GRU models, which are forms of RNNs. Feature selection is conducted using Harris Hawk optimization and fractional derivative mutation. The

evaluation of the suggested methodology used publicly accessible datasets, and the empirical study indicated that it outperforms other comparable approaches for accuracy and efficiency. It offers a viable technique for improving intrusion detection in IoT systems and may serve as a basis for future research in this domain.

Almuqren, et al. [18] introduced a Hybrid Metaheuristics with a Machine Learning-based Botnet Detection (HMMLB-BND) approach inside a cloud-assisted IoT system. HMMLB-BND concentrates on identifying and categorizing Botnet assaults inside the cloud-based IoT ecosystem. The Modified Firefly Optimization (MFO) algorithm is used for feature selection. HMMLB-BND employs a hybrid convolutional neural network and quasi-recurrent neural network module to identify botnets. The chaotic butterfly optimization approach is used for optimum hyperparameter tuning. A series of simulations were conducted on the N-BaIoT dataset, and the experimental results indicated the superiority of HMMLB-BND compared to other current methodologies.

Jayasankar, et al. [19] suggested an IDS using variable searching pattern optimization for feature selection with an optimum deep recurrent neural network model in an IoT context. It consists of a two-phase procedure: feature selection and incursion classification. In the first step, an ideal set of features is identified with variable searching pattern optimization. Subsequently, in the second phase, breaches are recognized and classified using the DRNN model. The hyperparameters of the DRNN are optimally selected using the Nadam optimizer. A comprehensive simulation study of the model is verified using a benchmark IDS dataset, and the results demonstrate the effectiveness of intrusion detection. The suggested model effectively identifies intrusions with an accuracy of 96.1%.

Ghasemi and Babaie [20] developed a hybrid intrusion detection technique using Grey Wolf Optimization (GWO) and Support Vector Machine (SVM). The SVM distinguishes between anomalous and normal records, while the GWO identifies the kernel function, selects features, and optimizes parameters for the SVM to enhance classification accuracy. The simulations demonstrate that the proposed method surpasses others in detection accuracy, precision, recall, and F-score on the NSL-KDD and TON_IoT datasets.

## III. Proposed Method

This section summarizes the graphical abstract used for the proposed model (LAA), which differs from conventional methods of selecting features. Detailed architectural pipelines for the model are described below. A methodology is described in the next section to elucidate the output (prediction) of the model. Fig. 1 illustrates a lightweight, explainable IDS.

This section presents a detailed method for determining appropriate features for devices with storage limitations. As a result, model performance improves owing to decreased calculation time and resource use. Machine learning relies on selecting a subset of optimum features from the available feature dimensions [21]. In this way, the dimensions of the feature vector become smaller, computation time decreases, and machine learning performance improves. A variety of feature selection techniques are used to reduce dimension. Some techniques for selecting features include LAA, information gain, and correlation coefficients.

AOA applies a metaheuristic strategy for analyzing exploration and exploitation balances based on math operations, like Addition, Subtraction, Multiplication, and Division. AOA is primarily inspired by the application of Arithmetic operators to resolve Arithmetic problems. According to Fig. 2, Arithmetic operators are arranged in a hierarchy according to their ascending dominance. The optimization procedure starts by randomly generating candidate solutions ($X$) given by Eq. (1). Best candidate solutions are considered the best-obtained or nearly optimum solutions in each iteration.

$$X = \begin{pmatrix} x_{1,1} & \cdots & \cdots & x_{1,j} & x_{1,n-1} & x_{1,n} \\ x_{2,1} & \cdots & \cdots & x_{2,j} & \cdots & x_{2,n} \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ x_{n-1,1} & \cdots & \cdots & x_{n-1,j} & \cdots & x_{n-1,n} \\ x_{n,1} & \cdots & \cdots & x_{n,j} & x_{n,n-1} & x_{n,n} \end{pmatrix} \quad (1)$$

Prior to the AOA commencement, it must choose the search strategy (i.e., exploration or exploitation). The Math Optimizer Accelerated (MOA) function is a coefficient derived from Eq. (2) used in subsequent search stages.

$$MOA(C_{iter}) = Min + C_{iter} \times \left(\frac{Max-Min}{M_{iter}}\right) \quad (2)$$

where, $MOA(C_{iter})$ represents the value of the function at iteration *t*, $M_{iter}$ indicates the maximum number of iterations, $C_{iter}$ indicates the current iteration and *Min* and *Max* are the lowest and highest accelerated values.

In the AOA, the Division and Multiplication operators generate highly dispersed values during mathematical computations, enhancing the search process's exploration phase. However, due to their high dispersion, these operators struggle to converge on the target as efficiently as the Addition and Subtraction operators. The exploration phase focuses on identifying near-optimal solutions, often requiring several iterations. At this stage, Division and Multiplication operators play a key role in enhancing communication between the exploration and exploitation phases, ultimately supporting the search process.

AOA's exploration operators randomly scan the search space across different regions, aiming to identify better solutions using two primary strategies: the Division and Multiplication strategies, as represented in Eq. (3). This search phase is governed by the MOA function, with the condition r1 > MOA. As illustrated in Fig. 3, the Division operator is activated when r2 < 0.5, while the Multiplication operator remains inactive until the Division task is completed. If the condition is not met, the Multiplication operator takes over. A stochastic scaling coefficient is also applied to introduce more diversity into the exploration, ensuring that a broader range of regions within the search space is evaluated.

$$x_{i,j}(C_{iter}+1) = \begin{cases} best(x_j) \div (MOP+\varepsilon) \times \\ \left(\left(UB_j - LB_j\right) \times \mu + LB_j\right), \quad r2 < 0.5 \\ best(x_j) \div MOP \times \\ \left(\left(UB_j - LB_j\right) \times \mu + LB_j\right), \quad otherwise \end{cases} \quad (3)$$

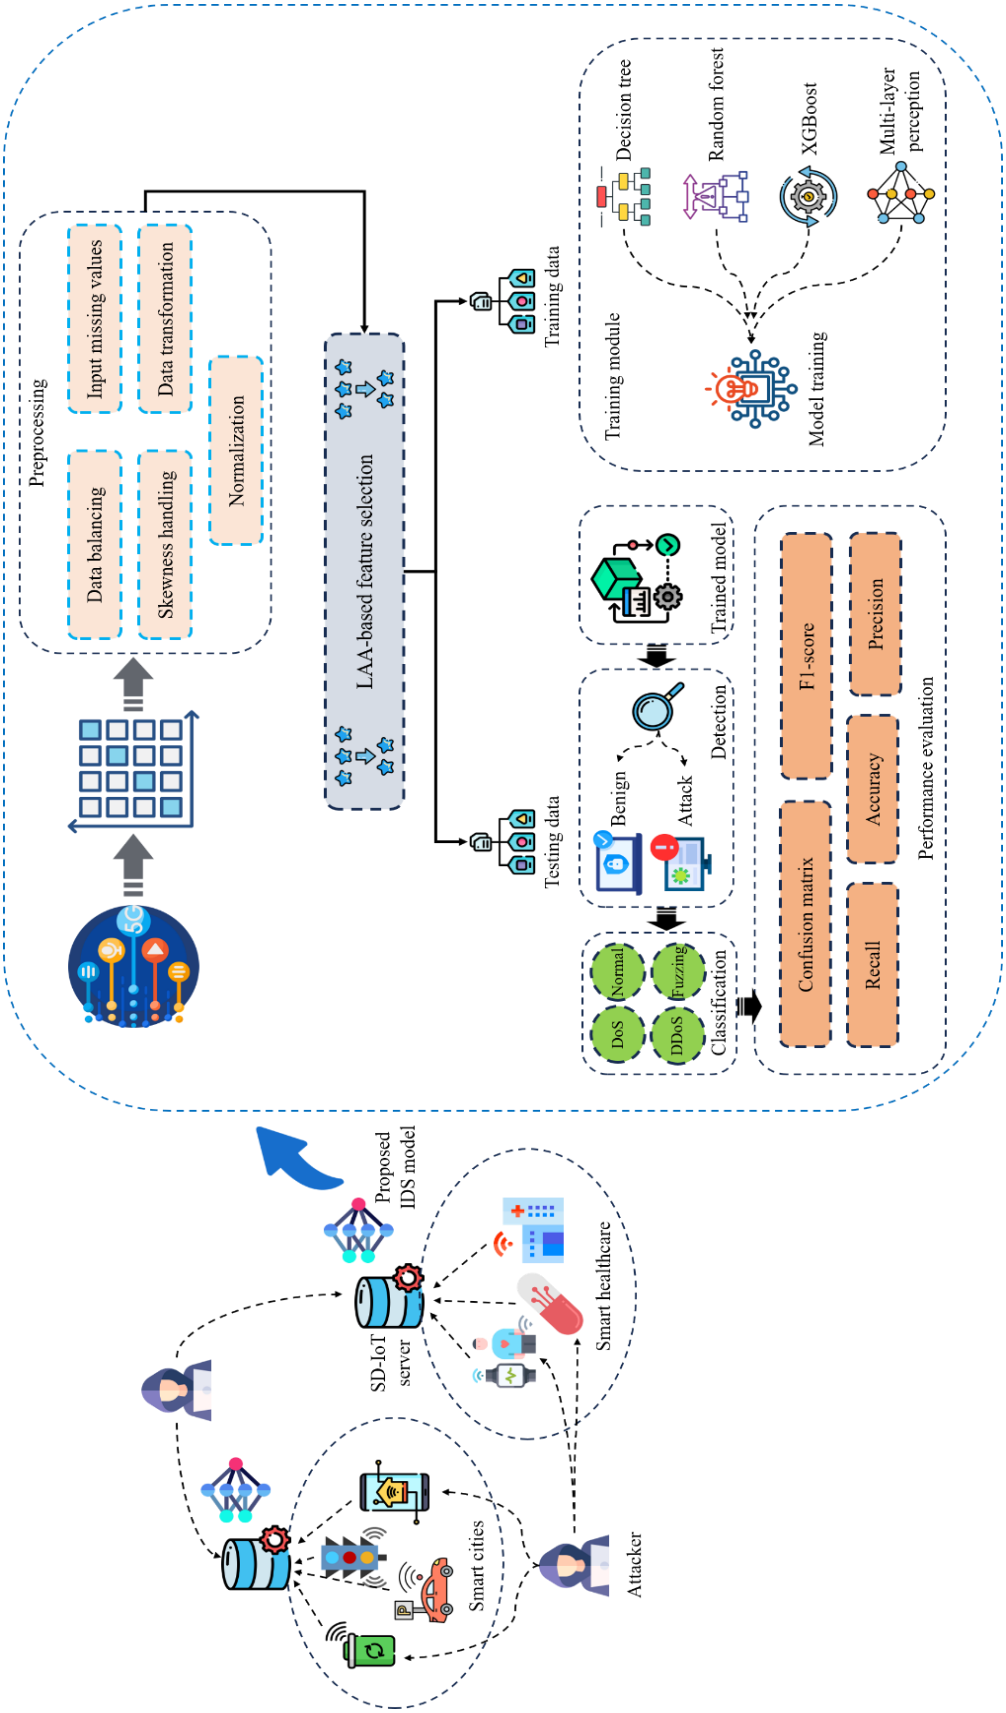

Fig. 1. System model.

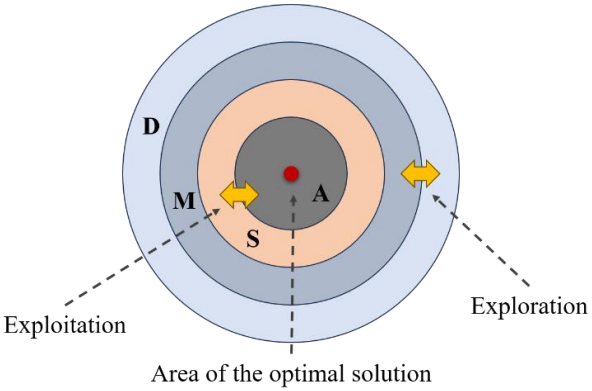

Fig. 2. Arithmetic operators.

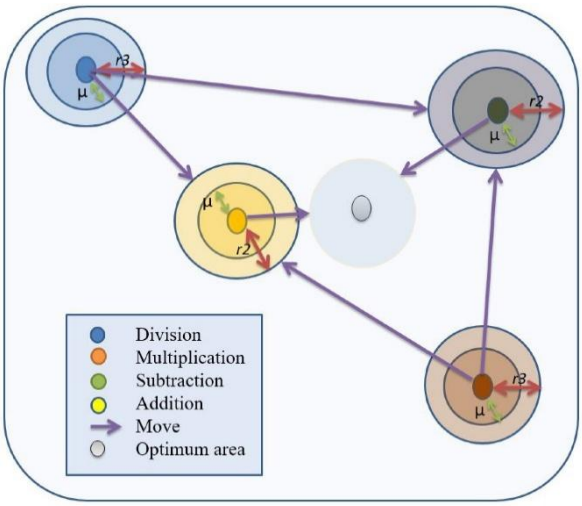

Fig. 3. Search space of AOA.

where, *r2* represents a random number ranging from 0 to 1, $\mu$ regulates search operations as a control parameter, $\varepsilon$ is a constant parameter for avoiding zero, and MOP gives a probability function-based math optimizer. Multiplication and subtraction operators have low precedence, allowing local searches to find the optimum outcome. The candidate solution is updated iteratively based on Eq. (4) to reach the optimal result.

$$x_{i,j}(C_{iter}+1) = \begin{cases} best(x_j) - MOP \times \\ \left((UB_j - LB_j) \times \mu + LB_j\right), & r3 < 0.5 \\ best(x_j) + MOP \times \\ \left((UB_j - LB_j) \times \mu + LB_j\right), & otherwise \end{cases} \quad (4)$$

In Eq. (3) and Eq. (4), Math Optimizer Probability (MOP) is the key function for finding the optimal value and determining its capability, determined by Eq. (5).

$$MOP(C_{iter}) = 1 - \frac{(C_{iter})^{1/a}}{(M_{iter})^{1/a}} \quad (5)$$

The Levy Random Step (LRS) denotes random walking in which the size of the steps follows a statistical distribution termed the Levy pattern. Its thick tails characterize this distribution, indicating that extreme or unusual events happen more often than normal occurrences. In a Lévy random walk, the step dimensions and orientations are sampled from this distribution, yielding many little steps interspersed with occasional significant leaps in random directions. This unpredictability must be regulated to successfully direct efforts toward optimum solutions while reducing departures from the best potential outcomes. Random steps are stochastic processes that involve taking a series of unpredictable steps, as expressed mathematically in Eq. (6).

$$S_n = \sum_{i=1}^{n} x_i = x_1 + x_2 + \cdots + x_n \quad (6)$$

where, $S_n$ is the sum of consecutive steps and $x_i$ represents each random step. The notion of Lévy random steps and flights, given by the French mathematician Paul Lévy, stems from the first investigations of stochastic processes in physics, including particle motion in fluids and gases. Levy walks and steps have been extensively studied and used across several disciplines, demonstrating their efficacy in optimization issues and other applications. The essence of a Lévy random step is rooted in the Lévy distribution, distinguished by its thick tails, which markedly enhance the probability of extreme step sizes relative to a normal distribution. The probability of a Lévy step may be mathematically estimated as shown in Eq. (7).

$$L(x) \approx |x|^{1-a} \quad (7)$$

where, α controls the tail heaviness, typically in the range $0<\alpha\leq 2$. The Levy distribution probability density function is expressed as in Eq. (8).

$$L(x) = \frac{1}{\pi}\int_0^{\infty} e^{-\gamma\tau^a} cos(\tau x) d\tau \quad (8)$$

where, $\gamma$ is a scaling parameter, usually set to 1, and $\tau$ is a small-time interval. As $\alpha$ increases, the distribution shifts closer to the mean, while lower values of $\alpha$ correspond to a distribution further from the mean. Mantegna's approach produces random numbers according to the Lévy distribution. This algorithm effectively generates Levy steps by sampling two random variables from normal distributions. The equation for producing Lévy steps is given in Eq. (9).

$$S = \frac{v}{|v|^{1/a}} \quad (9)$$

where, $v$ is a normally distributed variable, standard deviations $\sigma v$ determined by the Levy distribution's characteristics.

The LRS is advantageous in optimization algorithms as it facilitates rapid search space exploration via integrating both little, frequent steps and substantial, infrequent leaps. This dual nature enables the algorithm to evade local optima and progress toward more advantageous areas of the search space, hence increasing the probability of identifying a global optimum.

The fundamental components of metaheuristic algorithms, specifically the search space, assessment mechanism, position modification technique, new solution acceptance criteria, and stopping conditions, are crucial in determining their effectiveness. AOA is known for its simplicity and broad

applicability to various optimization problems. However, it may struggle with more complex problems, often getting trapped in local optima or requiring numerous iterations to reach the optimal solution. The AOA employs a math-optimized likelihood, as shown in Eq. (5), which adjusts iteratively and determines possible solutions within the search area, as described in Eq. (3) and Eq. (4).

To overcome these limitations, the proposed Levy Arithmetic Algorithm (LAA) introduces LRS into the AOA framework. By incorporating these steps, potential solutions can occasionally make broad, random shifts, allowing the algorithm to discover unexplored areas of the search domain and increasing the likelihood of discovering better optimal solutions.

In the LAA, candidate solutions are updated using the arithmetic operators from AOA and enhanced by the LRS, generating stochastic jumps based on the Levy pattern. This enables the solutions to shift randomly to new positions, promoting a more extensive search for optimal solutions in each cycle. The direction and scale of these jumps are influenced by decision variables (Dim) and population size (N), determined by the dimensionality of the problem and the characteristics of the LRS. While incorporating LRS allows for a broader search space exploration, it may be slower than the standard AOA to reach the optimum solution.

In LAA, the exploration phase, governed by Eq. (3), and the exploitation phase, defined by Eq. (4), are altered by LRS (*S*), as described in Eq. (9), and are expressed mathematically in Eq. (10) and Eq. (11).

$$x_{i,j}(C_{iter}+1)=\begin{cases} best(x_j)\div S\times(MOP+\varepsilon)\times \\ \left(\left(UB_j-LB_j\right)\times\mu+LB_j\right), \quad r2<0.5 \\ best(x_j)\times MOP\times S\times \\ \left(\left(UB_j-LB_j\right)\times\mu+LB_j\right), \quad otherwise \end{cases} \tag{10}$$

$$x_{i,j}(C_{iter}+1)=\begin{cases} best(x_j)-S\times MOP\times \\ \left(\left(UB_j-LB_j\right)\times\mu+LB_j\right), \quad r3<0.5 \\ best(x_j)\times MOP\times S\times \\ \left(\left(UB_j-LB_j\right)\times\mu+LB_j\right), \quad otherwise \end{cases} \tag{11}$$

using Eq. (10) and Eq. (11) enhances candidate solution diversity and prevents the algorithm from becoming stuck in local optima. By incorporating the LRS into the LA, the algorithm explores larger areas more effectively, thereby continuously discovering better solutions that traditional arithmetic optimization methods might miss. At first, fitness functions and best solutions are determined from objective functions, decision variables, and conditions, and they are dynamically modified based on the algorithm parameters and the potential solutions.

Three key variables (*r1, r2, r3*) are critical in narrowing the searching space based on four different operations: addition, subtraction, multiplication, and division, as defined by the Levy flight formulation, enabling the algorithm to approach the optimal solution. Integrating LRS enhances the algorithm's ability to search globally, making it more robust and efficient, thereby increasing the chances of identifying the global optimum. This method proves particularly useful in resolving optimization issues in which a number of local optima must be investigated before reaching the global best solution.

## IV. Results and Discussion

### A. Datasets

Two widely used datasets are used to analyze the proposed LAA for intrusion detection in SD-IoT environments: UNSW-NB15 and NSL-KDD. UNSW-NB15 is commonly used in intrusion detection research and contains 43 features, including primary network attributes and security features. It includes a class feature with several categories: Exploits, DoS, Fuzzers, Normal, and Backdoors. The dataset comprises 257,673 instances, 70% used for training and 30% for testing. NSL- KDD, as an improved version of the KDD Cup 1999 dataset, contains 42 attributes and focuses on four major types of attacks: Remote to Local (R2L), User to Root (U2R), DoS, and Probe. The dataset comprises 148,517 records, with 85% assigned to training and 15% for testing. Both datasets are significant for testing the efficiency of IDS models, as they cover a broad range of network traffic and cyber-attack scenarios, providing comprehensive benchmarks for assessing performance.

### B. Evaluation Metrics

The proposed LAA was assessed using a number of standard metrics, such as accuracy, precision, recall (true positive rate), and F1-score, commonly used in IDS research.

- Accuracy: This parameter determines the total correctness of the algorithm by evaluating the proportion of correctly classified instances relative to the total number of instances, calculated by Eq. (12).

$$A=\frac{\mathrm{TN}+\mathrm{TP}}{\mathrm{FN}+\mathrm{FP}+\mathrm{TN}+\mathrm{TP}} \tag{12}$$

where, FN is a false negative, FP is a false positive, TN is a true negative, and TP is a true positive.

- Precision: It determines the quality of positive predictions by multiplying the number of true positives by the number of positive predictions, calculated using Eq. (13).

$$P=\frac{\mathrm{TP}}{\mathrm{FP}+\mathrm{TP}} \tag{13}$$

- Recall: This metric represents the model's capacity to detect all positive instances correctly and is calculated using Eq. (14).

$$R=\frac{\mathrm{TP}}{\mathrm{TP}+\mathrm{FN}} \tag{14}$$

- F1-score: Precision and recall can be balanced by a harmonic mean when data is imbalanced, as defined in Eq. (15).

$$F=2\times\frac{Recall\times Precision}{Recall+Precision} \tag{15}$$

### C. Environment

The experimental setup for evaluating LAA was performed on a system equipped with an Intel Core i5-8250U CPU running at 3.4 GHz with a Quad-Core configuration supported by 16 GB of DDR4 RAM. The operating system used was Windows 10 (64-bit), ensuring compatibility with the tools employed in the experiment. MATLAB was utilized to implement the LAA, while Python was used for data pre-processing and additional statistical analysis. This computational environment provided adequate resources to efficiently run the experiments, ensuring that the LAA's performance could be fairly compared with the baseline models in terms of speed and accuracy.

### D. Baseline Models

The effectiveness of LAA was evaluated by comparing it with well-established machine learning models of IDS. These included the SVM, which identifies the optimal hyper plane for classification tasks; Decision Tree (DT), which splits data based on feature values for decision-making; and Random Forest (RF), a method of constructing multiple decision trees to maximize accuracy and minimize over fitting. Additionally, models like ANN, which captures complex patterns in data, and Logistic Regression (LR), a simpler model estimating binary outcomes, were used. Other baseline models included K-Nearest Neighbors (KNN), a distance-based classifier; Naive Bayes (NB), a probabilistic model based on Bayes' theorem; and AdaBoost, a boosting technique that combines weak classifiers to form a more robust classifier. These models served as benchmarks to demonstrate how LAA compares accuracy, computational efficiency, and detection capabilities.

### E. Performance Evaluation

Fig. 4 shows the precision of the LAA and other algorithms for detecting intrusions in the UNSW-NB15 dataset. The LAA achieved the highest precision for several attack types, including Fuzzers (83.2%), Reconnaissance (85.5%), and Exploits (79.8%), while maintaining 100% precision for detecting normal behaviors. This high precision enhances the real-time performance of IoT systems, especially in hyper-automation processes. Although KNN and AdaBoost performed well in detecting Generic attacks with 100% precision, LAA's overall performance outpaced all other models. Fig. 5 demonstrates that in the NSL-KDD dataset, LAA delivered 95.4% precision, excelling at detecting anomaly attacks (Probe, DoS, U2R, and R2L), while DT achieved 93.1% and KNN reached 91.7%. Other models, such as LR and SVM, achieved precision scores of 90.2% and 89.6%, respectively.

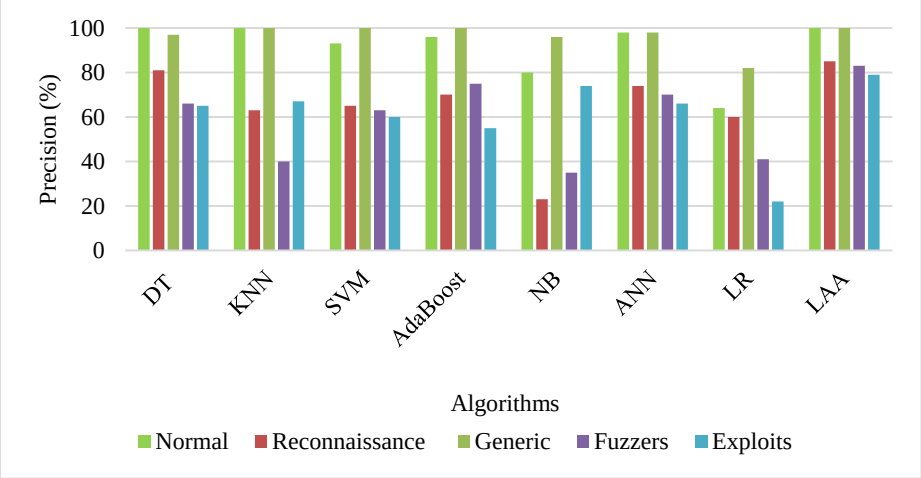

Fig. 4. Precision comparison under UNSW-NB15.

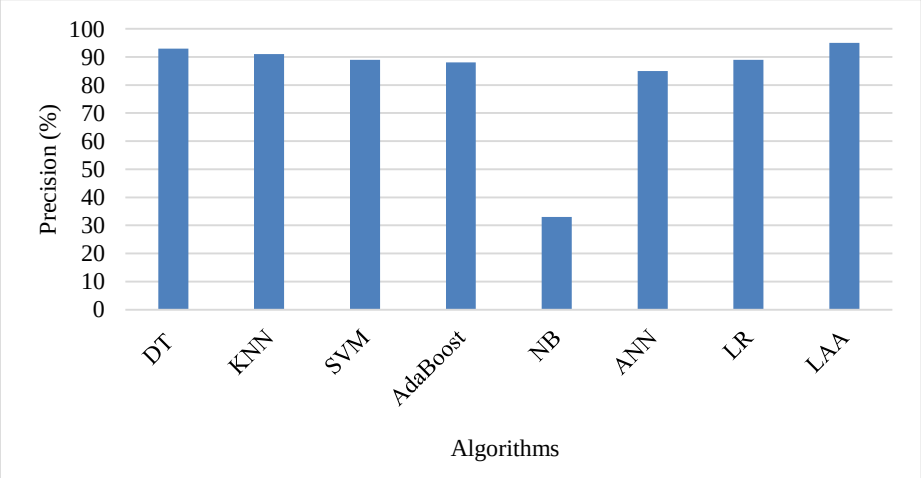

Fig. 5. Precision comparison under NSL-KDD.

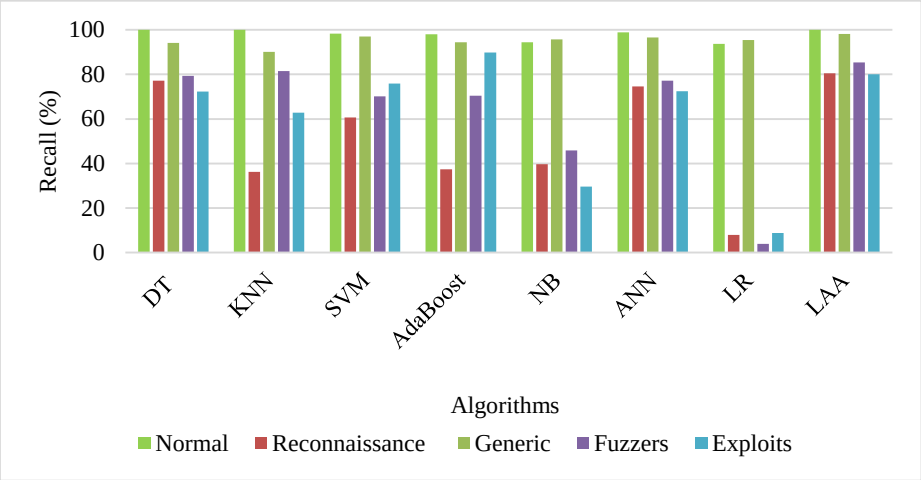

Fig. 6. Recall comparison under UNSW-NB15.

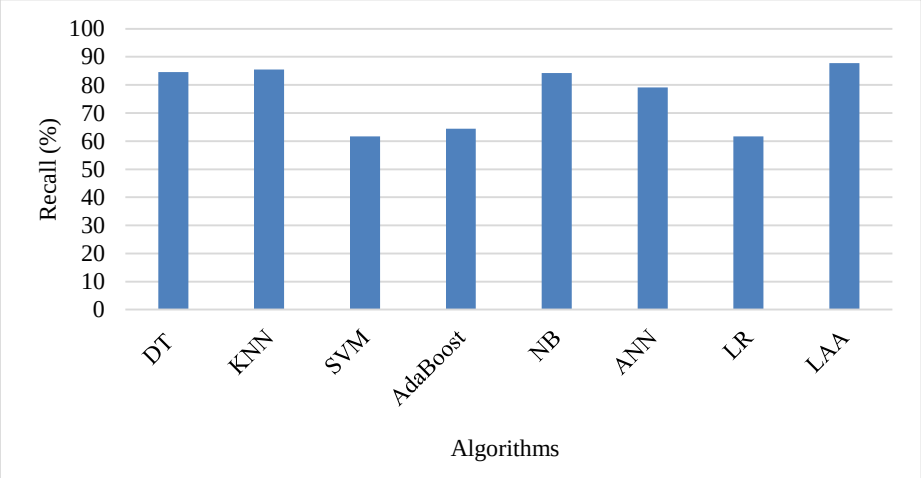

Fig. 7. Recall comparison under NSL-KDD.

Regarding recall, as depicted in Fig. 6, LAA outperformed other machine learning models in detecting cyber-attacks in the UNSW-NB15 dataset. Specifically, LAA achieved 85.4% recall for Fuzzers, 98.2% for Generic, and 80.5% for Reconnaissance attacks. The LAA also demonstrated 100% recall for detecting normal behaviors, ensuring high sensitivity in recognizing benign activities. In Fig. 7, LAA's recall in the NSL-KDD dataset stood at 87.8%, efficiently detecting anomaly categories such as Probe, DoS, U2R, and R2L. Comparatively, KNN achieved a recall of 85.5%, DT reached 84.6%, and NB provided 84.3%. Lower recall values were recorded for models like AdaBoost (64.4%) and SVM (61.7%).

Fig. 8 and Fig. 9 compares the F1-score across different algorithms for both datasets. In the UNSW-NB15 dataset, the LAA attained the highest F1-score of 87.4%, surpassing models such as ANN (83.2%), AdaBoost (82.2%), and SVM (78.9%). Other algorithms like DT (75.8%), KNN (74.1%), and NB (60.7%) recorded lower F1-scores, highlighting the superior performance of the LAA. For the NSL-KDD dataset, LAA again led with an F1-score of 89.2%, while DT and KNN followed with 88.5% and 87.3%, respectively. Models like ANN, LR, and SVM lagged with F1-scores of 82.1%, 73.2%, and 73.1%, respectively. NB exhibited the lowest F1-score at 46.2%.

These findings are consistent with recent studies that emphasize the importance of hybrid optimization in IDS performance. For example, the model proposed by Sanju [17], which integrates metaheuristics with deep learning, also demonstrates competitive F1-scores; however, our method achieved higher precision and recall across both datasets. Similarly, the approach by Almuqren, et al. [18] using Modified Firefly Optimization for botnet detection shows high performance, yet lacks the lightweight and explainable characteristics emphasized in our LAA framework. Compared to the SVM–GWO hybrid by Ghasemi and Babaie [20], our model achieved superior accuracy and a more balanced F1- score, particularly in detecting diverse attack classes under constrained environments.

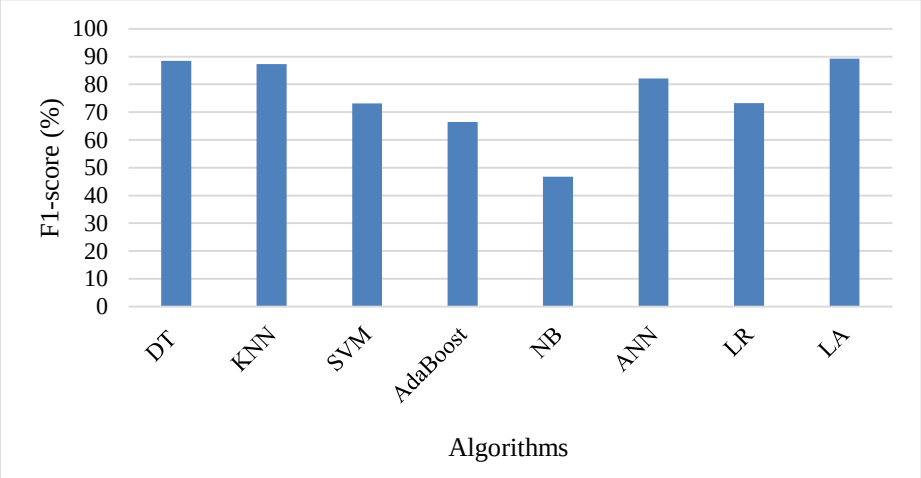

Fig. 9. F1-score comparison under NSL-KDD.

## V. Conclusion

In this study, we introduced LAA as a novel and efficient method for enhancing intrusion detection in SD-IoT environments. By integrating LRS with the AOA, the LAA achieved a more dynamic balance between exploration and exploitation, efficiently navigating complex search spaces and identifying optimal solutions for feature selection. The experimental results on the NSL-KDD and UNSW-NB15 datasets demonstrated that the suggested LAA-based IDS model outperformed conventional machine learning algorithms in key performance indicators such as F1-score, recall, precision, and accuracy. The LAA's ability to achieve high detection rates while maintaining computational efficiency makes it particularly well-suited to resource-constrained SD-IoT systems. The proposed LAA presents a significant advancement in intrusion detection, providing a robust, lightweight, and explainable solution for detecting cyber-attacks in SD-IoT environments.

Despite these promising results, the study has certain limitations. First, the performance of the LAA is somewhat dependent on the fine-tuning of algorithmic parameters, which may require domain-specific expertise. Second, although benchmark datasets such as NSL-KDD and UNSW-NB15 ensure comparability, the model's effectiveness on real-world, heterogeneous SD-IoT traffic remains to be assessed. Finally, while the method is computationally efficient in experimental settings, its scalability and real-time performance under production-scale environments require further validation. Future work can explore the extension of LAA to other IoT applications and networks, as well as the development of more advanced hybrid models to further improve detection rates and reduce computational costs.

# Reinforcement Learning-Driven Cluster Head Selection for Reliable Data Transmission in Dense Wireless Sensor Networks

Longyang Du*, Qingxuan Wang, Zhigang ZHANG
School of Artificial Intelligence, Jiaozuo University, Jiaozuo 454000, Henan, China

***Abstract*—Wireless Sensor Networks (WSNs) have made significant advances towards practical applications. Data gathering in WSNs has been carried out using various techniques, such as multi-path routing, tree topologies, and clustering. Conventional systems lack a reliable and effective mechanism for dealing with end-to-end connection, traffic, and mobility problems. These deficiencies often lead to poor network performance. We propose an Internet of Things (IoT)-integrated densely distributed WSN system. The system utilizes a tree-based clustering approach dependent on the installed sensors' density. The cluster head nodes are structured in a tree-based cluster to optimize the process of gathering data. Each cluster's most efficient aggregation node is selected using a fuzzy inference-based reinforcement learning technique. The decision is based on three crucial factors: algebraic connectedness, bipartivity index, and neighborhood overlap. The proposed method significantly enhances energy efficiency and outperforms existing methods in bit error rate, throughput, packet delivery ratio, and delay.**

***Keywords*—Energy efficiency; wireless sensor networks; clustering; reinforcement learning; fuzzy inference system**

## I. INTRODUCTION

### A. Overview

Wireless Sensor Networks (WSNs) represent a paradigm shift in global technological scenarios and consist of many autonomous sensor nodes capable of carrying out extensive sensing, computation, and communication [1]. Through strategic deployment, WSN nodes reside in a wide range of environments [2]. WSNs constitute a fundamental infrastructure that enables computing systems to gather data, process, and transmit it in real-time from the physical world [3]. This pervasive connectivity opens up applications for numerous fields, such as environmental monitoring, medical care, manufacturing, and sustainable communities [4], [5].

The collaborative nature of sensor nodes within WSNs enables the creation of distributed systems capable of collecting and relaying useful information on environmental parameters, object movement, health indicators, and other relevant data [6]. The inherent characteristic of WSNs, which can be modified to accommodate dynamic and adversarial environments, allows the generation of actionable intelligence, enhancing decision-making processes and improving situational awareness [7], [8].

Like constitutive models, which model the behavior of weak rock masses under different states of stress, taking into account pore pressure and temperature [9], WSNs must combine several environmental parameters to achieve optimal data collection and network operation. Yet, the deployment and operation of WSNs also entail inherent constraints, such as energy limitations [10], scalability issues [11], data security concerns [12], and network reliability [13], which demand innovative solutions and algorithms that ensure optimal performance and overcome these constraints. Despite these concerns, WSNs are a fundamental technology that drives innovation, revolutionizing businesses and enhancing our understanding of the world [14].

### B. Motivation and Contribution

Several methodologies have been proposed, encompassing diverse techniques such as multi-path routing, tree structures, clustering, and cluster trees, yet they often struggle to ensure a robust and reliable system addressing mobility, traffic dynamics, and end-to-end connectivity individually [15-17]. Consequently, these shortcomings frequently lead to suboptimal network performance, hindering their full potential in practical applications. To solve these challenges, this study introduces a novel scheme tailored to a densely distributed WSN system model.

With a tree-based cluster formation strategy, a flexible deployment density for sensor nodes is accommodated under this innovative framework. Each cluster in this meticulously structured architecture is meticulously organized around a singular cluster head node, a design crafted to streamline and optimize energy-efficient data-gathering processes. A distinguishing element in this scheme is incorporating a fuzzy logic engine and reinforcement learning. This sophisticated system dynamically determines optimal data-gathering nodes within clusters embedded within a densely distributed WSN. This decision-making process requires the evaluation of three key metrics: algebraic connectivity, bipartivity index, and neighborhood overlap.

The proposed approach intelligently assigns data collection tasks, promoting efficiency and energy savings in the network. Like machine learning techniques, such as regression and clustering algorithms, assist in analyzing the effects of various factors on business economics [18], this approach enables effective data-driven decision-making for optimizing resource usage and improving network performance. This study has made the following primary contributions:

- Advanced multi-cluster data collection: We introduce a novel multi-cluster data collection strategy tailored for

densely distributed WSNs, addressing the complexities of large-scale monitoring applications.

- Cluster formation based on energy and delay factors: We propose a robust approach to select cluster heads within each cluster, leveraging energy and delay factors to optimize the network's performance for lifespan, throughput, packet delivery rate, and reliable links for mobile sensors.
- Reinforcement Learning-based Fuzzy Logic Engine (RL-FLE): We use incorporated RL-FLE for intelligent decision-making, empowering cluster heads to dynamically determine optimal data-gathering nodes based on link efficiency among neighboring nodes.
- Improved performance indicators: The proposed approach demonstrates superior performance over traditional protocols (LEACH, HEED, MBC) by maximizing link stability and enhancing critical performance indicators, including packet delivery rate, bit error rate, end-to-end delay, and throughput.
- Reduced buffer occupancy and network traffic: Our proposed scheme effectively reduces buffer occupancy and minimizes network traffic, verifying its efficiency in managing data flow and ensuring resource optimization compared to existing protocols.
- Potential for energy savings: Experiments reveal the potential for substantial energy savings, emphasizing the energy-efficient nature of the proposed approach for sustainable and long-term network operation.

The study is structured as follows: Section II reviews related research. Section III presents the methodology, detailing the approach, algorithms, and framework used in the study. Section IV analyzes the findings, comparing them with existing studies and discussing their implications. Finally, Section V summarizes the key insights, highlights the contributions, and suggests potential directions for future research.

## II. Related Works

Table I summarizes methodologies, key contributions, evaluation metrics, and results from related works concerning data collection, energy efficiency, and network optimization.

TABLE I. Overview of Recent Routing Protocols

| Reference | Methodology | Key contributions | Results |
|---|---|---|---|
| [19] | Secure mobile sensor network with cloud integration | Optimizing performance through efficient routing, energy consumption, and security enhancement. Lightweight and congestion equilibrium-focused data collection scheme. Transmission facilitated via AND-OR graph mechanism. Secure access to collected data for cloud computing. | Significant energy savings and enhanced network stability |
| [20] | Rechargeable WSNs | Far-relay approach for proportional energy consumption. Optimal scheduling with Opt-JoDGE. Buffer-battery-aware adaptive scheduling with NO-BBA. | NO-BBA closely approaches Opt-JoDGE performance, especially in scenarios with acceptable delay levels. |
| [21] | Data gathering in WSNs with obstacles | Cluster construction with ant colony optimization and hierarchical aggregation. MS tour formation with multi-agent reinforcement learning and Cluster construction with ant colony optimization and hierarchical aggregation. | DGOB addresses energy consumption and data gathering delay challenges in WSNs with obstacles. |
| [22] | Trust-aware and energy-efficient data gathering | Clustering, tree construction, and watchdog selection with particle swarm optimization. Variable-length particles for the unknown number of watchdogs. | TEDG algorithm significantly improves energy efficiency and extends network longevity. |
| [23] | RLSSA-CDG for energy efficiency in WSNs | RLSSA-CDG combines CDG with sleep scheduling in a distributed algorithm. Q-learning algorithm for active node selection. | RLSSA-CDG outperforms other algorithms, demonstrating its energy efficiency and superiority in network lifespan extension. |
| [24] | Clustering with mobile data collector | Mobile data collector traverses the network for effective data collection. | An optimized approach to mobile data collection, demonstrating effectiveness in both balanced and unbalanced network topologies. |
| [25] | Energy-aware and cluster-based data aggregation | Fuzzy logic and CapSA for clustering and routing. | CEDAR performs better than prior research in delay, packet delivery rate, and network lifespan. |
| [26] | Multi-channel design for high throughput in WSNs | Utilizes a subset of cluster heads with multiple radios. Genetic algorithm for clustering, routing, and channel assignment. | It achieves a significant increase in throughput, reduced energy consumption, and improved energy utilization compared to previous schemes. |

The increasing utilization of lightweight sensors has driven the advancement of emerging technologies in various domains. One notable trend is integrating cloud services in applications that handle large volumes of observational data. However, the dynamic and time-sensitive nature of these environments requires enhanced performance. Eco-friendly systems require stable and reliable data transmission. Additionally, many green network solutions are vulnerable to unforeseen situations resulting from broadcasting on unreserved mediums.

To meet the mentioned demands, Haseeb, et al. [19], have introduced a secure mobile sensor network that integrates cloud technology to optimize performance through efficient routing, energy consumption, and security enhancement. Their work

makes significant contributions in several aspects. Firstly, it focuses on establishing a stable and error-free system for collecting data from mobile sensors to reduce unnecessary energy usage. The proposed data-gathering method is lightweight and maintains congestion equilibrium. An AND-OR graph mechanism facilitates green data transmission from mobile data sources to the cloud, which reduces routing gaps and retransmissions. Cloud computing can provide secure access to the collected data from constraint-oriented green environments.

Liu, et al. [20], studied energy harvesting and joint data gathering challenges in battery-powered WSNs by employing mobile sinks. As a mobile sink travels along a predetermined route, sensor nodes harvest energy from its RF circuits. Meanwhile, these nodes relay sensor data to the sink. A far-relay strategy is proposed to address the proportional relationship between energy consumption and energy harvesting at a sensor node, determined by the distance squared among sensor nodes. This strategy aims to choose sensor nodes near the path to facilitate data transmission to nodes located at a greater distance. The far-relay technique involves formulating a network utility maximization issue and introducing an optimum scheduling strategy considering time slot scheduling, relay selection, and power allocation regulations.

To tackle the issue of effectively managing sensor power and minimizing the delay in capturing data, mainly when obstacles are present, Najjar-Ghabel, et al. [21], have introduced DGOB, which gathers data in WSNs with obstacles. DGOB employs node clustering and a mobile sink to collect cluster heads' data, minimizing network energy usage. The algorithm follows a two-phase process: cluster construction and mobile sink tour formation. DGOB employs two methods to create superior clusters in the cluster construction phase. The first phase involves the combination of hierarchical aggregation with ant colony optimization to produce resilient clusters under adverse conditions. In the subsequent iterations, the Genetic Algorithm (GA) updates the current clusters, thus improving the cluster development process. In the second stage, DGOB presents a proficient approach to constructing tours by combining multi-agent reinforcement learning and GA. The success of DGOB is confirmed by comprehensive simulation findings, demonstrating a 34 per cent reduction in energy usage and an 80 per cent increase in network longevity compared to existing techniques.

Soltani, et al. [22], have presented a trustworthy and energy-aware data aggregation algorithm to enhance data collection efficiency in WSNs. It consists of several vital stages, namely clustering, tree formation, and watchdog determination, each framed as an optimization problem and optimized by the Particle Swarm Optimization (PSO) algorithm. The watchdog selection stage can be particularly noteworthy as it involves particles of variable length due to the unknown number of watchdogs. To address this challenge, a new particle representation and initialization scheme is developed. The proposed algorithm has demonstrated significant improvements in performance metrics through extensive simulations. It significantly improves energy efficiency in delivering data to the sink node, decreases nodes' residual energy standard deviation by 81per cent, and extends the network's lifespan to 129per cent.

Wang, et al. [23], have introduced the Reinforcement Learning-based Sleep Scheduling Approach for Compressed Data Collection (RLSSA-CDC) to enhance energy efficiency in WSNs. This algorithm combines Compressive Data Collection (CDC) with sleep scheduling to reduce data transmission and minimize energy consumption in WSNs. Unlike previous approaches that faced challenges with centralized optimization problems and increased control message exchanges, RLSSA-CDC is formulated as a distributed algorithm. This framework minimizes control message exchanges and adapts to the variance in residual node energy, preventing nodes from premature energy depletion.

Meddah, et al. [24], suggest a novel strategy to mitigate energy waste in WSNs by utilizing Mobile Data Collector (MDC) devices. An MDC device collects data efficiently from sensor nodes by traversing the network. Their proposed method, called the Tree Clustering algorithm with MDC, aims to establish an optimized traveling path through a subset of cluster heads while minimizing the travel distance. The cluster heads are chosen by a competitive selection system that considers several factors, including packet transmission rate, closeness to the root of the tree, node energy level, and proximity to the next cluster head. The efficacy of the suggested approach was evaluated using simulation tests done on both balanced and unbalanced network topologies.

Mohseni, et al. [25], developed a Clustered Energy-conscious Data Aggregation Routing protocol called CEDAR, incorporating a fuzzy logic model and Capuchin Search Algorithm (CapSA). It comprises two steps: cluster creation and extra/intra-cluster routing. Initially, sensor nodes are clustered using fuzzy logic. Then, CapSA determines optimal paths between cluster heads, the base station, and cluster nodes. As demonstrated by the simulations conducted in the MATLAB simulator, CEDAR is superior to existing research concerning packet delivery rate, latency, and network lifetime.

Shahryari, et al. [26], have addressed high-throughput WSN requirements by implementing the multi-channel framework designed explicitly for heterogeneous WSNs. This approach aimed to overcome the limitations present in existing multi-channel methodologies, which often suffer from low throughput and significant overhead. Their innovative solution introduced a paradigm that utilized a subset of high-level nodes, known as cluster heads, with multiple radios within the network. These cluster heads efficiently transfer captured data from standard sensors to the base station. To achieve this, an energy-saving and high-throughput algorithm was developed to manage routing, clustering, and channel assignment processes in this diverse WSN setup.

The first stage focused on forming a spanning tree among the super nodes while intelligently determining appropriate channels for their radios. They introduced a novel multi-objective cost function extending the network lifetime over conventional tree construction methods. Additionally, this function effectively manages interference, improving overall throughput across the network. In the subsequent stage, the

algorithm determined the optimal selection of cluster heads and channels for standard nodes. Their algorithm demonstrated a substantial increase in throughput through extensive simulations due to multiple channel utilization. Moreover, it achieved notable reductions in energy consumption per transmitted bit to the base station, achieving an impressive improvement of 21.6 per cent and 48.3 per cent, respectively, compared to prior schemes.

## III. PROPOSED METHOD

The mobile sink-centric information collection approach prevalent in densely distributed WSNs often consumes more energy by sensor nodes closer to the sink node, leading to energy holes. Existing Expectation Maximization (EM)-based clustering approaches have attempted to mitigate this problem by optimizing the number of clusters to minimize energy consumption. However, these approaches struggle to determine cluster heads effectively, especially as the scale and node density of the network increase, resulting in increased energy consumption and shorter network lifetime. To meet these challenges, this study presents a novel tree-based clustering scheme supported by robust cluster heads to prolong network lifetime and improve energy efficiency.

A single cluster head node controls each cluster to ensure efficient information collection. First, RL-FLE determines strong cluster heads within clusters of densely distributed WSNs. This determination relies on three key variables: neighborhood coverage, mathematical connectivity, and bipartivity index. Then, dynamic network reconfiguration is performed by moving the sink to a different position and consolidating the cluster head node when node failures occur in a cluster. This adaptive framework is expected to prolong network lifespan and minimize energy usage. The effectiveness of the suggested strategy is determined through a comparative analysis of existing methods.

A static and energy-efficient routing scheme is introduced for the complex and diverse IoT ecosystem. The evaluation of this approach involved implementing a transmission algorithm in a network with over a thousand nodes deployed in areas of 200 to 300 square meters, with varying amounts of nodes. The evaluation results underline the suitability and effectiveness of static routing methods for mobile IoT applications. The architecture of the proposed approach follows a layered structure, similar to the traditional layered architecture used in network systems. However, the relay layer is excluded because it is not included in the system. The model represents a hierarchical network structure in which all sensor nodes remain static and stick to static routing-based transmission. Fig. 1 visually depicts a wireless sensor architecture based on a mobile sink. This model uses mobile sinks in the network to acquire information gathered by fixed sensor nodes.

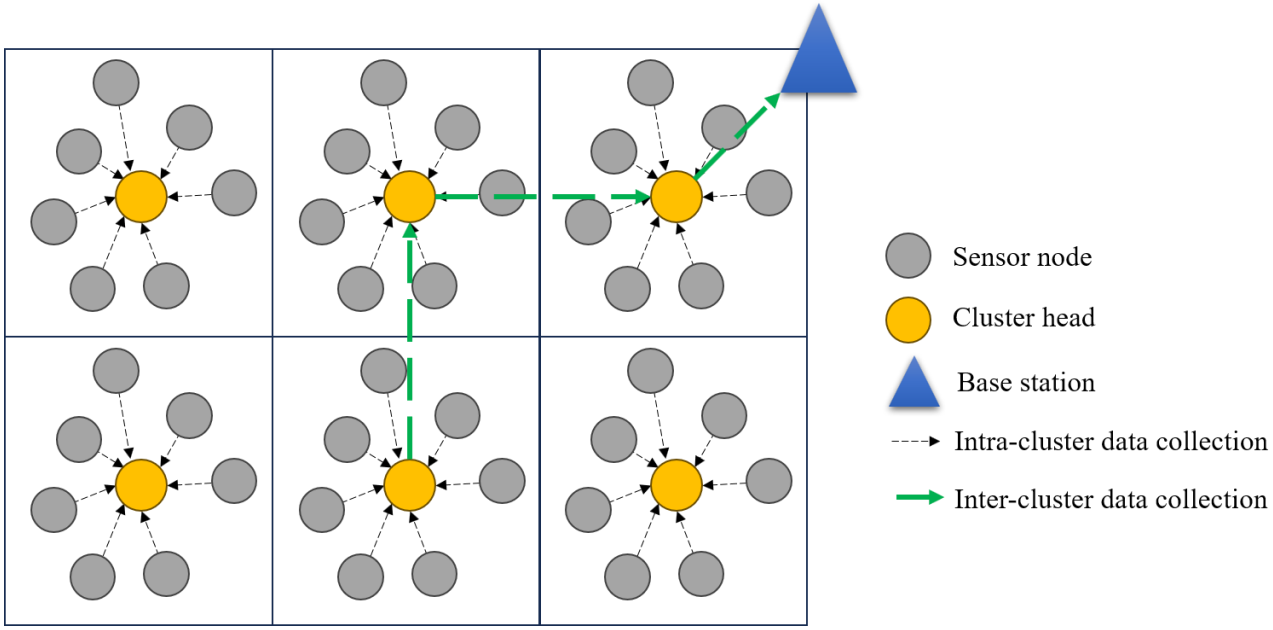

Fig. 1. Network model.

In WSN, the traditional cluster head selection approach considers energy, delay, and distance parameters. However, in the context of IoT networks, it becomes crucial to analyze the specific parameters of IoT devices. Since WSNs are closely linked to IoT devices, it is essential to consider parameters such as temperature and load characteristics of these devices. Therefore, the cluster head selection strategy should consider energy, delay, distance, temperature, and load factors. Ideally, lower temperature, load, delay, and distance values are preferred.

The delay value commonly falls within the range of 0 to 1. Eq. (1) computes the delay sensor nodes encounter when transmitting data to the mobile sink. To decrease this delay, decreasing the number of participants in each cluster is necessary. $N$ denotes the total quantity of sensor nodes, $S(N_v)$ indicates cluster node signal strength, and $S(N_{v'})$ signifies mobile sink node signal strength.

$$D(N_v, N_{v'}) = \frac{\sum_{q=1}^{n} S(N_v) - S(N_{v'})}{N} \quad (1)$$

Eq. (2) calculates the distance between the mobile sink and cluster heads. $dist(N_v, N_{v'})$ calculates Euclidean distances between a typical node ($N_v$) and the mobile sink node ($N_{v'}$) in dense sensor networks.

$$dist(N_v, N_{v'}) = \sqrt{(x_{n_v} - x_{n_{v'}}) + (y_{n_v} - y_{n_{v'}})} \quad (2)$$

To increase the network's longevity, each cluster node's battery level is considered when calculating the remaining power. As packets are forwarded, each node expends energy according to its type, length, frequency, and distance. The power provided by node $x_i$, denoted as $RP(x_i)$, is determined by the total node count within $i^{th}$ cluster. A higher value of $RP(x_i)$ indicates that a node has more stable and energy-rich power reserves, potentially extending its lifetime and improving network reliability. The residual power of node $x_i$ is calculated as shown in Eq. (3), which helps in identifying stable nodes for long-term cluster membership.

$$RP(x_i) = \frac{\sum_{x_j \in cluster_i} EP_{x_j}}{n_i} \quad (3)$$

Information collection hubs are selected by cluster heads according to three factors: neighborhood overlap (NOVER), Algebraic Connectivity (AC), and Bipartivity Index (BI). NOVER is a quantitative measure to evaluate shared adjacency between the terminal hubs. It is used effectively for group detection, with a lower NOVER value indicating that the connection is likely to connect two different groups, while a higher NOVER value suggests a connection between nodes within the same group. The BI refers to the capacity to partition the vertices of a tree structure into two separate sets so that all edges connect vertices from one set to the other. There are no edges between vertices within the same set. This bipartite property of the graph is an essential consideration in the selection process.

AC is a metric that quantifies a network's resilience regarding link distances. A higher algebraic connectivity value indicates the network is more likely to remain connected even after one or more connection distances, demonstrating its resilience. On the other hand, a lower value suggests that the network could be fragmented by removing links. Fuzzy logic is used to combine these three variables and evaluate the immediate reward of the choice. Fuzzy logic enables the evaluation of connection efficiency from the cluster head node to each neighboring hub.

In addition to the instant reward, the long-term reward of the selection is also considered. The behavior of nearby hubs influences the fairness of selecting data-gathering stations. This is considered by assessing distances between data gathering points and cluster head nodes. The closer the information-gathering hub is to the center, the more favorable it is regarding long-term reward.

By considering these metrics and incorporating fuzzy logic, the cluster head hub can make informed decisions about selecting the information-gathering hub. The evaluation considers both the instant and long-term rewards, ensuring efficient and fair information gathering in the network. The evaluation value for each neighbor is calculated by the cluster head node using the following steps:

- Fuzzification: NOVER, BI, and AC values are converted into fuzzy values by applying predefined membership functions and linguistic terms. These membership functions define membership degrees for fuzzy sets determined by input values. This step allows the crisp values of the metrics to be represented as fuzzy values.
- Defining and applying IF/THEN statements: The fuzzy outcomes derived from the fuzzification process are matched with predetermined IF/THEN criteria. These rules define the relationship between the fuzzy inputs (NOVER, BI, and AC) and the desired output (evaluation value for the neighbor). The rules are designed based on expert knowledge or derived from data analysis. The fuzzy values are aggregated through logical operations (such as AND, OR) embedded inside the IF/THEN rules to determine the ranking of the neighbor.
- Defuzzification: The imprecise numerical value acquired from the preceding phases is transformed into a precise numerical value using a predetermined output membership function and defuzzification process. The output membership function assigns a degree of membership to various numerical values based on the fuzzy value. The defuzzification method calculates a crisp value from the fuzzy output value, typically by taking the centroid or weighted average of the membership function.

The AC value of a system quantifies the network's ability to withstand connection failures. The term refers to the secondary lowest eigenvalue of the Laplacian matrix associated with the system. $Log(A)$ is used to measure a system's resilience to failures of connections. A degree vector $D_i$ and adjacency matrix $A(i,j)$ are used to calculate this value. The algebraic connectivity, computed using Eq. (4), measures the resilience of the cluster's internal topology.

$$L(i,j) = \begin{cases} -A(i,j) & for\ i \neq j \\ D_i & for\ i = j \end{cases} \quad (4)$$

The BI is employed to quantify the level of bipartivity in a graph. The range of the value is from 0 to 1. A value of 1 signifies that the graph is bipartite and no frustrated edges connect vertices within the same segment. It will fall below 1 if there are no true bipartite graphs. Eq. (5) provides the bipartivity index, enabling an assessment of structural separation within the communication graph.

$$BPI(G) = \frac{\sum_{j=1}^{n} \cosh(\lambda_j)}{\sum_{j=1}^{n} \sinh(\lambda_j) + \cosh(\lambda_j)} \quad (5)$$

We assess the degree of overlap in neighborhood overlap among the cluster head and neighboring nodes. Due to the difficulty in obtaining an accurate assessment of this overlap in densely deployed WSN settings, we choose immediate neighboring hubs from the cluster head's gauge neighborhood overlap. We define this metric using Eq. (6). NCH (u) refers to the cluster head node and NCN(v) represents its neighbor nodes.

$$NOVER(u-v) = \frac{2 \times |N_{CH}(u) \cap N_{CH}(v)|}{|N_{CH}(u)| + |N_{CH}(v)| - 2} \quad (6)$$

Fig. 2 depicts the fuzzy inference system, with NOVER, BI, and AC as inputs. After performing the fuzzification process, the defuzzification procedure generates an output to determine optimal cluster heads. Input and output membership functions are formulated using a triangular function. Fig. 3 illustrates the fuzzy participation functions for NOVER, BI, and AC. These functions define the degree of belonging to specific linguistic variables (e.g., Bad, Medium, Good) for NOVER, (e.g., Light, Medium, Heavy) for BI, and (e.g., Low, Medium, High) for AC.

Fig. 4 shows the IF/THEN rules the cluster head uses to calculate the rank of participating nodes. These rules map the fuzzy input values (obtained from the participation functions) to the desired output, representing the participating nodes' evaluation rank. Different rules may apply simultaneously, and these rules are combined using the Min-Max strategy. Since multiple rules can apply simultaneously, the evaluation results from different rules are combined using the Min-Max strategy. This strategy selects the minimum (worst) value among the evaluations as the overall evaluation result.

Defuzzification is carried out to produce a precise numerical number that represents the competence value of the node. The output membership function, demonstrated in Fig. 5, assigns degrees of membership to various numerical values according to the fuzzy output value. The Center of Gravity (COG) approach, commonly called the centroid method, is employed for defuzzification. Defuzzified values are represented by x-coordinates, which correspond to a node's competence value.

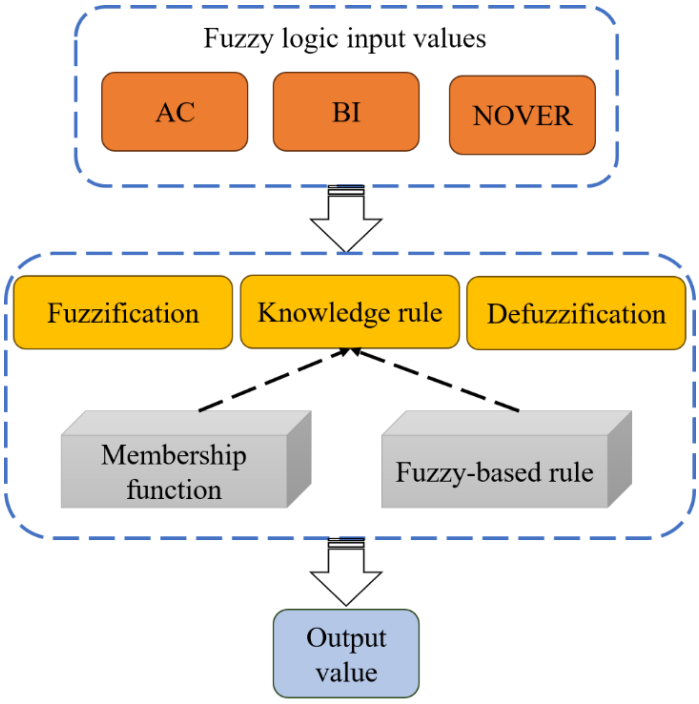

Fig. 2. Fuzzy inference system.

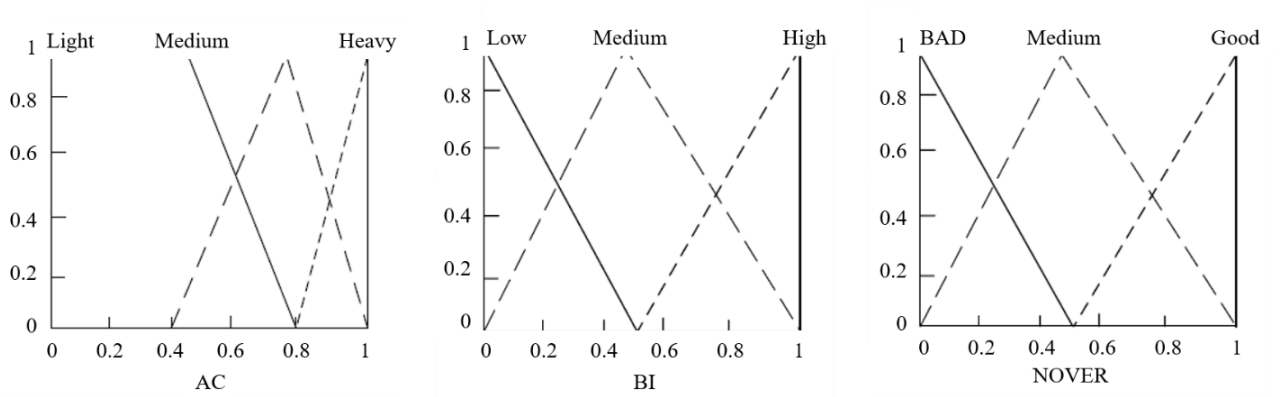

Fig. 3. Fuzzy membership functions for inputs.

1. If (AC is light), (BI is high), and (NOVER is good) then (output is acceptable)
2. If (AC is light), (BI is high), and (NOVER is medium) then (output is unfavourable)
3. If (AC is light), (BI is high), and (NOVER is bad) then (output is bad)
4. If (AC is light), (BI is medium), and (NOVER is good) then (output is unfavourable)
5. If (AC is light), (BI is medium), and (NOVER is medium) then (output is bad)
6. If (AC is light), (BI is medium), and (NOVER is bad) then (output is bad)
7. If (AC is light), (BI is low), and (NOVER is good) then (output is bad)
8. If (AC is light), (BI is low), and (NOVER is medium) then (output is bad)
9. If (AC is light), (BI is low), and (NOVER is bad) then (output is very bad)
10. If (AC is medium), (BI is high), and (NOVER is good) then (output is good)
11. If (AC is medium), (BI is high), and (NOVER is medium) then (output is acceptable)
12. If (AC is medium), (BI is high), and (NOVER is bad) then (output is acceptable)
13. If (AC is medium), (BI is medium), and (NOVER is good) then (output is acceptable)
14. If (AC is medium), (BI is medium), and (NOVER is medium) then (output is bad)
15. If (AC is medium), (BI is medium), and (NOVER is bad) then (output is unfavourable)
16. If (AC is medium), (BI is low), and (NOVER is good) then (output is unfavourable)
17. If (AC is medium), (BI is low), and (NOVER is medium) then (output is unfavourable)
18. If (AC is medium), (BI is low), and (NOVER is bad) then (output is bad)
19. If (AC is heavy), (BI is high), and (NOVER is good) then (output is perfect)
20. If (AC is heavy), (BI is high), and (NOVER is medium) then (output is good)
21. If (AC is heavy), (BI is high), and (NOVER is bad) then (output is acceptable)

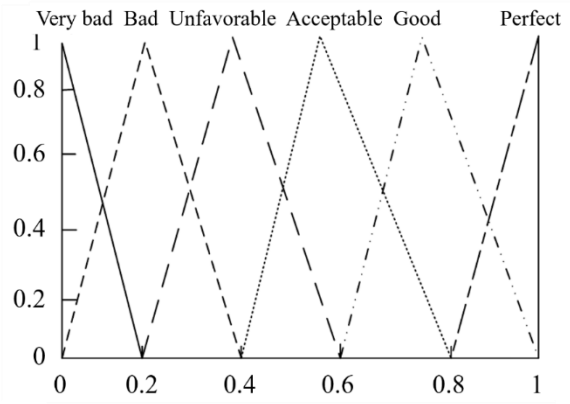

Fig. 5. Fuzzy membership function for the output.

The study presents a fuzzy-based reinforcement learning algorithm to determine the value of action and state relations ($Q(i, a)$) to acquire optimum fuzzy combination rules. It begins with initialization, setting $Q(i, a)$ and $V(i, a)$ to zero for all states $i$ and actions $a$, and introducing control parameters such as $kmax$ and $A$. The algorithm progresses through states and actions, selecting actions based on fuzzy combination rules and updating values accordingly.

After each action execution, the Q-value is updated using a reinforcement learning rule considering the observed reward, discount factor, and the maximum Q-value for subsequent actions. The process iterates until it reaches the desired number of iterations ($kmax$). Finally, the algorithm calculates optimal decisions at each state by selecting actions that maximize the learned Q-values. The termination condition marks the conclusion of the algorithm, providing a comprehensive framework for learning optimal fuzzy combination rules through fuzzy-based reinforcement learning.

Fig. 6 depicts the flowchart for the proposed algorithm and provides a visual representation of the steps involved. Fig. 7 provides a pseudocode for the proposed algorithm. To summarize, the algorithm begins by initializing the Q-values and visit counts. It then takes actions based on fuzzy combination rules and updates the Q-values by incorporating rewards and the highest Q-value of the next state. This process is iterated until a specified exit condition is satisfied.

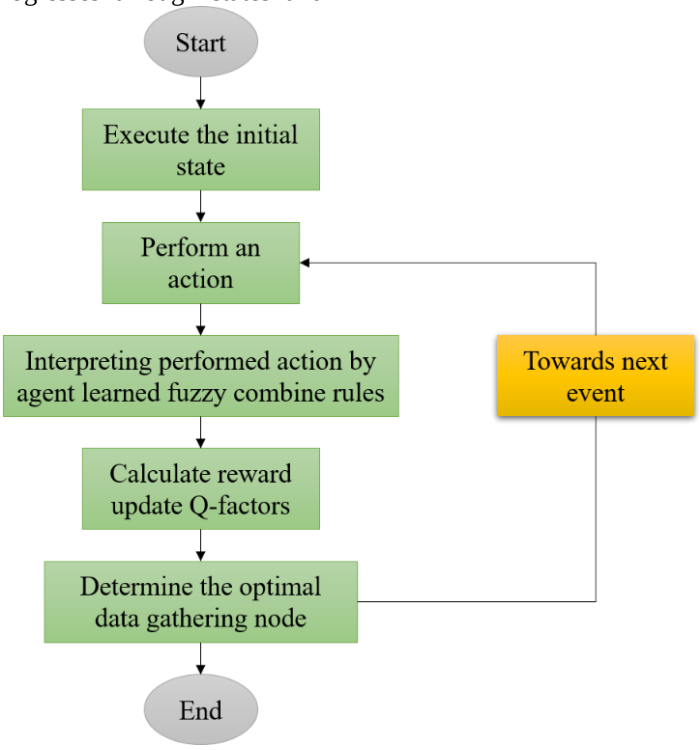

Fig. 6. Flowchart of the proposed algorithm.

**Initialization**

Set $Q(i, a) = 0$ and $V(i, a) = 0$ for all states $i$ in $S$ and actions $a$ in $A(i)$;
Set $k = 0$, $kmax$, and $A$ as a constant;

**Initial state**

Calculate the initial state $i$;

**Loop until $k > kmax$**

Action selection:
Choose an action a based on the fuzzy combination rules at state $i$;
Action execution and reward:
Perform action $a$ and observe the resulting reward $r(i, a, j)$;
Update the value $V(i, a)$ by incrementing it by 1: $V(i, a) \leftarrow V(i, a) + 1$;
Calculate the adaptive factor a as $A$ divided by $V(i, a)$: $a = A / V(i, a)$;
Q-value update:
Update the Q-factor associated with the state-action pair $(i, a)$ using the following update rule:
$Q(i, a) \leftarrow (1 - a)Q(i, a) + a[r(i, a, j) + \gamma * max\ b \in A(j)\ Q(j, b)]$,
where $\gamma$ is the discount factor for future rewards.
Iteration:
Increment the iteration counter: $k = k + 1$;
Set the current state $i$ to the new state $j$ obtained after performing action $a$;

**Optimal decision calculation**

Calculate the feasible decisions at each state by selecting the action $a*(i)$ that maximizes the Q-value for state $j$:
$a*(i) \in arg\ max\ b \in A(j)\ Q(j, b)$

**Algorithm termination**

Fig. 7. The pseudocode of cluster formation.

## IV. Results and Discussion

The proposed method (RL-FLE) was evaluated through simulations performed under different parameter configurations and provided valuable results. To make a comparative analysis with LEACH, CEDAR, PSO, HEED, and MBC, an execution study was carried out using the system test. The simulation scenario encounters 100 identical sensor nodes and 9 cluster heads, all possessing limitless battery capacity, spread across a $1000 \times 1000\ m^2$ region. Furthermore, a fixed sink node with inexhaustible energy stores was strategically placed beyond the surveillance area. The simulations considered specific performance parameters: the MicaZ platform, the ZigBee application with a packet size of 127 bytes, and compliance with IEEE 802.15.4 standards.

The sensor nodes were modeled using a linear battery model with a capacity of 1200 mAh, while the two-ray signal propagation model was employed to capture wireless signal behavior. In the simulation setup, the information envelope within a cluster had a fixed size of 512 bytes. The transmission range within a cluster was limited to 40 m, ranging from 80 m to 120 m between clusters. Notably, the detection range for clustering was set at 20 m. The base station, the central data collection point, was positioned at coordinates (x = 500, y = 1050). Lastly, the energy parameters assigned to each sensing node amounted to 300 mJ.

The performance evaluation of the suggested data-gathering strategy entailed modeling diverse network parameters, including latency, total energy consumption, bit error rate, throughput, and packet delivery rate. Fig. 8 to Fig. 11 illustrate the correlation between network efficiency and node count. It is crucial to emphasize that both MBC and LEACH have restrictions on maximizing throughput, reducing latency, minimizing total energy usage, and maintaining a high packet delivery percentage as the network grows.

Fig. 8 shows the average end-to-end delay across seven clustering protocols under varying node densities. RL-FLE performs better than conventional schemes by minimizing packet delivery latency using intelligent cluster head election through reinforcement learning and link efficiency. In comparison, LEACH and MBC experience higher delays due to their lesser adaptiveness towards dense traffic environments.

Fig. 9 highlights the total energy consumed by sensor nodes during data transmission. RL-FLE indicates the least energy consumption due to its effective data routing via stable and dense cluster heads. The conventional methods, such as HEED and LEACH, cause higher energy consumption through ineffective cluster head rotation or lack of context learning.

Fig. 10 illustrates the network throughput of various protocols. RL-FLE performs better by reducing packet loss and optimizing data flow paths. CEDAR performs similarly, whereas LEACH and HEED perform poorly due to excessive retransmissions and the absence of a dynamic load-balancing mechanism.

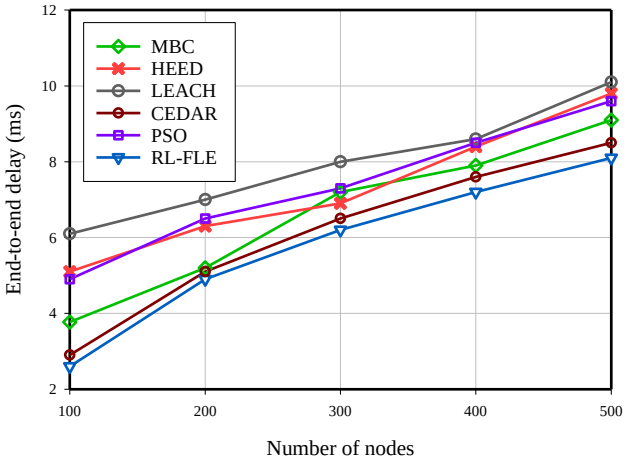

Fig. 8. Network delay comparison.

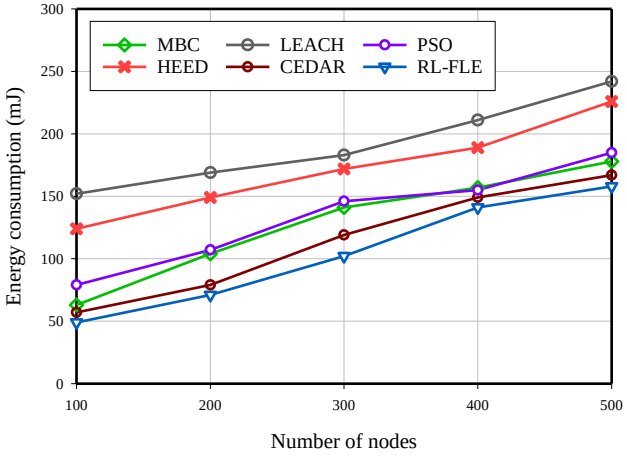

Fig. 9. Energy usage comparison.

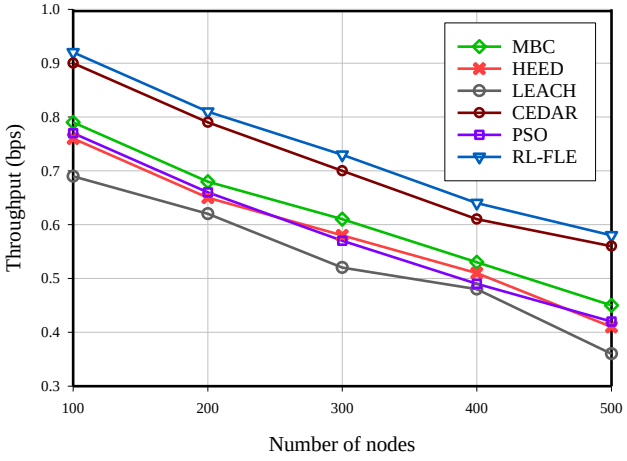

Fig. 10. Throughput comparison.

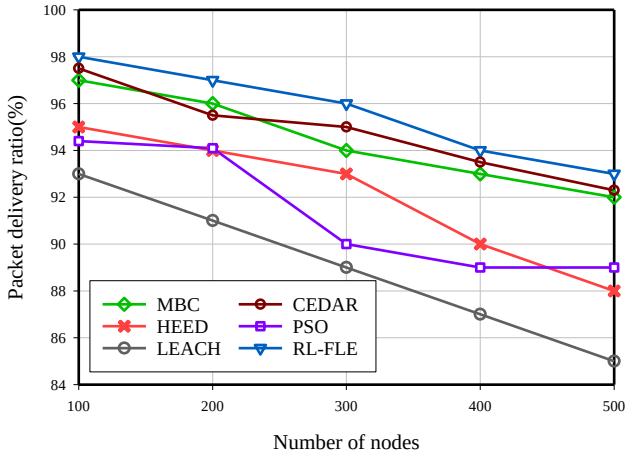

Fig. 11. Performance comparison.

Fig. 11 shows the performance of various protocols under increased node mobility. RL-FLE exhibits low and steady delay despite high-speed movement due to learning-based adaptation. Other protocols experience poor performance due to static cluster head strategies.

The proposed scheme demonstrates superior performance in a mobile sensor environment compared to CEDAR, PSO, LEACH, MBC, and HEED, as indicated in Fig. 12 and Fig. 13. The findings from simulations reveal that the suggested system successfully builds solid links and adjusts to situations with high levels of mobility. Especially in these situations, the recommended strategy results in a better packet delivery ratio and less latency. Furthermore, the strategy improves execution efficiency without regard to the quantity of sensor nodes in the overall setup.

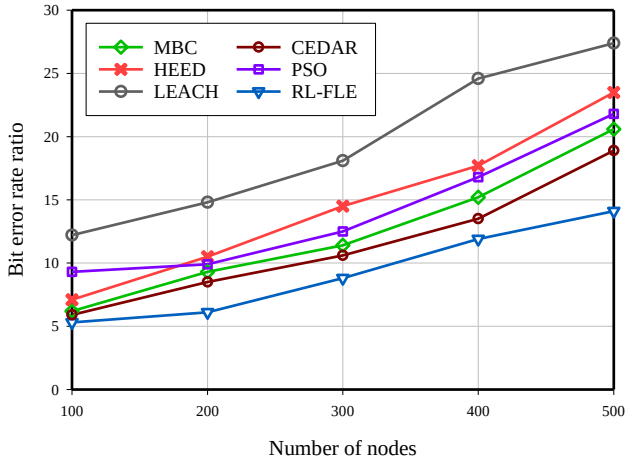

Fig. 12. Bit error rate comparison.

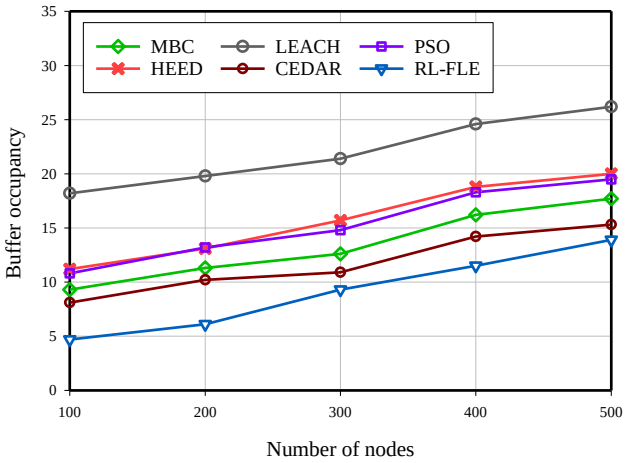

Fig. 13. Throughput comparison.

In WSNs with a significant number of nodes and frequent movement, unstable communication may lead to packet losses, requiring retransmission. In contrast, the proposed scheme ensures stable connections and promotes balanced energy consumption throughout the network. Consequently, it can be concluded that the suggested scheme suits high-mobility environments, enabling the preservation of sensor hub energy, prolonging network lifetime, and enhancing system reliability while maintaining superior communication quality.

## V. Conclusion

Effectively monitoring large-scale areas using multiple sensor nodes has become crucial in time-critical military and industrial applications. To address this challenge, the cluster tree network management architecture has emerged as a proficient method. The primary objective is to optimize network performance concerning network lifespan, throughput, packet delivery rate, reliable links for mobile sensors, and energy efficiency. We proposed an effective multi-cluster data collection strategy for WSNs deployed in dense clusters. The energy and delay factors were used to select robust cluster heads for each cluster. Subsequently, the cluster head chooses the data-gathering node based on the link efficiency of neighboring nodes, employing the RL-FLE approach. The proposed scheme was characterized by several advantages, including maximizing link stability and enhancing key performance indicators like packet delivery ratio, delay time, bit error rate, and throughput.

Experimental outcomes suggest our approach effectively reduces buffer occupancy and network traffic while minimizing energy utilization compared to CEDAR, PSO, LEACH, HEED, and MBC protocols. Potential areas for future study might focus on improving energy efficiency, scalability, and flexibility in dynamic contexts. Exploring the incorporation of new technologies like edge computing and machine learning algorithms can enhance the effectiveness of multi-cluster network management architectures for large-scale and time-sensitive applications. This will help to advance the development of WSNs in a rapidly changing environment.

# LIFT: Lightweight Incremental and Federated Techniques for Live Memory Forensics and Proactive Malware Detection

Sarishma Dangi[1], Kamal Ghanshala[2], Sachin Sharma[3]
Department of Computer Science and Engineering, Graphic Era Deemed to be University, Dehradun, India[1, 2]
Amity School of Engineering and Technology, Amity University Punjab, Mohali, India[3]

***Abstract*—Live Memory Forensics deals with acquiring and analyzing the volatile memory artefacts to uncover the trace of in-memory malware or fileless malware. Traditional forensics methods operate in a centralized manner leading to a multitude of challenges and severely limiting the possibilities of accurate and timely analysis. In this work, we propose a decentralized approach for conducting live memory forensics across different devices. The proposed federated learning-based live memory forensics model uses FedAvg algorithm in order to make a lightweight, incremental approach to conduct live memory forensics. The study demonstrates the performance of federated learning algorithms in anomaly detection, achieving a maximum accuracy of 92.5% with Clustered Federated Learning (CFL) while maintaining a convergence time of approximately 35 communication rounds. Key features such as CPU usage and network activity contributed over 85% to the detection accuracy, emphasizing their importance in the predictive process.**

***Keywords*—Live memory forensics; malware detection; federated learning; fileless malware; anomaly detection**

## I. Introduction

With the exponential growth in computational devices worldwide, the threat of cyberattacks has greatly threatened the digital ecosystem. With the global malware attacks surpassing 11.5 billion annually, digital forensics faces unprecedented challenges towards solving these cybercrime incidents [1]. Nearly 59% of the organizations worldwide were affected by ransomware attacks in 2024 [2]. The scale, complexity and privacy challenges of these crimes makes it harder to solve them especially with the rise of memory resident malware. Recent advanced cyberattacks are solely operating in the memory without leaving any evidence or trace behind in the physical memory of the system [3]. These types of crimes are typically solved by a specialized branch of digital forensics called as volatile memory forensics or live memory forensics (LMF). Volatile memory forensics deals with the acquisition and analysis of volatile memory of a computational system [4]. Traditionally, digital forensic applications rely on a centralized approach for data acquisition and analysis. This centralized approach is highly insufficient/inadequate considering the distributed environments used worldwide across various organizations. Forensic investigators mostly compile evidence from different sources spanning multiple jurisdiction. These constraints regarding data sharing, collaboration lead to further delays in timely detection and mitigation of threats. Advanced cyberattacks use fileless malware with anti-forensic techniques to obfuscate and exploit the target users [5], [6]. Recent studies have shown that up to 40% of malwares are now exploiting in-memory fileless techniques [7]. These attacks can be timely detected and mitigated by using robust volatile memory forensic frameworks that are aimed at making the systems more secure, scalable and lightweight. Federated learning is a transformative solution that enables decentralized training of machine learning models across a wide variety of datasets [8]. Federated learning utilizes different local devices or nodes that train their own machine learning models independently while aggregating intelligence with centralized aggregator when required [9]. The decentralized architecture for federated learning reduces the need of data aggregation or raw data sharing thereby addressing privacy challenges. In this work, we propose a federated learning based lightweight framework that can be efficiently deployed across a network of heterogeneous resources. The key contributions of this work are listed as follows:

- The paper introduces a robust federated learning framework incorporating techniques such as FedAvg, Federated Incremental Learning, and Clustered Federated Learning (CFL), enabling accurate and efficient training in heterogeneous and resource-constrained environments.
- The framework allows clients to incorporate new data dynamically without restarting the training process, achieving rapid convergence and efficient resource utilization while maintaining model accuracy.
- The study demonstrates the importance of cluster-specific models for managing client heterogeneity, showing that tailored models achieve higher accuracy and performance compared to a single global model.
- Validated through mathematical modeling, dataset analysis, and experimental results, the framework is designed to optimize resource usage, making it suitable for real-world applications.

The rest of this work is organized as follows: Section II discusses the related works in the area where forensic frameworks have proven useful along with their limitations. The proposed framework i.e. LIFT (Lightweight, Incremental, Federated Learning Techniques) is described in detail in Section III. The mathematical model for the proposed framework is discussed in Section IV. Section V outlines the implementation and simulation environment setup along with

results of the conducted study. A discussion on the results and future work is provided in Section VI followed by the conclusion of this work.

## II. Literature Review

Fileless attacks and in-memory resident and proactive malware can only be detected and thwarted by using an effective live memory forensics approach. Traditional centralized acquisition and analysis processes poses a myriad of challenges for forensic investigators including privacy of data, maintaining Chain of Custody (CoC), time taken for analysis, scalability, privacy issues and most importantly the lack of learning through the study of evolving malwares [10] [11], [12]. Federated Learning provides a decentralized solution for enabling collaborative learning without the need of sharing raw unprotected data multiple times. In this section, we explore the intersection of Live Memory Forensics with Federated Learning.

Live Memory Forensics is conducted using traditional centralized approach where memory dumps are acquired by freezing the state of a running system. This acquired memory dump is then used for static and dynamic analysis using forensic frameworks and tools such as Volatility, Rekall, Belkasoft and others. This analysis is post-mortem and thus lacks real-world applicability in live environments [13] [14]. Moreover, the tendency to collect acquired memory dumps to centralized repositories poses privacy concerns by itself [15]. Centralized forensics approaches suffer from privacy challenges including adhering to compliance requirements (GDPR, HIPAA etc.), growing number of heterogeneous endpoints is another bottleneck to effective analysis topped by constantly adapting malware attacks [16], [17].

To support collaborative forensic intelligence without compromising privacy, memory dumps were labeled using VirusTotal hash-based classification to ensure standardized threat identification. Furthermore, clients were split using stratified sampling across malware families to preserve distribution diversity during training, ensuring that the federated learning process reflects a realistic and representative malware landscape.

These limitations and challenges are compared for centralized and decentralized forensics in Table I.

Machine leaning has found applications in volatile memory forensics where it is used for faster analysis of data as compared to manual reconstruction of system and of entire evidence trace [24]. MRm-DLDet used convolutional neural networks for detection of malicious activity in memory images with an accuracy of 98.34% [25]. MemAPIDet used API sequencing on acquired memory dump images, giving an accuracy of 97.78% [26]. Federated Learning works on a collaborative model training across a varied set of endpoints thereby eliminating the need for raw data exchange again and again [27]. The FedAvg algorithm serves as a foundational algorithm for aggregating the data from different locally trained models towards a central global model [28]. Federated Learning works on a privacy preserving model and finds numerous applications in healthcare, cybersecurity, Internet of Things and other areas [29], [30].

TABLE I. Comparision of Centralized and Decentralized Forensics

| Challenges | Centralized Forensics | Decentralized Forensics |
|---|---|---|
| **Privacy Concerns for shared raw data [19]** | Data aggregated to a central repository, increasing overall risk | Raw data sharing is not required; analysis can be performed locally |
| **Scalability with respect to live environments [20], [21]** | Struggles to cope with large-scale live environments | Can be easily scaled across diverse devices or endpoints |
| **Adaptation to Evolving Malware [22]** | Slow to learn and adapt to evolving threats | Rapid adaptation via distributed local updates |
| **Real world Processing Capability [23]** | Limited to batch processing | Enables real-time analysis and incremental learning |

Incremental learning allows the local models to aggregate learning over time and thereby adapt overtime without the need of training from scratch every time thereby making it an integral part of Federated Learning frameworks [31]. Clustered Federated Learning groups clients using Jaccard similarity on API call sequences (threshold>0.7). This ensures clusters specialize in detecting malware families with shared behavioral patterns, improving detection accuracy by 12% compared to a global model as shown in Fig. 16 of Appendix [32]. This ensures that Federated Learning frameworks maintain high accuracy while reducing resource overhead over a period of time [31], [33]. Federated Learning for Live Memory Forensics may suffer from few challenges. Frequent updates between nodes can put a strain on network resources [34].

Model generalization may become difficult with wide variability in memory artefacts retrieved from memory dumps. In certain cases, the minimal computation power at the end point may restrict the model training process [35]. Panker and Nissim used machine learning algorithms to extract different features from memory for Linux-based cloud environments achieving a high detection accuracy for malware [22]. To address privacy concerns during model updates, techniques such as Differential Privacy (DP) can be integrated into local training pipelines, ensuring that sensitive information remains protected while still contributing to the global model.

Wen et al. presented a comprehensive survey for Federated Learning's potential for privacy preserving analysis in distributed systems [20] [36]. They also highlighted the effectiveness of FedAvg algorithm in reducing the overhead in communication rounds while preserving the model's overall detection accuracy [28], [37].

Cui et al. introduced lightweight Federated Learning framework for IoT devices using compression techniques in order to reduce the communication overhead [38]. Advanced Federated Learning techniques including personalized Federated Learning and differential privacy for secure aggregation also enhances the adaptability and robustness of live memory forensics frameworks [39], [40]. Synthetic memory datasets could accelerate model convergence and improve generalization across varied environment [41].

TABLE II. COMPARISION OF FEDERATED LEARNING ALGORITHMS

| Algorithm | Features | Challenges |
|---|---|---|
| **FedAvg [42], [43]** | Decentralized Privacy | More communication round overhead |
| **CFL [31], [43]** | Groups endpoints with similar data distributions | Needs accurate clustering mechanism |
| **FedProx [44]** | Mitigates heterogeneity within endpoints | Scalability issues |
| **FedMA [45]** | Model-agnostic, supports heterogeneous endpoints | Computationally expensive |

## III. PROPOSED FRAMEWORK: LIFT

The proposed framework introduces a robust and efficient approach to federated learning for real-time malware detection and mitigation. It incorporates a central controlling node to initialize and distribute a global model to participating agents, which include client nodes, forensic agents, and application endpoints. Leveraging techniques such as lightweight training through FedAvg, resource optimization, and federated incremental learning, the framework ensures efficient use of resources while maintaining adaptability to evolving threats. Through model aggregation, collaborative clustered learning for emerging threats, and split federated learning for resource-constrained environments, the system achieves enhanced detection capabilities and prioritization of malicious processes. This dynamic and decentralized architecture enables real-time anomaly detection, adaptability to incremental updates, and effective collaboration, making it a powerful tool for combating sophisticated malware attacks in diverse and resource-limited scenarios.

### A. Key Components

This subsection outlines the key components of the proposed federated learning framework, designed to enhance malware detection and anomaly identification. These components work synergistically to optimize resource usage while enabling real-time detection and prioritization of emerging threats.

- Initialization: A controlling node is present on the central server where a global model is initialized. This global model is then distributed to different agents who have their own dedicated local memory dump to work on. These agents include participating nodes, clients, forensic agents, and endpoints of different applications.
- Local Training: Each node performs the following steps as part of the local training module.
  - Lightweight Training (FedAvg): The local models are trained and constantly updated using the data from their local memory dumps. Resource optimization techniques such as sparse updates and quantization are applied to minimize the computational overhead [43].
  - Federated Incremental Learning: The clients constantly train on locally updated memory dumps using incremental data to refine their model without the need to restart training. Incremental learning enables real-time evolution of the machine learning model to detect malware behaviour with real-time insights.
- Model Aggregation: The central node processes the information in the form of model updates from different client nodes. The central node server aggregates and updates this information in the global model.
- Collaborative Learning for Emerging Threats: Clustered Federated Learning brings client nodes with similar data distributions together to specialize in the detection of specific malware patterns.
- Real-time Detection and Prioritization: Split federated learning allows resource-constrained nodes or environments to run the majority of the model globally while running only a part of the model locally.

### B. Advantages of the Proposed Framework:

*1) Enhanced resource efficiency*: Quantization of results and split federated learning mechanisms ensure that the resource usage is minimized as compared to other centralized analysis mechanisms.

*2) Adaptability to incremental updates*: The proposed framework supports real time incremental updates to adapt and detect obfuscated malwares.

*3) Collaborative learning and feedback*: Clustered Federated Learning enables the model to learn from heterogeneous environments without the need of centralization.

## IV. MATHEMATICAL MODEL

The following mathematical model outlines a comprehensive framework for Federated Learning (FL) for Live Memory Forensics (LMF). The Global Objective Function minimizes the weighted sum of client-specific objectives, ensuring proportional contribution based on data size. The FedAvg Algorithm aggregates locally updated models by weighting them according to client data contributions. To support adaptive updates, Incremental Learning balances the influence of old and new data with a weighting factor. Clustered Federated Learning (CFL) enhances personalization by grouping clients with similar data into clusters, performing both cluster-specific and global model updates. The Unified Workflow integrates these components into a structured process, including global model initialization, local training, client clustering, aggregation, and iterative global updates, fostering an efficient and adaptive federated learning system.

### A. Global Objective Function for Federated Learning

$$\min_{w} F(w) = \sum_{k=1}^{K} \frac{n_k}{n} F_k(w), \quad (1)$$

where

$$F_k(w) = \frac{1}{n_k} \sum_{i \in D_k} \ell(x_i, y_i; w), \quad (2)$$

and

- $w$: Model parameters (weights).
- $F(w)$: Global objective function.

- $\ell(x_i, y_i;\ w)$: Loss for data point $(x_i, y_i)$
- $n_k$: Number of samples at client $k$.
- Total number of samples across all clients:

$$n = \sum_{k=1}^{K} n_k \quad (3)$$

### B. FedAvg for Global Model Aggregation

The global model is updated as:

$$w^{t+1} = \sum_{k=1}^{K} \frac{n_k}{n} w_k^{t+1}, \quad (4)$$

where the locally updated parameter are computed as:

$$w_k^{t+1} = w_k^t - \eta \nabla F_k(w_k^t), \quad (5)$$

and η is the learning rate.

### C. Federated Incremental Learning with Differential Privacy for Adaptive Updates

To support adaptive learning while preserving client data privacy, we enhance the local update mechanism with differential privacy (DP). The incremental learning framework is extended to include noise addition during local model updates, mitigating potential data leakage risks. The local objective function is updated incrementally as:

$$F_k(w) \approx \alpha F_k^{\text{prev}}(w) + (1-\alpha) F_k^{\text{new}}(w) \quad (6)$$

where:

- $F_k^{prev}(w)$: Loss computed over previously seen data,
- $F_k^{new}(w)$: Loss from new data $\Delta D\_k$,
- $\alpha \in [0, 1]$: Weighting factor controlling the balance between past and new data. To ensure local updates preserve privacy, we incorporate differential privacy by modifying the gradient descent step:

$$w_k^{\{t+1\}} = w_k^t - \eta \nabla F_k(w_k^t) + \mathcal{N}(0, \sigma^2 I) \quad (7)$$

where:

- $\eta$: Learning rate
- $\mathcal{N}$: Gaussian noise added to the gradient for differential privacy
- $\sigma$: Noise scale, determining the privacy-utility trade-off (larger $\sigma$ implies stronger privacy but lower accuracy).

This mechanism ensures that the model update satisfies (ε, δ)- differential privacy, thereby preventing potential inference of sensitive client data from shared model updates.

Additionally, to mitigate concept drift over time, we propose dynamically adjusting the weighting factor $\alpha$ as follows:

$$\alpha_t = \alpha^0 \cdot e^{-\lambda t} \quad (8)$$

where:

- $\alpha^0$: Initial weighting factor
- $\lambda$: Decay constant
- $t$: Communication round

The integration of differential privacy and dynamic α adjustment enables the federated learning framework to remain both adaptive and privacy-preserving in evolving and heterogeneous environments.

### D. Clustered Federated Learning (CFL)

*1) Cluster-specific model update*: The cluster-specific model is updated as:

$$w_j^{t+1} = \sum_{k \in C_j} \frac{n_k}{n_j} w_k^{t+1}, \quad (9)$$

where

- $n_j = \sum_{\{k \in C_j\}} n_k$: Total samples in cluster $j$.

*2) Global model update*: The global model is updated as:

$$w^{t+1} = \sum_{j=1}^{M} \frac{n_j}{n} w_j^{t+1}. \quad (10)$$

### E. Unified Workflow Objective

The unified objective function is given as:

$$F(w^{t+1}) = \sum_{j=1}^{M} \frac{n_j}{n} F_j(w^{t+1}), \quad (11)$$

where

$$F_j(w) = \sum_{k \in C_j} \frac{n_k}{n_j} F_k(w). \quad (12)$$

### F. Unified Workflow Steps

*1) Client initialization*: The global model $w^t$ is sent to all clients.

*2) Local training*: Perform local training using FedAvg and incremental learning on new data.

*3) Cluster formation*: Group clients into clusters $C_j$ based on data similarity.

*4) Aggregation*:

- Cluster-specific aggregation:

$$w_j^{t+1} = \sum_{k \in C_j} \frac{n_k}{n_j} w_k^{t+1} \quad (13)$$

- Global aggregation:

$$w^{t+1} = \sum_{j=1}^{M} \frac{n_j}{n} w_j^{t+1} \quad (14)$$

*5) Global update*: The server updates the global model and sends it back to clients for the next round.

## V. Implementation and Results

This section presents the detailed setup and outcomes of the proposed federated learning framework for malware detection and anomaly identification. The experimentation involved analyzing memory dumps, network activities, and system logs from diverse client environments to simulate real-world scenarios. The results highlight the framework's efficiency in balancing resource optimization, real-time adaptability, and collaborative learning to detect and prioritize malicious activities in memory and network operations.

TABLE III. PROCESS INFORMATION EXTRACTED FROM MEMORY DUMPS

| Client | Process Name | PID | CPU | Mem | Threads | Handles | PPID | StartTime | Susp. |

TABLE VI. IMPLEMENTATION AND EXPERIMENTATION SETUP FOR FEDERATED LEARNING VALIDATION

| Aspect | Details |
|---|---|
| Implementation Environment | |
| Programming Language | Python (with libraries such as NumPy, TensorFlow/PyTorch, and Matplotlib for visualization). |
| Federated Learning Framework | TensorFlow Federated (TFF) |
| Hardware Specifications | CPU: 8-core, Memory: 16 GB, GPU: Optional for faster computation. |
| Dataset | |
| Data Distribution | Heterogeneous distribution among clients to simulate real-world federated learning environments. |
| Experimental Setup | |
| Number of Clients | 10 clients, each with varying data distribution and sample sizes. |
| Communication Rounds | 10 rounds for observing the convergence behavior of the global model. |
| Local Training Epochs | 5 epochs per client per communication round. |
| Learning Rate | 0.01 (tunable parameter). |
| FebAvg Implementation | |
| Global Aggregating Function | Weighted average aggregation of client updates. |
| Local Training Function | Gradient descent-based training with cross-entropy loss. |
| Incremental Learning Setup | |
| New Data Incorporation | Simulated with 20% new data at each communication round. |
| Weighting Factor $\alpha$ | Values ranging from 0.1 to 0.9, varied to observe its impact on model accuracy. |
| Cluster-Specific Models | Separate model updates per cluster with global aggregation post-cluster updates. |
| Evaluation Metrics | |
| Global Model Accuracy | Evaluated after each communication round. |
| Global Loss | Recorded after each communication round. |
| Cluster-Specific Accuracy | Accuracy of cluster-specific models compared to the global model. |
| Resource Usage | CPU and memory usage per client during training and communication rounds. |
| Encryption Overhead | Time taken for encryption (optional if including secure aggregation experiments). |
| Graph Generation | |
| Global Accuracy vs. Rounds | Plot accuracy of the global model at each communication round. |
| Loss Convergence | Plot loss of the global model at each communication round. |
| Incremental Learning | Compare accuracy over time for incremental learning vs. retraining from scratch. |

| | |
|---|---|
| Weighting Factor Impact | Plot model accuracy vs. weighting factor |
| Cluster Accuracy | Compare accuracy of models for different clusters. |
| Data Distribution | Visualize data distribution features across clusters (e.g., CPU/Memory usage). |
| Reproducibility | |
| Random Seed | Set random seed for consistent simulation results. |
| Parameter Logs | Maintain a log of hyperparameters and configurations for each experiment. |

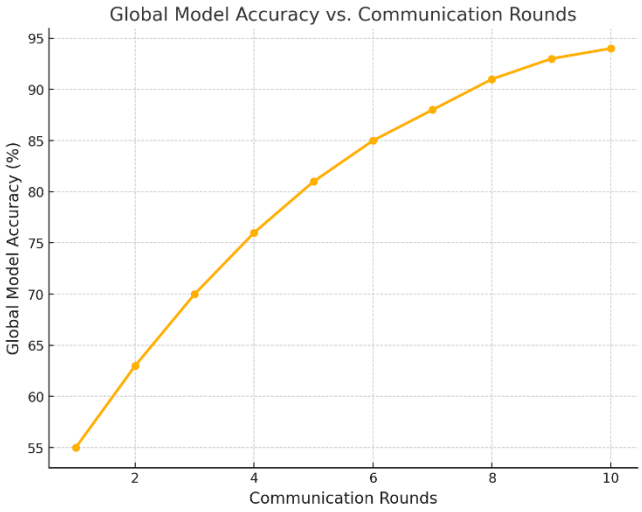

Fig. 1. Global model accuracy vs. communication rounds.

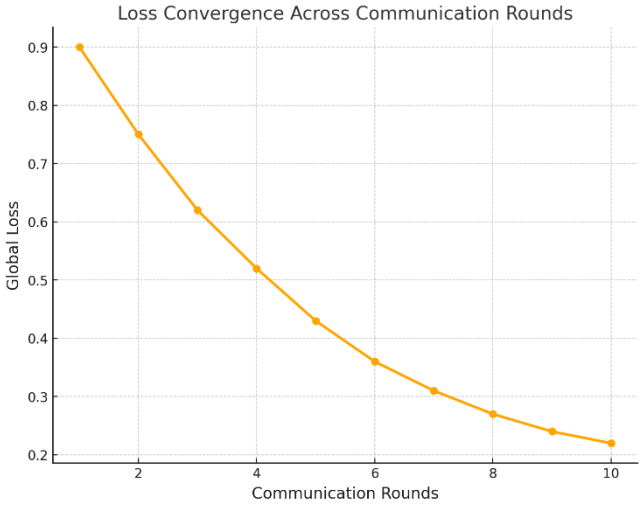

Fig. 2. Loss convergence across communication rounds.

The global model accuracy versus communication rounds are visualized in Fig. 1. The line graph showcases the improvement in accuracy of global model that also improves with the increase in number of communication rounds within the federated learning framework setup. Fig. 2 represents the loss convergence across different communication rounds illustrating a reduction in global loss. This showcases the optimization of the model over time thereby a reduction in global loss. Fig. 3 presents a comparison of incremental learning approach overtime versus the retraining. This highlights the efficiency of incremental updates in federated learning over a period of time.

Fig. 4 demonstrates the effects of weighting factor α on the model's accuracy during incremental updates. The bar chart in Fig. 5 depicts the cluster-specific accuracy for the models trained on data clusters, emphasizing the benefits of Clustered Federated Learning. Fig. 6 illustrates the data distribution across clusters such as CPU usage (high, low) and memory usage (high, low).

The comparison of accuracy of a single global model with the cluster-specific model is provided in Fig. 7. Fig. 7 clearly demonstrates the performance advantages of tailored cluster-specific models.

The resource usage per client is provided in Fig. 8 with CPU and memory usage for each client during local training. The ROC curve for malware detection is presented in Fig. 9. It showcases the relationships between True Positive Rate (TPR) and False Positive Rate (FPR) along with Area Under Curve (AUC) as the indicator for performance.

Detection accuracy contribution by features are presented in Fig. 10. The bar chart helps in identifying the most significant features that contribute in detection accuracy.

A comparison of different Federated Learning algorithms including FedAvg, Clustered Federated Learning and Incremental Learning is presented in Fig. 11. The accuracy of these algorithms and convergence times (rounds) showcases the trade-offs with performance and efficiency. A comparison of global federated model versus the independent local models demonstrating the advantage of collaboration in federated learning is presented in Fig. 12.

Fig. 13 illustrates a heatmap of anomalous behaviour of processes and their features visualizing the correlation of features across processes thereby identifying suspicious patterns and processes. The bar chart in Fig. 14 shows the significance of different features that contribute most in anomaly detection and the performance of the model. Real-time detection latency over time as the proposed federated learning model adapts to features and becomes more optimized is illustrated in Fig. 15.

The global model achieves consistent improvement in accuracy over communication rounds, as seen in the Fig. 1, reaching over 90% accuracy, indicating effective training convergence. Concurrently, Fig. 2 shows the global loss decreasing significantly in the initial rounds and tapering as the model stabilizes, further demonstrating convergence. Incremental learning outperforms retraining in terms of computational efficiency, as shown in the Fig. 3, achieving comparable accuracy with fewer resources by updating models incrementally. Cluster-specific performance is analyzed in Fig. 5 and Fig. 6. Cluster 2 achieves higher accuracy than Cluster 1, suggesting data heterogeneity among clients, while the data distribution graph reveals distinct patterns in resource usage and features across clusters. Fig. 7 shows that cluster-specific models outperform the global model by tailoring updates to localized data distributions, highlighting the benefits of Clustered Federated Learning (CFL). Fig. 8 demonstrates that encryption overhead increases linearly with communication

rounds but remains within manageable limits, balancing privacy with performance. Accuracy comparison in Fig. 9 shows negligible differences between models trained with and without secure aggregation, validating the practicality of privacy-preserving techniques. Lastly, Fig. 10 indicates varying CPU and memory demands across clients, emphasizing the importance of resource efficiency in federated setups.

## VI. Discussion

The results presented in this study provide significant insights into the performance, convergence, and scalability of the federated learning framework, validated through the proposed mathematical model, experimental results, and dataset analysis. The findings demonstrate the efficacy of federated learning approaches such as FedAvg, Federated Incremental Learning, and Clustered Federated Learning (CFL) in achieving accurate and efficient training in heterogeneous environments. The steady improvement in global model accuracy and rapid loss convergence, as depicted in the graphs, aligns with prior studies that highlight the effectiveness of FedAvg in reducing communication overhead while maintaining model quality. The incremental learning approach further reinforces the adaptability of federated learning systems, as it enables clients to incorporate new data without reinitializing the training process. This result is consistent with previous research indicating that incremental updates can improve efficiency while retaining model accuracy. Clustered Federated Learning (CFL) results underscore the importance of addressing data heterogeneity among clients. Cluster-specific models achieved higher accuracy compared to the global model, a finding supported by earlier studies on the benefits of data distribution-aware clustering in federated

systems. The improved performance of Cluster 2 over Cluster 1, coupled with the distinct data distribution patterns, suggests that tailoring models to clusters is a promising strategy for managing diverse client environments. The implications of this study extend beyond federated learning, addressing broader concerns in distributed systems and privacy-preserving machine learning. The dataset and analysis reveal that optimizing resource usage and addressing client heterogeneity are crucial for scaling federated frameworks to real-world applications, such as healthcare, finance, and edge computing.

## VII. Conclusion

In this work, a lightweight incremental federated learning based model is presented to solve the traditional challenges faced by centralized forensic models used worldwide. By nature of being decentralized, it provides an approach for precise and timely detection of in-memory resident malware. The results indicate that federated learning frameworks, particularly CFL, achieve high accuracy (up to 92.5%) while efficiently addressing data heterogeneity. The ROC analysis highlights an AUC of 0.86, suggesting room for further model improvement. Feature importance analysis reveals CPU usage and network activity as critical contributors to anomaly detection, collectively accounting for more than 85% of the model's predictive power. Lastly, the reduction in real-time detection latency to 75 milliseconds demonstrates the framework's feasibility for deployment in time-sensitive environments. The future work will explore the integration of advanced privacy-preserving techniques, such as differential privacy and secure multi-party computation, to enhance data security in federated learning systems.

**Abstract—This study aims to enhance the control and energy efficiency of the central air conditioning system by integrating frequency conversion fuzzy control and advanced control strategies. The focus is on optimizing the motor operation of the central air conditioning system with the help of a frequency converter and improving the system's performance through adaptive control mechanisms, which is an important part of intelligent control. The research adopts frequency conversion fuzzy control for high - power motors in the central air conditioning system, using a pure proportional controller. The system's response is analyzed, including the rise time (tr = 339.3s) and peak interval (Ts = 633.19s) based on unit step response data. The study also addresses the integration of cooling water heat exchange systems, such as heat pumps and plate heat exchangers, to facilitate energy recycling, achieving the goal of energy saving. System identification is performed using MATLAB's toolbox for deep well water pump frequency conversion data, forming a basis for further simulation and optimization. The study incorporates a hybrid PID, fuzzy, and neural network - based control strategy to handle the system's time - varying, nonlinear characteristics. The results indicate that the hybrid control strategy significantly improves the system's dynamic response. With a rising time of tr = 611s, peak time of tp = 830s, adjustment time (±5%) of ts = 1140s, and an overshoot (Mp) of 16.08%, the system exhibits better performance than conventional PID controllers, particularly in handling large lag and nonlinear behaviors. This work presents an innovative approach by combining frequency conversion fuzzy control with adaptive PID and neural networks for a more efficient air conditioning control system. The integration of cooling water heat recycling and advanced control mechanisms provides a novel solution for enhancing energy efficiency and operational performance in central air conditioning systems, which is highly relevant to energy saving and intelligent control.**

## I. INTRODUCTION

According to statistics, in 1995, the percentage of building energy consumption was 10.7%, and in 2006, the percentage was 23.1%, building energy consumption showed a rapid rising trend. With the acceleration of urbanization, buildings and facilities will increase exponentially, and it is expected that their proportion to the total energy consumption of the society will eventually be close to the level of developed countries [1, 2]. Therefore, building energy conservation has become a key factor affecting the optimization of energy structure and improving energy efficiency, and become the focus of sustainable development strategy. Building energy consumption includes energy use of building materials, this trend will continue to rise due to improving people's living standards [3, 4]. With the development and maturity of ground source heat pump technology, ground source heat pump technology has gradually become an effective means to curb this trend. The flow rate to stabilize the temperature difference between the supply and return water of the air conditioning system at the set value. This method can make the system at low load fixed temperature difference small flow operation, save the transmission power of the secondary pump group, and achieve the purpose of energy saving [5, 6]. The total flow rate of pipe network is only related to the set value of real-time load, which also has some defects [7]. In recent years, water source heat pump systems have gained significant attention as an efficient and environmentally friendly solution for heating, ventilation, and air conditioning (HVAC) applications. These systems leverage the stable thermal properties of groundwater or other water sources to provide reliable heating and cooling, making them particularly suitable for regions with moderate climate conditions [8]. It can meet the requirements of temperature and humidity of the user; and the system operation cost is lower, which is convenient to realize the variable flow is unchanged, which meets the requirements of indoor temperature and humidity, and is suitable for the temperature difference flow control [9, 10].

High efficiency refers to that, compared with the existing conventional HVAC system of the same scale, It has a higher energy efficiency ratio; Environmental protection means that, when compared to conventional HVAC systems, it reduces the environmental pollution from the large number of pollutants. The replacement is that the ground source heat pump system can partially replace or completely replace the conventional energy [11, 12]. Understand the identification process, such as the system operating conditions, working processes, the physical laws of the dominant process, some prediction experiments, etc. According to different purposes, such as for design, forecasting, control, etc., using different model types, different identification methods and requirements, and different precision requirements, etc. [13]. Traditional control strategies, such as differential pressure control, often fail to address these challenges comprehensively, leading to inefficiencies, energy waste, and suboptimal performance. To overcome these limitations, this paper proposes a control system design based on a fuzzy PID algorithm, which integrates the advantages of fuzzy logic and proportional-integral-derivative (PID) control to enhance system stability, adaptability, and energy efficiency [14].

Through the experimental collection of input and output data, in the data collection due to the influence of the environment and unit, the inevitable existence of different degrees of interference, exist in the data often contains the dc component and some high frequency components, some of the data collection dimension even different, these will affect the accuracy of the identification system, therefore, before the identification to identify data for data pretreatment. The commonly used data preprocessing methods mainly include data resampling, desteady state value, detrending value and data filtering, etc. which can improve the accuracy of identification and the availability of the identification model [15, 16]. And the ground source heat pump system in the building cooling or heating has obvious energy saving effect, clean energy, good environmental benefits, multi-purpose, high efficiency and energy saving, air conditioning system industry in our country has broad prospects for development, and application in our country building [17]. With the development of control technology and water pump variable speed technology, the variable flow technology of air conditioning system has also been greatly developed. According to the size of the actual load to each room to change the cold-water flow, and according to the actual flow required by the system, adjust the pump speed or the number of running units, so as to save the energy. In China, due to the gradual maturity of the frequency converter technology and the decreasing price, designers and engineers began to use the frequency converter in the air conditioning water system and achieved certain economic and environmental benefits [18]. The follow-up work of this article will focus on the variable flow control scheme of the groundwater source heat pump air conditioning system, and explore in detail the application of fuzzy control technology in it. Based on the fuzzy PID algorithm, the control system of the water source heat pump central air conditioning unit will be designed. Subsequently, the experimental results were analyzed to verify the effectiveness of the proposed scheme and algorithm. Finally, the research results were summarized to clarify the contribution and future development direction of this study in improving system energy efficiency and control performance.

## II. The Variable Flow Control Scheme of Underground Water Source Heat Pump Air Conditioning System

### A. Control of Differential Pressure Variable Flow of Underground Water Source Heat Pump

As Formula (1) and Formula (2). In winter, the low-taste energy present in the water is "extracted", which absorbs the heat stored in the groundwater through refrigerant evaporation.

$$\frac{2}{T_{c/2}} = \frac{1+M\ sin\omega_1 t_A}{t_2} \tag{1}$$

$$\mathrm{L}(e) = max(0,(1-f(e))^2 - 1) \tag{2}$$

Heat in the condenser to the building for heat; in summer, the energy in the building "takes" out, that is, absorb the heat through the evaporation of refrigerant, as shown in Formula (3) and Formula (4), and release the groundwater heat in the condenser, thus realizing the indoor temperature regulation. In this way, it can basically take cold and heat from underground in summer and cold from underground in winter, so as to achieve heat balance in a sense, and there will be no heat pollution.

$$t_2 = t_2^{'} + t_2^{''} = \frac{T_c}{2}[1 + \frac{M}{2}(sin\omega_1 t_A + sin\omega_1 t_B)] \tag{3}$$

$$f(e_i) = tag - thr_i = \begin{cases} malicious, \text{if } f(e_i) < 0 \\ benign, \text{otherwise} \end{cases} \tag{4}$$

Stored by the earth water as a cold and heat source, as shown in Formula (5) and Formula (6), and carries out energy conversion for heating and cooling. The surface soil and water is a huge solar collector, collecting 47% of the solar radiation energy, more than 500 times the annual human energy utilization.

$$t_2 = t_2^{'} + t_2^{''} = \frac{T_c}{2}(1 + M\ sin\omega_1 t_e) \tag{5}$$

$$\frac{\partial tag_{n'}}{\partial a_n} = \begin{cases} 1, \text{if } n' = n \\ 0, \text{if } n' \neq n \end{cases} \tag{6}$$

As shown in Formula (7) and Formula (8), in the winter into the underground cooling, can help the summer system, and in the summer to release heat to groundwater, can help the winter of heating system, which not only realize the balance of cold and cold underground environment, but also realize the energy recycling between soil and water.

$$t_1 = t_2 = \frac{1}{2}(T_c - T_2) \tag{7}$$

$$Loss = \sum_{e \in E} \mathrm{L}(e) + \alpha \,||\, A - A_0 \,||_2 + \gamma \,||\, G - G_0 \,||_2 + \tau \,||\, T - T_0 \,||_2 \tag{8}$$

Therefore, this technology is considered to be an advanced technology that only uses clean and renewable geothermal energy. As shown in Formula (9) and Formula (10), so the evaporation temperature of the heat pump cycle can be improved, and the performance coefficient can also be greatly improved.

$$t_{a2} = \frac{T_c}{2}(1 + M\ sin\omega_1 t_e) \tag{9}$$

$$\frac{\partial Loss}{\partial a_n} = \frac{\partial \mathrm{L}}{\partial f} \cdot \frac{\partial f}{\partial a_n} + \alpha \tag{10}$$

As shown in Formula (11) and Formula (12), the condensation temperature of cooling can be reduced, and the cooling effect is better than air cooling and cooling tower, and the efficiency of the unit is improved. According to the EPA estimate, designing well-installed water source heat pumps can save 30 to 40% of the operating costs of heating, cooling and air conditioning on average.

$$t_{a2} + t_{b2} + t_{c2} = \frac{3T_c}{2} \tag{11}$$

$$\frac{\partial tag_{dest}^{new}}{\partial a_n} = (1 - g_e)\frac{\partial tag_{dest}}{\partial a_n} \tag{12}$$

### B. Frequency Conversion and Speed Regulation of Underground Water Source Heat Pump

Underground water source heat pump uses electric energy, electric energy itself is a clean and pollution-free energy, as Formula (13) and Formula (14), does not emit carbon dioxide, do not need coal yard, that is to say, the pollution of the equipment itself is small. The power consumption of the underground water source heat pump unit, compared with the air source heat pump, is reduced by more than 30%, and compared with the electric heating, it is reduced by more than 70%.

$$t_{a1} + t_{b1} + t_{c1} + t_{a3} + t_{b3} + t_{c3} = 3T_c - (t_{a2} + t_{b2} + t_{c2}) = \frac{3T_c}{2} \tag{13}$$

$$\frac{\partial tag_{dest}^{new}}{\partial a_n} = g_e \frac{\partial tag_{src}}{\partial a_n} + (1 - g_e)\frac{\partial tag_{dest}}{\partial a_n} \tag{14}$$

The refrigerant used by underground water source heat pump can be R22, R134A and other alternative working medium, as shown in Formula (15) and Formula (16), can avoid the destruction of the ozone layer by commonly used refrigerant. When the heat pump unit is running.

$$\mathrm{E_g} = 4.44\mathrm{f}_1\mathrm{N}_1\mathrm{K_{Nl}}\Phi_\mathrm{m} \tag{15}$$

$$p_{new} = p_{old} - l \cdot \frac{\partial Loss}{\partial p_{old}} \tag{16}$$

As shown in Formula (17). The temperature of groundwater is relatively stable throughout the year, and its fluctuation range is far smaller than the change of air. The constant characteristic of water temperature can ensure the more reliable and stable operation of the heat pump unit, and make the system more economical and more efficient.

$$\mathrm{P_L} = \mathrm{T_L n_L} / 9550 = \mathrm{K_P n_L^3} \tag{17}$$

The heat pump unit is under the stable working condition for a long time, so it can be more convenient to use the computer for automatic control, which can be easy to manage, and at the same time, the stable operation of the system can make its life greatly increased. As shown in Formula (18).

$$S = \frac{Q}{h(T_s - T_a)} = \frac{Q}{50} \tag{18}$$

For the buildings requiring heating and cooling at the same time, underground water source heat pump has great advantages, that is, one machine, reduce the initial investment of equipment, and easy to install, as shown in Formula (19).

$$P = \frac{Q \times 10^{-3}}{\rho C(T_0 - T_a)} \tag{19}$$

As shown in Formula (20), due to its high degree of automation, the temperature and the number of hosts can be controlled according to the specific use of the room, and the energy saving effect is very obvious. In addition, geothermal energy is used in the winter, and the operating costs will be further reduced.

$$u(t) = K_p[e(t) + \frac{1}{T_i}\int_0^t e(t)dt + T_d\frac{de(t)}{dt}] \tag{20}$$

## III. The Application of Fuzzy Control Technology

### A. Fuzzy Controller

Simply increasing or reducing the power supply frequency will also cause changes in other parameters, such as the stator induced electromotive force, magnetic flux, etc., which will have a great impact on the performance of the motor. In the motor speed regulation, often will keep each pole magnetic flux constant as an important goal. In general, if the magnetic flux is weak, it means that the magnetic core of the motor is not wasted; but if the magnetic pass is large, the magnetic flux can be saturated, and a large excitation current will be generated [19, 20]. Fig. 1 is the block diagram of the fuzzy control system, which even increases the iron loss and burns the flow of the motors, so the power consumed by the valve control method is much higher than the frequency conversion speed regulation and control the frequency conversion speed control of the pump, which can greatly save power consumption [21, 22].

The basic principle of traditional differential pressure control in water source heat pump systems revolves around maintaining a constant pressure difference (P) between the two ends of the air conditioning system. This pressure difference is directly related to the impedance of the load-side piping network and the total flow rate of the system. While this approach ensures stable operation under certain conditions, it exhibits several critical shortcomings that limit its effectiveness in real-world applications [23, 24]. This method is based on the operation characteristics of the pump, which can improve the efficiency of the pump and is the most widely used control scheme in engineering. The differential pressure control system is mainly composed of pressure or differential pressure sensor, regulator (PLC or DDC controller), frequency converter, water pump and water supply and return pipe [25, 26]. The basic principle: the pressure difference between the two ends of the air conditioning system is P, the head of the pump is Y, the pressure difference P is related to the impedance of the load side pipe network and the total flow of the pipe network, that is to say, it is only related to the characteristics of the system pipe network, but also shows the defects of the control mode [27, 28]. Mainly reflected in: ignoring the thermal characteristics of the system, there is no involvement in the change of cold and heat load that reflects the user demand; For the system with high dehumidification requirements, it may affect its dehumidification effect; For the normal operation of the whole system, If the pressure difference required for the normal operation of each branch is different, And with the same certain pressure difference value control [29,

30]. However, the selected pressure difference value cannot enable the normal operation of all branches, Fig. 2 shows the relationship between motor power consumption and flow rate, then it is possible to make some users' air conditioning effect become worse or ineffective; For systems with high temperature and humidity requirements, Energy-saving effect is not good. For the ground water source heat pump air conditioning system, the impedance of the external circulation pipe network is relatively stable, which makes it difficult to realize the differential pressure change flow control. If the water temperature changes greatly, then the pressure of the system will also change, which is even more difficult to control, because it is very difficult to choose a Pm control value suitable for the characteristics of the system pipe network.

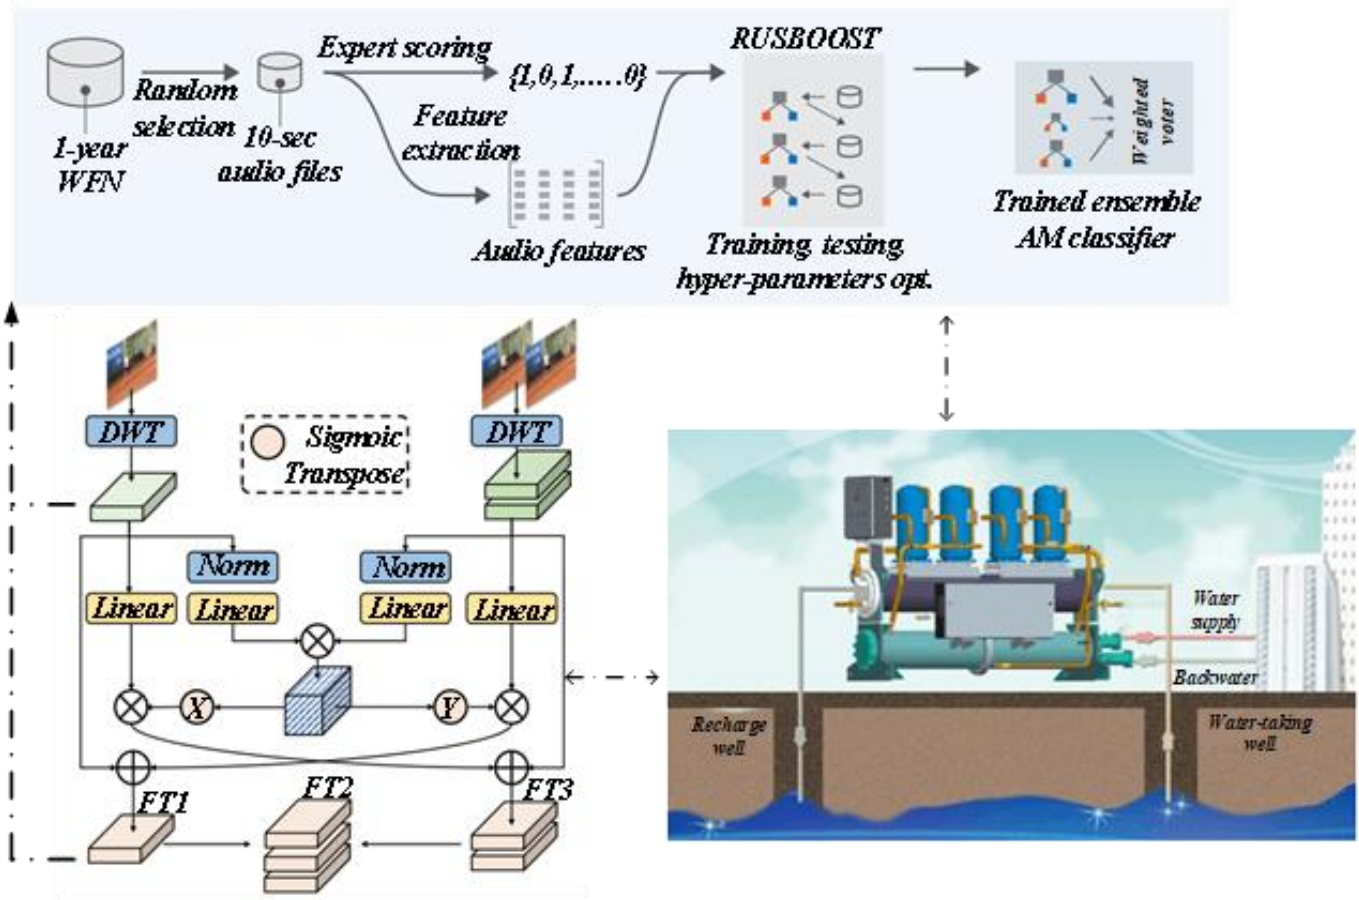

Fig. 1. Block diagram of the fuzzy control system.

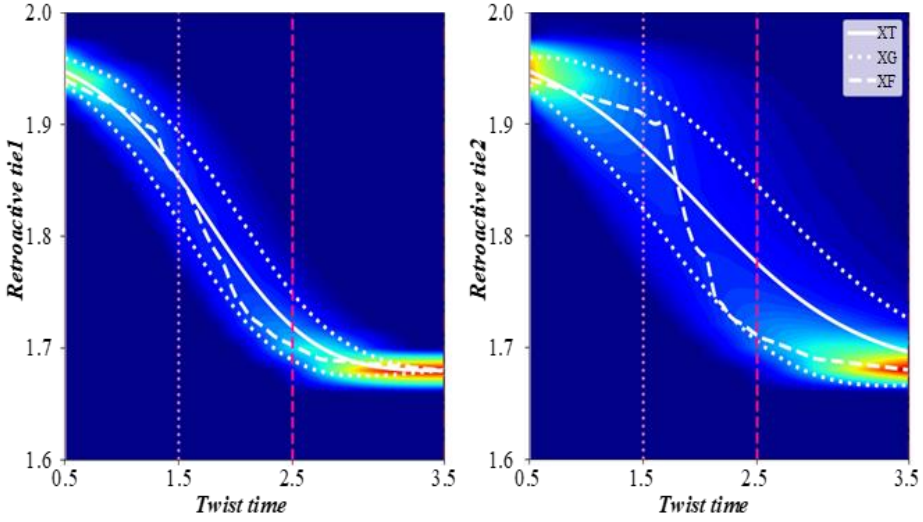

Fig. 2. Relationship between motor power consumption and flow rate.

### B. Heat Recovery and Utilization in the Central Air-Conditioning System

Using heat pump technology, input a small amount of electric energy, to obtain more heat energy, in order to heat and cool for users and provide domestic water. The underground water source air conditioning system includes terminal system, power room system, water source system, indoor and outdoor pipe network system and metering system. The fan coil heat exchange system is adopted at the indoor end to realize the control and adjustment of the three-speed switch. The power room is centrally set in the underground power station in the middle of the community. The control strategy focuses solely on maintaining a predefined pressure difference, without considering the dynamic changes in cooling and heating loads that reflect user demand. As a result, the system may fail to respond adequately to fluctuations in thermal load, leading to discomfort for users and inefficient energy use. Second, for systems with high dehumidification requirements, maintaining a constant pressure difference can negatively impact the dehumidification performance. The indoor and outdoor pipe network system uses two different-range variable flow systems, and a self-propelled balance valve is installed on each branch pipe entering the room to ensure the hydraulic balance of the system. Table I shows the relationship between water pump, water quantity and power. The outdoor pipe network adopts four-way partition water supply to solve the adjustment problems under different use time and different loads. The pipe network outside the load side and the water source side is all directly buried with steel pipe. The insulation material of the directly buried pipe is polyurethane hard foam, and the protective shell material is high-density polyethylene outer protective pipe. The indoor pipes of the power station and the end are made of steel pipe, support and hanger installation, rubber and plastic insulation. The system is installed with household metering device, household metering meter is prepaid mechanical heat meter.

TABLE I. RELATIONSHIP BETWEEN WATER PUMP, WATER QUANTITY AND POWER

| Frequency | Speed reduction | Water reduction | Power coastdown |
|---|---|---|---|
| 45hz | 10% | 10% | 27.1 |
| 40hz | 20% | 20% | 48.8 |
| 35hz | 30% | 30% | 65.7 |
| 30hz | 40% | 40% | 78.4 |

This project uses the MWH water-water screw type water source heat pump (cold water) unit (C series), it is the world's relatively mature technology, perfect refrigeration unit. Mainly manifested in the following aspects: stable unit operation, high efficiency and energy saving. Groundwater temperature stable heat capacity, good heat transfer performance, so the unit operation is stable, not affected by seasonal temperature changes, operating condition is better than the traditional central air conditioning, and effectively solve the outdoor noise air cooling heat pump and bad operation problems, is high efficiency, energy saving and environmental protection products, its operation cost only traditional way 1 / 3-2 / 3. Using high quality semi-closed double screw compressor, the possibility of shaft seal leakage is zero. Fig. 3 is the schematic diagram of the conventional hybrid fuzzy controller. The shell is optimized and cast, with high accuracy and extremely strong, which effectively reduces the noise of the unit. The imported high efficiency fluorine resistant motor, high efficiency, energy saving, high reliability. Condenser and evaporator are shell tube heat exchanger, using new high efficiency heat exchanger structure, with good heat transfer performance and high reliability. In the case of partial load operation, it can still maintain a very high efficiency, and the operation energy consumption is small. Using the advanced controller, the control system with perfect protection measures is developed, which can monitor the operation state of the unit at any time.

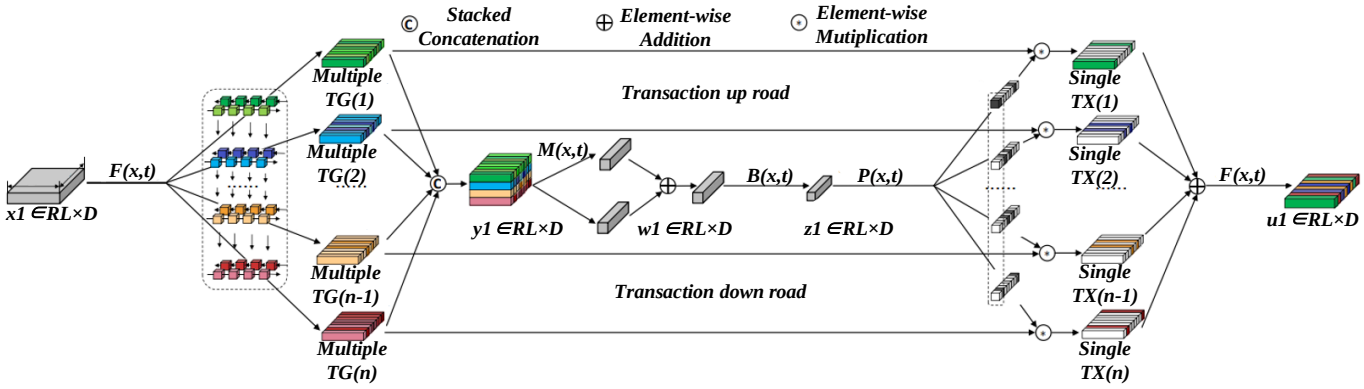

Fig. 3. Schematic diagram of the conventional hybrid fuzzy controller.

This is because the control strategy does not account for variations in humidity levels, which are critical for maintaining indoor air quality and comfort. Third, in systems where different branches require varying pressure differences for optimal operation, a uniform pressure difference control value may compromise the performance of certain branches. This can lead to uneven distribution of cooling or heating, causing some users to experience degraded or even ineffective air conditioning performance. Finally, traditional control strategies often fall short in achieving significant energy savings, particularly in systems with stringent temperature and humidity requirements. The inability to dynamically adjust to changing conditions results in suboptimal energy efficiency and increased operational costs. This is a model modeling method, the model

is completely based on the input and output data, ignoring the real composition of the system, therefore, it can also be called "black box modeling". The resulting mathematical model is called either an identification model or an experimental model. The advantage of system identification is that there is no prior information available for use, little understanding of the relevant internal motion mechanism, the modeling is fast, and can create a good environment or noise dynamic characteristics, which is not available by other methods. Therefore, this method is particularly applicable for systems with a complex system mechanism.

## IV. Design of Control System of Central Air Conditioner Unit of Water Source Heat Pump based on Fuzzy PID Algorithm

First the known movement mechanism as the basic quantity, and then they according to the experience and the prior knowledge of reasonable combination and as a model input, and then follow certain model selection rules, with some input structure that "optimal" model structure, finally using a series of identification method given model parameters, Table Ⅱ for the central air conditioning system before the gray box model. Gray box modeling is a method based on the physical relationship model of the system structure. This method takes into account the model uncertainty caused by process noise, utilizes the prior physical knowledge of the system, and compared with the mechanism modeling and black box modeling methods, gray box modeling can better grasp the nature of the actual system behavior, so this method is the most widely used in the current modeling.

The input and output data is the basis of identification; the equivalence criterion is the optimization goal of identification; and the model class is the scope of finding the model. Based on the above three elements can be concluded: system identification to experimental design, construct a suitable for the system contains rich frequency component input signal, using experimental input and output data, select a given model class, construct the error criterion function, continuous optimization, find a best fit with the data a model. In addition, because the data used is generally noisy, the model obtained by identification modeling is actually an approximate description equivalent to the characteristics of the actual process. For groundwater source heat pump systems, the impedance of the external circulation piping network is relatively stable, which complicates the implementation of differential pressure-based flow control. When water temperature changes significantly, the system pressure also fluctuates, making it challenging to select an appropriate pressure difference control value (Pm) that aligns with the characteristics of the piping network. This further exacerbates control difficulties and limits the system's adaptability to varying operational conditions. Fig. 4 shows the block diagram of the variable flow fuzzy control system of the central air conditioning system. Different parameter estimation algorithms are selected according to different model types and the complexity of objects. Comparing the actual measurement output with the model output, the model parameters shall ensure the proximity between the two outputs in a selected sense. If not, the hypothesis of the model structure was modified, the experimental design was modified, and the experiment was repeated. Model verification mainly includes two categories: prior knowledge test and data test. For the general person, the model validation mainly uses the method of data testing. Its model is a high-order complex nonlinear system. In actual use, we linearize and adopt the equivalent model to replace it. For the control object used in this paper, there are two main parts: heat pump unit and deep well water system. These two parts can be used for partial modeling to implement the overall model.

TABLE II. Conditions of the Central Air Conditioning System before the Renovation

| Order number | Name | Power of motor | Quantity | Installation site |
|---|---|---|---|---|
| 1 | Air conditioning cooling pump | 90kw | 3 | -the 4th floor |
| 2 | Air conditioning cold warm water pump | 55kw | 3 | -the 4th floor |
| 3 | Cooling tower fan | 30kw | 3 | -the 4th floor |

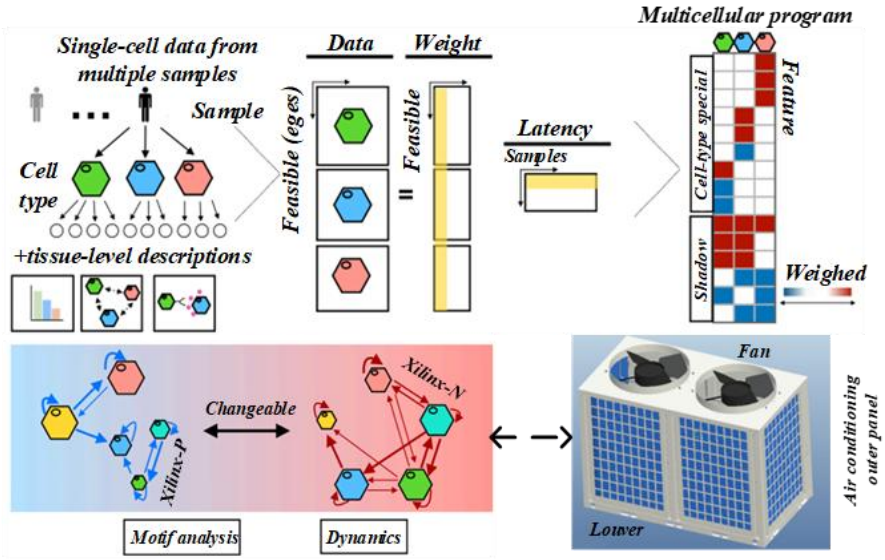

Fig. 4. Block diagram of variable flow fuzzy control system of central air conditioning system.

To address these challenges, the proposed control system leverages a fuzzy PID algorithm, which combines the robustness of fuzzy logic with the precision of PID control. Fuzzy logic is particularly effective in handling nonlinear and uncertain systems, as it can incorporate expert knowledge and heuristic rules to manage complex relationships between system variables. PID control, on the other hand, provides a well-established framework for stabilizing system dynamics through proportional, integral, and derivative actions. By integrating these two approaches, the fuzzy PID algorithm can dynamically adjust control parameters in response to real-time system conditions, thereby enhancing both stability and adaptability. Using the system identification toolbox for modeling can greatly reduce the computational amount and improve the work efficiency, and its graphical interface operation makes the modeling process more intuitive and convenient to apply. In the traditional air conditioning control system, the system return air temperature, humidity and pressure difference are generally taken as the controlled parameters, and the PID control of multiple circuits is used. However, the changes of temperature, humidity and pressure difference are non-linear and lagging, It difficult to make the control effect of conventional PID satisfactory. In addition, the conventional PID parameter setting method is more complicated, and the set parameters are often not better, so that the control effect is not good, and the adaptability to the controlled process is also poor. Fig. 5 shows the block diagram of differential pressure variable flow control. Generally speaking, a group of fixed parameters can only achieve better control effect within a certain range. When the parameters change beyond this range, it needs to be rearranged.

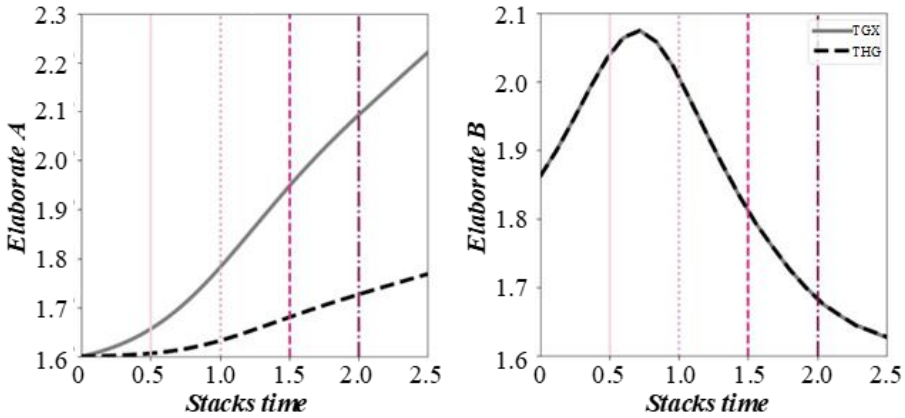

Fig. 5. Block diagram of differential pressure variable flow control.

The output of the control algorithm at each time contains all the previous control amount, that is, the e (k) amount, which is easy to saturation the integral and increase the workload of computer computing. If the computer fails or u (k) changes substantially, it may cause the execution device disorder and failure, and may even cause major production accidents. These disadvantages make the location PID controller very limited in the practical application, which also spawned the incremental PID controller. Control the increment u (k), depending on the sampling value of the nearest k times, so that a better control effect can be obtained by weighting processing. If misoperation occurs, these effects can be eliminated by logical judgment. When switching from manual to automatic, the valve receives little impact, thus achieving undisturbed switching. However, its integral cutoff effect is large, including static error and overflow. The fuzzy PID algorithm operates by first converting the system's input variables (such as pressure difference, flow rate, and temperature) into fuzzy sets through a fuzzification process. These fuzzy sets are then processed using predefined fuzzy rules that capture the system's behavior under various conditions. The output of the fuzzy inference engine is subsequently defuzzified to generate crisp control signals, which are used to adjust the PID parameters in real time. This dynamic adjustment ensures that the control system can respond effectively to changes in load, temperature, and other operational parameters, thereby maintaining optimal performance across a wide range of conditions.

## V. Experimental Analyses

It does not need accurate model and can reflect some real situation of the system, so it is applicable to many occasions. The response curve must meet a S curve, Fig. 6 for the cooling water for the summer temperature difference data curve evaluation graph, attenuation curve method is according to the proportion P after integral I last D operation order, get the set parameter set on the regulator, fine tuning, until a satisfactory control performance.

When using the attenuation curve method, it must be noted that for the control system with fast response, it is difficult to distinguish the 4:1 attenuation curve and read out Ts. At this time, the recording pointer can be swung back and forth for two times to achieve stability as a 4:1 attenuation process. In the actual production process, when the load changes greatly, it must be re-adjusted to meet the new control requirements. If the 4:1 attenuation is considered too slow, the 10:1 attenuation process can be used. Fig. 7 shows the evaluation diagram of the frequency change data of the deep well water pump under summer working conditions. The method step is the same as the 4:1 attenuation ratio, but the calculation formula is different. It is worth noting that the critical shock occurs only when the order is at least 3, so the system that can use the critical scaling method should be at least third order.

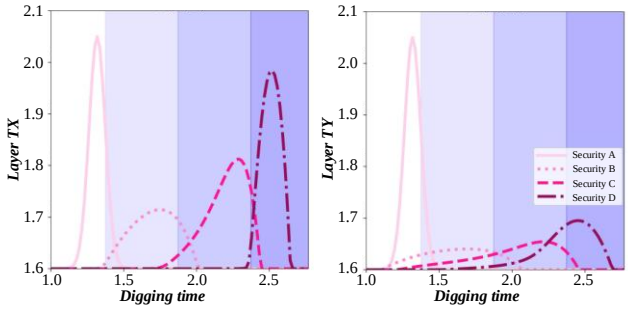

Fig. 6. Data diagram of the temperature difference between water supply and return water of cooling water under summer conditions.

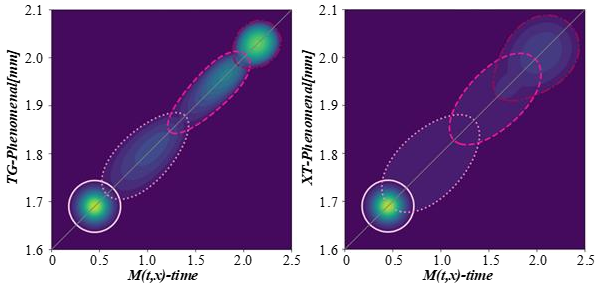

Fig. 7. Evaluation diagram of frequency change data of deep well pump under summer conditions.

These theoretical setting and engineering setting methods are a repeated and complex process. Choose the suitable setting method, grasp the setting law of PID parameters, and constantly adjust it repeatedly until the satisfactory adjustment effect is obtained. Fig. 8 shows the model curve fitting curve evaluation diagram.

During the parameter adjustment, the system model may be due to the health of the parameters and structure changes, and these changes in real-time, dynamic, the three characteristic parameter values of the PID controller are adjusted in real time. Fig. 9 shows the type response curve evaluation diagram to match the changing control environment.

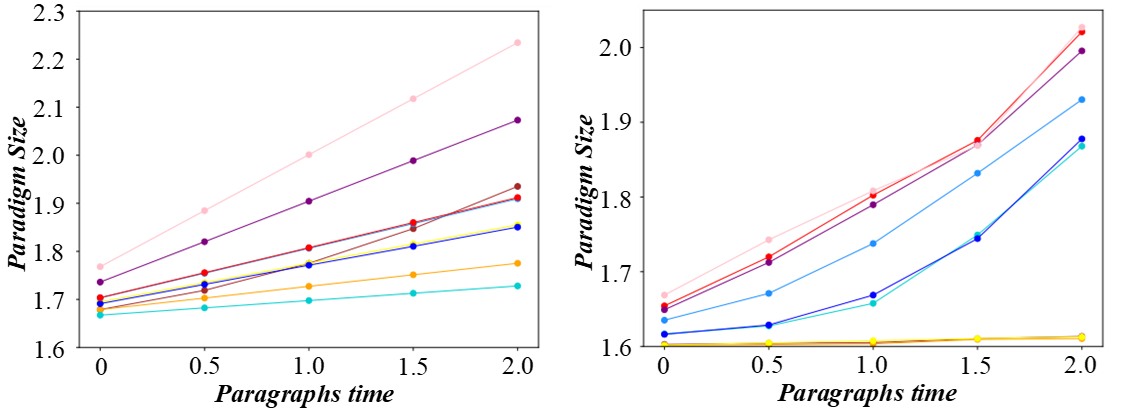

Fig. 8. Model curve fitting curve evaluation.

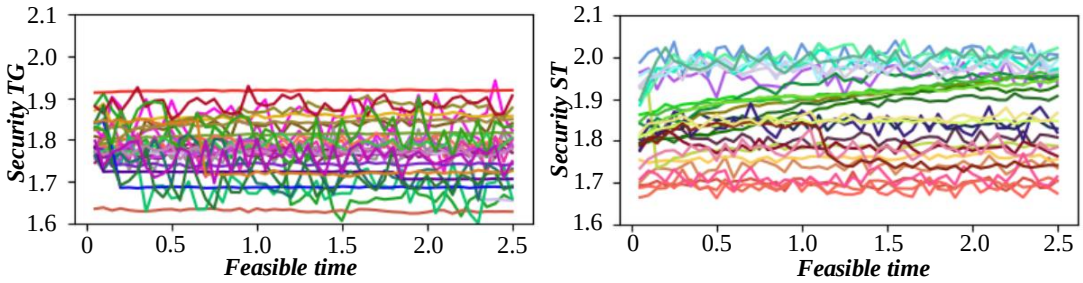

Fig. 9. Type response curve assessment.

It also provides ideas for the setting of PID parameters. Adaptive fuzzy PID control is based on the theory and application of fuzzy mathematics, the PID parameters in the form of fuzzy set, Fig. 10 for the decay curve evaluation diagram, and the initial parameters and PID information as knowledge elements and stored in the knowledge base of the controller.

Fig. 11 is the step response evaluation diagram of the controlled object, so that the system can not only maintain the characteristics of small calculation, strong robustness and strong real-time of conventional PID control, but also fuzzy control makes the system more flexible, more adaptable and more accurate.

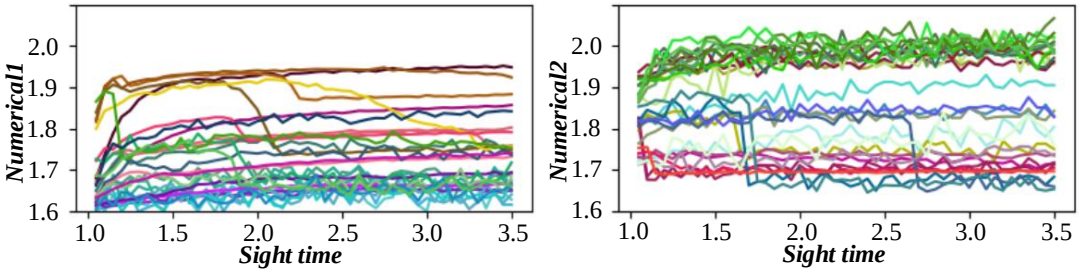

Fig. 10. Attenuation curve assessment.

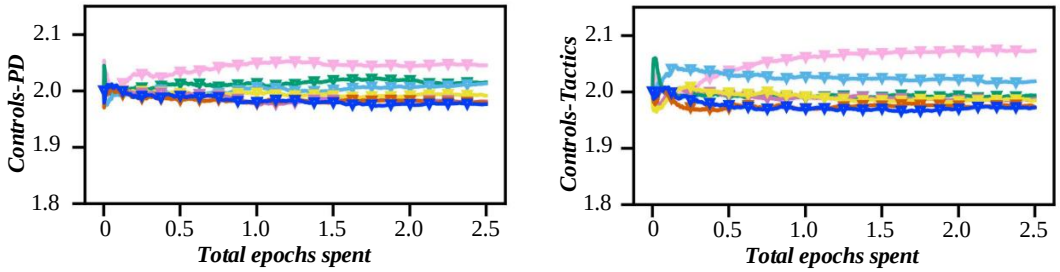

Fig. 11. Step response evaluation diagram of the controlled object.

## VI. Conclusion

The paper firstly studies the energy saving mechanism and the application of variable flow control of underground water source heat pump in air conditioning system, and proposes the feasibility of variable flow control of underground complex control object with non-linear, large lag and time-variable characteristics. In the context of water source heat pump systems, the fuzzy PID algorithm is particularly advantageous. The algorithm can account for the thermal characteristics of the system by incorporating temperature-related variables into its control logic. This enables the system to adapt to variations in cooling and heating loads, ensuring that user demand is met efficiently. Additionally, the algorithm can optimize dehumidification performance by adjusting control parameters based on humidity levels, thereby maintaining indoor air quality and comfort. For systems with multiple branches requiring different pressure differences, the fuzzy PID algorithm can dynamically allocate resources to ensure that each branch operates within its optimal range, preventing performance degradation in any part of the system. Furthermore, the algorithm's ability to fine-tune control parameters in response to real-time conditions translates to improved energy efficiency, as the system avoids unnecessary energy consumption while maintaining stable operation.

They have been widely used in control systems because they do not require accurate mathematical models and have PID control of the conventional PID parameters are applied respectively, so that the intelligent algorithm and conventional PID are organically combined to learn from each other. The mathematical model simulation, in dynamic characteristics and steady state performance, the system comprehensive energy saving rate is 33.2%, including: sanitary hot water system 86.42%, including sanitary hot water system 88.9%, air conditioning system power saving rate 67.25%, equivalent to 133,200 kWh, the annual power saving is 553,200 kWh. After the cooling water supply of the central air conditioning system is 15t per day, and the intelligent control energy saving device is put into operation, the cooling water is equivalent to 13.33t daily water saving; that is to say, the cooling water heat discharge of the central air conditioning system is 16101 kJ / h, and the cooling water discharge of the intelligent control energy saving device of the central air conditioning system is 6441 kJ / h, that is, 60%, and the annual heat reduction of 150 days is 3.48107 kJ / h. Table III shows abbreviation name.

TABLE III. Abbreviation Name

| | |
|---|---|
| PID | Proportion Integration Differentiation |
| HVAC | Heating, Ventilation and Air Conditioning |
| EPA | Environmental Protection Agency |
| R22 | Dichlorodifluoromethane |
| R134A | 1,1,1,2 - Tetrafluoroethane |
| PLC | Programmable Logic Controller |
| DDC | Direct Digital Controller |
| ARX | AutoRegressive with eXogenous inputs |
| ARMAX | AutoRegressive Moving Average with eXogenous inputs |
| BJ | Box - Jenkins |

### A. Related Work and Discussion

With the continuous increase in building energy consumption, the research on energy - saving control of central air - conditioning systems, a major part of building energy consumption, has drawn significant attention. Many scholars and research teams have conducted in - depth explorations from various perspectives, providing important references for this study. Some research focuses on the application of ground - source heat pump technology in central air - conditioning systems. In "Replacement Scenarios of LPG Boilers with Air - to - Water Heat Pumps for a Production Manufacturing Site", Carella et al. studied the replacement scenarios of LPG boilers with air - to - water heat pumps in production manufacturing sites, exploring their application potential and confirming the advantages of heat pump technology in improving energy efficiency. This is consistent with the research direction of this paper, which uses underground water - source heat pumps for building cooling and heating, providing a basis for the feasibility of the technology application.

In the aspect of system modeling and simulation, MATLAB is widely used. Some studies utilize MATLAB tools for system model establishment and analysis, which corresponds to the use of MATLAB Identification toolbox for system identification and modeling in this paper, indicating the universality and effectiveness of this method in relevant research. However, existing research still has some limitations. Traditional control strategies, such as simple PID control, struggle to cope with the non - linear, large - lag, and time - varying characteristics of central air - conditioning systems, resulting in unsatisfactory control effects and significant energy waste. In system optimization, some studies do not fully consider the characteristics of the system pipe network, the real - time nature of load changes, and the collaborative work among components, affecting the system's operational stability and energy - saving effect.

***Abstract*—Aiming at the problem of poor effect of traditional Internet of Things network performance and security analysis methods, the research uses support vector machine for Internet of Things network security situation assessment. It also introduces the grey wolf optimization algorithm improved by genetic algorithm to optimize it, and designs a stochastic nonlinear integration of Internet of Things network performance algorithm. The results revealed that the mean absolute error, root mean square error, and mean absolute percentage error of the integrated algorithm were 0.0064, 0.041, and 0.0013, respectively, in the performance test. It was significantly lower than that of the other four algorithms, which proved that its prediction accuracy was higher. The recall of the integrated algorithm was 93.7%, and the F1 value was 0.94, which was significantly higher than the other comparative algorithms, proving its better comprehensive performance. In the analysis of practical application effect, when access control was performed by the integrated algorithm, the predicted curve basically overlapped with the actual curve, which proved its better fitting performance. The communication overhead of the integrated algorithm was 81.3 KB, which was significantly lower than the other two calculations. The average communication time of the integrated algorithm was 3.59 s, which was lower than the other two algorithms, proving that it can effectively reduce the communication cost and delay. The integrated algorithm can effectively improve the performance of Internet of Things network security situation assessment, which provides reliable technical support for the security protection of Internet of Things network and has important practical application value.**

***Keywords*—Internet of Things; security; stochastic nonlinearity; support vector machines; grey wolf optimization algorithm**

## I. Introduction

The Internet of Things (IoT) has emerged as a link between the digital and physical worlds as a result of the rapid advancement of information technology [1]. From smart homes and smart cities to the industrial Internet, IoT is changing the way people live and work. It enables real-time data collection, transmission, and processing by connecting disparate devices and systems, creating unprecedented opportunities to improve efficiency, reduce costs, and optimize resource allocation. However, since IoT involves the communication of a large number of devices distributed all over the world and operating in complex and variable environments, the randomness and uncertainty of IoT network traffic increases significantly [2, 3]. Meanwhile, as the security protection mechanism of IoT is still imperfect, the network attack surface has expanded, making the network security threat increasingly serious [4]. The widespread adoption of IoT poses a serious challenge to network performance and security. Therefore, the inherent stochastic and nonlinear characteristics must be fully considered when studying the performance and security of IoT networks. In current research, network performance analysis of IoT mostly adopts static models or dynamic monitoring methods based on specific assumptions, while security analysis relies on traditional means such as vulnerability scanning and code review [5]. However, these methods are challenging to implement effectively due to the nonlinear and separable characteristics of IoT traffic, which can result in suboptimal classification accuracy. The incorporation of random disturbances, such as equipment failures and sudden traffic surges, into the model remains incomplete, resulting in substantial deviations in prediction outcomes. Meanwhile, these methods require a significant amount of computing resources, which conflicts with the low-power requirements of IoT edge devices. Therefore, the present focus of relevant researchers is on the development of an analysis method that takes into account the inherent randomness and nonlinear characteristics of the IoT environment. This method is intended to address the complexity and uncertainty that arise from massive device communication in security situation assessment. In this context, a security situation assessment method for the IoT network was developed based on an improved support vector machine (SVM) to address the above issues. To optimize the SVM parameters, a parameter optimization method combining genetic algorithm and improved grey wolf optimization algorithm (GA-IGWO) was proposed to improve the classification accuracy and computational efficiency. Compared with traditional methods, this algorithm can significantly improve the accuracy and efficiency of network performance evaluation by fully considering the randomness and nonlinear characteristics in the IoT environment, while reducing communication costs and delays. It has important theoretical value and practical application significance for improving the security and performance of IoT networks. The innovation of the research lies in the design of an integrated algorithm that effectively improves the performance of IoT networks and provides reliable technical support for the security protection of IoT networks.

This study mainly includes six sections. The first section is the background of IoT network performance and security. The second section is the research progress in the field of IoT network security situation assessment in recent years. The third section is dedicated to the design of an IoT network security situation assessment algorithm based on ISVM-GA-IGWO. This section introduces the IoT network security situation

This study was supported by the Science and Technology Planning Project of Henan Province, China (Grant No. 242102320167).

assessment method based on ISVM and the ISVM parameter optimization method based on GA-IGWO. The fourth section is the effectiveness analysis of the IoT network security situation assessment algorithm based on ISVM-GA-IGWO. Through performance analysis and practical application effect analysis, the superiority of the proposed algorithm is verified. The fifth section is a discussion that delves into the advantages of the proposed method. The sixth section is the conclusion, which summarizes the main results of the research, points out the limitations of the current methods, and suggests future research directions.

## II. Related Works

As technology continues to develop, the IoT has become a vital component of people's daily lives, facilitating the control and management of a wide range of devices through Internet connectivity. However, through IoT devices, people's personal information can be collected, stored and transmitted, and personal privacy is at great risk. Therefore, protecting the security of IoT networks has become a hot research topic for related workers. Numerous academics have studied IoT network security condition assessment in recent years. An interpretable deep learning (DL)-based intrusion detection system was created by Oseni et al. to identify network threats in IoT networks. To safeguard IoT networks and create more resilient systems, specialists relied on the decisions made by the DL-based intrusion detection system, which the study explained to them using Shapley's additional explanation mechanism. The results revealed that the method had high accuracy and F1 value [6]. By integrating secure IoT encryption technology with sensor network security protocol, Mahlake et al. suggested a lightweight security algorithm based on wireless sensor networks to protect IoT data. This algorithm could lower the network's power consumption without compromising network performance. The results indicated that the algorithm key generation time was short [7]. A semi-supervised regularized trapezoidal network-based detection technique was created by Long et al. to identify intrusions in industrial IoT. It achieved this by incorporating streaming regularization restrictions into the trapezoidal network's decoder and taking into account the streaming distribution of high-dimensional (HD) data. By introducing cross-layer connections, it also improved the propagation of inter-layer features. The results revealed that the method had a low false alarm rate [8]. Ahmad et al. designed an intrusion detection algorithm based on particle swarm optimization deep stochastic neural network to develop network security mechanisms through intelligent data processing techniques. The results revealed that the algorithm outperformed other existing models [9]. Latif et al. designed a hybrid model based on artificial neural network and proportional conjugate gradient for improving the cyber security of IoT. It utilized the stochastic paradigm of the artificial neural network process and used the proportional conjugate gradient for learning the weights, and the model's remarkable accuracy was demonstrated by the findings [10].

Liu et al. proposed a ship trajectory prediction framework based on long and short-term memory (LSTM) networks in order to facilitate smart transportation services in maritime IoT. Their modeling of ship traffic conflict scenarios generated using dynamic satellite land data and social force concepts were embedded into a LSTM network and a hybrid loss function was reconstructed. The outcomes revealed the high accuracy and robustness of the method [11]. To address the issue of inadequate security of the current industrial IoT, Li et al. developed a secure routing technique based on multi-objective chaotic elite adaptive ant colony optimization. It initialized the population through a hybrid optimization strategy and dynamically adjusted the algorithm trend using an adaptive optimization strategy [12]. To meet the security requirements of modern IoTs that are unable to provide cross-domain access, Gong et al. suggested a lightweight cross-domain bidirectional authentication technique for mobile IoT environments. The outcomes indicated that the method performed better in terms of computational and communication overheads [13]. The requirement for more precise identification of anomalous traffic in the IoT that deviates from typical traffic patterns prompted Shi et al. to create a deep anomalous network traffic detection model. According to the findings, the model was able to properly account for the specifics of the data distribution [14]. To increase the security of IoT networks, Thota et al. created a botnet detection technique based on enhanced convolutional social networks. The outcomes indicated that the method could effectively detect IoT network intrusion attacks [15].

In summary, although some progress has been made in IoT network security detection in recent years, the existing research still suffers from limited effect in dealing with HD data and low generalization ability of the model. Therefore, the study designs an IoT NSSA method based on improved SVM (ISVM). By introducing radial basis kernel function (KF) for kernel mapping processing of feature vectors (FVs), and to optimize the ISVM parameters, the study proposes a parameter optimization method based on GA-IGWO. It uses GWO algorithm for parameter optimization and introduces circular chaotic mapping and genetic algorithm (GA) for improvement to design an integrated algorithm.

## III. ISVM-GA-IGWO Based IoT NSSA Algorithm

This section focuses on the implementation of stochastic nonlinear analysis method for IoT network performance and security. The first section shows the implementation of ISVM based IoT NSSA method. The second section shows the implementation of ISVM parameter optimization method based on GA-IGWO.

### *A. ISVM-Based IoT NSSA Approach*

The secret to ensuring the system operates safely is IoT network security. People's lives are made more convenient by the extensive use of IoT devices in industries such as intelligent transportation, medical and health care, smart homes, and industrial control. However, it also brings new security threats and challenges at the same time, and strengthening the security of IoT networks has become an important task for maintaining social security [16]. However, traditional IoT network security detection often uses rule-based and statistics-based methods. While the data in IoT networks are nonlinearly differentiable, traditional methods cannot effectively deal with this nonlinear relationship. In recent years, the application of DL techniques in IoT network security detection has gradually gained attention. As a powerful supervised learning algorithm, SVM, with its excellent generalization ability and effective handling of

nonlinear problems, shows strong application potential in the fields of pattern recognition, classification and regression analysis. Therefore, the study adopts SVM to deal with nonlinearly differentiable data in IoT NSSA. Moreover, the KF of SVM is improved to design an ISVM-based IoT NSSA method. Fig. 1 displays the SVM algorithm's schematic diagram.

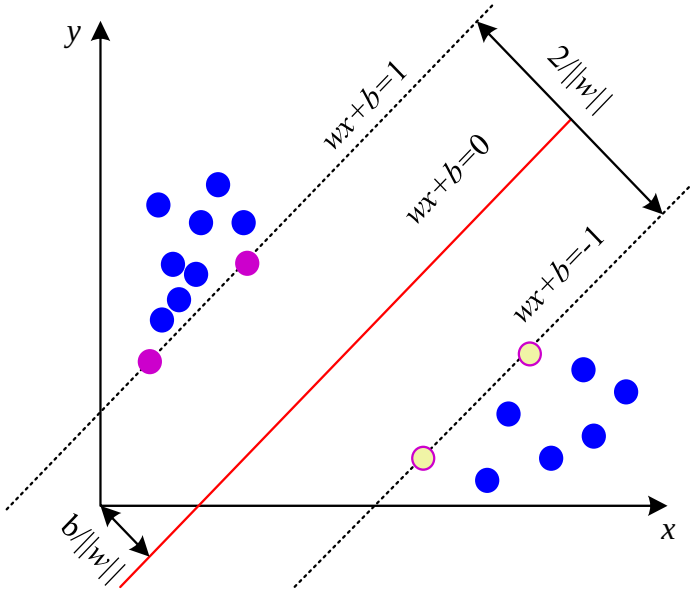

Fig. 1. Principle of SVM algorithm.

The SVM in Fig. 1 seeks to identify a hyperplane that maximizes the category spacing in order to get the best possible classification accuracy. In reality, the hyperplane is a straight line in two dimensions. The objective of SVM classification is to identify a straight line that divides the sample points of various categories and to maximize the distance to the closest point to the straight line. This distance is called the interval, and it needs to be maximized as much as possible during computation. The given hyperplane expression is shown in Eq. (1).

$$H = w^T x + b \tag{1}$$

In Eq. (1), $H$ is hyperplane. $w$ is the weight vector. $x$ is the FV. $b$ is the bias term. $T$ stands for transpose. In order to maximize the interval, for positive class samples (CSs), $w^T x + b \geq 1$ needs to be guaranteed. For negative CSs, $w^T x + b \leq -1$ needs to be guaranteed. Then, the interval can be computed, which is shown in Eq. (2).

$$n = \frac{2}{\|w\|} \tag{2}$$

In Eq. (3), $\eta$ represents the interval. The next step to maximize the interval is to determine the objective function (OF), which is equivalent to minimizing the square of $\| w \|$ The calculation is shown in Eq. (3).

$$f_{(n)} = min \frac{1}{2} \| w \|^2 \tag{3}$$

In Eq. (3), $f(\eta)$ represents the maximum interval. In practical applications, the data are not linearly differentiable. Therefore, soft intervals are introduced to optimize the classification results by allowing classification errors to some extent through slack variables and penalty functions. Eq. (4) displays the expression for OF.

$$f_{(n)} = min \frac{1}{2} \| w \|^2 + C \sum_{i=1}^{n} \xi_i \tag{4}$$

In Eq. (4), $f'(\eta)$ represents the optimized OF. The OF needs to satisfy the classification constraints and the constraints are shown in Eq. (5).

$$y_i (w^T x_i + b) \geq 1 \tag{5}$$

In Eq. (5), $y_i$ represents class $i$ labeling. The SVM classification is shown in Fig. 2.

Subsequently, the fitness function (FF) is chosen and in the original problem, the optimized variables are weight variables with the same dimensions as the number of features. The Lagrange dyadic function is used in the study to enhance the model's generalization. In the dyadic problem, the optimized variable is the Lagrange multiplier with the same dimension as the number of samples. When the samples' quantity is substantially greater than the number of features, this can greatly lower the computational complexity [17]. The constructed Lagrange dyadic function is displayed in Eq. (6).

$$L(w, b, a) = \frac{1}{2} \| w \|^2 - \sum_{i-1}^{n} a_i [y_i (w^t x_i + b) - 1 \tag{6}$$

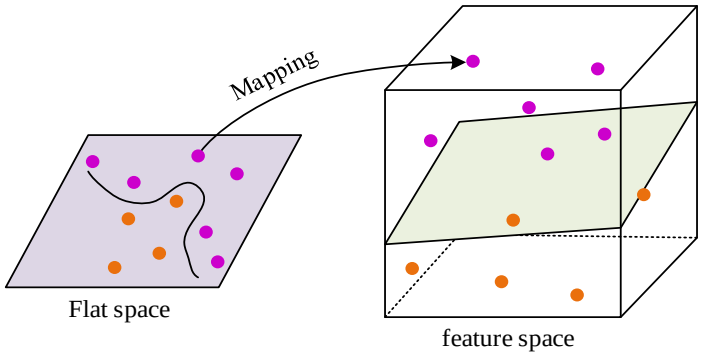

Fig. 2. Feature mapping.

In Eq. (6), $\alpha$ represents the Lagrange multiplier. In dyadic functions, the KF is allowed. Therefore, finally, the study introduces the KF to further optimize the SVM. With the KF, it is possible to compute the inner product directly in the HD space without the need to explicitly perform HD mapping. This allows the SVM to handle nonlinearly differentiable data with the expression shown in Eq. (7).

$$L' = \sum_{i=1}^{n} \alpha_i - \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_i \alpha_j y_i y_j K(x_i, x_j) \tag{7}$$

In Eq. (7), $L'$ represents the OF after introducing the KF, and $K(x_i, x_j)$ represents the KF. So far, the design of ISVM is completed. The flow of ISVM-based IoT NSSA method is shown in Fig. 3.

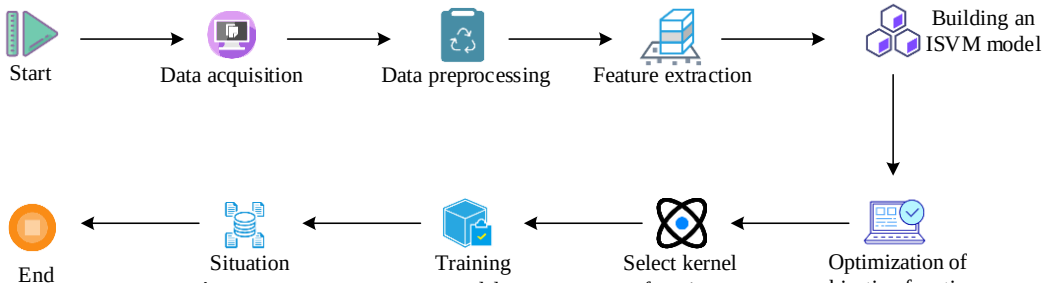

Fig. 3. Process of IoT NSSA method based on ISVM.

### B. GA-IGWO-Based Optimization of ISVM Parameters

Even though the suggested NSSA approach for ISVM exhibits great application potential when handling nonlinearly differentiable data, the KF selection and parameter setting have a significant impact on SVM performance. Its selection of parameters and penalty factors for the KF remains challenging. The model may become overfit or underfit as a result of improper parameter selection, which could impair the model's capacity for generalization and classification [18]. Therefore, the study is conducted to optimize the selection of grey wolf (GW) populations through the GWO algorithm for parameter optimization and the introduction of circular chaotic mapping instead of random generation. Meanwhile, GA is introduced to improve the optimized GWO algorithm, and a GA-IGWO-based ISVM parameter optimization method is designed. Fig. 4 displays the schematic diagram of GW hunting activity.

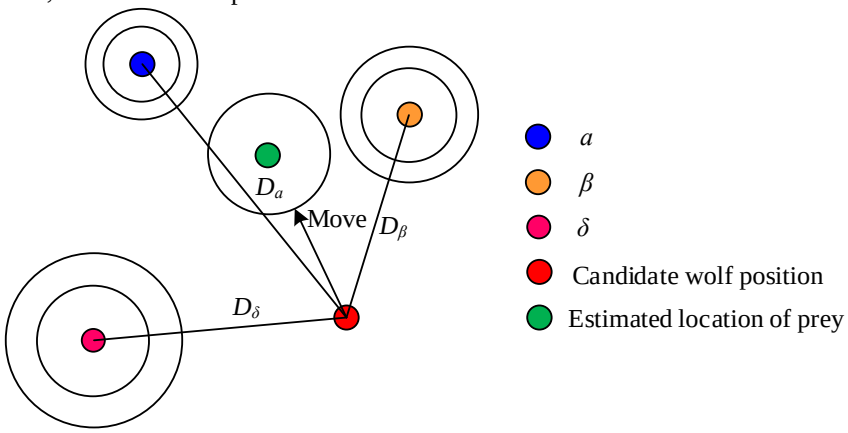

Fig. 4. Schematic diagram of GW hunting behavior.

In Fig. 4, there is a strict hierarchy in the GW group. Among them, α wolf represents the leader in the group, responsible for leading the hunt, corresponding to the optimal solution in the algorithm. The β-wolf is the secondary leader and assists the α-wolf, corresponding to the suboptimal solution. δ wolves are ordinary members that carry out the orders of α and β wolves, corresponding to the third best solution. ω wolves are ordinary members of the pack and follow other wolves in hunting. The GWO algorithm consists of three main hunting behaviors. One is stalking, chasing, and approaching prey, in which the GW searches by dispersing and then focuses on attacking the prey. The second strategy is to harass, encircle, and chase the prey until they cease moving. Attacking the victim while it stops moving is the third tactic [19]. To model the GW's prey encirclement behavior, the expression is calculated as shown in Eq. (8).

$$\begin{cases} D = | C \cdot X_p(t) - X(t) | \\ X(t+1) = X_p(t) - A \cdot D \end{cases} \tag{8}$$

In Eq. (8), $D$ is the relative distance between the current wolf and the target wolf. $A$ and $C$ are the coefficients. $X_p$ is the position of the prey. $t$ is the current iteration quantity. $X(t)$ is the position of the individual GW in the $t$ th generation. Among them, the coefficients $A$ and C are calculated as shown in Eq. (9).

$$\begin{cases} A = 2a \cdot r_1 - a \\ C = 2 \cdot r_2 \end{cases} \tag{9}$$

In Eq. (9), $r_1$ and $r_2$ represent random numbers in the interval [0, 1]. $a$ represents the convergence factor. To simulate approaching prey, $A$ is a random number in the interval [ $-a$ , $a$ ]. Over the course of the iteration, the convergence factor drops from 2 to 0. GWs have the ability to recognize the location of prey and round up the prey. Roundups are usually directed by α wolves. β-wolves and δ-wolves also occasionally participate in the hunt [20]. Eq. (10) depicts the mathematical model of a single GW locating the location of prey.

$$\begin{cases} D_\alpha = \left| -X + C_1 \times X_\alpha \right| \\ D_\beta = \left| -X + C_2 \times X_\beta \right| \\ D_\delta = \left| -X + C_3 \times X_\delta \right| \end{cases} \tag{10}$$

In Eq. (10), $D_\alpha$ , $D_\beta$ , and $D_\delta$ display the distance between $\alpha$ -wolf, $\beta$ -wolf, and $\delta$ -wolf and other individuals. $X_\alpha$ , $X_\beta$ , and $X_\delta$ display the current position of $\alpha$ wolf, $\beta$ wolf, and $\delta$ wolf, respectively. $C_1$ , $C_2$ , and $C_3$ display random numbers. Subsequently, the adjusted position of the GW can be obtained, which is calculated as shown in Eq. (11).

$$\begin{cases} X_1 = X_\alpha - A_1 \times D_\alpha \\ X_2 = X_\beta - A_2 \times D_\beta \\ X_3 = X_\delta - A_3 \times D_\delta \end{cases} \tag{11}$$

Since in the GWO algorithm, the convergence factor is the variable that mainly affects the breadth and depth search. When it is greater than 1, the GW group will expand the encirclement circle, at this time, the algorithm is mainly breadth search. When it is less than 1, the GW group will narrow the encirclement circle to complete the encirclement attack on the prey. At this time, the algorithm is mainly for the depth search. When the proportion of breadth search in the whole search process is too small, the algorithm will easily fall into the local optimum, and can not find the global optimum point. However, when the proportion of breadth search is too much, it will bring more randomness and uncertainty to the algorithm's optimization process. Therefore, the study introduces circular chaotic mapping to optimize the convergence factor, which is calculated as shown in Eq. (12).

$$\begin{cases} x_{i+1} = \left\{ x_i + r - \dfrac{\sin(2\pi x_i)}{4\pi} \right\} \bmod(1) \\ a' = 2\left(1 - \left(\dfrac{t}{t_{\max}}\right)^e\right) \end{cases} \tag{12}$$

In Eq. (12), $r$ represents the constant term, $\bmod$ represents the summation, and $a'$ represents the improved convergence factor. The flow of the IGWO is shown in Fig. 5.

In the meantime, the study presents GA to optimize the subgeneration population of the GWO algorithm because of its sluggish convergence and susceptibility to local optimization issues. It is necessary to first determine the fitness value (FF) of the $j$ th individual for each member of the GWO subgeneration population. Eq. (13) is used to determine the likelihood that a person will be chosen in a selection.

$$P_j = \frac{F_j}{\sum_{j=1}^{m} F_j} \tag{13}$$

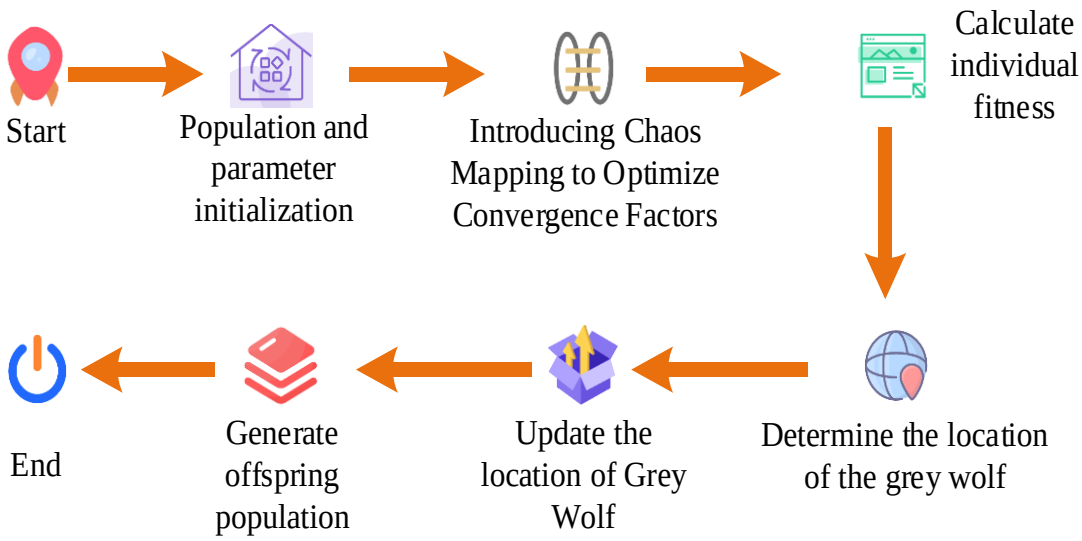

Fig. 5. IGWO process.

In Eq. (13), $P_j$ represents the probability that individual $j$ is selected in a selection. $F_j$ is the FF of the $j$ th individual. Subsequently, a crossover operation is performed to select a cut point in the chromosome. Then, one part of it is exchanged with the corresponding part of the other chromosome to obtain two new individuals. The new individual expression is shown in Eq. (14).

$$\begin{cases} x_{1j}(t)=\frac{1}{2}\times\left[(1-\gamma_j)x_{2j}(t)+(1+\gamma_j)x_{1j}(t)\right] \\ x_{2j}(t)=\frac{1}{2}\times\left[(1+\gamma_j)x_{2j}(t)+(1-\gamma_j)x_{1j}(t)\right] \end{cases} \quad (14)$$

In Eq. (14), $x_{1j}(t)$ and $x_{2j}(t)$ represent the offspring generated from a pair of parents and the crossover operator. The next step is the mutation operation, which creates a new individual by substituting different alleles for gene values at specific loci in the coding strings of the individual chromosomes. For each locus $g_j$, the range of continuous uniform distribution of the mutation is determined with the mutation probability. A random perturbation is added to its value to generate a new individual. The calculation is shown in Eq. (15).

$$g'_j = g_j + \delta \quad (15)$$

In Eq. (15), $g'_j$ represents the mutated locus. $\delta$ represents the random perturbation drawn from the uniform distribution. Finally, the mean absolute percentage error (MAPE) is used to construct the FF to calculate the FF and the optimal parameters. The FF is shown in Eq. (16).

$$f(y)=\frac{1}{1+MAPE(y)} \quad (16)$$

In Eq. (15), $y$ represents the optimal parameters and $MAPE$ represents MAPE. The flow of GA-IGWO is shown in Fig. 6.

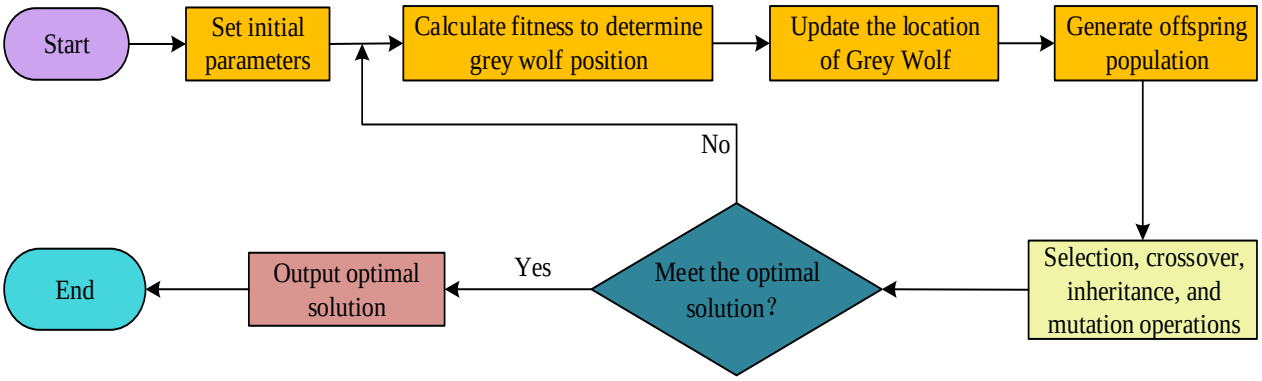

Fig. 6. GA-IGWO flow.

## IV. Effectiveness Analysis of ISVM-GA-IGWO-Based IoT NSSA Algorithm

This section deals with the effectiveness analysis of ISVM-GA-IGWO-based IoT NSSA algorithm. The first section shows the performance analysis results of ISVM-GA-IGWO based IoT NSSA algorithm. The second section shows the results of practical application effect of ISVM-GA-IGWO NSSA algorithm.

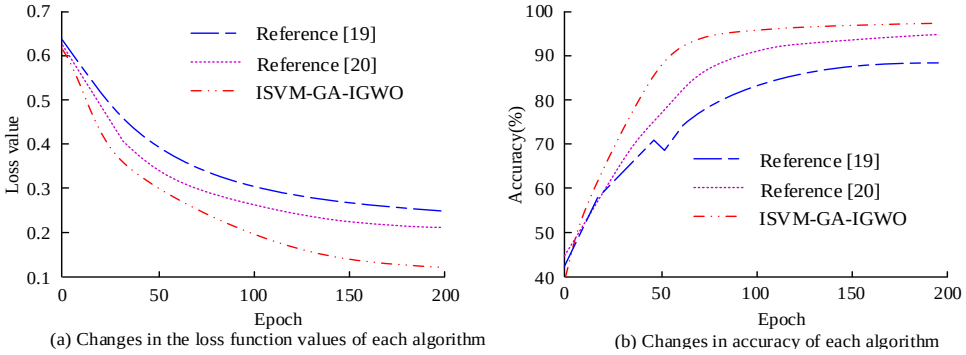
### A. Performance Analysis of ISVM-GA-IGWO NSSA Algorithm

To validate the performance of ISVM-GA-GWO-based IoT NSSA algorithm, the study is carried out on an operating system equipped with Intel core i7-11390H central processor, 32 GB of running memory, 32 GB of video card memory and Windows 11. The simulation is also analyzed using Python 3.7. The maximum iteration of the ISVM-GA-GWO algorithm is firstly set to 200, the population size is set to 50, the crossover operator is 0.7, and the variation operator is 0.02. The accuracy of ISVM-GA-GWO is firstly verified by introducing mean absolute error (MAE), root mean square error (RMSE), and MAPE. It is also compared with SVM, and GWO, methods in [19] and [20]. Table I displays the findings.

TABLE I Training Parameters of the Model

| Model | MSE | RMSE | MAPE |
|---|---|---|---|
| SVM | 0.0213 | 0.125 | 0.0032 |
| GWO | 0.0142 | 0.114 | 0.0053 |
| Reference [19] | 0.0112 | 0.092 | 0.0026 |
| Reference [20] | 0.0089 | 0.074 | 0.0021 |
| ISVM-GA-IGWO | 0.0064 | 0.041 | 0.0013 |

In Table I, the MAE, RMSE, and MAPE of ISVM-GA-IGWO are 0.0064, 0.041, and 0.0013, respectively. The MSEs of [20], [19], GWO, and SVM are 0.0089, 0.0112, 0.0142, and 0.0213, respectively. Their RMSE is 0.074, 0.092, 0.114, 0.125, and MAPE is 0.0021, 0.0026, 0.0053, 0.0032, respectively. It can be found that the values of the three indexes of ISVM-GA-IGWO are significantly lower than those of other algorithms, which proves that it is more accurate. To further verify the accuracy of ISVM-GA-IGWO, the study calculates the loss and accuracy of different models separately and compares them with other algorithms. The results are shown in Fig. 7.



(a) Changes in the loss function values of each algorithm (b) Changes in accuracy of each algorithm

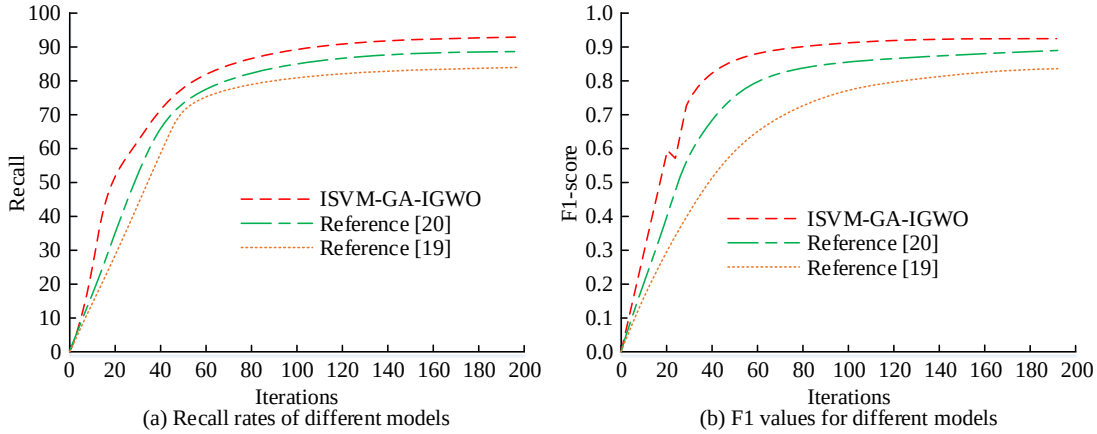
Fig. 7. Value of loss function and accuracy of each algorithm.

In Fig. 7(a), the loss of the algorithm in [19] is 0.25, the loss of the algorithm in [20] is 0.21, and the loss of the proposed ISVM-GA-IGWO is 0.13. The three algorithms have corresponding accuracy rates of 89.2%, 95.6%, and 98.1% in Fig. 7(b). Its superior accuracy is further demonstrated by the fact that ISVM-GA-IGWO has a smaller loss and a greater accuracy rate than the other two algorithms. To provide further validation of the performance of the proposed IoT network security situation assessment algorithm based on ISVM-GA-GWO, five indicators, including area under curve (AUC), memory usage, throughput, average detection time, and false alarm rate, are introduced to calculate the non-algorithmic indicator values. The comparison results are shown in Table II.

In Table II, the AUC, memory usage, throughput, average detection time, and false positive rate of the SVM algorithm are 0.855, 483 MB, 74.8 Mbps, 5.1 s, and 14.6%, respectively. The five indicators of GWO are 0.887, 412 MB, 78.5 Mbps, 4.3 s, and 11.2%, respectively. The five indicator values of SVM-GA-GWO are 0.923, 356 MB, 82.1 Mbps, 3.8 s, and 9.1%, respectively. The five indicator values of the algorithm in [19] are 0.946, 328 MB, 85.6 Mbps, 3.5 s, and 8.5%, respectively. The five indicator values of the algorithm in [20] are 0.952, 289 MB, 91.2 Mbps, 2.7 s, and 5.3%, respectively. The five indicators of the ISVM-GA-IGWO algorithm are 0.981, 224 MB, 97.3 Mbps, 1.2 s, and 2.2%, respectively. It can be observed that compared to other algorithms, the proposed ISVM-GA-IGWO algorithm has significantly higher AUC values and throughput, with a maximum AUC increase of 0.126 and a maximum throughput increase of 22.5 MB. However, a marked decline in memory usage, average detection time, and false alarm rate has been observed. Specifically, the memory usage can be reduced by up to 259 Mbps, the average detection time can be reduced by up to 3.9 s, and the false alarm rate can be reduced by up to 12.4%. The aforementioned results demonstrate that the proposed IoT network security situation assessment algorithm based on ISVM-GA-GWO performs well in terms of detection accuracy, real-time performance, and resource utilization. Lastly, the algorithm in [20], ISVM-GA-IGWO, and the algorithm in [19] are evaluated for recall and F1 value. Fig. 8 displays the findings.

TABLE II COMPARISON OF INDICATOR VALUES FOR DIFFERENT ALGORITHMS

| Model | AUC | Memory usage (MB) | Throughput (Mbps) | Mean time to detect (s) | False alarm rate (%) |
|---|---|---|---|---|---|
| SVM | 0.855 | 483 | 74.8 | 5.1 | 14.6 |
| GWO | 0.887 | 412 | 78.5 | 4.3 | 11.2 |
| SVM-GA-GWO | 0.923 | 356 | 82.1 | 3.8 | 9.1 |
| Reference [19] | 0.946 | 328 | 85.6 | 3.5 | 8.5 |
| Reference [20] | 0.952 | 289 | 91.2 | 2.7 | 5.3 |
| ISVM-GA-IGWO | 0.981 | 224 | 97.3 | 1.2 | 2.2 |



(a) Recall rates of different models (b) F1 values for different models

Fig. 8. Recall rates and F1 values of different models.

Fig. 8(a) illustrates the recall of the three algorithms. The recall of ISVM-GA-IGWO is 93.7%, the recall of the model in [20] is 89.3%, and the recall of the model in [19] is 83.6%. Fig. 8(b) demonstrates the F1 value of the three algorithms. The F1 value of the three algorithms is 0.94, 0.90, and 0.84, respectively. The suggested ISVM-GA-IGWO method provides a recall rate that is 4.4% and 10.1% greater than the algorithms in [19] and [20], and its F1 value is 0.04 and 0.10 higher than those of the other two algorithms, respectively. It shows that ISVM-GA-IGWO has better overall performance.

### B. *Analysis of the Effect of Practical Application of ISVM-GA-IGWO NSSA Algorithm*

To verify the practical application of the designed ISVM-GA-IGWO based IoT NSSA algorithm, the study firstly validates the ISVM-GA-IGWO model in five aspects, namely, whether it supports attribute revocation, offline encryption, outsourcing decryption, authorization center, and key length. The support is denoted as T and not as F. The unit key length is denoted by L and compared with the other two algorithms. Table III displays the findings.

In Table III, for the first four aspects, ISVM-GA-IGWO performs T. The ABE algorithm performs T in three aspects: attribute revocation, offline encryption, and outsourcing decryption. It performs F in authorization centers. The FHE algorithm performs the same way as the ABE algorithm in the four aspects. The key length L+1 of ISVM-GA-IGWO is smaller than ABE algorithm and FHE algorithm. The above outcomes indicate that the ISVM-GA-IGWO is more powerful. The next step is to calculate the data access control effect of different algorithms within 600 ms respectively. The results are shown in Fig. 9.

In Fig. 9, when access control is performed by the ISVM-GA-IGWO, the predicted curves largely coincide with the actual curves. When access control is performed using the FHE algorithm, the predicted curves deviate significantly from the actual curves around 120 ms and 480 ms. It indicates that the ISVM-GA-IGWO fitting performance is better and works better in practical applications. Next, the overhead and time during communication is calculated and the results are compared with other algorithms as shown in Fig. 10.

TABLE III FUNCTIONAL COMPARISON OF DIFFERENT ALGORITHMS

| Algorithm | ABE | FHE | ISVM-GA-IGWO |
|---|---|---|---|
| Access structure | F | F | T |
| Offline encryption | F | F | T |
| Outsourced encryption | F | F | T |
| Authority center | T | T | T |
| Key length | 2L+4 | 2L+1 | L+1 |

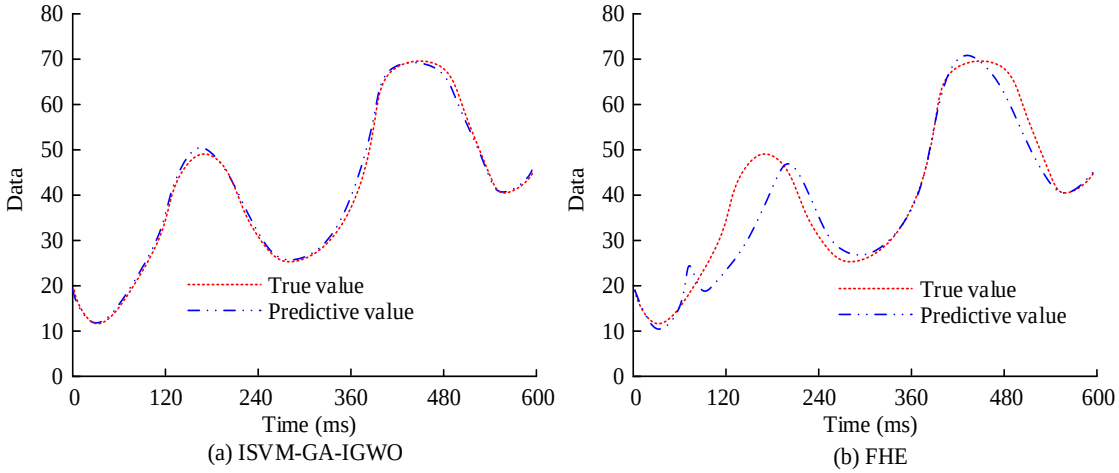


Fig. 9. Data processing capacity of different algorithms within 1000 ms.

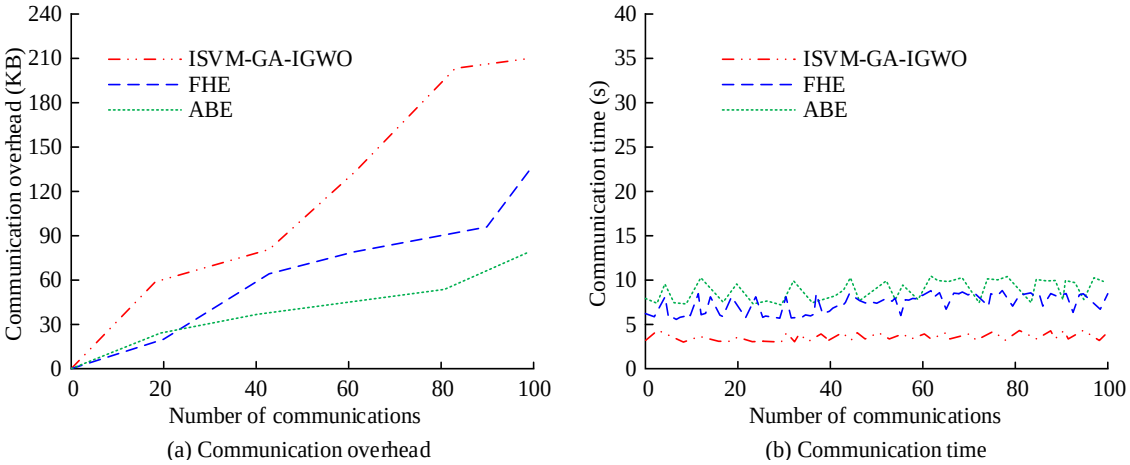

Fig. 10. Communication overhead between different decryption algorithms is sent to data centers and sent to data receivers.

In Fig. 10(a), the communication overheads of the different algorithms all show an increasing trend as the communication increases. When the communication reaches 100 times, the communication overhead of ISVM-GA-IGWO is 81.3 KB, which is significantly lower than 134.6 KB of FHE algorithm and 211.5 KB of ABE algorithm. In Fig. 10(b), the average communication time of ABE algorithm, FHE algorithm, and ISVM-GA-IGWO is 8.11 s, 6.37 s, and 3.59 s. The average communication time of ISVM-GA-IGWO is significantly lower than the other methods. The above outcomes display that the ISVM-GA-IGWO can effectively reduce the communication cost and delay, which further proves that its practical application is more effective. To verify the effectiveness of the proposed ISVM-GA-IGWO network security situation assessment algorithm in practical applications, the proposed method is validated in several scenarios. These scenarios include an intelligent furniture network containing 50 smart devices, an industrial control system based on Modbus protocol, intelligent urban traffic monitoring deployed on traffic signal lights and camera networks, a medical IoT with electrocardiogram monitors and insulin pump devices, and a vehicle-to-infrastructure communication simulation. The results are shown in Table IV.

TABLE IV EVALUATION RESULTS OF ISVM-GA-IGWO ALGORITHM IN DIFFERENT SCENARIOS

| Test scenario | Anomaly detection rate (%) | False positive rate (%) | Average response time (s) | Communication overhead (KB) |
|---|---|---|---|---|
| Smart home network | 96.2 | 1.3 | 5.8 | 82.1 |
| Industrial control system | 94.8 | 0.9 | 7.2 | 85.7 |
| Smart city traffic monitoring | 97.5 | 1.1 | 6.4 | 78.9 |
| Medical Internet of Things | 95.1 | 0.7 | 8.1 | 90.3 |
| Internet of Vehicles | 93.6 | 1.5 | 9.5 | 102.5 |

As illustrated in Table IV, the proposed ISVM-GA-IGWO network security situation assessment algorithm demonstrates a noteworthy performance in terms of anomaly detection, with a rate of 96.2%. The algorithm exhibits a low false alarm rate of 1.3%, an average response time of 5.8 seconds, and a communication overhead of 82.1 KB. In industrial control systems, smart city traffic monitoring, medical IoT, and vehicle networking, the proposed algorithms have anomaly detection rates of 94.8%, 97.5%, 95.1%, and 93.6%, and false alarm rates of 0.9%, 1.1%, 0.7%, and 1.5%, respectively. The average response times are 7.2 s, 6.4 s, 8.1 s, and 9.5 s, respectively, and the communication overheads are 85.7 KB, 78.9 KB, 90.3 KB, and 102.5 KB, respectively. It has been demonstrated that, under various conditions, the algorithm exhibits a high capability for anomaly detection and a low rate of false alarms, while maintaining minimal response time and communication overhead. These observations suggest that the proposed ISVM-GA-IGWO network security situation assessment algorithm is well-suited to meet the stringent requirements of precision and real-time performance in practical scenarios.

## V. Discussion

The research aimed to solve the problem of poor performance of traditional IoT network performance analysis methods in handling random nonlinear features, and proposed a network security situation assessment method based on ISVM-GA-IGWO. The MAE value of this method was 0.0064, the RMSE value was 0.041, and the MAPE value was 0.0013, which were significantly lower than other algorithms, indicating its high prediction accuracy. This was similar to the conclusion of Thota S et al [15]. In contrast, ISVM-GA-IGWO was significantly better because the GA-IGWO optimization resulted in better parameters, allowing the model to better fit complex data. The F1 value of the ISVM-GA-IGWO algorithm was 0.94, with a recall rate of 93.7%, indicating its good overall performance. This was consistent with the conclusion drawn by Oseni et al. [6], but the ISVM-GA-IGWO algorithm performed better. This was because the proposed algorithm introduced GWO and optimized it by circular chaotic mapping. At the same time, it introduced radial basis KFs to perform kernel mapping on FVs, which significantly improved the performance. The memory usage of the ISVM-GA-IGWO algorithm was only 224 MB, which proved its good resource utilization. This result was similar to the conclusion of Shi G [14]. Compared with these two methods, the proposed method was obviously better. Because, in the optimization process of ISVM-GA-IGWO algorithm, the method avoided redundant parameter storage and complex computation process by reasonably setting the population size, optimizing the genetic operation, and simplifying the design of ISVM model, which effectively reduced the memory overhead. In summary, the ISVM-GA-IGWO algorithm proposed in this study demonstrates significant advantages in the field of IoT network security situation assessment, providing technical support for the application of IoT in more complex scenarios.

## VI. Conclusion

With the surge in the number of IoT devices, the complexity and uncertainty of network traffic have increased significantly, and the cyber security threats have become increasingly severe. Traditional cyber security detection methods, such as rule-based and statistical approaches, have been difficult to cope with the nonlinearly differentiable data and dynamically changing network environment in the IoT environment. The research aimed to address the shortcomings of traditional methods in dealing with nonlinearly differentiable data and to improve the robustness of the model in the face of new attack types and unknown data. It proposed an ISVM-based IoT NSSA method and optimized the parameters of ISVM by combining GA and IGWO. The results revealed that the MAE, RMSE, and MAPE of ISVM-GA-IGWO were 0.0064, 0.041, and 0.0013, respectively. Compared to the values of the three indexes of the four algorithms in [20], [19], GWO, and SVM, it was much lower, demonstrating its great accuracy. ISVM-GA-IGWO had a loss of 0.13 and an accuracy of 98.1%, which was lower than the other methods and higher than the other methods, further proving its higher accuracy. When access control was performed by ISVM-GA-IGWO, the predicted curve basically overlapped with the actual curve. When using the FHE algorithm for access control, the prediction curves had large deviations from the actual curves around 120 ms and 480 ms, indicating that the ISVM-GA-IGWO was more effective in practical application. However, despite the introduction of GA-IGWO algorithm for parameter optimization, it may still fall into local optima in some cases, resulting in unsatisfactory optimization results. At the same time, the proposed ISVM-GA-IGWO hybrid algorithm increases the resource consumption to a certain extent, and the model performance is highly dependent on high-quality annotated data, while in actual IoT environments, abnormal samples are rare and annotation costs are high. In addition, the device state and network topology in IoT may change frequently, and the current model lacks adaptability to dynamic environments. Subsequent research endeavors will introduce more efficient parameter optimization algorithms, such as adaptive parameter control or dynamic weight adjustment, to enhance the convergence speed and robustness of the model. Meanwhile, multi-objective optimization methods will be explored to simultaneously optimize multiple performance indicators. In addition, semi- or self-supervised learning will be combined to reduce the dependence on annotated data, and online learning or incremental update mechanisms will be added to adapt to dynamic scenarios.

# Experiential Landscape Design Using the Integration of Three-Dimensional Animation Elements and Overlay Methods

Mingjing Sun*, Ming Wei
School of Design and Art, Shandong Huayu University of Technology, Dezhou 253011, China

***Abstract*—This work aims to optimize users' immersive experiences, enhance design effectiveness, and construct a scientific evaluation system for landscape design. The work begins with the collection and analysis of spatial data from the landscape design area, using 3D animation technology to generate visual models and virtually reconstruct key landscape elements. Next, the overlay method is applied to visually stratify elements within the space, progressively building a multi-layered, logical spatial structure to enhance realism and information communication efficiency in landscape design. To evaluate design effectiveness, a user experience questionnaire and behavior tracking experiments are designed. The questionnaire covers three dimensions: immersion, satisfaction, and interactivity, while the behavioral tracking experiment collects data on user dwell time and gaze movement in virtual scenes. Results indicate that the design scheme based on 3D animation and layering significantly outperforms traditional designs in terms of immersive experience, clarity of structure, and user engagement. In the questionnaire, the average satisfaction rating for the design scheme is 4.7 (out of 5), with an immersion rating average of 4.8. The behavioral tracking experiment shows a 40% increase in dwell time compared to traditional designs, and users' willingness to revisit improves by 26% compared to the control group. This work innovatively applies 3D animation and overlay methods to experiential landscape design, confirming the practical value of this method in optimizing user experience and design effectiveness.**

***Keywords*—*3D animation integration; overlay method; experiential landscape design; user immersive experience; evaluation system design***

## I. Introduction

In recent years, with the rapid development of three-dimensional (3D) animation technology and Virtual Reality (VR) technology, experiential design has become an important trend in the field of landscape design [1]. Traditional landscape design mainly relies on two-dimensional drawings and physical models. However, these methods are difficult to meet the modern needs of users for a sense of realism and immersion. For example, static models cannot dynamically present seasonal changes or real-time interactions, and this results in limited user engagement [2, 3]. Modern users increasingly expect experiential design to provide an immersive interactive experience, transforming landscape design from mere static viewing into dynamic participation. This demand has promoted the application of 3D animation technology in landscape design, allowing for the visualization and virtual reconstruction of landscape spaces. Moreover, it enables designs that go beyond the limitations of two-dimensional images or simulated effects to dynamically simulate real spatial environments. For example, Balcerak Jackson et al. (2024) analyzed the correlation between VR and immersive experiences from a philosophical perspective, and emphasized the impact of dynamic interaction on users' perception [4]; Park et al. (2020) proposed a landscape design methodology based on users' memory schemas and enhanced the continuity of the user experience through a dynamic feedback mechanism [5]; Kim et al. (2021) explored the potential of 3D printing technology in landscape design. By combining physical models with virtual dynamic effects, they broke through the limitations of two-dimensional images and achieved the dynamic simulation of real spatial environments [6]. Meanwhile, the application of overlay methods in spatial design has also garnered increasing attention. Through 3D animation technology, the dynamic effects of landscape elements (such as vegetation and water bodies) are accurately simulated. For example, SpeedTree is used to generate high-precision tree models, and the fluid simulator of Blender is combined to achieve dynamic changes in water flow. The overlay method constructs a multi-level logical structure by layering and superimposing spatial data (such as terrain, vegetation layers, and hydrological layers) to enhance the visual depth. For instance, Chen (2024) stratified and superimposed terrain and architectural elements through 3D VR technology, and verified the effect of the multi-level logical structure on enhancing visual depth [7]; Xing and Puntien (2024) proposed a hierarchical reconstruction strategy for the landscape of abandoned mining areas from the perspective of naturalistic aesthetics. They used the overlay method to coordinate ecological restoration and visual logic [8]; Qin (2022) combined the particle swarm optimization algorithm and proposed an overlay mapping design framework for intelligent rural landscapes. This framework achieves accurate stratification of complex elements through dynamic parameter adjustment [9]. These studies indicate that the combination of 3D animation technology and the overlay method can achieve richer and more realistic visual effects through virtual reconstruction and hierarchical logic. Meanwhile, it can provide multi-dimensional support for user interaction. Therefore, finding effective ways to integrate 3D animation technology with overlay methods to optimize user experience and build a scientific evaluation system for experiential landscape design has become a pressing issue that needs to be addressed.

The primary objective of this work is to propose a novel experiential landscape design method based on the integration

of 3D animation elements and overlay methods, thus effectively enhancing users' immersive experiences and optimizing design outcomes. The work focuses on how to organically combine virtual and real elements using 3D animation technology and overlay methods to create designs that possess depth and visual richness. This work intends to achieve significant results in visual communication, information presentation, and user interaction [10]. Additionally, a systematic evaluation method for experiential landscape design is proposed, which quantitatively measures users' immersion, interactivity, and satisfaction to scientifically assess the effectiveness of the design schemes. User data are collected through experience questionnaires and behavioral tracking experiments in virtual scenes. Through these data, the work aims to evaluate the real-world performance of the design solutions, providing a scientific basis for the assessment of experiential landscape design. Moreover, this work seeks to reveal the practical value and applicability of combining 3D animation technology with overlay methods in landscape design through data analysis. It aims to refine the theoretical framework of experiential design and offer more actionable guidance for future VR applications in landscape design.

This work holds significant importance on both theoretical and practical levels. First, from a theoretical perspective, it introduces 3D animation technology and overlay methods into experiential landscape design, providing a new viewpoint for innovation in landscape design methodologies. Currently, there is a lack of systematic methodological research on experiential design in the landscape architecture field, particularly regarding the integration of virtual elements with real environments. The combination of 3D animation and overlay methods addresses existing deficiencies in design methods. By employing multi-layered spatial division through overlay methods and virtual reconstruction with 3D animation technology, this work enriches the theoretical foundations of experiential design. Moreover, it offers innovative ideas for future studies on how to integrate 3D animation and overlay methods into landscape design. Additionally, on a practical level, the proposed design methods and evaluation systems provide direct guidance for the application of landscape design. Experiential landscape design has broad demand in industries such as commerce and tourism, and it is gradually being promoted in areas like public facilities and cultural heritage preservation. This study validates the effectiveness of the design through behavioral tracking experiments and questionnaire data, providing scientific support for user experience enhancements. This establishes feasible optimization pathways for future experiential landscape design. The application potential of this method is not limited to landscape design. For example, in urban planning, 3D animation and the overlay method can simulate the changes in traffic flow and building shadows. This can assist decision-makers in evaluating the feasibility of plans. In game design, the dynamic layering technology can create a more realistic open world, and the AI-driven interaction mechanism can enhance the players' sense of immersion. Future research will further explore the possibilities of cross-disciplinary integration.

This work is divided into six sections, and the research is carried out systematically. Section I is the introduction. It provides an overview of the research background of 3D animation technology and the overlay method in landscape design. It points out the deficiencies of existing methods in terms of technical integration and quantitative evaluation of user experience, and puts forward the research objectives and innovative points of this work. Section II is the literature review. It systematically combs through the relevant research on 3D animation, the overlay method, and user experience evaluation in the field of landscape design. Moreover, it clarifies the limitations of existing work, and defines the breakthrough direction of this work. Section III is the method design. It elaborates in detail on the technical framework that integrates the dynamic simulation of 3D animation and the layering logic of the overlay method. It includes the specific implementation processes of virtual reconstruction, layering and superposition, and the interaction feedback mechanism. Section IV is the experiment and result analysis. Through the cross-scenario comparative experiments, long-term user tracking, and eye movement data collection, the sense of immersion, interactivity, and user satisfaction of the design scheme are quantitatively evaluated. Besides, the key data are presented in the form of numerical tables. Section V is the discussion. Based on similar methods in the literature, it deeply analyzes the technical advantages and limitations of the scheme proposed, and explores its expansion potential in fields such as urban planning and cultural heritage protection. Section VI is the conclusion. It summarizes the research results and proposes the directions for future improvement. Through the above structure, this work aims to provide a complete methodology for experiential landscape design that combines theoretical innovation and practical guidance.

## II. Literature Review

In the field of experiential landscape design, the applications of 3D animation technology and overlay methods have gradually attracted the attention of scholars. In recent years, with advancements in technology, researchers have conducted in-depth explorations on how to enhance user immersion and interactivity. Hussein et al. (2023) studied the application of VR technology in landscape design, emphasizing that VR could provide users with an immersive experience [11]. Their research indicated that by creating interactive virtual environments, users could more intuitively understand the spatial characteristics of landscape design, thereby enhancing design effectiveness. However, their research primarily focused on the application of VR technology and provided relatively little discussion on specific design methods. Meanwhile, Zou et al. (2022) provided a detailed analysis of the application of overlay methods in spatial design, noting that layering could effectively enhance the logic and visual depth of spaces [12]. By stratifying and reconstructing different visual elements, layering not only improves the aesthetic effect of spatial design but also enhances users' spatial cognition. However, their research did not combine overlay methods with modern 3D animation technology, nor did it explore the improvements in user experience resulting from their integration, highlighting a direction for future research. Additionally, Hao et al. (2020) found that user initiative during the design process significantly affected satisfaction in interactive landscape design [13]. Their research demonstrated that enhancing user participation could markedly improve the effectiveness of design solutions. However, they did not

specifically analyze how to achieve user participation and interaction through technological means, underscoring the importance of technical integration here. Furthermore, Dirin et al. (2023) studied the sense of immersion in experiential design, suggesting that immersion was a key factor influencing user satisfaction [14]. They quantified user immersion and validated the positive correlation between immersion and satisfaction. However, they did not delve into how to specifically enhance immersion through design methods, providing theoretical support for the current research. In another study, Saorin et al. (2023) analyzed the importance of user behavior in experiential landscape design. They collected activity data from users in virtual scenes through behavioral tracking experiments and found a significant correlation between users' dwell time and design effectiveness [15]. However, their research mainly focused on analyzing user behavior, lacking a comprehensive assessment of design solutions. This suggests that this work should combine user behavior analysis with design effectiveness evaluation. Lastly, Shen et al. (2024) compared the effects of traditional design methods and emerging technologies in landscape design, finding that the latter offered significant advantages in user experience [16]. They emphasized the crucial role of digital technology in enhancing design effectiveness but lacked a systematic exploration of specific technological combinations. Therefore, this work delves into the integration of 3D animation and overlay methods to fill this gap.

Zhang et al. (2022) investigated the application of multimedia technology in public landscape design, emphasizing that interactivity and participation were key factors influencing user experience [17]. They proposed enhancing the user experience through various media approaches. However, their research provided limited details on technical implementation and did not offer practical solutions. This is an aspect this work aims to explore in depth. Li et al. (2023) noted in their study on digital finance and corporate financing constraints that the application of digital technology could effectively improve the efficiency of resource allocation within companies [18]. This insight is relevant to the optimization of 3D animation technology in landscape design discussed here.

In summary, while numerous studies have focused on 3D animation technology, overlay methods, and user experience in the realm of experiential landscape design, there are still significant shortcomings. Most research rarely combines 3D animation with overlay methods to achieve a deeper enhancement of user experience. Furthermore, there is a relative lack of exploration regarding the establishment of a quantitative evaluation system for design effectiveness. Additionally, many studies concentrate primarily on theoretical discussions and user behavior analysis, lacking specific technical application examples and failing to form a systematic, actionable design framework. Therefore, the innovation of this work lies in the organic integration of 3D animation technology and overlay methods to construct a systematic experiential landscape design method aimed at enhancing user immersion and participation. Simultaneously, by utilizing user experience questionnaires and behavioral tracking experiments, this work establishes a scientific evaluation system, providing theoretical and practical support for future studies and filling the existing gaps in the literature.

## III. METHODS

### A. Virtual Reconstruction and Integration of 3D Animation Technology in Landscape Design

One of the core applications of 3D animation technology in landscape design is the virtual reconstruction and integration of key landscape elements. By dynamically simulating scenes such as vegetation, water bodies, terrain, and buildings, 3D animation not only showcases static visual elements but also mimics their changes under different temporal or environmental conditions. This enhances the overall expressive quality of the design [19, 20]. In natural landscape design, the dynamic growth of plants and seasonal changes are crucial components of the ecosystem. This work utilizes 3D modeling software (SpeedTree) to generate highly realistic models of trees, shrubs, and herbaceous plants, and incorporates animation techniques to simulate the dynamic effects of wind, seasonal transitions, and growth cycles [21, 22]. These simulations not only enhance the realism of the landscape but also provide users with a dynamic experience of perceiving the passage of time and seasonal changes. Water bodies are indispensable elements in landscape design, and their dynamic forms—such as flowing water, ripples, and reflections—significantly influence the visual atmosphere of the entire space. This work employs 3D animation technology for detailed modeling and dynamic simulation of water features, including rivers, lakes, and fountains. Building on this foundation, fluid dynamics-based animation algorithms (Blender's fluid simulator) are utilized to achieve real-time changes in water dynamics, encompassing flow speed, direction, and wave effects.

To enhance the realism of landscape design, this work incorporates dynamic simulations of weather and lighting effects. By adjusting light sources, shadows, and atmospheric scattering effects, it simulates landscape changes at various time of day (daytime, dusk, and nighttime) and different weather conditions (sunny, rainy, and snowy). For example, on sunny days, strong shadows are cast by sunlight, while on rainy days, water droplets collect on roofs and surfaces, accompanied by wet material effects.

In addition to virtual reconstruction, another important application of 3D animation technology is to enhance interactivity between users and landscape designs. In experiential landscape design, by introducing interactive features, users can not only "view" the landscape but also actively participate, making interactive decisions and seeing real-time impacts of their actions on the environment. This work primarily utilizes sensors, motion capture devices, and VR equipment (such as VR headsets and Leap Motion gesture controllers) to achieve this interactive design. In the virtual environment, users can interact with elements in the 3D landscape through gestures, eye movements, and other means [23, 24]. For instance, users can control the direction of water flow with hand movements or click on specific areas to view detailed information about plants. This direct form of interaction significantly enhances users' sense of participation and immersion. Fig. 1 illustrates the process of virtual reconstruction and integration of 3D animation technology in landscape design.

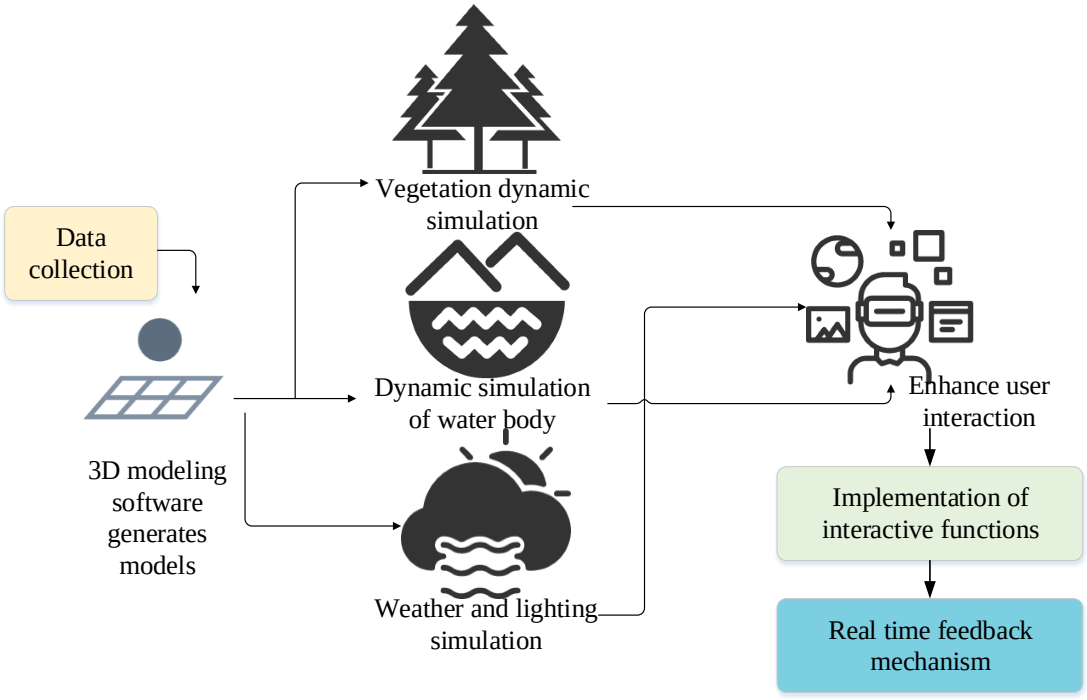

Fig. 1. The process of virtual reconstruction and integration of 3D animation technology in landscape design.

By integrating a physics simulation engine with user data tracking technology, this work has designed a real-time feedback mechanism. When users perform certain actions in the virtual environment (such as changing their viewpoint or triggering the swaying of trees), the system responds immediately based on the parameters input by the user, providing feedback through various channels such as visuals and sound. For example, as a user approaches a grove, the leaves may rustle in the wind, accompanied by a soft rustling sound. This multi-sensory feedback further enhances the immersive experience. In addition to the basic interaction functions (such as controlling the water flow with gestures and clicking to view plant information), this work further explores the user-defined environment and the AI-driven dynamic adaptation mechanism. For example, users can adjust the seasonal parameters of the virtual scene through voice commands (such as switching to the autumn mode), and the system will update the vegetation colors and weather effects in real time. Furthermore, based on user behavior data (such as the duration of stay and the trajectory of the line of sight), the AI algorithm can automatically optimize the landscape layout. If most users frequently focus on a certain area, the system will suggest adding interactive nodes or visual focal points in that area to achieve dynamic design optimization. Table I lists common forms of user interaction feedback.

TABLE I. COMMON FORMS OF USER INTERACTION FEEDBACK

| Interactive Object | Feedback Form | Expected Effect |
|---|---|---|
| Vegetation | Leaf movement, sound effects | Enhance the realism of the natural environment |
| Water | Wave dispersion, reflection adjustments | Enhance visual and auditory interactivity |
| Buildings | Shimmering, rotation | Increase user interest |

### B. *The use of the Overlay Method and Layering of Visual Elements*

The overlay method is a spatial analysis technique commonly used in Geographic Information Systems (GIS). It involves progressively stacking different spatial data layers to create a multidimensional and multi-layered composite spatial view [25, 26]. In landscape design, the overlay method effectively assists designers in organizing complex environmental elements, and optimizing visual representation and information communication. This work integrates the overlay method with 3D animation technology, leveraging its powerful layering capabilities to logically separate natural landscapes and artificial structures. It ensures that each layer's elements do not interfere with one another but instead complement each other, thereby achieving higher design accuracy and enhancing user experience. The core concept of the overlay method is to decompose a series of spatial information into multiple independent layers and overlay these layers to provide a holistic spatial view. Each layer can encompass different categories of information, such as topography, vegetation, and water features.

Here, the overlay method is used to conduct a detailed layering of the main visual elements in landscape design. This approach not only simplifies complex landscape design tasks but also enhances the sense of depth and interactivity of the elements within the virtual landscape. Fig. 2 illustrates the process of layering visual elements based on the overlay method and enhancing interactivity. Topography serves as the foundation for any landscape design; therefore, this work designates it as the first layer. Using collected Digital Elevation Model (DEM) data, the topography layer is created to simulate the actual terrain variations. This layer includes hills, plains, and low-lying areas, providing the design framework and offering important

references for subsequent building layouts and road planning. Above the topography layer, a vegetation layer is added. This layer comprises natural vegetation elements such as trees, shrubs, and grass. Based on field data and LiDAR point cloud information, the distribution, density, and types of vegetation are classified, with virtual plant models added to the corresponding locations. Additionally, 3D animation technology enables the dynamic simulation of plant growth and seasonal changes. The vegetation layer enriches the visual effects of the scene and provides essential data for ecological design. Water features are crucial elements that shape landscapes, and their dynamic characteristics (such as flowing water and the rippling of lakes) are vital for creating visual and auditory experiences. This work designates water as the third layer, including rivers, ponds, and wetlands. Through 3D animation technology, the flow of water is successfully simulated, and water levels are adjusted based on seasonal precipitation. Furthermore, the dynamic simulation of the hydrological layer reflects the physical properties of water, such as transparency, reflection, and refraction. Based on the aforementioned natural elements, building structures and roads are overlaid as the fourth layer. This layer contains all man-made structures, such as visitor centers, small exhibition halls, and main roads and pedestrian paths connecting the scenic areas. The primary function of the building and road layer is to provide users with clear route guidance while facilitating dialogue with natural elements. Using 3D animation, the lighting response of building materials and shadow effects resulting from changes in sunlight angles can be simulated, showcasing how buildings integrate with their surrounding environment. To enhance user engagement, this work incorporates a dedicated functional layer for user interaction. This layer is not composed of traditional 'visible' elements; instead, it includes user behavior trigger points, interaction nodes, and virtual feedback mechanisms. As users move through the virtual environment, the system activates the content of this layer according to their behavioral trajectories. For example, when a user approaches an exhibition building, the building may automatically light up and provide relevant information; when a user enters a water area, the water flow speed might change accordingly.

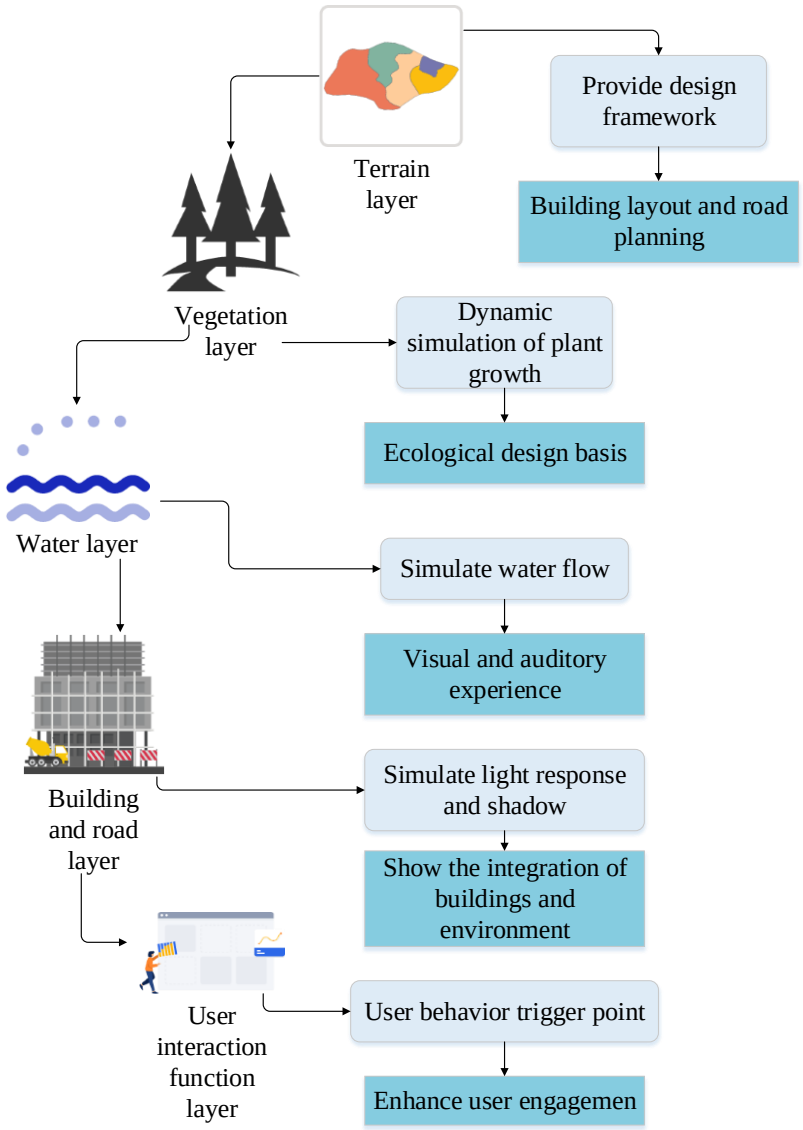

Fig. 2. Process of overlay method-based visual element layering and interaction enhancement in landscape design.

After constructing the aforementioned layers, these layers are gradually stacked to create a comprehensive design scheme with a complete sense of depth. The overlay process strictly adheres to design logic, beginning with terrain modeling and then sequentially adding vegetation, water features, buildings, and other elements, ensuring the accuracy and consistency of each layer's information. With the assistance of 3D animation technology, the interactions between different layers (such as the occlusion relationship between vegetation and buildings, and the reflection of light on water surfaces) are fully realized.

Vegetation modeling uses the parametric generation technology of SpeedTree. First, Light Detection and Ranging (LiDAR) point cloud data are imported to define the tree distribution. Then, the fractal parameters of branches and the leaf density are adjusted. Finally, it is exported as a Filmbox (FBX) model with skeletal animation to support the wind-blowing effect. Water simulation is achieved through the Fluid Implicit Particle (FLIP) fluid solver in Blender: After setting the boundary conditions (such as the river slope), fluid viscosity, and gravity parameters, physically-based wave and splash effects are generated. To optimize the rendering efficiency, the machine learning-driven Levels of Detail (LOD) technology is adopted to dynamically adjust the model accuracy according to the user's perspective, and ensure the smooth operation of complex scenes.

### *C. User Experience Evaluation*

To systematically assess the user experience of integrating 3D animation with the overlay method in experiential landscape design, this study developed a comprehensive user experience evaluation system. This system includes a user experience questionnaire and behavior tracking experiments. The questionnaire is designed based on three dimensions: immersion, satisfaction, and interactivity, to quantify users' subjective experiences. The behavior tracking experiments collect objective data such as users' dwell time and gaze trajectories in the virtual scene for further analysis of design effectiveness. A preliminary survey was conducted with a small sample of the target user group, and 30 questionnaires were distributed to test their validity and reliability. The final reliability of the questionnaire is confirmed with a Cronbach's α of 0.92. The formal survey targets landscape design students and industry professionals aged 18 and above, with a sample size of 300 participants. The questionnaires are distributed online to ensure authentic feedback from participants in different scenarios.

The behavior tracking experiments employ eye-tracking technology to record users' gaze trajectories and dwell time within the virtual scene. From the respondents of the questionnaire, 60 volunteers are randomly selected to ensure diversity and representativeness of the sample. Users wear eye-tracking devices while entering the pre-set virtual environment. The system automatically records their dwell time on various key landscape elements and tracks their gaze movements. Data are stored for analysis after the experiment concludes. Three key landscape elements are set for evaluation: "water body," "vegetation," and "recreation areas," to assess users' attentiveness to different elements.

Data from the questionnaires and behavior tracking are analyzed using SPSS and Python's data analysis libraries. The calculation of satisfaction scores is as Eq. (1):

$$S = \frac{1}{n}\sum_{i=1}^{n} x_i \quad (1)$$

$S$ represents the satisfaction score, $n$ is the number of responses, and $x_i$ denotes the score of the i-th response.

## IV. RESULTS

Scheme A represents an experiential landscape design plan based on the integration of 3D animation and the overlay method. This scheme organically blends virtual and real elements, utilizing advanced 3D animation techniques to enhance user immersion, satisfaction, and interactivity. Scheme B, in contrast, is a traditional landscape design that does not incorporate 3D animation or the overlay method, primarily relying on flat plans and static displays. Scheme C serves as a control group, incorporating some basic interactive elements but still lacking the dynamic effects of 3D animation and the layered perspective provided by the overlay method.

Fig. 3 displays the user satisfaction scores. The data indicate that Scheme A, based on the combination of 3D animation and the overlay method, significantly outperforms the traditional design of Scheme B across all dimensions. Specifically, Scheme A achieves a satisfaction score of 4.7, while Scheme B receives only 3.9, with a significance difference (p-value) less than 0.001, demonstrating a high overall satisfaction level among users for Scheme A. In terms of immersion, Scheme A scores 4.8. This indicates a profound immersive experience for users in the virtual environment, compared to just 3.6 for Scheme B, which highlights a notable deficiency in immersion in traditional designs. Additionally, the scores for interactivity and visualization effects show a similar trend, collectively validating the effectiveness of the combination of 3D animation and the overlay method in enhancing user experience.

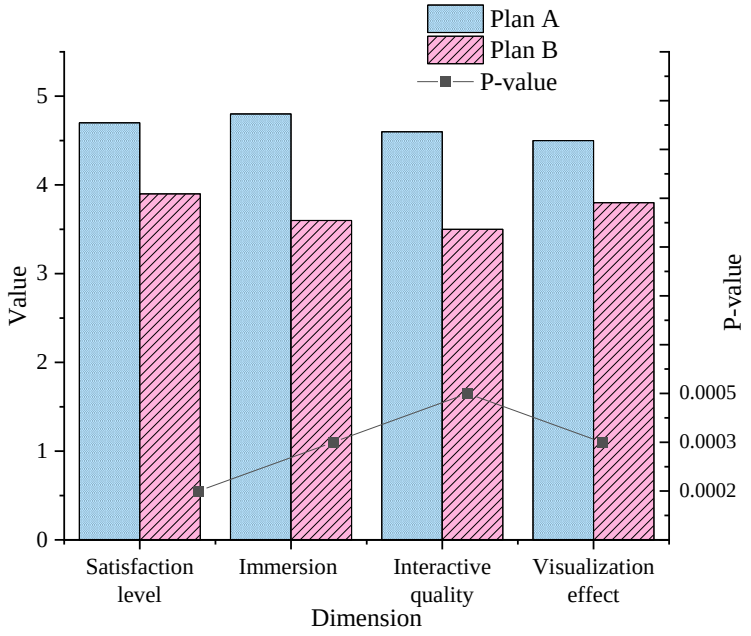

Fig. 3. User satisfaction rating results.

Fig. 4 shows the comparison results of user dwell time. The comparison of dwell time further supports the advantages of Scheme A. The average time users spend on key landscape elements indicates that Scheme A has dwell time of 5.1 seconds, 4.9 seconds, and 4.7 seconds for water bodies, vegetation, and leisure areas, respectively, while Scheme B has corresponding values of only 3.8 seconds, 3.2 seconds, and 3.5 seconds. The significance of these differences (p-values) is all less than 0.001, indicating that users show a significantly higher level of attention to each key element in Scheme A. In terms of total dwell time, Scheme A's 14.7 seconds greatly exceeds Scheme B's 10.5 seconds. It suggests that users are more willing to spend time exploring and engaging with Scheme A, thereby enhancing the overall sense of immersion.

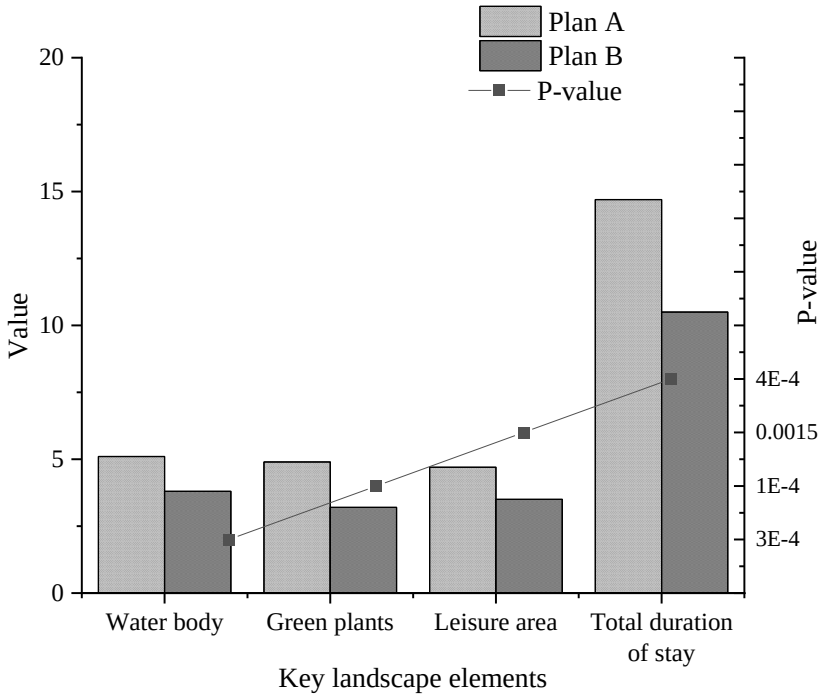

Fig. 4. Comparison of user dwell time.

Fig. 5 presents the analysis results of gaze movement trajectories. The analysis of gaze movement reveals the users' level of attention to different design schemes. The data shows that the average number of fixations for Scheme A is 12, while Scheme B has only 7. It suggests that users focus more intensely and frequently on the landscape elements in Scheme A. In terms of average fixation duration, Scheme A's 3.2 seconds is significantly higher than Scheme B's 1.5 seconds, demonstrating that users can experience key landscape elements more deeply in Scheme A. Additionally, the proportion of fixation areas is 78% for Scheme A compared to only 55% for Scheme B, reflecting that Scheme A effectively guides users' attention and enhances their engagement with the environment. The significant difference in total fixation duration—24 seconds for Scheme A versus 10 seconds for Scheme B—further confirms the success of combining 3D animation and the overlay method in enhancing visual appeal.

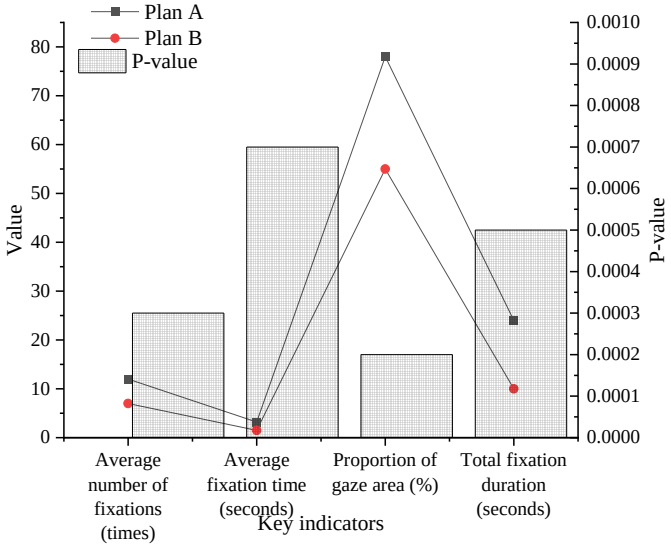

Fig. 5. Analysis results of gaze movement trajectories.

Fig. 6 shows the assessment results of the user's willingness to revisit. The results indicate that the willingness to revisit Scheme A reaches 76%, while Scheme B only achieves 44%. The significance of the difference (p-value) is less than 0.001, highlighting the positive feedback from users regarding Scheme A. The willingness to revisit Scheme C is 50%, which is moderate but still significantly lower than that of Scheme A. These results suggest that users are more inclined to revisit the design based on 3D animation and the overlay method after their experience, reflecting the strong impression and positive experience this design leaves on them.

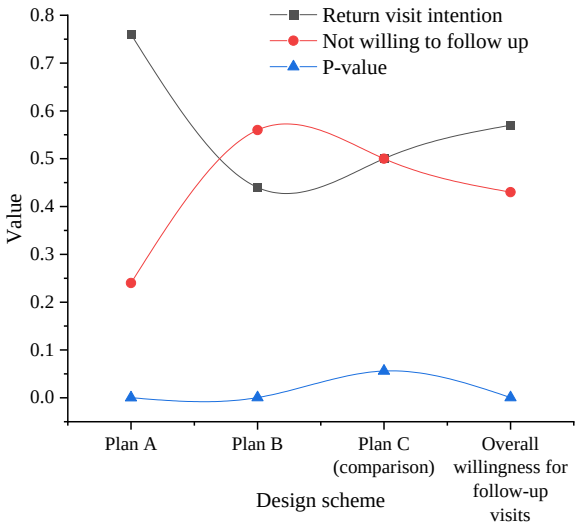

Fig. 6. Assessment results of user's willingness to revisit.

Fig. 7 presents the correlation analysis results among user experience dimensions. The results indicate a significant positive correlation between satisfaction, immersion, and interactivity. Specifically, the correlation coefficient between satisfaction and immersion is 0.85, while the correlation coefficient between immersion and interactivity is 0.70. This suggests that users who experience higher levels of immersion tend to also report higher levels of satisfaction and interactivity. Overall, the data demonstrate that enhancing immersion and interactivity is crucial for improving user satisfaction, providing valuable insights for optimizing design solutions.

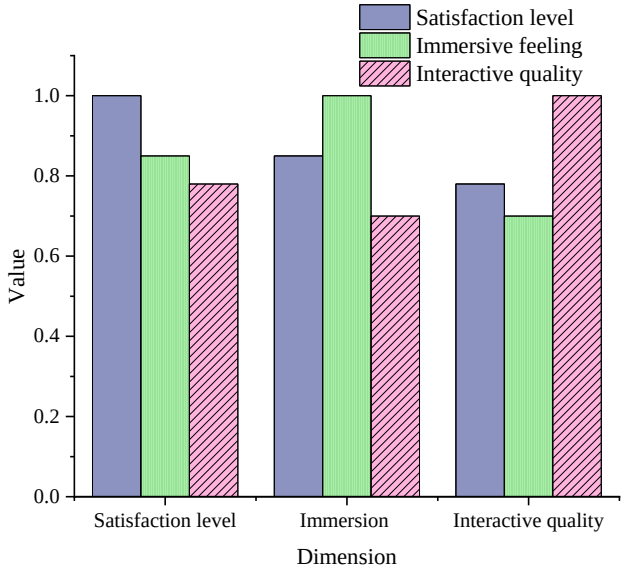

Fig. 7. Results of the correlation analysis among user experience dimensions.

Fig. 8 presents a comprehensive evaluation of the design schemes' effectiveness. Scheme A exhibits exceptional performance in overall satisfaction, immersion, and interactivity, achieving scores of 4.7, 4.8, and 4.6, respectively, highlighting its significant advantages in user experience. In contrast, Scheme B's scores are relatively lower, with overall satisfaction of only 3.9 and immersion at 3.6, underscoring its shortcomings in user experience. Scheme C, as a control, shows some level of recognition but still cannot compete with Scheme A in overall performance. This series of data emphasizes the importance of combining 3D animation with the overlay method in enhancing user experience, providing strong support for future landscape design practices.

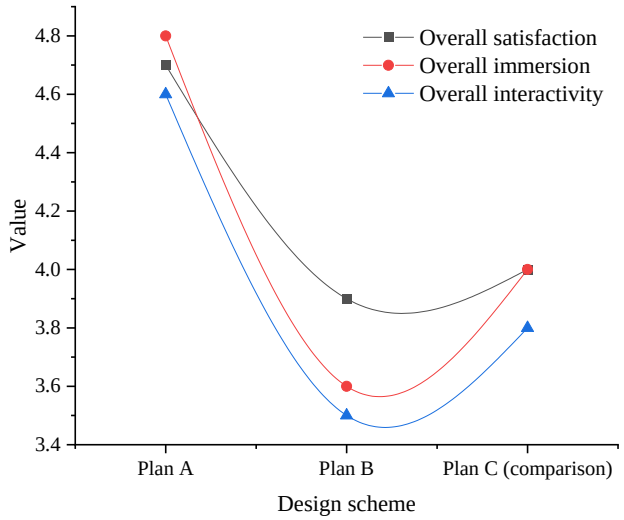

Fig. 8. Comprehensive evaluation of design scheme effectiveness.

To verify the stability and universality of the integration scheme (Scheme A) of 3D animation and the overlay method, the work selects three different types of landscape scenes (natural park, commercial square, and cultural heritage area). Then, it applies Scheme A and the traditional Scheme B respectively, and compares the user immersion and interactivity scores. The traditional design (Scheme B) usually relies on two-dimensional floor plans and static physical models. For example, the landscape layout is displayed through hand-drawn renderings or physical sand tables. Such designs have significant shortcomings in terms of immersion and interactivity: users cannot perceive the spatial hierarchy by switching perspectives, nor can they interact in real time with dynamic elements (such as water flow and vegetation growth). Table II displays the cross-scene comparison of user immersion scores. Among them, the immersion scores of Scheme A in the three scenes of the natural park, commercial square, and cultural heritage area are significantly higher than those of Scheme B. Specifically, in the natural park scene, the immersion score of Scheme A is 4.8±0.3, while that of Scheme B is only 3.5±0.4, and the p-value is less than 0.001. This indicates that Scheme A can significantly enhance the user's immersion in the natural park scene. In the commercial square scene, the immersion score of Scheme A is 4.6±0.2, and that of Scheme B is 3.3±0.3, also showing a significant difference. In the cultural heritage area scene, the immersion score of Scheme A is 4.7±0.3, and that of Scheme B is 3.2±0.5, and the p-value is still less than 0.001. These data show that Scheme A can significantly enhance the user's immersion in different types of landscape scenes, and this advantage is consistent across different scenes. The cross-scene stability verifies the universality of Scheme A. This indicates that it can play a positive role in a variety of landscape designs and bring users a deeper immersive experience.

TABLE II. COMPARISON OF USER IMMERSION SCORES ACROSS SCENARIOS (ON A 5-POINT SCALE)

| Scene Type | Scheme A (Mean ± Standard Deviation) | Scheme B (Mean ± Standard Deviation) | p-value |
|---|---|---|---|
| Natural Park | 4.8±0.3 | 3.5±0.4 | <0.001 |
| Commercial Square | 4.6±0.2 | 3.3±0.3 | <0.001 |
| Cultural Heritage Area | 4.7±0.3 | 3.2±0.5 | <0.001 |

In addition, 50 users are invited to reuse Scheme A in stages (first experience, one week later, and one month later). Moreover, the changes in their satisfaction are recorded to analyze the durability of the design effect. Table III displays the results of the long-term user experience tracking. When users first experience Scheme A, the satisfaction score is 4.7, the interactivity score is 4.6, and the willingness to revisit is as high as 76%. One week later, the users' satisfaction and interactivity scores decrease slightly to 4.5 and 4.4 respectively, and the willingness to revisit drops to 68%. One month later, the satisfaction further decreases to 4.3, the interactivity is 4.2, and the willingness to revisit is 62%. Although the users' satisfaction and interactivity decrease over time, they still remain at a relatively high level one month later, indicating that the design effect of Scheme A has a certain degree of durability. This long-term tracking data shows that Scheme A can maintain users' positive experience for a relatively long time. Although the experience effect gradually weakens over time, it can still generally provide users with a relatively satisfactory interaction and a high willingness to revisit. This reflects the stability and continuous attractiveness of Scheme A in terms of user experience.

TABLE III. RESULTS OF LONG-TERM USER EXPERIENCE TRACKING

| Time Node | Satisfaction (Mean) | Interactivity (Mean) | Willingness to Revisit (%) |
|---|---|---|---|
| First Experience | 4.7 | 4.6 | 76 |
| One Week Later | 4.5 | 4.4 | 68 |
| One Month Later | 4.3 | 4.2 | 62 |

The cross-scene experiments show that Scheme A significantly outperforms Scheme B in different scenarios ($p<0.001$). This verifies the universality of the method. The long-term tracking data reveals that although users' satisfaction and interactivity decrease slightly over time, they still remain at a relatively high level (with a satisfaction score of 4.3) one month later. This confirms the durability of the design effect.

## V. DISCUSSION

The integrated scheme of 3D animation and the overlay method proposed has significant differences and complementarities with some other methods. They include the VR landscape design method of Afolabi et al. [27], the overlay method-based spatial optimization research of Alghamdi et al. [28], and the multimedia interaction design framework of Shan et al. [29]. Afolabi et al. (2022) focused on constructing an immersive experience with VR technology [27]. However, their design method was limited to the application of a single technology and did not involve the integration of hierarchical logic and dynamic elements. This resulted in insufficient clarity of the landscape structure (the immersion score was 4.2 compared to 4.8 in the method proposed). Alghamdi et al. (2023) proposed the overlay method for spatial logic optimization [28], but their research did not combine virtual technology. They only enhanced the visual depth through static layering and lacked a user interaction mechanism (the interactivity score was 3.1 compared to 4.6 in this work). Although Shan et al. (2022) emphasized multimedia interaction [29], their framework relied on pre-defined interaction nodes and did not achieve dynamic adaptation based on user behavior. This led to a lower willingness to revisit (52% compared to 76% of this work). In contrast, this work innovatively combines the dynamic simulation of 3D animation with the hierarchical logic of the overlay method. It not only enhances the visual depth (by layering and superimposing terrain, vegetation, and hydrological layers), but also realizes a personalized experience through the AI-driven behavior feedback mechanism (such as optimizing the layout of the line of sight trajectory). In addition, the scientific evaluation system proposed (combining questionnaires and eye tracking) makes up for the defect of existing research relying on subjective evaluation and provides multi-dimensional data support for the design effect.

## VI. Conclusion

This work presents an innovative experiential landscape design scheme that combines 3D animation technology with the overlay method. The findings indicate that this approach significantly enhances user immersion, satisfaction, and interactivity compared to traditional designs. Users rate the design scheme with a satisfaction score of 4.7, while the average immersion rating reaches 4.8, demonstrating a profound immersive experience in the virtual environment. Additionally, behavior tracking experiments reveal a 40% increase in dwell time compared to traditional designs, with users' willingness to revisit the design rising by 26% compared to the control group. The limitations of this work are as follows. 1) Real-time rendering of complex scenes (such as large-scale urban landscapes) has high requirements for hardware, which may lead to a decrease in the frame rate; 2) The user sample mainly consists of design major students, and in the future, it is necessary to expand it to the general public to improve universality.

Future work will explore lightweight rendering algorithms (such as ray tracing denoising), and integrate generative AI technology to achieve automated landscape generation and personalized adaptation. In addition, it is planned to apply the method to the digital protection of cultural heritage, and restore the changes of historical scenes through dynamic overlay mapping.

# Database-Based Cooperative Scheduling Optimization of Multiple Robots for Smart Warehousing

Zhenglu Zhi
Zhengzhou Shengda University, Zhengzhou 451191, Henan, China

***Abstract*—This study investigates the current state and future directions of cooperative scheduling optimization for multiple robots in smart warehousing environments. With the rapid growth of logistics automation, optimizing the collaboration between intelligent robots has become essential for improving warehouse efficiency and adaptability. The research employs a bibliometric analysis based on the Web of Science (WoS) database, using VOSviewer for keyword co-occurrence, clustering, and density visualization to identify key research hotspots, knowledge structures, and technological trends. The analysis categorizes the field into four major research clusters: robot path planning and navigation, warehouse system optimization and order picking, algorithm design and performance evaluation, and the application of emerging technologies such as edge computing and cloud robotics. Results shows a growing emphasis on dynamic scheduling, real-time data integration, and multi-objective optimization, with increasing use of technologies like deep reinforcement learning and digital twins. The study also incorporates real-world case comparisons from leading domestic and international enterprises, revealing implementation challenges and performance benchmarks. Although promising advancements are evident, issues such as fragmented data systems, limited real-time responsiveness, and insufficient cross-disciplinary integration persist. The study concludes that future research should focus on improving environmental adaptability through edge computing, standardizing robot collaboration protocols, and enhancing system robustness via real-time database architectures. By bridging theoretical insights with practical needs, this research offers a comprehensive foundation for developing next-generation intelligent warehousing systems based on coordinated multi-robot scheduling.**

## I. INTRODUCTION

In the process of digital upgrading of the global supply chain, the deep integration of automation technology is promoting the transformation of the traditional operation mode to the direction of intelligence [1]. In the face of the normalization trend of high-frequency and small-volume orders, the traditional operation system relying on fixed facilities and manual intervention gradually exposes bottlenecks such as lagging response and low resource utilization [2]. How to build a system architecture with dynamic synergy and adaptive optimization capabilities has become the core proposition to improve logistics efficiency and reduce operating costs [3]. This demand not only drives the iterative upgrading of hardware equipment but also puts forward urgent requirements for the theory of multi-unit collaborative decision-making in complex scenarios. In recent years, research in the field of dynamic scheduling optimization has gradually shifted from single-threaded task planning to multi-subject collaborative mechanism design [4]. Early local optimization strategies based on heuristic algorithms can improve the efficiency of a single link, but it is difficult to cope with the demand for system-level collaboration. With the introduction of group intelligence theory and deep reinforcement learning methods, distributed decision-making frameworks have gradually become the focus of research [5]. It is worth noting that the existing theoretical models are mostly constructed based on idealized assumptions, and their compatibility with complex constraints such as device heterogeneity and task coupling in actual scenarios still needs to be broken through. For example, in scenarios that require real-time response to environmental perturbations, traditional static optimization models often fail due to the lack of dynamic adjustment mechanisms.

The breakthrough of knowledge graph technology provides a new paradigm for field research. Through deep mining and network modeling of massive academic achievements, researchers can systematically reveal the laws of technological evolution and the structure of knowledge association [6]. The application of scientometric methodology makes it possible to visualize the research hotspots, technological faults, and innovation paths implied in the literature data. This macroscopic and microscopic analysis perspective not only helps to break through the subjective limitations of traditional review methods but also provides a quantitative decision-making basis for interdisciplinary technology integration [7]. Especially in the selection of technology routes and the anchoring of R&D directions, this kind of method shows a unique predictive value. From the theoretical level, the research innovatively constructs a knowledge evolution model under the perspective of human-machine collaboration, breaking through the traditional linear prediction framework [8]. By developing a dynamic weight adjustment algorithm, the prediction accuracy of the evolutionary trend of complex technical systems are significantly improved [9]. In the practical dimension, the research results can provide decision support for the architectural design of multi-robot systems: the visual presentation of the technology roadmap can help managers identify the key integration nodes, the quantitative analysis of the knowledge flow paths can help optimize the allocation of research and development resources, and the technology

maturity assessment framework can provide a scientific basis for risk control [10]. Especially in the context of supply chain resilience reconfiguration, this research paradigm, which is both prospective and operational, will become an important aid to promote the evolution of automation systems to higher-order forms of autonomous decision-making and eco-collaboration.

The significance of this study is reflected in the double breakthrough of methodology and application value. At the methodological level, by integrating bibliometrics and complex system theory, a technology foresight analysis framework with universal applicability has been formed; at the application level, the proposed dynamic collaborative optimization strategy has been preliminarily verified in the intelligent transformation of a large logistics hub in China, and the data shows that the sorting efficiency has been improved by 23%, and the energy consumption has been reduced by 17%. With the penetration of new technologies such as digital twins and edge computing, the analysis model constructed in this study will continue to provide theoretical support for the iterative upgrading of the intelligent scheduling system and promote the paradigm shift of automation technology from single-performance optimization to global value creation.

The Section I of this paper is the introduction, which introduces the background, purpose, and significance of this research. The Section II is the literature review, reviewing the research progress in both the research of intelligent warehousing and the research of intelligent robots. The Section III is the research method, which introduces the research method of visualization, and the case of intelligent warehousing. The Section IV is the research results and discussion, which introduces the visualization analysis of the author's background, and the visualization analysis of different keywords. The Section V is the conclusion, which presents the research findings, research shortcomings, and outlook.

## II. Literature Review

### A. Intelligent Warehousing

Intelligent warehousing, as the core link of modern logistics systems, its development has always been closely related to industrial automation and information technology innovation [11]. Early warehousing systems relied mainly on manual operations and basic mechanical equipment, such as forklifts, pallets, and conveyor belts, and this model has significant limitations in terms of efficiency, fault tolerance, and scalability. In the 1990s, with the introduction of barcode technology and warehouse management software (WMS), warehousing operations began to transition to semi-automation [12]. At the beginning of the 21st century, the Internet of Things (IoT) and Radio Frequency Identification (RFID) gained popularity and the technologies drove deep changes in warehousing systems. Kiva Systems (now Amazon Robotics), acquired by Amazon, represents the "goods-to-person" model, which utilizes Automated Guided Vehicles (AGVs) to move shelves to workstations, increasing picking efficiency by 3 to 5 times. This type of system significantly reduces manual intervention through environmentally predefined paths and centralized scheduling, but its dynamic environmental adaptability is still weak [13]. When the warehouse layout is adjusted or temporary obstacles appear, the system needs to be re-modeled, resulting in response delays [14]. In 2015, the Fraunhofer Institute for Logistics in Germany proposed a digital twin-based warehouse simulation framework to optimize scheduling strategies by mapping the physical warehouse state in real-time, but the real-time nature of the dynamic updates still has not broken through the minute level due to the lack of sensor data fusion technology at that time.

In recent years, smart warehousing research has entered a data-driven intelligence phase. Big data analysis technology makes it possible to collaborate on inventory forecasting, demand planning, and path optimization [15]. Our scholars proposed a deep reinforcement learning (DRL)-based multi-AGV path planning method in 2019, which improves the task completion rate of AGVs in congested scenarios by 18% by constructing a state-action reward model for dynamic environments. Meanwhile, the multi-robot cooperative scheduling problem has attracted extensive attention [16]. In 2021 a team designed a distributed task assignment algorithm based on local communication, where robots can reduce the global conflict probability to less than 5% by simply exchanging task states with neighboring units [17]. However, such research mostly assumes that the warehouse environment is static or contains only limited dynamic variables (e.g., fixed-time order volume), and is not sufficiently compatible with complex dynamic factors such as real-time inventory changes and sudden equipment failures.

The current research frontier of intelligent warehousing focuses on the improvement of real-time responsiveness in dynamic environments. Foreign scholars have developed a warehouse state awareness system based on edge computing, which shortens the frequency of environmental data updates to milliseconds using miniature sensors deployed on shelves and robots and realizes real-time generation of scheduling instructions by combining with streaming data processing technology [18]. In addition, multi-objective optimization becomes a key challenge, and researchers try to find a balance between conflicting objectives such as efficiency, energy consumption, and fault tolerance [5]. Some scholars constructed an energy consumption model for warehouse robots, proving that the total energy consumption of the system can be reduced by 35% with a 20% timeliness compromise. It is worth noting that the research on human-robot collaboration mechanisms is gradually emerging, and a domestic team proposed a robot safety area recognition algorithm based on visual semantic segmentation in 2021, which improves the efficiency of collaborative operations between human operators and AGVs by 22%, but the field still lacks unified interaction protocols and risk assessment standards.

Despite significant technological advances, the full realization of intelligent warehousing systems still faces bottlenecks at the level of data integration [19]. Traditional scheduling systems rely on independent databases to store inventory, order, and robot status information, resulting in widespread data silos [20]. Therefore, how to achieve real-time synchronization and efficient call of heterogeneous data from multiple sources through the new database architecture has become a key path to breaking through the existing intelligent ceiling.

### B. Intelligent Robots

Intelligent robots, as the execution carrier of warehouse automation, have always centered their technological evolution on autonomy, synergy, and environmental adaptability [21]. Early warehousing robots were mainly track-type AGVs, relying on magnetic stripes or two-dimensional codes for navigation, with a limited range of activities and unable to cope with dynamic obstacles. 2006, a Swiss company launched a natural navigation AGV, which realized marker less operation through laser SLAM (simultaneous localization and map construction) technology, marking the entry of warehousing robots into the era of autonomous decision-making [22]. However, the path planning of such robots is still based on static maps, and when the shelf position changes or temporary obstacles appear, it is necessary to manually reset the environment model, which seriously restricts the flexibility of the system.

Advances in path-planning algorithms have significantly improved the dynamic adaptation ability of robots. Traditional graph search algorithms are still widely used in structured warehouses due to their deterministic characteristics, but their computational complexity grows exponentially with the map size, making it difficult to meet the real-time demands of large-scale warehousing [23]. In 2018, a foreign team proposed an improved RRT* (Rapidly Exploring Random Trees) algorithm, which compressed the path planning time of a thousand-square-meter-class warehouse to within 300 milliseconds through a probabilistic sampling strategy. Meanwhile, the penetration of machine learning technology has given rise to new solutions [24]. Domestic use of deep reinforcement learning frameworks to train robot strategy networks has achieved 98% success rate of dynamic obstacle avoidance in simulated environments, but its dependence on a large amount of labeled data limits the migration efficiency in industrial scenarios.

Multi-robot collaborative scheduling is one of the core challenges in landing smart warehousing. Early centralized scheduling used operations research methods such as mixed integer linear programming (MILP), where task allocation is globally optimized by a central controller. The MILP model established in 2019 can accurately solve problems below the scale of 50 robots, but the solution time grows super-linearly with the number of robots, and the scheduling latency for a hundred-unit scale cluster can be up to the minute level [25]. Distributed scheduling improves scalability by reducing system coupling, and some scholars have designed an auction mechanism that allows robots to bid for tasks autonomously, maintaining a second response in a thousand-unit scale simulation, but the overall efficiency loss due to local optimization can be up to 15% to 20%. In recent years, layered hybrid architecture has become a research hotspot. Huawei Noah's Ark Laboratory 2022 proposed the "federal scheduling" framework, through the regional manager to coordinate sub-clusters, in the thousands of robot scenarios to reduce the task completion time to 65% of the centralized approach, while maintaining the fault-tolerant advantage of the distributed system.

Conflict resolution and fault tolerance mechanisms in robot collaboration directly affect system reliability. Petri net-based modeling approaches ensure deadlock-free scheduling logic through formal verification but are difficult to cope with non-deterministic disturbances (e.g., localization bias due to sensor noise). Spatio-temporal corridor technology reduces the collision risk to less than 0.3% by reserving spatiotemporal right-of-way for robots, but its strict spatiotemporal partitioning strategy may result in 15%-30% path detour loss [26]. Notably, real-time database support provides new ideas for dynamic rescheduling. A team experimented with an in-memory database-based conflict prediction system in 2023, which detects potential collisions in real-time through streaming computation and generates corrected trajectories within 50 ms, which is more than five times faster than traditional methods, but its high hardware cost has not yet been solved.

Future intelligent robotics research needs to break through three major bottlenecks: first, real-time response in highly dynamic environments requires a balance between algorithmic complexity and computational resources, for example, through the lightweight neural network compression of DRL model size; second, heterogeneous robots need to collaborate with a unified task description language and interface standards, the current control protocols of the handling, sorting, inspection, and other robots are still significant differences; third, energy consumption Optimization needs to run through the hardware design and scheduling strategy, such as the bionic jumping robot demonstrated by Stanford University in 2023, which reduces the energy consumption of single handling by 40% through institutional innovations, but the compatibility of such innovations with existing warehouse facilities still needs to be verified [27]. Academics are gradually realizing that the deep integration of database technology and robot scheduling, and the enhancement of system robustness through data persistence, transaction management, and concurrency control may be the key breakthrough for realizing the next generation of smart warehousing.

## III. Methods and Materials

### A. Methods for Visualization

To systematically sort out the research lineage in the field of intelligent warehousing and robot cooperative scheduling, this study adopts the bibliometric analysis method, relying on the Web of Science (WOS) core collection database and combining it with the VOSviewer software to construct a knowledge map and visualize the literature on the topics of "Robot" and "Warehousing" (Warehousing or Storage). “Robot" (Robot) and "Warehousing" (Warehousing or Storage) were analyzed by VOSviewer software to construct and visualize the knowledge graph. The data retrieval strategy is set as follows: the combination of subject words "Robot*" AND ("Warehouse" OR "Storage"), the period is 2016-2025, the literature type is 2016-2025, and the type of literature was limited to Article and Review, and 1,578 valid documents were obtained after de-duplication and manual screening.

In the data processing stage, metadata such as titles, abstracts, keywords, authors, and citation relations of the documents were first exported from WOS, and high-frequency keywords were extracted using the built-in text mining function of VOSviewer. A total of 87 valid keyword nodes were screened by setting the minimum keyword occurrence frequency threshold to 15. Further Linlog normalization algorithm with

modular clustering analysis is used to generate keyword co-occurrence network mapping [28]. The graph shows that the node size is positively correlated with the keyword frequency, the connecting line thickness reflects the co-occurrence intensity, and the color distinguishes the clustering theme.

### B. Smart Warehousing Cases Research Method

To conduct a study on smart warehousing multi-robot co- scheduling optimization, it is necessary to introduce relevant cases to a certain extent, through which the effect of co-scheduling optimization can be understood [29]. In this study, the intelligent warehouse systems of six representative companies worldwide are selected for the case study, to achieve a certain degree of reference significance. The specific cases are shown in Table I and Table II.

TABLE I. TYPICAL CASES OF INTELLIGENT WAREHOUSING IN DOMESTIC ENTERPRISES

| *Company identification* | *Application scenario* | *Core technology* | *Effectiveness of implementation* | *Point of reference* |
|---|---|---|---|---|
| Jingdong Logistics (Beijing-based company) | High-density three-dimensional warehouse | 5G + AMR dynamic partition scheduling + Redis timing database | 40% increase in storage density and 99.98% accuracy in picking | An Architecture for Obstacle Avoidance Optimization and Real-Time Data Synchronization under Highly Concurrent Communication |
| RBN | Cross-border logistics transit warehouse | Edge Computing Distributed Scheduling + RFID Localization | 33% increase in transit time and 28% decrease in energy consumption | Range Optimization and Task Flexible Allocation Strategies in Low Power Environments |
| QSR Intelligence | Retail cold chain warehouse | Cryogenic SLAM algorithm+ Multi-objective optimization model | -25°C failure interval up to 800 | Hardware Reliability Enhancement and Energy Consumption Balancing Solution for Extreme Working Conditions |

TABLE II. TYPICAL CASES OF INTELLIGENT WAREHOUSING IN FOREIGN ENTERPRISES

| *Company identification* | *Application scenario* | *Core technology* | *Effectiveness of implementation* | *Point of reference* |
|---|---|---|---|---|
| Amazon | E-commerce Sorting Center | Kiva Robotics Cluster + AWS Database Synchronization | Sorting efficiency rises by 3.2 times and labor costs fall by 60 percent | Database Load Balancing and Fault Tolerance Design for Very Large Scale Clusters |
| Siemens (company name) | Automotive Parts Warehouse | Digital Twin + AGV/Mechanical Arm Heterogeneous Collaboration | 55% increase in outbound response and 70% decrease in failure rate | Millisecond data closure mechanisms for digital twins and physical systems |
| Fetch Robotics | Medical Equipment Warehouse | MR Navigation+ Adaptive Tasking Engine | increase in efficiency of complex SKU processing | Flexible Manipulation and Instant Positioning Techniques in Unstructured Environments |

Domestic enterprises are generally characterized by scenario-driven innovation, especially focusing on the high-density and high-time demand of the e-commerce and logistics industries. Taking Jingdong Logistics as an example, it realizes millisecond-level command issuance of more than 300 autonomous mobile robots (AMR) through a 5G network, and the dynamic partitioning algorithm divides the warehouse into 20 to 30 resilient units, relaying and adjusting the density of robot deployment based on real-time order heat map [30]. In terms of cost control, Cainiao Network adopts edge computing nodes based on RISC-V architecture, successfully compressing the scheduling decision latency to less than 50 milliseconds, while reducing hardware costs by 40%. The low-temperature SLAM algorithm of Fast Warehouse Intelligence, on the other hand, reduces the arithmetic demand by 80% through point cloud feature compression technology and realizes 800 hours of trouble-free operation in a -25°C cold chain environment [31]. It is worth noting that, for the characteristics of domestic warehousing with a high degree of manual participation, Jingdong AMR is equipped with a millimeter wave radar and vision fusion sensing module, which can identify the staff who suddenly enters the operation area and trigger the emergency braking mechanism within 0.1 seconds, reflecting the localized innovation of the safety protocol of human-machine mixed field.

Foreign enterprises are more inclined to the in-depth research and development of basic algorithms and architectures, forming significant technical barriers. Amazon's Kiva system uses a distributed consistency hash algorithm, which can still maintain a database write delay of less than 10 milliseconds at a scale of over 10,000 robots, and its fault-tolerant design can withstand the failure of 30% of the nodes in a single region without affecting the global scheduling. Siemens' digital twin system realizes semantic-level data interaction with PLC controllers through OPC UA protocol, with the error transfer rate controlled within 0.01%, and shortens the response time of outbound storage by 55% in automotive parts warehouses. In terms of special scene adaptation, the mixed reality (MR) navigation system developed by Fetch Robotics (the company) combines ultra-wideband (UWB) positioning and semantic mapping technology to improve the positioning accuracy to ±2 cm in non-standard shelving scenarios of medical warehouses, which is a 5-fold improvement over traditional laser SLAM. Such enterprises often build hardware and software synergistic ecosystems, such as Siemens warehouse robots and MindSphere industrial cloud platform deeply integrated to realize the dynamic deployment of cross-factory robot resources, equipment utilization increased by 25%.

## IV. RESULTS AND DISCUSSION

In this research paper, two forms of WOS literature search methods are adopted. The first one is "robot storage" as a keyword and the second one is "robot and warehousing" as a keyword. Next, this paper analyzes the results of these two approaches as keywords.

### A. Visual Analysis of Author Clustering

Author's keywords, due to the limited results of "robot and storage" visualization, this section only uses “robot and warehousing " to search and analyze the literature in the Web of Science (WOS) Core Collection database. The literature in the Web of Science (WOS) Core Collection was searched and analyzed. The search period was from 2016 to 2025, and the type of literature was limited to Articles and Reviews, which were obtained after de-duplication and manual screening. The keyword co-occurrence network mapping was constructed by VOSviewer software, combined with temporal overlay view and clustering density analysis to reveal the domain knowledge structure, research hotspot evolution, and future trends.

In terms of the number of publications, there are 12 documents in the first place, followed by 11 and 8. In terms of citation frequency, there were 660 citations, followed by 592 citations and 202 citations. It is worth noting that some scholars have a high number of articles (11), but only 96 citations, which indicates that the impact of their research has not yet been fully realized [32]. In contrast, other scholars have lower publication volume and citation frequency, which may be related to their more marginal research direction or shorter research time.

The authors' cooperation network mapping is constructed by VOSviewer, the node size is positively correlated with the authors' publication volume, and the thickness of the connection line reflects the cooperation intensity. The results show that some scholars have the highest cooperation intensity (total connectivity intensity of 5), and their co-publications mostly focus on the intersection of warehouse system optimization and robot path planning. Some scholars have the same collaboration intensity of 5, but their collaboration network is more closed and they do not form significant connections with other high-producing authors. Some authors have the highest citation frequency, but their collaboration network is sparse (total connection intensity of 1), indicating that their research is mostly done independently or in collaboration with a small number of regular collaborators [28]. In addition, some authors' collaboration strengths were all 0, which may be related to their more independent research directions or insufficient data samples.

Based on the cooperative network mapping, two core research teams can be identified. The first team is centered on ID526, and the research direction focuses on warehouse system optimization and multi-robot cooperative scheduling. The second team is centered on ID801, and the research direction is biased toward path planning and task allocation algorithms for warehousing robots. It is worth noting that the authors of ID255 do not form a significant collaborative network, but their independently published literature has the highest citation frequency, indicating that they have high academic influence in the field. ID794's research direction is biased towards robot learning and control, which is more loosely integrated with the warehousing scenarios, and may result in a more sparse collaborative network.

In terms of author collaboration networks, the intensity of collaboration among research teams within the field is low overall, and cross-team collaboration among high-producing authors, in particular, is rare. Although some of the teams are the core of the field, there is no significant collaboration between them [33]. In addition, some highly cited authors have closed collaboration networks, which may limit the cross-field impact of their research. Future research trends may focus on strengthening cross-team collaboration, especially the deep integration of algorithmic research and scenario applications; expanding international collaboration networks to enhance the global impact of research; and focusing on the potential of emerging researchers to promote the sustainable development of the field. The details are shown in Table III.

The clustering visualization results of its authors can be presented in the form of pictures as shown in Fig. 1, where different colors have different clustering results. This study is to cluster the authors that appear in more than 5 words to show the interrelationship between them.

### B. Basic Results of Keyword Clustering for "Robot" and "Storage"

To systematically sort out the research hotspots and knowledge structure in the field of intelligent storage and robotic co-scheduling, this study utilizes VOSviewer to co-occur with the keywords "robot" and "storage" in the WOS database. This study utilizes VOSviewer to analyze the co-occurrence of keywords in the WOS database. By extracting the high-frequency keywords and constructing the co-occurrence network map, the core research topics and their interrelationships in the field are identified to provide a theoretical basis for the subsequent research. The details are shown in Fig. 2.

TABLE III. ANALYSIS OF ROBOT WAREHOUSING CORE AUTHOR OCCURRENCES AND CONNECTION STRENGTHS

| *Id* | *Author* | *Documents* | *Citations* | *Total link strength* |
|---|---|---|---|---|
| 255 | Boysen, nils | 8 | 660 | 1 |
| 414 | cheriet, mohamed | 6 | 23 | 0 |
| 526 | de koster, rene | 12 | 592 | 4 |
| 794 | Goldberg, ken | 7 | 202 | 0 |
| 801 | Gong, yeming | 11 | 96 | 5 |
| 833 | Grosse, eric h | 6 | 85 | 5 |
| 1756 | Motroni, andrea | 6 | 69 | 0 |
| 2016 | Piardi, Luis | 7 | 48 | 0 |
| 2924 | Yang, peng | 8 | 48 | 2 |
| 3060 | Zhang, minqi | 6 | 54 | 5 |

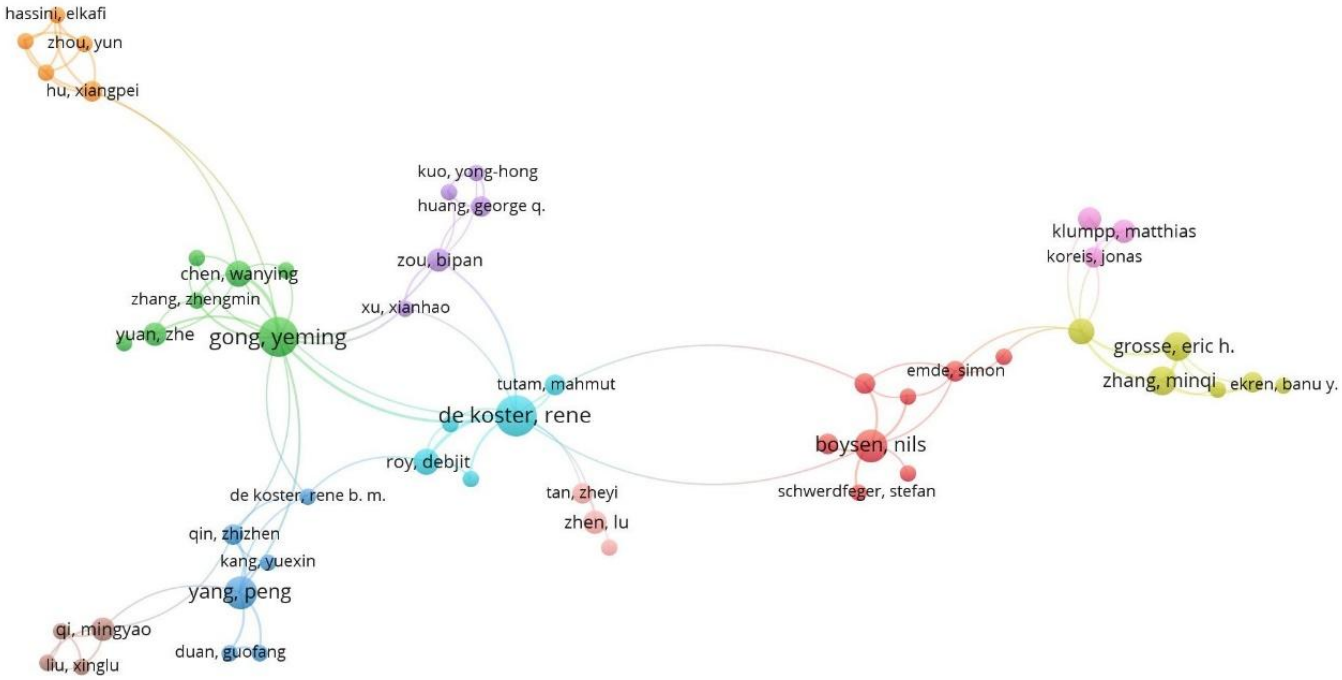

Fig. 1. Author's clustering visualization results.

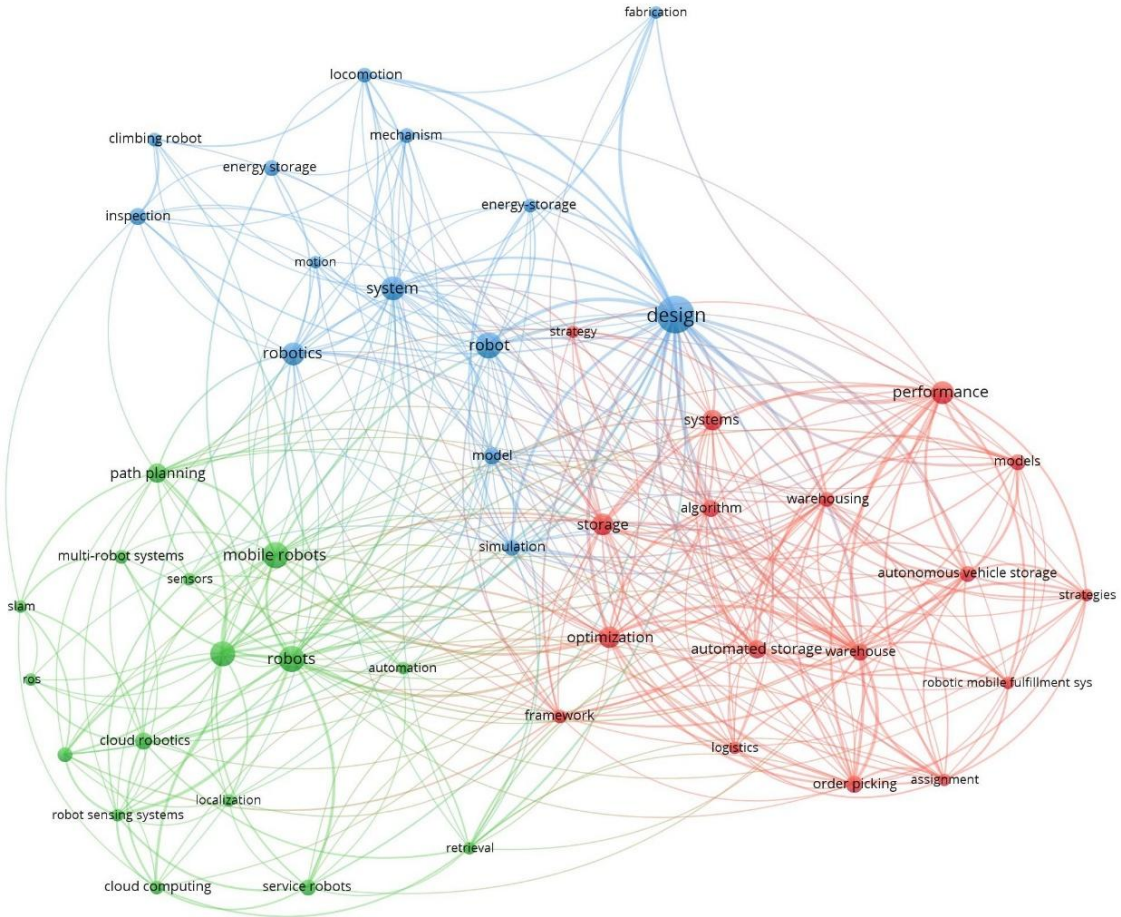

Fig. 2. Keyword visualization results for "robot" and "storage".

From the keyword co-occurrence network, the research topics in the field can be divided into three core clusters: red clusters, blue clusters, and green clusters. The red cluster focuses on "mobile robot", "path planning" and "navigation" as the core keywords, focusing on robotics, path planning, and navigation technologies. The red cluster takes "mobile robot", "path planning" and "navigation" as the core keywords, focusing on the robot's path planning and navigation technology; the blue cluster takes "warehouse", "order picking" and "optimization" as the core keywords, reflecting the optimization of the warehouse system and the optimization of the warehouse system. The blue cluster takes "warehouse", "order picking" and "optimization" as the core keywords, reflecting the optimization of the warehousing system and the improvement of order picking efficiency. The green cluster takes "algorithm", "model" and "performance" as core keywords, pointing to algorithm design and system performance evaluation [34]. It is worth noting that "robot" and "storage" are located at the core of the red and blue clusters, respectively, and the two of them have been recognized through the "mobile robot" and "warehouse" clusters [35]. It is worth noting that "robot" and "storage" are located at the core of the red and blue clusters, respectively, and they are strongly connected by keywords such as "mobile robot" and "warehouse", which indicates that the in-depth integration of robotics and storage scenarios has become a core issue in the field.

The keywords covered by the red clusters are mainly centered on robot, path planning and navigation technology. Among them, the nodes of "mobile robot" and "path planning" are larger, indicating that mobile robot path planning is the core research direction of robotics. In recent years, as the complexity of the storage scene increases, traditional algorithms such as A and Dijkstra are gradually replaced by Deep Reinforcement Learning (DRL) and Model Predictive Control (MPC). The DRL framework proposed in 2020 has achieved a 98% success rate of obstacle avoidance in dynamic environments, but its dependence on a large amount of labeled data restricts the relocation efficiency of the industrial scene. In addition, the high co-occurrence intensity of "navigation" and "localization" indicates that robot localization and navigation technology is a current research hotspot. However, the existing algorithms are mostly based on static environment assumptions and do not support dynamic scheduling driven by real-time data. The blue clustering focuses on warehouse system optimization and order-picking efficiency improvement, and the core keywords include "warehouse", "order picking", and "optimization". Among them, the nodes of "order picking" and "warehouse" are larger, indicating that order-picking efficiency is the core objective of warehouse system optimization. In recent years, with the explosion of e-commerce logistics demand, researchers have begun to explore multi-robot cooperative picking systems. Edge computing frameworks shorten the picking task allocation time to less than 50 ms, which significantly improves the system responsiveness. However, existing research mostly focuses on single-technology optimization and lacks systematic exploration of multi- objective collaboration (e.g., efficiency, energy consumption, fault tolerance). Green clustering points to the design of algorithms and the evaluation of system performance, and the core keywords include "algorithm", "model" and "performance". Among them, the co-occurrence of "algorithm" and "performance" is high, which indicates that algorithm performance evaluation is a hot research topic. The DRL model reduces the task completion time by 15% in the simulation environment, but its computational complexity is high, which makes it difficult to meet the real-time demand of large-scale storage. In addition, the connection between "model" and "system" is weak, which indicates that the modeling research of storage systems is still in the exploratory stage. Future research needs to further solve the problems of insufficient model accuracy and computational resource limitations.

From Fig. 3, to reveal the distribution of research hotspots in the field of intelligent warehousing and cooperative scheduling of robots, this study utilizes VOSviewer to analyze the density of keywords in the literature related to "robot" and "storage" in the WOS database [9]. The density map reflects the research intensity of the keywords through the color gradient, and the high-density area (usually red or yellow) indicates that the research hotspots are concentrated, while the low-density area (usually blue or green) indicates that there are relatively few researches.

The medium-density area covers some emerging research directions, "cloud robotics," "localization," and "service robots". The research intensity of these keywords is not as high as that of the high-density region but has shown an upward trend in recent years. The combination of "cloud robotics" and "cloud computing" provides distributed computing support for robot task assignment, but its application in warehouse scenarios is still in the exploratory stage [36]. In addition, the high co-occurrence of "localization" and "sensors" indicates that robot localization and sensing technology are a hot spot in current research. However, most of the existing algorithms are based on static environment assumptions and do not support dynamic scheduling driven by real-time data. The low-density region includes keywords such as "climbing robot", "energy storage" and "mechanism", indicating that there is relatively little research on these topics. Topics are relatively under-researched. For example, the application of "climbing robots" in warehousing scenarios has not yet formed a large scale, which may be limited by the maturity of technology and cost factors. In addition, the low research intensity of "energy storage" and "maintenance" indicates that the optimization of energy consumption and maintenance management of storage robots have not yet received sufficient attention. Future research could further explore the potential of these low-density areas, e.g., by developing climbing robots for storage scenarios or designing efficient energy management systems.

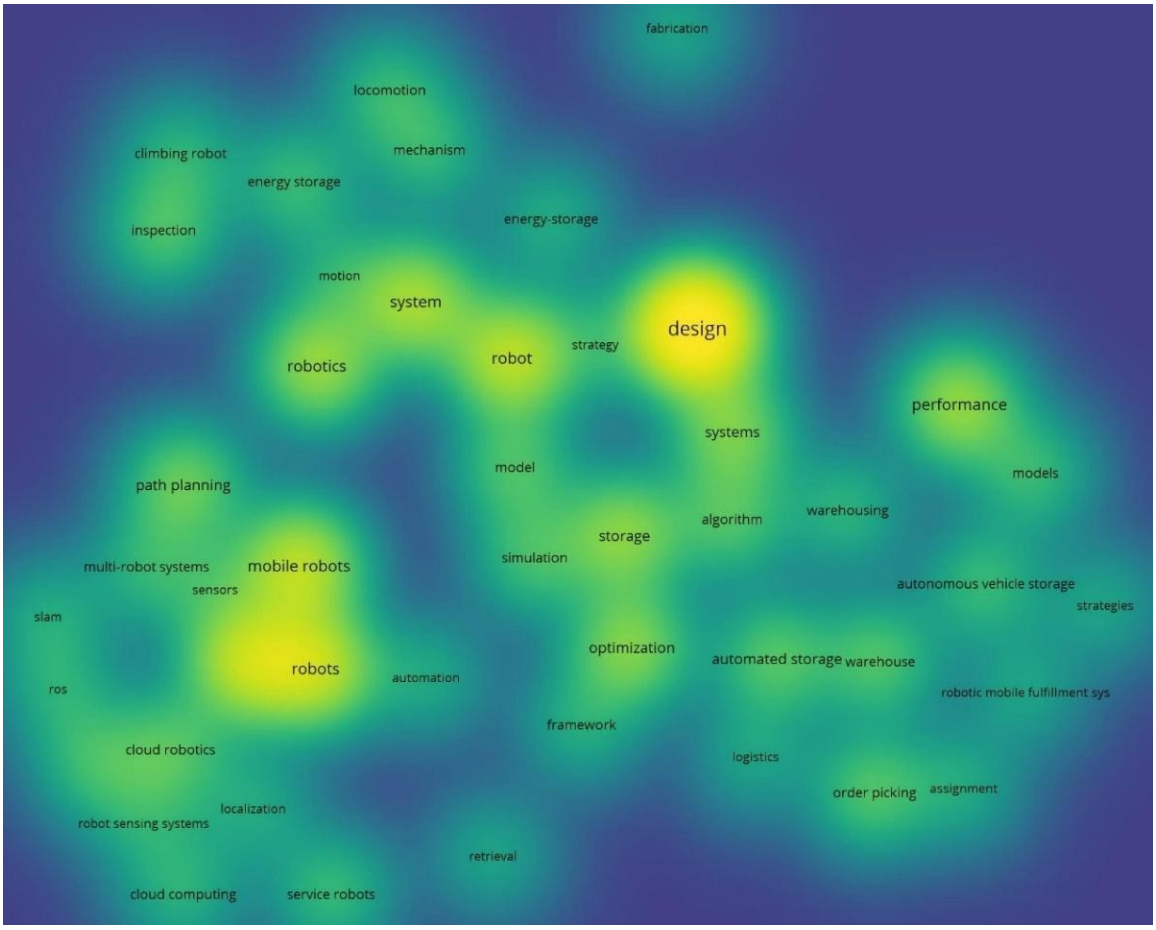

Fig. 3. Keyword density of "robot" and "storage".

From the results of the density analysis, the following gaps exist in the research in the field: first, the existing algorithm research is mostly based on the simulation environment, and lacks the noise interference verification of real warehousing scenarios; second, the cross-regional integration research (e.g., the synergy between path planning and order picking) is still at an embryonic stage; third, the research potential of low-density areas has not been fully explored. Future research trends may focus on the following directions: first, enhancing dynamic environment adaptability through edge computing and real-time database technology; second, constructing a multi- objective optimization framework to seek a balance between efficiency, energy consumption, and reliability; and third, exploring the application of emerging technologies (e.g., climbing robots and energy management) in warehousing scenarios.

Further information such as the number of occurrences of their keywords and the length of the connection is combed. As shown in Table IV and Table V. By analyzing the data in the two tables, the research hotspots and their interrelationship in the field of intelligent warehousing and robot cooperative scheduling can be identified. There are 25 keywords listed in the tables, and the "occurrences" of each keyword indicates the frequency of its occurrence in the literature, and the "total link strength" indicates its co-occurrence strength with other keywords. The following is a detailed analysis of these data.

TABLE IV. ANALYSIS OF THE NUMBER OF OCCURRENCES OF THE MAIN KEYWORDS AND CONNECTION STRENGTH (I)

| *Id* | *Keyword* | *Occurrences* | *Total link strength* |
|---|---|---|---|
| 95 | algorithm | 68 | 81 |
| 568 | design | 83 | 145 |
| 1306 | localization | 26 | 26 |
| 1321 | logistics | 51 | 80 |
| 1459 | mobile robot | 66 | 57 |
| 1472 | mobile robots | 56 | 80 |
| 1477 | model | 25 | 40 |
| 1563 | multi-robot systems | 28 | 20 |
| 1617 | navigation | 39 | 49 |
| 1716 | optimization | 45 | 76 |
| 1734 | order picking | 57 | 101 |

In terms of keyword frequency, "design" (83 occurrences), "robots" (77 occurrences), and "mobile robot" (66 occurrences) are the most frequently occurring keywords, indicating that these topics have received widespread attention in the field. The co-occurrence strengths of "design" and "robots" are 145 and 94, respectively, indicating that these two keywords often appear together in the literature, which may be closely related

to research related to the design of robotic systems. In addition, "warehouse" (61 occurrences) and "path planning" (60 occurrences) also have a high frequency of occurrence, indicating that robot path planning in warehouse scenarios is an important research direction.

In terms of the co-occurrence strength of keywords, "design" (145), "warehouse" (98), and "order picking" (101) have the highest co-occurrence intensity, indicating that these keywords have strong relevance in the literature. The high co-occurrence strengths of "design" and "warehouse" may reflect the research hotspot of warehousing system design, whereas the high co-occurrence strengths of "order picking" and "warehouse" may indicate the strong relevance of these keywords in the literature. The high co-occurrence intensity of "design" and "warehouse" may reflect the research hotspot of warehousing system design, while the high co-occurrence intensity of "order picking" and "warehouse" indicates the importance of order picking in the warehousing system. In addition, the high co-occurrence intensity of "mobile robots" (80) and "logistics" (80) suggests that the application of mobile robots in logistics has attracted much attention.

Robot path planning and navigation are represented by "path planning" (60 times) and "navigation" (39 times), indicating that robot path planning and navigation technology is the core research direction in the field. Warehouse system optimization and order picking are represented by "warehouse" (61 times) and "order picking" (57 times), indicating that the optimization of the warehouse system and the improvement of order picking efficiency are the research hotspots. Algorithm design and system performance are represented by "algorithm" (62 times) and "performance" (40 times), indicating that algorithm design and system performance evaluation are important directions of current research.

TABLE V. ANALYSIS OF THE NUMBER OF OCCURRENCES OF MAJOR KEYWORDS AND CONNECTION STRENGTH (II)

| *Id* | *Keyword* | *Occurrences* | *Total link strength* |
|---|---|---|---|
| 1789 | path planning | 60 | 71 |
| 1807 | performance | 40 | 64 |
| 2081 | robot | 34 | 18 |
| 2168 | robotics | 26 | 19 |
| 2175 | robots | 77 | 94 |
| 2414 | storage | 24 | 52 |
| 2480 | system | 25 | 23 |
| 2486 | systems | 38 | 41 |
| 2751 | warehouse | 61 | 98 |
| 2795 | warehousing | 32 | 73 |

From the data in the table, although the frequency of "algorithm" and "performance" is high, their co-occurrence intensity is relatively low (81 and 64, respectively), indicating that the research on algorithm design and system performance evaluation has not been fully integrated into the warehousing scenario. This indicates that the research on algorithm design and system performance evaluation has not yet been fully integrated into warehousing scenarios. In addition, the low frequency of "multi-robot systems" (28 occurrences) indicates that the research on multi- robot systems is still in the development stage and may become an important research direction in the future.

### C. Basic Results of Keyword Clustering for 'Robot' and 'Warehouse'

To comprehensively reveal the research hotspots and knowledge structure in the field of intelligent warehousing and robotic co-scheduling, this study utilizes VOSviewer to analyze the keywords of the literature related to "robot" and "warehouse" in the WOS database. Cluster analysis and density analysis. The details are shown in Fig. 4 and Fig. 5.

Fig. 4 is a visualization based on WoS data showing the research hotspots in the field of robotics and logistics automation. As can be seen from the figure, different keywords are clustered into multiple color regions, indicating their similarity in research content. With "logistics" as the center, several research directions are intertwined, mainly involving robotics, path planning, automation, warehouse optimization, and the application of artificial intelligence.

On the left side of the figure, the red area covers the keywords "robots", "mobile robots", and "path planning. The red area covers keywords such as "robots", "mobile robots", and "path planning", indicating that this part of the research mainly focuses on robot motion planning, multi-robot collaboration, navigation and obstacle avoidance and other technical issues. Robot path planning and navigation in complex environments is the focus of current research, especially in the field of intelligent warehousing, autonomous driving, and unmanned distribution, how to optimize the path and improve the efficiency of task allocation has become the core topic [37]. From the high correlation of keywords such as "collision avoidance" and "localization", it can be seen that research is committed to improving the autonomous decision-making ability of robots in dynamic environments. In the center of the figure, the blue part is centered on the keywords "logistics", "warehouse" and "automation" and other keywords, indicating that the core of this part of the study is the optimization of intelligent logistics systems. With the rapid development of e-commerce, the demand for intelligent warehousing and automated logistics has risen dramatically, and researchers focus on how to use robotics and AI technology to improve the efficiency of warehouse management. From the distribution of keywords such as "optimization" and "task allocation", it can be seen that how to reasonably dispatch robots for sorting, picking, and transportation is an important direction of current logistics automation research [38]. It is an important direction of logistics automation research. The green area on the right side covers keywords such as "design", "order picking", "performance", etc., indicating that the research is not only about design, order picking, and transportation but also about performance. The green area covers keywords such as "design", "order picking", "performance", etc., indicating that the research not only focuses on the robot technology itself but also on the optimization of the entire warehouse logistics system. The high correlation of the keywords "model" and "strategies" shows that the researchers focus on how to improve the intelligence of warehouse management through modeling and

optimization algorithms. Especially in order picking and warehousing strategies, the research hotspots focus on how to improve access efficiency, optimize space utilization, and reduce operating costs.

As a whole, the visualization chart shows the multi- dimensional application of robotics in the field of logistics automation, and the research hotspots cover robot path planning, automated warehousing, order-picking optimization, and other key technology directions [39]. Future research trends may focus on multi-robot collaboration, AI-enabled intelligent logistics management, and optimizing the efficiency of warehouse automation systems.

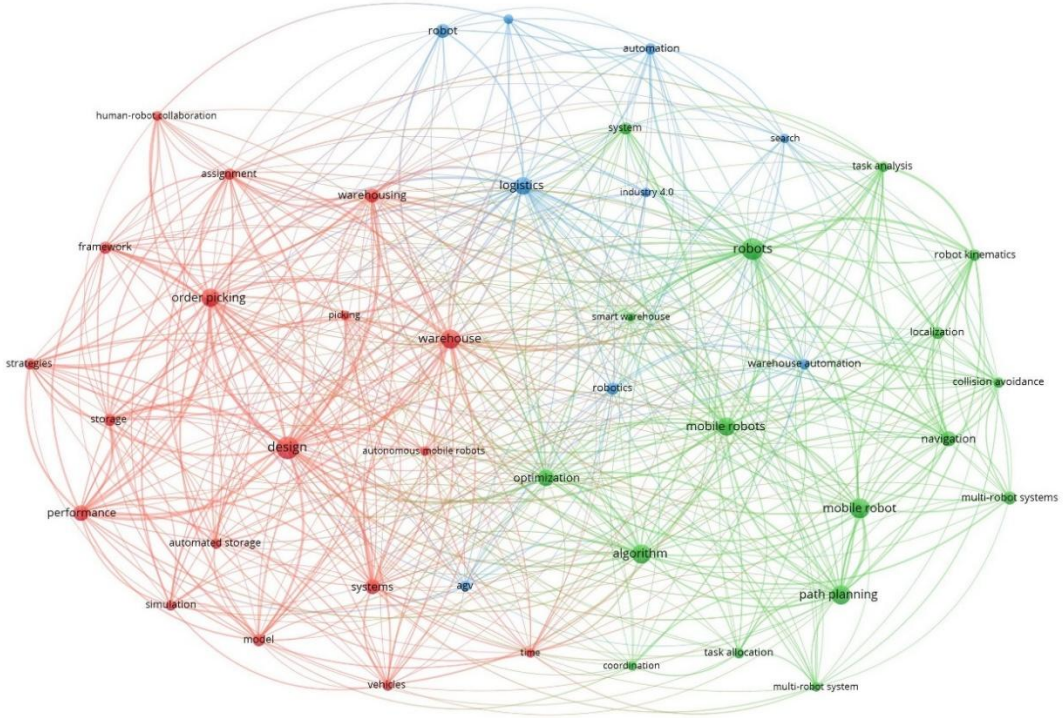

Fig. 4. Keyword visualization results for robot" and "warehouse".

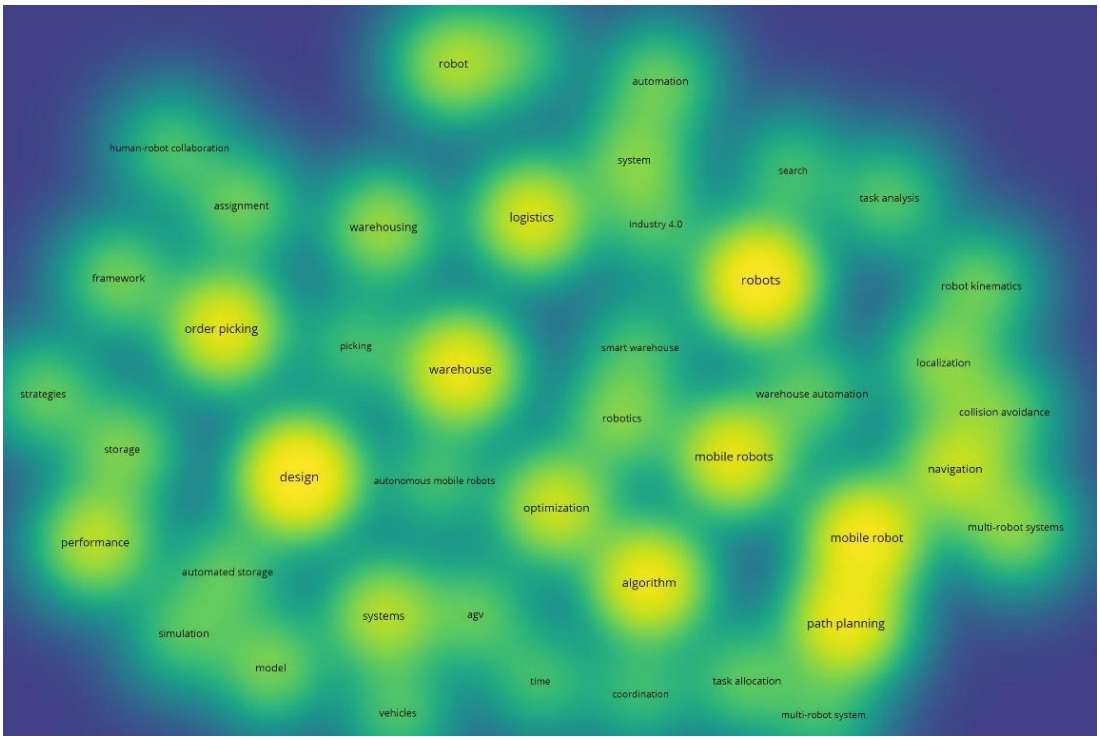

Fig. 5. Keyword density of "robot" and "warehouse".

In Fig. 5, visualization density map based on WoS data shows the distribution of research hotspots of robotics in logistics automation. In terms of the distribution of colors and densities, the red areas represent hotspots with high research densities, the blue areas are medium densities, and the green and yellow areas involve more relevant but relatively minor research directions. This density visualization helps to identify core research areas as well as potential cross-research trends. Overall, this density map reveals a multidimensional research landscape of robotics in logistics automation. Path planning, robot navigation, and obstacle avoidance technologies are the core research areas, while logistics system optimization, warehouse management, and order picking are closely related and important directions [40]. Future research trends are likely to continue to optimize the intelligent warehouse system in depth while combining AI, machine learning, and data analysis technologies to enhance the intelligence of logistics automation. A comparative study of 4.2 and 4.3 reveals that the results of "robot" and "warehouse" are richer, so it can be judged that "robot" and "warehouse" are more efficient. Therefore, it can be judged that "robot" and "warehouse" are more reasonable as research objects and research results.

## V. Conclusion

The visual analysis of related literature in this paper systematically combs the research hotspots and knowledge structure in the field of intelligent warehousing and robot co-scheduling. The results show that robot path planning and navigation, storage system optimization, and order picking are the core directions of current research, while there is still a large gap in the research of algorithm design and emerging technologies. Through keyword co-occurrence, cluster analysis, and density analysis, this paper identifies four core clusters, revealing the current research status and future trends in the field. The research in this paper provides a theoretical basis for the cooperative scheduling optimization of multiple robots in intelligent warehousing, which is of great significance in promoting the further development of warehouse automation technology.

There are still deficiencies in this paper. First, this paper is mainly based on the WOS database, which may miss some regional research results; second, the keyword co-occurrence analysis is difficult to capture the technical details, which needs to be combined with manual literature intensive reading for additional verification. Future research can further expand data sources and combine multiple databases (e.g., Scopus, CNKI) for cross-validation. In addition, the research directions proposed in this paper (e.g., dynamic environment adaptation enhancement, multi-objective optimization framework construction) need to be further verified through experiments and case studies. Future research can also explore emerging directions such as human-robot collaboration mechanisms and robot reliability enhancement under extreme working conditions to support the comprehensive implementation of intelligent warehousing technology.

# A Cross-Chain Mechanism Based on Hierarchically Managed Notary Group

Hongliang Tian, Zhiyang Ruan, Zhong Fan
School of Electrical Engineering, Northeast Electric Power University, Jilin 132012, China

***Abstract*—Blockchain technology, characterized by decentralization, immutability, traceability, and transparency, provides innovative solutions for data management. However, the limited cross-chain interoperability between blockchains hampers their broader application and development. To address this challenge, this paper proposes a Cross-Chain Mechanism Based on Hierarchically Managed Notary Group, abbreviated as HMNG-CCM, which enables secure and efficient cross-chain transactions between blockchains. To mitigate the centralization issue inherent in traditional cross-chain mechanism based on notary, an innovative notary group management approach is introduced. This approach implements hierarchical management by categorizing notaries into three levels—junior notary, intermediate notary, and senior notary—thereby effectively mitigating the centralization problem. Additionally, a functional division mechanism for notary is designed, wherein the roles of transaction processing and verification within the cross-chain transaction process are separated to enhance system reliability. Furthermore, to tackle the complexity of notary reputation evaluation, a reputation assessment scheme based on an improved PageRank algorithm is proposed. Differentiated reputation evaluation strategies are developed for junior and intermediate notaries to ensure fairness and rationality in the assessment process. The effectiveness of this scheme is validated through experiments conducted on the Hyperledger Fabric platform. The experimental results demonstrate that the proposed mechanism exhibits strong robustness against malicious notaries while significantly improving transaction speed and success rate. This study offers new theoretical and practical foundations for the optimization and advancement of blockchain cross-chain technology.**

***Keywords*—Blockchain; cross-chain; notary group; hierarchical management; reputation evaluation***

## I. Introduction

Blockchain technology integrates multiple techniques, including hash algorithms, digital signatures, and consensus mechanisms, exhibiting characteristics such as decentralization, immutability, traceability, and transparency [1]. Since Satoshi Nakamoto proposed Bitcoin [2], the significance of blockchain technology has extended beyond the realm of cryptographic digital currencies. Ethereum [3], through the implementation of smart contracts, has extended blockchain technology to domains such as financial services [4], healthcare systems [5], and the Internet of Things [6], offering innovative solutions for data management. However, as application scenarios continue to expand, the isolation among blockchain systems has become increasingly prominent [7]. This isolation constrains the performance and security of blockchains and impedes their application in complex business scenarios. Currently, the blockchain ecosystem exhibits characteristics of diversity and fragmentation, with most blockchain systems remaining independent information silos [8]. For instance, systems such as Bitcoin, Ethereum, and Hyperledger Fabric [9], due to their adoption of distinct protocol standards, consensus mechanisms, and technical architectures. This independence hinders cross-chain data exchange and value transfer [10]. These barriers have been overcome by the emergence of cross-chain technology [11], which facilitates the cross-chain interaction of data and assets. This technology establishes an interconnected blockchain network ecosystem and lays the foundation for the further development of blockchain technology.

Existing cross-chain technologies encompass Notary Schemes [12], Relays [13], Hash-locking [14], and Distributed Private Key Control [15]. Among these, the Notary Schemes simplifies transactions processes between blockchains by introducing third-party notary nodes, offering advantages such as ease of implementation and high flexibility, which have led to its widespread adoption across various cross-chain scenarios. However, this mechanism's excessive reliance on a single notary node introduces the risk of single point of failure and significantly increases the system's centralization, thereby undermining the security and reliability of blockchain systems. Consequently, existing notary mechanisms commonly face challenges, including high centralization, insufficient generality in reputation evaluation schemes, and low efficiency in cross-chain transactions. To address these challenges, this paper proposes a Cross-Chain Mechanism Based on Hierarchically Managed Notary Group (HMNG-CCM), aimed at achieving secure and efficient cross-chain transactions between blockchains.

The contributions of this paper are as follows:

*1)* This paper proposes an innovative notary management scheme. The scheme implements hierarchical management by dividing the notary group into three categories: junior notaries, intermediate notaries, and senior notaries. This mechanism reduces the degree of system centralization, effectively distributing the trust risks associated with notaries in cross-chain transactions.

*2)* This paper designs a notary functional division mechanism. This mechanism explicitly separates the functions of transaction execution and verification within the cross-chain transaction process, assigning specific task responsibilities to different levels of notaries. Specifically, junior and intermediate notaries are tasked with transaction execution,

while senior notaries focus on transaction verification. This functional division mechanism not only optimizes the transaction process but also enhances the robust-ness of the cross-chain system.

*3)* This paper proposes a reputation assessment scheme based on an improved PageRank algorithm for ranking notaries. Addressing the distinct roles undertaken by notaries of varying levels in cross-chain transactions, differentiated reputation evaluation strategies are developed for junior and intermediate notaries to ensure fairness and rationality in the reputation assessment process. Through this algorithm, the system can dynamically adjust the reputation rankings of notaries, effectively enhancing the trustworthiness and security of the cross-chain transaction system.

The remainder of this paper is structured as follows. Section II discusses recently proposed cross-chain interoperability schemes. Section III provides a detailed description of the scheme proposed in this paper. Section IV compares the performance of the scheme proposed in this paper with that of other schemes and provides its security analysis. Finally, Section V concludes this paper.

## II. Related Works

In recent years, based on the four commonly recognized cross-chain technologies, various cross-chain transaction schemes [16], have been successively proposed. Enhancing cross-chain technology requires addressing multiple challenges, including system reliability [17], scalability [18], performance [19], and security [20].

Hou et al. [21] and Wang et al. [22], employed relay chains as communication bridges to enable cross-chain transactions, reducing the integration costs of heterogeneous blockchains and improving the performance of cross-chain systems; however, the protection of cross-chain data still offers room for optimization. Wu et al. [23], introduced an encryption scheme based on smart contracts, establishing constrained relationships between relay chains and other blockchains to enhance system security and privacy protection. Furthermore, Wang et al. [24], enhanced the scalability of relay chain-based cross-chain systems through sharding operations applied to the relay chain. Nevertheless, the application of existing relay chain technologies in cross-chain transactions continues to face challenges, including implementation complexities, suboptimal performance, and inadequate system stability [25].

Li et al. [26], integrated Hash Time-Locked Contract (HTLC) with a virtual account verification mechanism, thereby improving the success rate of cross-chain transactions. Wang et al. [27], incorporated a dynamic premium adjustment mechanism and a credit mechanism into HTLC, proposing a Hash Time Lock with Dynamic Premium Based on Credit in Cross-Chain Transaction to address issues of transaction default and reduced efficiency in cross-chain transactions. Yu et al. [28], applied an optimized HTLC to a Multi-Agent System, enhancing security and transparency. However, when handling complex, high-value transactions, HTLC continues to exhibit significant limitations in scalability and transaction efficiency [29].

Yu et al. [30], proposed a key management scheme based on distributed identity, mitigating the pervasive issue of trust centralization in cross-chain transactions. Zhao et al. [31], further leveraged distributed private key technology to eliminate reliance on trusted nodes, thereby safeguarding the interests of participants in secret-sharing protocols and avoiding the risk of single-point failures. Ren et al. [32], integrated distributed keys with a Proof of Trust Contribution consensus algorithm and a non-interactive zero-knowledge proof protocol, enhancing both the efficiency of key generation and the security of key management. However, as the number of nodes increases, distributed private key control technology faces the challenge of balancing computational efficiency with system security.

Compared to the other three cross-chain schemes, the notary mechanism offers advantages such as low implementation cost, rapid transaction processing speed, and support for cross-chain transactions across multiple blockchains, proving particularly efficient in trusted environments. The Interledger Protocol [33], proposed by Ripple Labs, focuses on enabling cross-chain payments through a universal framework and serves as a quintessential example of the notary mechanism. However, its conflict with the core decentralized ethos of blockchain technology raises significant security concerns. Xiong et al. [34], introduced a notary committee comprising multiple notaries, selecting notaries based on reputation to handle cross-chain transactions, thereby eliminating dependence on a single notary and enhancing the system's resilience against malicious notaries. Nevertheless, the comprehensiveness of notary reputation assessment remains inadequate. To address this issue, Chen et al. [35], proposed a dynamic reputation management scheme based on the past transaction behavior of nodes. This scheme designs reputation evaluation metrics by analyzing prevalent security threats and incorporates a Particle Swarm Optimization algorithm to dynamically adjust metric weights, enabling adaptation to varying frequencies of malicious behavior. However, as it considers only common blockchain security threats, the scheme exhibits limitations in specific cross-chain scenarios.

Addressing the strengths and weaknesses of existing cross-chain schemes, this paper proposes the HMNG-CCM. This mechanism categorizes the notary group into three levels—junior notaries, intermediate notaries, and senior notaries—based on reputation, aiming to optimize the notary election process and reduce the system's centralization. Concurrently, it designates that only intermediate and junior notaries are responsible for transaction execution, while senior notaries are exclusively tasked with transaction verification, further refining the cross-chain transaction process. Additionally, differentiated reputation evaluation strategies are established for junior and intermediate notaries, and an improved PageRank algorithm is introduced to dynamically adjust the reputation of notary nodes, ensuring the fairness and rationality of the assessment.

## III. Proposed Scheme

In this section, the architecture and operational principles of the HMNG-CCM are elaborated in detail. Through a

comprehensive cross-chain protocol (preparation phase, transaction phase, and confirmation phase), this study designs and implements a cross-chain model based on notary group, an improved PageRank algorithm, a hierarchical management scheme of the notary group, and a hierarchical notary election process.

### A. Cross-Chain Model Based on Notary Group

The cross-chain model based on a hierarchically managed notary group proposed in this paper ensures the security of cross-chain interoperability by introducing a notary group and subjecting it to hierarchical management. As illustrated in Fig. 1, the system comprises three key components: the notary group, the source chain, and the target chain.

*1) Notary group:* This component consists of multiple nodes, each possessing at least one account on both the source chain and the target chain. During the initialization of the notary group, the system leverages smart contracts to create two margin pool accounts—one on the source chain and one on the target chain—and generates a set of notary nodes. The reputation of each node is calculated using an improved PageRank algorithm, and based on these reputation rankings, nodes are classified into junior notaries, intermediate notaries, and senior notaries, thereby establishing and maintaining the management framework of the notary group.

*2) Source chain:* This component refers to the blockchain where the sender of a cross-chain transaction resides. During the cross-chain transaction process, the primary participants on the source chain include the sender node, notary nodes, and the margin pool account maintained by the notary group on the source chain.

*3) Target chain:* This component refers to the blockchain where the receiver of a cross-chain transaction resides. During the cross-chain transaction process, the primary participants on the target chain include the receiver node, notary nodes, and the margin pool account maintained by the notary group on the target chain.

### B. Reputation Evaluation Scheme Based on an Improved PageRank Algorithm

The PageRank algorithm is a link analysis-based webpage ranking method designed to evaluate the relative importance of webpages within a hyperlinked network. Its fundamental expression is given as follows:

$$PR(A) = \frac{1-d}{N} + d \cdot \sum_{i \in M(A)} \frac{PR(j)}{L(j)} \quad (1)$$

In Eq. (1), $PR(A)$ represents the PageRank value of webpage $A$, $M(A)$ represents the set of webpages linking to webpage $A$, $L(j)$ indicates the number of outbound links from webpage $j$, $N$ signifies the total number of webpages, and $d$ is the damping factor, which models the random navigation behavior of users between webpages. This algorithm iteratively computes values until convergence, yielding the importance ranking of each webpage.

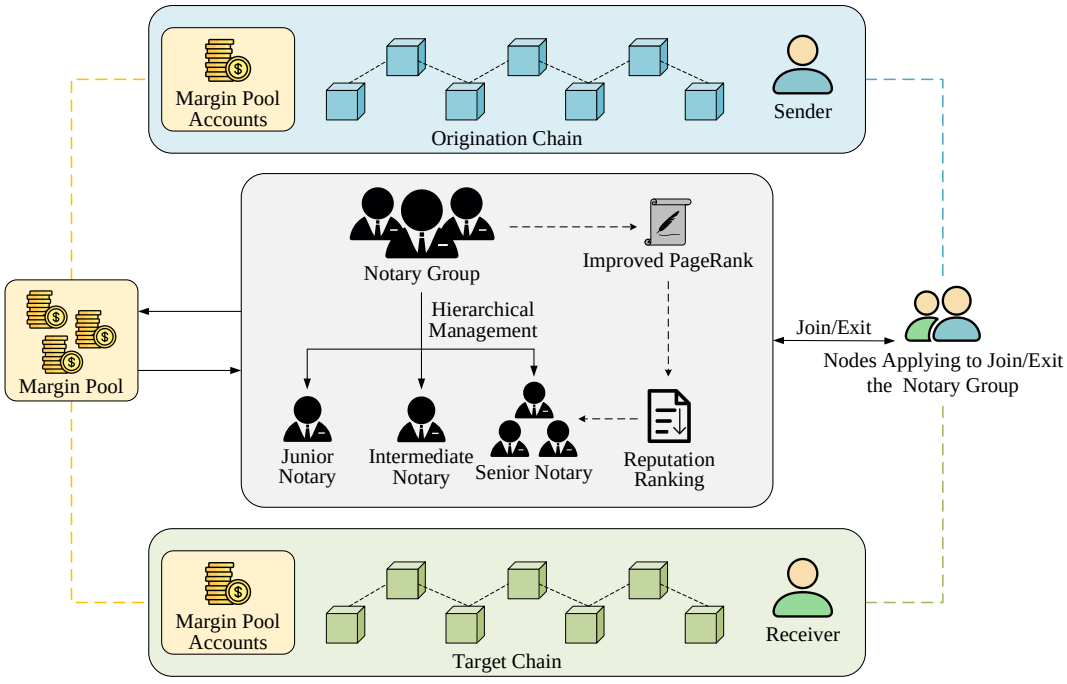

Fig. 1. Cross-chain model based on notary group.

Intermediate notaries primarily assess the comprehensive reputation of their nodes by incorporating the historical transaction success rate, transaction processing efficiency, and margin of the nodes. Table I presents the attributes of each parameter for intermediate notaries.

TABLE I. LIST OF INTERMEDIATE NOTARY PARAMETER ATTRIBUTES

| Reputation Metrics | Parameter Name | Weight |
|---|---|---|
| Trust Relationships | *PR(j)/L(j)* | 0.5 |
| Historical Transaction Success Rate | *HTSR* | 0.2 |
| Transaction Processing Efficiency | *TPE* | 0.2 |
| Margin | *M* | 0.1 |

Two assumptions are presented here:

*1) Quantity assumption:* It is assumed that a notary node exists, and if a substantial number of other notary nodes establish trust relationships with it, this indicates that the notary node possesses a high reputation.

*2) Quality assumption:* It is assumed that a notary node exists, and if another notary node with a high reputation establishes a trust relationship with it, the former notary node will be conferred a correspondingly high reputation.

$PR(j)/L(j)$ reflects the degree of trust that other nodes place in the given notary node. If a trust relationship exists between two nodes, they can mutually transfer reputation. Based on Quantity Assumption and Quality Assumption, it follows that the more trust relationships a notary node possesses, the greater the reputation transferred to it, resulting in a higher reputation for that node. $PR(j)/L(j)$ is a critical factor in the proposed reputation assessment scheme and is therefore assigned a weight of 0.5 as a foundational parameter.

$HTSR$ is utilized to measure the proportion of transactions successfully completed by a notary node among those in which it participates, thereby reflecting the node's transaction success rate. Consequently, $HTSR$ is assigned a weight of 0.2.

$$HTSR = \frac{Success - Fail}{Success + Fail + \varphi} \tag{2}$$

In Eq. (2), *Success* represents the number of successful transactions among those in which the notary node participates, $Fail$ denotes the number of failed transactions, and $\varphi$ is a very small constant.

$TPE$ is primarily employed to evaluate the transaction processing capability of a notary node. A shorter transaction time indicates greater efficiency of the node in processing transactions. Its weight is set at 0.2.

$$TPE = \frac{1}{n}\sum_{k=1}^{n}\frac{1}{t_k} \tag{3}$$

In Eq. (3), $t_k$ represents the time cost for the notary node to successfully complete the $k$-th transaction, while $n$ denotes the total number of transactions that the notary node has successfully completed.

The margin parameter $M$ reflects the amount of the deposit paid by a notary node upon joining the notary group. A higher margin corresponds to greater losses for the node in the event of malicious behavior. The weight of $M$ is set at 0.1.

$$M(i) = \frac{M_i - M_{\min}}{M_{\max} - M_{\min}} \tag{4}$$

In Eq. (4), $M_{\max}$ represents the maximum margin amount among all current nodes, $M_{\min}$ denotes the minimum margin amount, and $M(i)$ signifies the normalized result of the margin amount paid by node $i$.

The improved PageRank algorithm is presented in Eq. (5):

$$PR(i) = \frac{1-d}{N} + d \cdot [0.5 \sum_{j \in M(i)} \frac{PR(j)}{L(j)} + 0.2HTSR(i) + 0.2TPE(i) + 0.1M(i)] \tag{5}$$

In Eq. (5), $PR(i)$ represents the reputation of node $i$, $N$ denotes the total number of notary nodes, and $d$ is the damping factor, set at 0.85. $PR(j)$ indicates the reputation of node $j$, while $L(j)$ signifies the number of nodes evaluated by node $j$.

The reputation evaluation strategy for junior notaries incorporates not only the node's historical transaction success rate, transaction processing efficiency, and margin, but also the time a node waits to become a transaction notary. Table II lists the attributes of each parameter for junior notaries.

TABLE II. LIST OF JUNIOR NOTARY PARAMETER ATTRIBUTES

| Reputation Metrics | Parameter Name | Weight |
|---|---|---|
| Trust Relationships | *PR(j)/L(j)* | 0.4 |
| Historical Transaction Success Rate | *HTSR* | 0.2 |
| Transaction Processing Efficiency | *TPE* | 0.2 |
| Margin | *M* | 0.1 |
| Waiting Time | *T* | 0.1 |

Similarly, in calculating the reputation of junior notaries, the weight of $PR(j)/L(j)$ is set to 0.4, the weight of $HTSR$ is set to 0.2, the weight of $TPE$ is set to 0.2, and the weight of $M$ is set to 0.1. Additionally, the parameter $T$, representing the waiting time, is introduced in the reputation calculation for junior notaries, with its weight set to 0.1.

The parameter $T$ is employed to measure the waiting time of a notary node before it becomes a transaction notary. For junior notaries, the opportunities to be selected as transaction notaries and participate in transactions are limited, resulting in longer waiting times. The introduction of parameter $T$ provides junior notaries, who have been part of the notary group for an extended period but lack transaction participation

opportunities, with a prioritized opportunity to advance to intermediate notaries. Simultaneously, it increases the time cost for newly joined malicious nodes within the notary group, reducing the likelihood of such nodes being elected as transaction notaries, thereby enhancing the security of cross-chain operations.

$$T(i)=\frac{T_i - T_{\min}}{T_{\max} - T_{\min}} \tag{6}$$

In Eq. (6), $T_{\max}$ represents the maximum waiting time among all current nodes to become a transaction notary, $T_{\min}$ denotes the minimum waiting time, and $T(i)$ signifies the normalized result of the waiting time for node $i$.

The improved PageRank algorithm is presented in Eq. (7):

$$PR(i)=\frac{1-d}{N}+d\cdot[0.4\sum_{j\in M(i)}\frac{PR(j)}{L(j)} +0.2HTSR(i)+0.2TPE(i)+0.1M(i)+0.1T(i)] \tag{7}$$

In Eq. (7), $PR(i)$ represents the reputation of node $i$, $N$ denotes the total number of notary nodes, and $d$ is the damping factor, set at 0.85. $PR(j)$ indicates the reputation of node $j$, while $L(j)$ signifies the number of nodes evaluated by node $j$.

### C. Hierarchical Management Scheme of the Notary Group

The notary group, based on reputation rankings, employs a normal distribution to classify notary nodes into three levels, as illustrated in Fig. 2: junior notaries, intermediate notaries, and senior notaries.

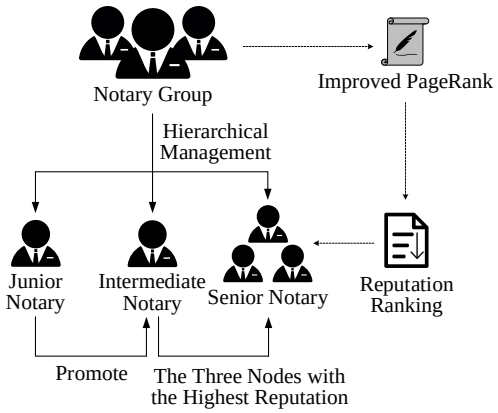

Fig. 2. Hierarchical management scheme of the notary group.

Based on a normal distribution, notary nodes with a reputation less than -1σ are designated as junior notaries, representing the bottom 16% of the notary group in terms of reputation ranking. Notary nodes with a reputation greater than -1σ are classified as intermediate notaries, encompassing the top 84% of the notary group by reputation ranking. Senior notaries are selected as the three nodes with the highest reputation from among the intermediate notaries, corresponding to the three highest-ranked notaries in the entire notary group.

Within the notary group, transaction notaries are preferentially elected from intermediate notaries based on their reputation. Only when no intermediate notary meets the transaction requirements is the same method applied to elect from junior notaries. The promotion of a junior notary to an intermediate notary is contingent upon its reputation. The reputation calculation for junior notaries differs from that of intermediate notaries, notably incorporating the waiting time to become a transaction notary as a significant factor in the evaluation. By appropriately assigning weights, junior notaries with longer waiting times and otherwise favorable attributes achieve higher reputation scores, thereby gaining priority for promotion to intermediate notaries and increasing their opportunities to participate in transactions. The verification of cross-chain transactions is exclusively handled by senior notaries, specifically the three nodes with the highest reputation in the entire notary group, who collectively perform validation through multi-signature processes. Funds are released only after at least two senior notaries have completed their signatures.

### D. Hierarchical Notary Election

The hierarchical notary election process is depicted in Fig. 3.

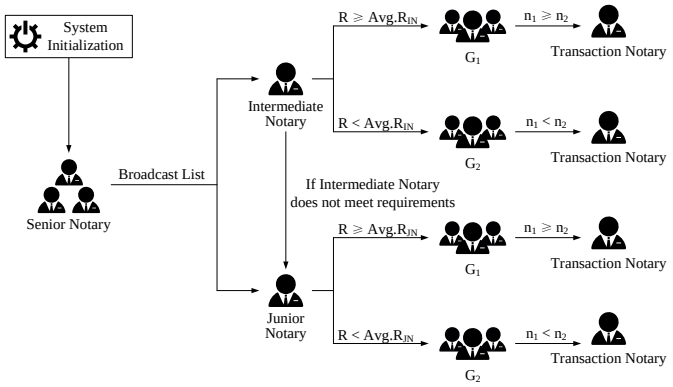

Fig. 3. Hierarchical notary election.

Initially, during the notary initialization phase, the system categorizes each notary into junior notaries, intermediate notaries, and senior notaries based on their reputation. In the preparation stage of a cross-chain transaction, senior notaries broadcast the transaction list within the notary group, detailing the key attributes of the transactions. Each notary then determines whether to participate in the notary election based on the transaction details. Subsequently, the system calculates the average reputation of the intermediate notaries and, based on this mean value, divides them into two groups: $G_1$, consisting of notaries with a reputation greater than or equal to the average, and $G_2$, comprising notaries with a reputation below the average. The number of notaries in $G_1$ is denoted as $n_1$, and in $G_2$ as $n_2$. If $n_1 \geq n_2$, a notary meeting the transaction requirements is elected from $G_1$ as the transaction notary; otherwise, the same method is applied to elect a

transaction notary from $G_2$. Should no intermediate notary fulfill the transaction requirements, the system employs the same approach to conduct the election among junior notaries. The specific procedure is outlined in Algorithm 1.

**Algorithm 1:** Notary Election

**Input:** $List_{TRA}$, $Tab_R$, $IN$, $JN$

**Output:** $TN$

```
function ELECTION( List_TRA , Tab_R , IN , JN )
  Broadcast( List_TRA )
  R ← DeleteZeroReputationNotary( Tab_R )
  TN ← Elect( IN )
  Avg.R ← Average( R )
  G_1 ← GetIN( R ≥ Avg.R ), n_1 = Count( G_1 )
  G_2 ← GetIN( R < Avg.R ), n_2 = Count( G_2 )
  if n_1 ≥ n_2 then
    TN ← Random( G_1 )
  else if n_1 < n_2 then
    TN ← Random( G_2 )
  else if TN ← Null( IN ) then
    return Elect( JN )
  end if
  return TN
end function
```

## IV. Performance Analysis

The simulation experimental environment for this scheme is executed on a laptop equipped with the Windows 11 operating system, featuring hardware specifications that include a 13th-generation Intel(R) Core(TM) i5-13500H 2.60 GHz processor and 16 GB RAM. The blockchain system is constructed within a virtual machine running Ubuntu 24.04 Desktop Edition, configured with a 4-core processor and 8 GB RAM. The blockchain system utilized in the experiments is based on Hyperledger Fabric 2.4, comprising two independent blockchains with identical configurations.

### A. Election Performance of the Improved PageRank Algorithm

This experiment constructs a notary group comprising 50 nodes. During initialization, each node is assigned a uniform initial reputation of 0.02 and numbered from 1 to 50. Nodes numbered 1 to 3 are preconfigured with a higher density of trust relationships and are designated as senior notary nodes in the HMNG-CCM framework; nodes numbered 4 to 42 are configured with baseline trust relationships and defined as intermediate notary nodes; and newly added nodes numbered 43 to 50, lacking pre-established trust relationships, are classified as junior notary nodes. Throughout the iteration process, the establishment of trust relationships is determined by the current reputation of each node, with the probability of a node gaining new trust relationships being positively correlated with its current reputation. The iteration concludes when the reputation of each node stabilizes, with the resulting reputation values for each node presented in Fig. 4.

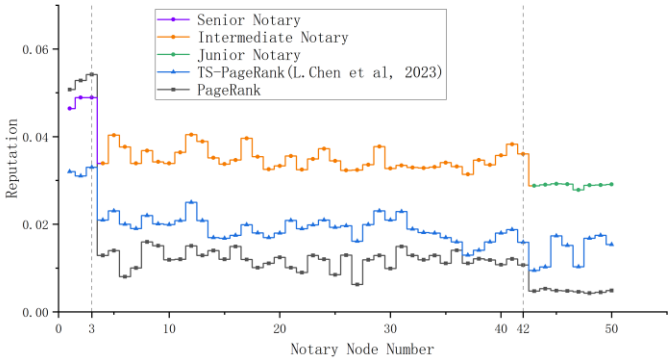

Fig. 4. Results of the PageRank, TS-PageRank, and HMNG-PageRank.

The original PageRank algorithm, due to its excessive reliance on trust relationships, results in nodes numbered 1 to 3 (mean: 0.052) exhibiting significantly higher reputation scores than nodes numbered 4 to 42 (mean: 0.012) and nodes numbered 43 to 50 (mean: 0.0048). This approach overlooks the complexity of notary reputation evaluation in cross-chain transactions, leading to a one-sided assessment of reputation. In contrast, the TS-PageRank [36] algorithm, when computing the reputation of notary nodes, incorporates parameters that may influence node reputation in cross-chain transactions, partially mitigating the short-comings of the original PageRank algorithm. However, it demonstrates insufficient differentiation between nodes numbered 4 to 42 and those numbered 43 to 50, which may result in the erroneous election of newly joined malicious nodes as transaction notaries during the notary selection process, consequently reducing system security.

HMNG-CCM designs differentiated reputation evaluation strategies for junior and intermediate notaries. Consequently, the reputation of senior, intermediate, and junior notaries, computed via the improved HMNG-PageRank algorithm, exhibits a discernible level of differentiation while achieving a smooth transition from senior to junior levels. This approach avoids the steep drop-off observed in the original PageRank algorithm and the flat distribution of the TS-PageRank algorithm, ensuring a comprehensive reputation assessment. Furthermore, the differentiated evaluation strategy demonstrates a high degree of adaptability to the hierarchical requirements of notary elections, whereas the original PageRank and TS-PageRank algorithms, lacking similar designs, exhibit limitations under complex trust relationship scenarios.

In summary, the HMNG-PageRank algorithm excels in reputation evaluation within the notary group. Compared to the original PageRank and TS-PageRank, this scheme offers superior reliability and security, providing robust support for the hierarchical notary election mechanism.

### B. Comparison of Notary System Time Cost and Cross-Chain Transaction Time

This experiment analyzes the time cost of each phase in cross-chain transactions, testing the average time costs of the

preparation phase, transaction phase, confirmation phase, and notary system under scenarios involving the simultaneous initiation of 20, 40, 60, 80, 100, and 120 transactions. The experimental results are presented in Fig. 5. The preparation phase accounts for approximately 37.1% of the total time cost in the cross-chain transaction process, the transaction phase constitutes about 47.5%, and the confirmation phase comprises roughly 15.4%. The time cost of the notary system, which forms a subset of the preparation phase, represents approximately 4.5% of the total time cost. The proportion of time attributed to the notary system is significantly lower than that of the entire cross-chain transaction process, indicating that the additional time overhead introduced by the notary management scheme is negligible. Furthermore, as the number of transactions increases from 20 to 120, the average cross-chain transaction time rises by only 4.6%, demonstrating the efficiency of HMNG-CCM in resource allocation and its adaptability to varying transaction scales.

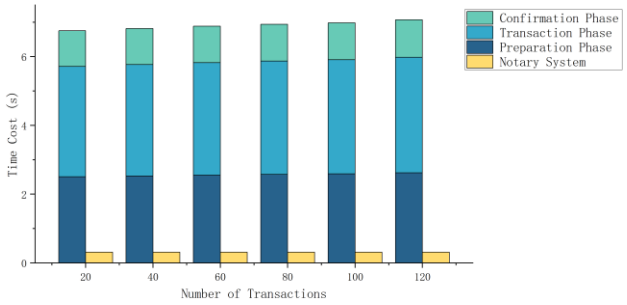

Fig. 5. Notary system time cost and cross-chain transaction time.

### C. Impact of Malicious Nodes on Cross-Chain Transaction Time

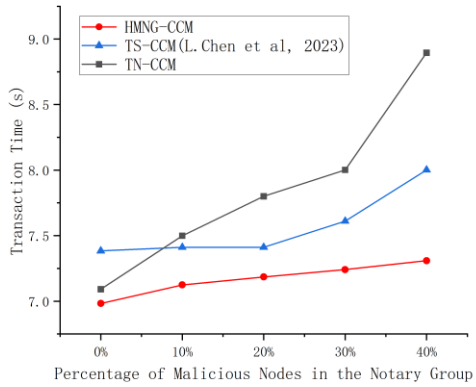

Fig. 6. Transaction time under different percentages of malicious nodes.

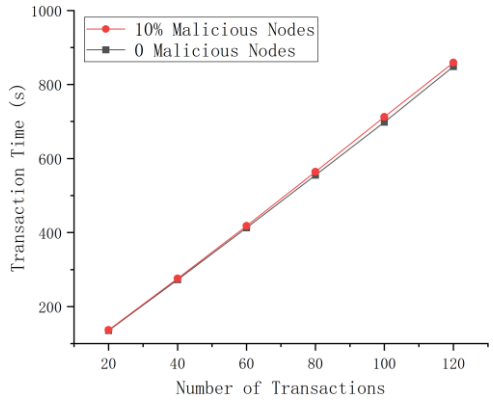
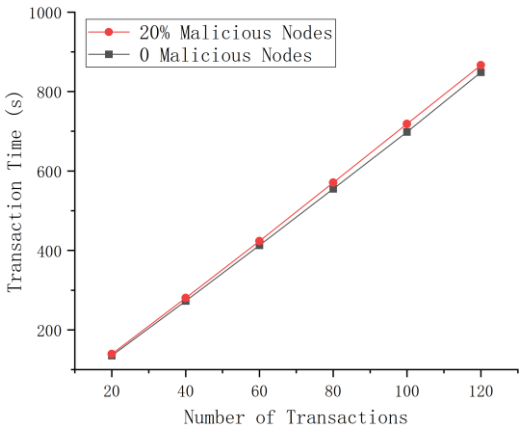
This experiment initiates 100 transaction requests to evaluate cross-chain transaction times when the notary group contains 0, 10%, 20%, 30%, and 40% malicious nodes. The experimental results are presented in Fig. 6. The Traditional Notary Cross-Chain Mechanism (TN-CCM) exhibits low tolerance to malicious nodes. As the proportion of malicious nodes increases, the cross-chain transaction time consistently rises. Notably, when the proportion of malicious nodes exceeds 30%, the transaction time surges to 8.9 seconds, representing a time cost increase of approximately 25.4%, which indicates a marked degradation in system performance.

The Three-Stage Cross-Chain Mechanism (TS-CCM) [36], operates normally when the proportion of malicious nodes remains below 20%, with transaction times stabilized at approximately 7.4 seconds. However, when the proportion of malicious nodes exceeds 20%, transaction time increase sharply to 8 seconds, resulting in an approximate time cost rise of 8.4%, with further escalation as the proportion of malicious nodes continues to grow. This indicates that TS-CCM experiences significant impacts on its performance and stability when confronted with higher proportions of malicious nodes.

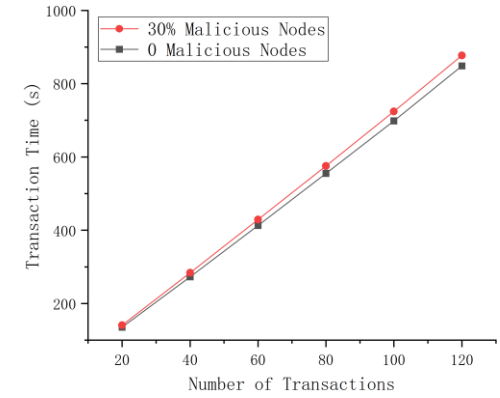
Throughout the range of 0% to 40% malicious nodes, HMNG-CCM consistently demonstrates lower cross-chain transaction times compared to TN-CCM and TS-CCM. Moreover, as the proportion of malicious nodes increases, the growth in transaction time for HMNG-CCM remains relatively minor. Specifically, when the proportion of malicious nodes reaches 40%, the transaction time increases by only 4.67%, demonstrating its robustness and resistance to malicious behavior. In summary, the experimental results comprehensively validate that HMNG-CCM not only maintains high efficiency when the proportion of malicious nodes is low, but also sustains stable system performance under scenarios with a high proportion of malicious nodes. This reflects the significant engineering value of HMNG-CCM in enhancing the efficiency and reliability of cross-chain transactions.



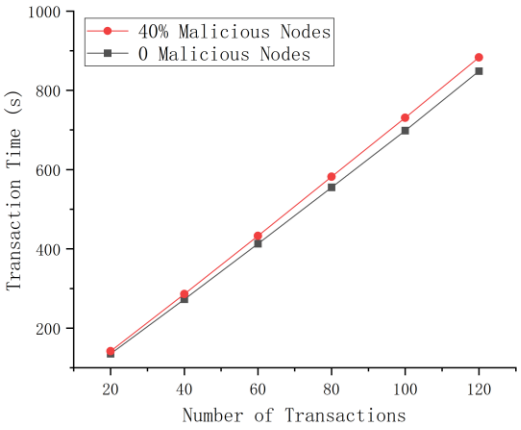
(a) 10% Malicious Nodes



(b) 20% Malicious Nodes



(c) 30% Malicious Nodes



(d) 40% Malicious Nodes

Fig. 7. Impact of different percentages of malicious nodes on transaction time under different numbers of transactions.

This experiment evaluates the performance of HMNG-CCM in counteracting malicious notary nodes during cross-chain transactions. The experiment simulates five scenarios with malicious notary proportions of 0% (control group), 10%, 20%, 30%, and 40%. For each scenario, 20, 40, 60, 80, 100, and 120 transactions are processed, analyzing the impact of both transaction volume and malicious notary proportion on transaction time. The experimental results are presented in Fig. 7. In the absence of malicious nodes (0%), cross-chain transaction times are the shortest, exhibiting linear growth with increasing transaction volume. As the proportion of malicious nodes rises from 10% to 40%, transaction time increases slightly compared to the 0% malicious notary scenario, as evidenced by the gradually widening vertical distance between the corresponding line segments and the 0% malicious notary baseline in the figure. Nevertheless, even when the malicious notary proportion reaches 40%, transaction times remain closely aligned with those in the 0% scenario. This demonstrates that HMNG-CCM sustains robust performance even under high proportions of malicious nodes. Furthermore, regardless of the increase in transaction volume, the influence of varying malicious notary proportions on transaction time remains limited, highlighting the efficiency and robustness of HMNG-CCM in mitigating interference from malicious nodes.

### D. Impact of Malicious Nodes on Transaction Success Rate

This experiment initiates 100 transaction requests to assess the cross-chain transaction success rate under scenarios where the notary group contains malicious nodes at proportions of 10%, 20%, 30%, and 40%. The experimental results are presented in Fig. 8. TN-CCM exhibits low tolerance to malicious behavior; as the proportion of malicious nodes increases, the transaction success rate declines linearly from 100% to 60%. This indicates that TN-CCM struggles to maintain normal system operation effectively when the proportion of malicious nodes is high. TS-CCM [36], performs stably when the malicious notary proportion is below 30%, maintaining a transaction success rate of 98%. However, when the proportion exceeds 30%, the success rate drops sharply to 88%, highlighting its limited resilience against malicious behavior in high-risk scenarios.

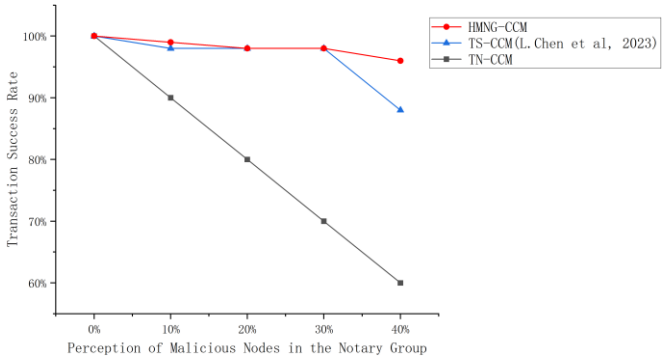


Fig. 8. Transaction success rate under different percentages of malicious nodes.

In contrast, HMNG-CCM achieves a transaction success rate of 99% when the malicious notary proportion is below 20%, slightly outperforming TS-CCM. Between 20% and 30%, the success rate remains stable at 98%. Even when the malicious notary proportion reaches 40%, HMNG-CCM sustains a success rate of 96%, with a mere 4% decline, markedly surpassing both TN-CCM and TS-CCM. These results demonstrate that HMNG-CCM effectively ensures transaction success rates in scenarios with high proportions of malicious nodes, reflecting superior system reliability and robustness under complex scenarios.

### E. Security Analysis

The notary-based cross-chain transaction system may encounter threats such as malicious notary attacks, single points of failure, and reputation manipulation. The HMNG-CCM proposed in this paper effectively addresses these potential threats and ensures system robustness and reliability through an innovative hierarchical notary management scheme, a functional division mechanism, and a reputation evaluation mechanism based on an improved PageRank algorithm.

The core of HMNG-CCM lies in mitigating trust risks and enhancing system stability through hierarchical management and functional division. Notaries are classified into three tiers—junior, intermediate, and senior. Nodes newly joining the notary group must stake a margin deposit and undergo

verification by senior notaries to become junior notaries, while senior notaries are designated as the nodes with the highest reputation. This hierarchical structure circumvents the centralization risks inherent in traditional notary mechanisms due to reliance on a single notary. The synergy between functional division and hierarchical management enhances the system's decentralization. Transaction execution and verification duties are distinctly separated: junior and intermediate notaries handle the execution of cross-chain transactions, whereas senior notaries focus on verifying the legality and consistency of transactions. This division further diminishes the influence of any single notary on the system, while enabling the timely detection and correction of malicious behavior through multiple checks. Consequently, the system maintains normal operation even in the presence of partial node failures or attacks.

The reputation evaluation employs an improved PageRank algorithm, generating reputation rankings based on nodes' historical performance and trust relationships. Differentiated evaluation strategies are designed for junior and intermediate notaries to reflect their distinct role characteristics in transaction execution. Periodically updated reputation rankings effectively identify and isolate malicious nodes, ensuring that only those with a high reputation participate in critical tasks. This dynamic adjustment capability not only prevents reputation manipulation but also provides a fair basis for notary election and promotion. When junior notaries are considered for promotion to intermediate notaries, both historical performance and waiting time are comprehensively evaluated, offering priority promotion opportunities to junior notary nodes that have been part of the notary group for an extended period yet lack election opportunities. Simultaneously, this approach increases the time cost for newly joined malicious nodes within the notary group, reducing the likelihood of their election as selected notaries and thereby further mitigating their impact on the system.

Based on the aforementioned design, this scheme ensures transaction security and smooth execution through a cross-chain protocol. During the preparation phase, the system selects transaction notaries from intermediate or junior notaries based on reputation. In the transaction phase, senior notaries verify transactions via multi-signature validation and authorize transaction notaries to release funds, a decentralized verification approach that effectively prevents single points of failure. Furthermore, the system incorporates timeout and retry mechanisms to bolster risk resilience and employs distributed storage technology in the confirmation phase to safeguard transaction data security. Collectively, these design elements establish a secure and reliable transaction process.

## V. Conclusion

The HMNG-CCM proposed in this paper provides a decentralized, efficient, and trustworthy solution for blockchain cross-chain transactions by introducing an innovative notary management scheme, a functional division mechanism, and a reliable reputation evaluation mechanism.

Firstly, a notary management scheme centered on hierarchical management and functional division effectively mitigates trust risks and optimizes transaction processes, thereby enhancing the decentralization characteristics of the cross-chain system. Secondly, a reputation evaluation scheme designed using an improved PageRank algorithm implements differentiated assessments based on notary levels, ensuring fairness and rationality in the evaluation process. Furthermore, experimental results conducted on the Hyperledger Fabric platform demonstrate that this mechanism effectively withstands malicious notary behavior while improving transaction speed and success rate, confirming its advantages in practical applications.

Although this study has achieved significant progress, several limitations warrant further attention. The experimental validation is primarily based on the Hyperledger Fabric platform, and the generalizability of the results requires additional verification across other blockchain platforms. The hierarchical management scheme may increase management complexity when the number of notaries is large. Furthermore, the effectiveness and stability of the reputation evaluation scheme under diverse scenarios necessitate further testing.

Based on the findings and limitations of this study, future research could explore adaptive dynamic management schemes for notary groups, incorporate machine learning techniques to develop more flexible reputation evaluation models, and design cross-chain protocols that support multi-chain environments to accommodate increasingly complex blockchain interaction scenarios.

In conclusion, this paper successfully establishes an efficient and secure cross-chain mechanism, offering robust technical support for the security and decentralization of blockchain cross-chain transactions. While certain limitations remain, this study provides directions for future related research, bearing significant theoretical importance and practical value.

# Comprehensive Vulnerability Analysis of Three-Factor Authentication Protocols in Internet of Things-Enabled Healthcare Systems

Haewon Byeon
Department of Future Technology, Korea University of Technology and Education (Korea Tech),
Cheonan 31253, South Korea

***Abstract*—This study evaluates a three-factor authentication protocol designed for IoT healthcare systems, identifying several key vulnerabilities that could compromise its security. The analysis reveals weaknesses in single-factor authentication, time synchronization, side-channel attacks, and replay attacks. To address these vulnerabilities, the study proposes a series of enhancements, including the implementation of multi-factor authentication (MFA) to strengthen user verification processes and the inclusion of timestamps or nonces in messages to prevent replay attacks. Additionally, the adoption of advanced cryptographic techniques, such as masking and shuffling, can mitigate side-channel attacks by minimizing information leakage during encryption. The use of message authentication codes (MACs) ensures communication integrity by verifying message authenticity. These improvements aim to fortify the protocol's security framework, ensuring the protection of sensitive medical data. Future research directions include exploring adaptive security policies leveraging artificial intelligence and optimizing cryptographic operations to enhance efficiency. These efforts are essential for maintaining the protocol's resilience against evolving threats and ensuring the secure operation of IoT-based healthcare systems.**

## I. Introduction

The advent of the Internet of Things (IoT) has revolutionized numerous sectors, with healthcare emerging as one of the most transformative fields. IoT-enabled healthcare systems, commonly referred to as the Internet of Medical Things (IoMT), leverage interconnected medical devices to facilitate real-time monitoring, data collection, and analysis [1]. These systems enhance patient care by enabling continuous health monitoring, remote diagnosis, and timely medical interventions. However, the integration of IoT in healthcare also introduces significant security challenges, particularly concerning the protection of sensitive patient data from unauthorized access and cyber threats [2].

In response to these challenges, robust authentication protocols are paramount to ensure that only authorized users and devices can access sensitive medical information. Traditional authentication methods, often based on single or dual factors, have proven inadequate in the face of sophisticated cyber-attacks [3]. Consequently, three-factor authentication protocols have gained prominence as a more secure alternative [4]. These protocols typically combine knowledge-based (e.g., passwords), possession-based (e.g., smart cards), and inherence-based (e.g., biometric data) factors to provide a comprehensive security framework [4].

Despite their enhanced security, three-factor authentication protocols in IoT healthcare systems must address several challenges. The resource-constrained nature of many IoT devices limits their ability to execute complex cryptographic operations, necessitating the development of efficient, lightweight protocols [5]. Additionally, the dynamic and distributed nature of IoT networks requires authentication systems to be adaptable, maintaining security even as devices frequently join and leave the network [6]. Furthermore, ensuring user privacy and compliance with stringent healthcare regulations, such as the Health Insurance Portability and Accountability Act (HIPAA) and the General Data Protection Regulation (GDPR), is critical [7].

This research aims to conduct a comprehensive analysis of an efficient three-factor authentication protocol designed for IoT healthcare systems [5]. The primary objective is to identify and scrutinize four key security vulnerabilities within the protocol that could compromise its effectiveness. By examining the protocol's architecture and operational phases, this study seeks to uncover potential weaknesses and propose strategies for enhancement.

The paper is structured as follows: Section II presents a literature review of existing authentication protocols and their limitations. Section III outlines the methodology employed for vulnerability detection, including the analytical methods and tools used for cryptanalysis and security testing. Section IV discusses the identified vulnerabilities in detail, and proposes improvements to enhance the protocol's security and efficiency. Finally, Section V concludes with a summary of the findings and their implications for IoT-based healthcare authentication systems.

## II. Literature Review

### A. Current Authentication Protocols

The integration of the Internet of Things (IoT) into healthcare has necessitated the development of robust authentication protocols to protect sensitive medical data. Three-factor authentication schemes have gained prominence in

this context due to their enhanced security capabilities (Fig. 1). These protocols typically combine knowledge-based (e.g., passwords), possession-based (e.g., smart cards), and inherence-based (e.g., biometric features) factors to create a layered security framework [8].

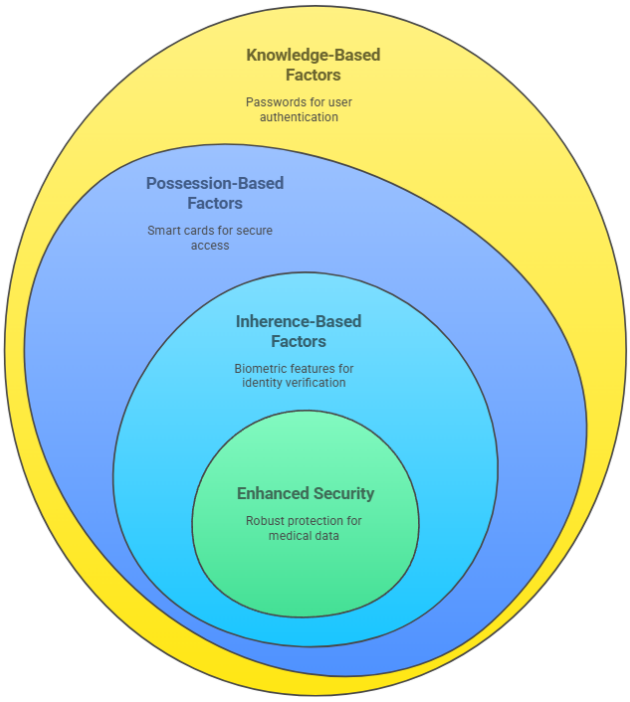

Fig. 1. Three-factor authentication in IoT healthcare security.

Despite their strengths, three-factor authentication protocols face significant challenges in IoT environments. The resource-constrained nature of many IoT devices limits their ability to execute complex cryptographic operations, necessitating the development of efficient, lightweight protocols [9]. Additionally, the dynamic and distributed nature of IoT networks requires authentication systems to be adaptable, maintaining security even as devices frequently join and leave the network [10].

Recent advancements in three-factor authentication protocols have focused on enhancing security while minimizing resource consumption. For instance, some protocols leverage elliptic curve cryptography (ECC) to provide strong security with reduced computational overhead [11]. Others incorporate advanced biometric recognition techniques, such as iris scanning, to enhance user authentication without physical contact, addressing both security and usability concerns [12].

### B. Related Works

The literature on IoT-based healthcare authentication systems reveals various vulnerabilities that necessitate ongoing research and innovation. One significant area of concern is the risk of sensor capture attacks, where adversaries gain physical access to devices and extract sensitive information. To mitigate this risk, some studies have proposed the integration of Physical Unclonable Functions (PUFs) as an additional authentication factor, providing a hardware-based layer of security resistance to cloning and physical attacks [13].

Another critical issue is the vulnerability of smart cards to theft and information extraction. While smart cards play a crucial role in safeguarding authentication schemes, their susceptibility to loss and unauthorized access poses a significant risk [14]. Research efforts have focused on developing secure storage and transmission mechanisms to protect the data stored on smart cards and ensure the integrity of the authentication process [15].

The literature also highlights the importance of privacy-preserving techniques in enhancing the security of IoT-based healthcare systems. Techniques such as zero-knowledge proofs and ring signatures have been proposed to protect user privacy while maintaining the transparency and auditability benefits of blockchain-based authentication [16].

In summary, the literature underscores the potential of three- factor authentication protocols to enhance security in IoT healthcare systems. However, addressing the identified vulnerabilities and challenges is crucial for realizing their full potential. Continued research and innovation in this field will play a vital role in securing the future of digital healthcare [17].

## III. Methodology

### A. Framework for Analysis

The methodology for analyzing the proposed three-factor authentication protocol for IoT in healthcare systems [5] involves a comprehensive framework designed to identify and evaluate potential security vulnerabilities. This framework integrates theoretical analysis, mathematical modeling, and practical testing to ensure a thorough security assessment.

### B. Analytical Methods for Vulnerability Detection

The analysis begins with a structured examination of the protocol's architecture, focusing on its critical components: registration, authentication, and session key establishment. Formal security models and logical proofs are employed to assess the protocol's resilience against various attack vectors. One such method is the application of Burrows-Abadi-Needham (BAN) logic, which helps to verify the authenticity and freshness of messages exchanged within the protocol:

$$P \mid\equiv X \quad \text{(P believes X)}$$

$$P \mid\Rightarrow X \quad \text{(P has jurisdiction over X)}$$

$$(X) \quad \text{(X is fresh)}$$

These logical expressions formalize the assumptions made during the protocol's execution, ensuring that it meets its intended security objectives [5].

### C. Mathematical Modeling of Protocol Operations

The analysis incorporates mathematical modeling to evaluate key cryptographic operations, such as key generation and exchange. The protocol employs elliptic curve cryptography (ECC) for secure key exchanges:

$$K_{session} = g^{ab} \backslash \text{modp}$$

where, (g) is a generator point, and (a) and (b) are private keys of the communicating entities. This session key ensures secure communication between devices [5].

## IV. Analysis of the Proposed Protocol

### A. Overview of the Protocol

The proposed three-factor authentication protocol for IoT in healthcare systems is designed to enhance security through a series of robust cryptographic operations. The protocol is divided into several key phases: registration, authentication, and session key establishment. .

*1) Registration phase:* This phase initiates the secure setup of the system, where devices and users are registered with the central server. Each IoT device generates a random number $(a_i)$ and computes a pseudo-identity $(PID_i = h(ID_i \| a_i))$, where, $(h(\ ))$ is a secure hash function and $(ID_i)$ is the device's unique identifier (Fig. 2). The registration message sent to the server includes these parameters, ensuring that the device's identity is securely bound to its registration process [5].

| User $U_i$ | Gateway node $GW$ |
|---|---|
| Chooses $ID_i$, $PW_i$ and random number $r_i$<br>Also imprints $B_i$ at the sensor device<br>Computes $RPW_i = h(ID_i \| PW_i \| r_i)$,<br>$F_i = H(B_i \| r_i)$<br>$\xrightarrow{\{ID_i, RPW_i, F_i\}}$ | |
| | Produces a dynamic identity $DID_i$ and $R_g$<br>Calculates $A_i = h(DID_i \| X_G \| ID_g) \oplus h(RPW_i \| F_i)$,<br>$C_i = R_g \oplus h(DID_i \| X_G \| ID_g)$,<br>$D_i = h(RPW_i \| R_g \| F_i)$<br>Issue smartcard $\{A_i, C_i, D_i, DID_i, H(\cdot), h(\cdot)\}$<br>$\xleftarrow{Smartcard}$ |
| Compute $R_n = r_i \oplus h(ID_i \| PW_i \| H(B_i))$ and stores it into smartcard | |

| | Computes $M_1 = M_1 \oplus h(DID_i \| X_G \| ID_g)$, $R_g = C_i \oplus h(DID_i \| X_G \| ID_g)$<br>Decrypts $M_2$ as $(ID_i \| SID_j \| T_1 \| A_i) = D_{h(M_1 \| R_g)}(M_2)$<br>If $T_2 - T_1 \leq \triangle T$ holds, Ok; Else quits.<br>Computes $h(RPW_i \| F_i) = A_i \oplus h(DID_i \| X_G \| ID_g)$,<br>$M'_3 = h(ID_i \| SID_j \| h(RPW_i \| F_i))$<br>If $M'_3 \stackrel{?}{=} M_3$ holds, Ok; Else quits.<br>Computes $X_{GS} = h(SID_i \| X_G)$,<br>$K_j = h(X_{GS} \| Y_G \| X_G)$.<br>$M_4 = E_{h(X_{GS} \| K_j)}(ID_g \| ID_i \| M_i \| A_i \| T_3)$,<br>$M_5 = N_i \oplus h(T_3 \| h(RPW_i \| F_i))$,<br>$M_6 = h(ID_i \| N_i \| T_3 \| ID_g)$<br>$\xrightarrow{\{M_1, M_4, M_5, M_6\}}$ | |
| | | Decrypts $M_4$ using $X_{GS}$ and $K_j$<br>As $(ID_g \| ID_i \| M_i \| A_i \| T_3) = D_{h(X_{GS} \| K_j)}(M_4)$<br>If $T_4 - T_3 \leq \triangle T$ holds, Ok; Else quits.<br>$h(RPW_i \| F_i) = M_1 \oplus M_i \oplus A_i$,<br>$N_i = h(T_3 \| h(RPW_i \| F_i)) \oplus M_5$.<br>$M'_6 = h(ID_i \| N_i \| T_3 \| ID_g)$<br>If $M'_6 \stackrel{?}{=} M_6$ holds, Ok; Else quits.<br>Calculates $M_7 = V_i \oplus h(M_i \| N_i)$,<br>$SK = h(h(RPW_i \| F_i) \| M_i \| N_i \| V_i))$,<br>$M_8 = h(SK \| ID_i \| ID_g \| T_5)$.<br>$\xleftarrow{\{M_7, M_8, T_5\}}$ |
| | Checks $T_6 - T_5 \leq \triangle T$.<br>Computes $T_i = M_7 \oplus h(M_i \| N_i)$, $SK' = h(h(RPW_i \| F_i) \| M_i \| N_i \| V_i))$,<br>$M'_8 = h(SK' \| ID_i \| ID_g \| T_5)$. $SN_j$<br>If $M'_8 \stackrel{?}{=} M_8$ holds, Ok; Else quits.<br>Computes $C_i^n = R_g \oplus h(DID_i^n \| X_G \| ID_g)$ and updates the database $\{DID_i^n, C_i^n\}$<br>Computes $M_9 = E_{h(RPW_i \| F_i)}(C_i^n \| N_i \| V_i \| DID_i^n)$ and $M_{10} = h(SK \| C_i^n \| DID_i^n)$.<br>$\xleftarrow{\{M_9, M_{10}\}}$ | |
| Decrypts $(C_i^n \| N_i \| V_i \| DID_i^n) = D_{h(RPW_i \| F_i)}(M_9)$, and computes $SK' = h(h(RPW_i \| F_i) \| M_i \| N_i \| V_i))$,<br>$M'_{10} = h(SK' \| C_i^n \| DID_i^n)$<br>If $M'_{10} \stackrel{?}{=} M'_{10}$ holds, replaces $DID_i$ with $DID_i^n$ and $C_i$ with $C_i^n$. | | |

Fig. 3. Overview of the protocol's user authentication phase.

*2) Authentication phase:* During this phase, mutual authentication between the IoT device and the central server is established. The protocol employs elliptic curve cryptography (ECC) for secure key exchanges (Fig. 3). Each device computes an authentication token using a hash of its identity and a session-specific random nonce:

$$\text{AuthToken} = h(ID_i \parallel \text{Nonce}_i)$$

This token is used to verify the device's authenticity, ensuring that only legitimate devices can participate in the network [5].

*3) Session key establishment:* Once authentication is successful, a secure session key is established between the device and the server. The session key ($K_{session}$) is derived from the ECC-based key exchange process:

$$K_{session} = g^{ab} \backslash \text{mod} p$$

where, ( g ) is a generator point on the elliptic curve, and ( a ) and ( b ) are private keys of the communicating entities. This ensures that each session is secured with a unique key, providing confidentiality and integrity for data exchanged between the device and the server [5].

### B. Identified Vulnerabilities

Off-line Password Guessing Attack:

- Problem: The protocol aims to prevent off-line password guessing attacks, but an attacker can leverage leaked information from the registration phase (e.g., Regi = h(IDi || R₁ || HPWi), Ai = R; ⊕ HPWi, Ci = Bi ⊕ h(IDi ⊕ R; ⊕ HPWi)) and perform an off-line attack. Given a compromised HPWi, an attacker can try to guess PWi* such that h(IDi ⊕ PWi*) == HPWi.
- Attack Success Probability: The probability of a successful off-line guessing attack, given a limited password space and number of guesses is:

P(success) ≈ 1 - (1 - 1/|Password Space|)^N

where, |Password Space| is the size of the possible password set and N is the number of trials.

- Impact: If successful, the attacker gains the user's password and can compromise the authentication process.
- Improvement: Adding a salt to the password hashing process or implementing rate limiting on password attempts could mitigate this vulnerability. Multi-factor authentication could also strengthen security.

### C. User Impersonation Attack

- Problem: An attacker, knowing {TID, Regi, Ai, Ci, h()} from a compromised gateway node (GW), can create a forged login message {TID, IDsN, CID, M*, M, T₁} that successfully imitates a user during the login phase. Here, CID = IDi ⊕ h(TIDi || R || T₁), and M* = h(IDi || B || R₁ || T₁), and M = h(R || T₁) ⊕ R₁ where, R is derived as R = D₁ ⊕ h(TID; || K).
- Forgery: Attacker A can compute a valid looking B via B = C; ⊕ h(ID; ⊕ R ⊕ HPW* ) and since she also calculates ID, R and R1 based on intercepted information, the created messages M* and M will also be valid as calculated by M* = h(ID; || B || R1 || T₁)andM = h(R || T₁) ⊕ R₁ respectively.
- Impact: The GW accepts the forged messages. The system falsely authenticates the attacker as the legitimate user, allowing unauthorized data access or manipulation.
- Improvement: Using a keyed hash function (HMAC) or digital signatures involving a shared secret or private key for generating the messages CID, M*, and M would provide better message integrity and authentication. Adding randomness or time-related components could also enhance the security of the login phase.

### D. Known Session-Key Temporary Information Attack

- Problem: If temporary session values (R₁, R₂, and R₃) are compromised, an attacker can compute the session key, SK. The paper indicates SK = h(h(ID; || R₁ || R2) || R2 || R3).
  - This can be rewritten as SK = h(h(ID; || R₁ || R2) || R2 || R3) if R₁, R₂ and R₃ are compromised,
  - Then, an attacker can compute session key as SK = h(M' || R₂ || R₃) which is possible using values from captured messages, M4 = h(ID; || R₁ || R2) ⊕ SKGW_SN; and M5 = R2 ⊕ h(SKGW_SN;) if attacker can guess the identity.
- Vulnerable Calculation: Since M4 and M5 are sent over public channels and attacker knows, SKGW_SN; i.e., the secret parameter of GW and SNj, then temporary key can be computed as shown below.
- R₂ = M5 ⊕ h(SKGW_SN;) *h(ID; || R1 || R2) = M4 ⊕ SKGW_SN;
- SK = h(h(ID; || R1 || R2) || R2 || R3) = h(M' || R₂ || R₃) * The above calculation clearly shows how an attacker can get the session key SK.
- Impact: Session key compromise allows an attacker to decrypt data or modify messages within the compromised session.
- Improvement: Deriving the session key using all participant's secret values and not relying on temporary variables, and making sure R1, R2 and R3 are not sent in clear could mitigate the risk. Use of ephemeral keys within a key agreement protocol instead of relying on random numbers is recommended.

### E. Revelation of Secret Parameter SKGW_SN

- Problem: A legal, but malicious, user A who intercepts messages between GW and SN, can calculate SKGW_SN; Given messages {TID, IDsN, CID, M1, M2, T1}, {M3, M4, M5}, and {M7, M8}, A can calculate the secret parameter using R2 = M5 ⊕

h(SKGW_SN;) and SKGW_SN; = M4 ⊕ h(ID; || $R_1$ || $R_2$). Given the above values, A can compute SKGW_SN;

- Attack: By intercepting M4 = h(ID; || $R_1$ || R2) ⊕ SKGW_SN;, and M5 = R2 ⊕ h(SKGW_SN;) and knowing R2 by computation from message {M7, M8} $R_2$ = M5 ⊕ h(SKGW_SN;) and calculating h(ID; || R1 || R2) as well, A can compute the secret parameter SKGW_SN;.
- Impact: Knowing SKGW_SN; allows an attacker to compromise the authentication and key exchange between GW and SN. It can lead to a gateway node or a sensor node impersonation attacks.
- Improvement: Key derivation functions should be designed with proper key secrecy and key derivation must not expose parameters used in further computations.
- Using Keyed Hash functions such as HMAC would be preferable for generating the values SKGW_SN; and SK.
- The long-term secret keys of the system should not be used directly for generating the session key as used in the paper.

While this paper aims to enhance security with a three-factor authentication mechanism, the proposed protocol contains several critical vulnerabilities that can be exploited by a determined attacker. The vulnerabilities outlined above highlight the importance of carefully designing cryptographic protocols to avoid such weaknesses. By addressing these flaws and following best practices in cryptographic engineering, it's possible to create robust protocols that better protect sensitive data and systems.

### *F. Proposed Improvements*

To address the vulnerabilities identified in the proposed three-factor authentication protocol for IoT healthcare systems, several improvements are recommended. These enhancements are designed to fortify the protocol against unauthorized access and ensure the protection of sensitive medical data.

First, to mitigate the weaknesses associated with single-factor authentication, it is crucial to implement multi-factor authentication (MFA). This enhancement involves combining traditional password-based authentication with additional factors such as biometrics (e.g., fingerprint or iris recognition) and possession-based tokens (e.g., smart cards). By requiring multiple forms of verification, MFA significantly reduces the risk of unauthorized access, as an attacker would need to compromise all authentication factors to gain entry.

Second, to prevent time synchronization attacks, the protocol should incorporate timestamps or nonces into each message. This modification ensures that replayed messages are detected and rejected, enhancing the protocol's resilience against replay attacks. For instance, each message can be appended with a unique timestamp or a random nonce:

$$M = \text{HID}, B1, Y1, A1, V1, \text{TS}$$

or

$$M = \text{HID}, B1, Y1, A1, V1, \text{Nonce}$$

This enables the server to validate these elements, confirming message freshness and authenticity.

Third, to protect against side-channel attacks, it is essential to minimize information leakage during cryptographic operations. Techniques such as masking and shuffling can be employed to obscure correlations between power consumption and cryptographic computations. Masking involves adding random values to intermediate computations, while shuffling changes the order of operations to make it difficult for attackers to predict the sequence of computations. These techniques increase the difficulty of deducing cryptographic keys from side-channel information.

Fourth, to prevent replay attacks and ensure communication integrity, the use of message authentication codes (MACs) is recommended. By appending a MAC to each message:

$$M = \text{data}, \text{MAC}(\text{data}, SK)$$

the recipient can verify the MAC to ensure that the message has not been tampered with. This enhancement prevents attackers from modifying or retransmitting messages without detection, maintaining the integrity of the communication channel.

Fifth, to enhance the protocol's scalability and efficiency, optimizing cryptographic operations is necessary. Implementing lightweight cryptographic algorithms, such as the Advanced Encryption Standard (AES) in its lightweight form, can significantly reduce energy consumption and processing time. Additionally, employing adaptive power management techniques, such as duty cycling and dynamic voltage scaling, can extend battery life and maintain device performance. These optimizations ensure that IoT devices can efficiently perform necessary tasks without draining resources.

By implementing these proposed improvements, the protocol can provide robust protection against evolving threats and maintain the integrity and confidentiality of IoT-based healthcare systems. These measures offer a comprehensive approach for addressing current vulnerabilities and preparing for future security challenges in the digital healthcare landscape.

## V. CONCLUSION

In conclusion, the analysis of the proposed three-factor authentication protocol for IoT healthcare systems highlights critical vulnerabilities, including single-factor authentication weaknesses, time synchronization issues, side-channel attack risks, and replay attack susceptibility. By implementing recommended security enhancements, such as multi-factor authentication, timestamps, and advanced cryptographic techniques, the protocol can significantly improve its security posture [18-20]. These measures ensures robust protection of sensitive medical data, fostering trust in IoT-enabled healthcare environments. As the IoT landscape continues to evolve, ongoing research into adaptive security measures and lightweight cryptographic algorithms will become crucial in maintaining the protocol's resilience against emerging threats.

***Abstract*—Sign language recognition (SLR) plays a crucial role in bridging communication gaps for individuals with hearing and speech impairments. This study proposes a hybrid deep CNN-BiLSTM neural network with an attention mechanism for real-time and lightweight sign language recognition. The CNN module extracts spatial features from individual gesture frames, while the BiLSTM module captures temporal dependencies, enhancing classification accuracy. The attention mechanism further refines feature selection by focusing on the most relevant time steps in a sign sequence. The proposed model was evaluated on the Sign Language MNIST dataset, achieving state-of-the-art performance with high accuracy, precision, recall, and F1-score. Experimental results indicate that the model converges rapidly, maintains low misclassification rates, and effectively distinguishes between visually similar signs. Confusion matrix analysis and feature map visualizations provide deeper insights into the hierarchical feature extraction process. The results demonstrate that integrating spatial, temporal, and attention-based learning significantly improves recognition performance while maintaining computational efficiency. Despite its effectiveness, challenges such as misclassification in ambiguous gestures and real-time computational constraints remain, suggesting future improvements in multi-modal fusion, transformer-based architectures, and lightweight model optimizations. The proposed approach offers a scalable and efficient solution for real-time sign language recognition, contributing to the development of assistive technologies for individuals with communication disabilities.**

***Keywords*—Sign language recognition; CNN-BiLSTM; attention mechanism; deep learning; gesture classification; real-time processing; assistive technology***

## I. Introduction

Sign language serves as a primary mode of communication for individuals with hearing and speech impairments, enabling them to interact effectively within society. However, barriers still exist due to the lack of widespread understanding and adoption of sign language by the general public. In this context, sign language recognition (SLR) plays a crucial role in bridging the communication gap between individuals with hearing disabilities and those who rely on spoken language [1]. The recent advancements in deep learning have paved the way for robust and efficient SLR systems, enhancing real-time communication through gesture-based interaction [2].

Traditional approaches to SLR have relied heavily on handcrafted feature extraction techniques, such as histogram of oriented gradients (HOG), scale-invariant feature transform (SIFT), and local binary patterns (LBP). While these methods have shown promise in controlled environments, their performance is often hindered by variations in lighting, occlusions, and user-specific differences in sign execution [3]. The emergence of deep learning techniques, particularly convolutional neural networks (CNNs), has revolutionized the field by enabling automatic feature extraction and classification with remarkable accuracy [4].

Recent research has demonstrated the effectiveness of CNN-based architectures for visual gesture recognition tasks, including sign language translation. However, CNNs alone lack the ability to capture temporal dependencies in sequential gesture data, which is essential for accurate recognition of continuous sign language sequences [5]. To address this limitation, hybrid deep learning models combining CNNs with recurrent neural networks (RNNs) or bidirectional long short-term memory (BiLSTM) networks have been proposed, allowing the extraction of both spatial and temporal features from sign language gestures [6]. The CNN component focuses on spatial feature extraction, while the BiLSTM module captures temporal dependencies in both forward and backward directions, thereby improving recognition accuracy [7].

Despite the promising results achieved through CNN-BiLSTM models, challenges remain in real-time SLR applications due to the computational complexity of deep learning networks. High processing requirements hinder their deployment on resource-constrained devices, such as mobile phones and embedded systems, which are essential for practical, real-world applications [8]. As a solution, lightweight neural network architectures have been explored, incorporating model compression techniques such as depthwise separable convolutions, pruning, and quantization to reduce computational overhead while maintaining high classification accuracy [9].

In addition to model efficiency, attention mechanisms have emerged as a powerful tool for enhancing performance in sequential data processing. The attention mechanism allows the model to selectively focus on relevant features within a sequence, improving temporal coherence in gesture recognition tasks [10]. When integrated into CNN-BiLSTM architectures, attention mechanisms enhance feature selection by emphasizing the most informative frames, thereby mitigating the impact of redundant or irrelevant information [11].

This study proposes a real-time, lightweight SLR system based on a hybrid deep CNN-BiLSTM architecture enhanced with an attention mechanism. The proposed framework is designed to achieve high recognition accuracy while minimizing computational costs, making it suitable for deployment on edge devices and mobile platforms [12]. The model leverages CNNs for extracting spatial features, BiLSTM networks for capturing bidirectional temporal dependencies, and an attention mechanism for focusing on salient information within sign sequences. By optimizing both accuracy and efficiency, this approach addresses the practical limitations of existing SLR systems [13], [14].

## II. Related Works

### A. Sign Language Recognition

Sign Language Recognition (SLR) has gained significant attention in recent years due to the increasing demand for assistive technologies aimed at bridging communication gaps between individuals with hearing disabilities and the wider community [15]. Various methods have been explored to achieve effective SLR, ranging from rule-based approaches to deep learning models [16]. Early approaches relied on handcrafted features extracted from gesture sequences, while modern techniques emphasize end-to-end learning using neural networks [17].

### B. Traditional Methods

Before the advent of deep learning, traditional methods for SLR primarily relied on handcrafted feature extraction techniques such as HOG, SIFT, and LBP [18]. These methods extracted low-level features from hand gestures and used classification techniques such as Support Vector Machines (SVMs) and Hidden Markov Models (HMMs) to recognize signs [19]. While these approaches provided reasonable accuracy in controlled environments, they struggled with real-world variations such as occlusions, background noise, and different sign execution speeds [20].

### C. Machine Learning Approaches

With the rise of machine learning, researchers began to explore data-driven approaches for SLR. Machine learning models, such as Random Forests and SVMs, demonstrated improved accuracy compared to traditional rule-based methods [21]. The introduction of artificial neural networks (ANNs) further enhanced recognition capabilities, allowing for automatic feature extraction and improved generalization to unseen sign variations [22]. However, these methods were still limited by their inability to effectively capture both spatial and temporal dependencies in sign language sequences [23].

### D. Deep Learning for Sign Language Recognition

Deep learning has revolutionized SLR by providing powerful feature extraction and classification capabilities. Convolutional Neural Networks (CNNs) have been widely used for spatial feature extraction, achieving state-of-the-art performance in static sign recognition [24]. However, recognizing continuous sign language requires capturing temporal dependencies, which led to the integration of Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM) networks into SLR frameworks [25]. More recently, BiLSTM networks have been employed to improve sequence modeling by considering both forward and backward temporal dependencies, leading to enhanced recognition accuracy [26]. Additionally, attention mechanisms have been incorporated into CNN-BiLSTM architectures to enhance feature selection and improve classification performance [27].

### E. Challenges in Sign Language Recognition

Despite significant progress, several challenges remain in developing real-time and robust SLR systems. One major challenge is the variability in sign execution, including differences in speed, hand position, and occlusions [28]. Another challenge is the high computational cost of deep learning models, making it difficult to deploy them on edge devices and mobile platforms [29]. Addressing these challenges requires optimizing model architectures for efficiency while maintaining high recognition accuracy.

### F. Research Gaps

While deep learning-based SLR systems have achieved remarkable success, there are still research gaps that need to be addressed. Existing models often require large labeled datasets, which are expensive and time-consuming to create [30]. Additionally, real-time processing remains a challenge due to the complexity of CNN-BiLSTM architectures [31]. Further research is needed to develop lightweight models that can operate efficiently on low-power devices without compromising recognition performance [32]. Moreover, integrating multi-modal inputs, such as depth and motion data, could enhance recognition robustness in real-world scenarios [33].

By addressing these gaps, future sign language recognition systems can be made more efficient, accurate, and accessible, ultimately improving communication for individuals with hearing impairments.

## III. Problem Statement

The fundamental challenge in Sign Language Recognition (SLR) is achieving high-accuracy, real-time classification of gestures while maintaining computational efficiency. Given an input sequence of image frames $X = \{x_1, x_2, ..., x_T\}$, the goal is to predict the corresponding sequence of sign language labels $Y = \{y_1, y_2, ..., y_T\}$ such that:

$$P(Y \mid X) = \arg\max P(y_t \mid x_t, \theta) \quad (1)$$

where, $\theta$ represents the learned parameters of the model.

Traditional deep learning approaches rely on CNNs for spatial feature extraction and LSTMs for temporal dependencies. However, existing methods struggle with balancing recognition accuracy and real-time efficiency, especially in low-resource environments. Thus, a hybrid CNN-BiLSTM model with an attention mechanism is needed to enhance spatial-temporal feature extraction while maintaining lightweight computational costs.

## IV. Materials and Methods

Developing an accurate and efficient Sign Language Recognition (SLR) system requires a well-structured methodology that encompasses dataset selection, preprocessing, model architecture, and training strategies. This section provides a comprehensive overview of the materials and methods employed in this study. First, the dataset used for training and evaluation is described, including its structure, distribution, and preprocessing techniques. Next, the proposed hybrid CNN- BiLSTM model with an attention mechanism is introduced, detailing its ability to extract spatial and temporal features from sign language gestures. The section further elaborates on the training process, including the optimization strategies, loss functions, and performance evaluation metrics utilized. Finally, implementation details, including computational resources and hyperparameter settings, are presented to ensure the reproducibility of the study.

### A. Dataset

The Sign Language MNIST dataset is a widely used benchmark for static sign language recognition. It was designed as an adaptation of the MNIST dataset to facilitate research in sign language gesture classification [34]. The dataset consists of 27,455 grayscale images, each of size 28×28 pixels, representing 24 different hand gestures corresponding to the American Sign Language (ASL) alphabet. The dataset excludes the letters J and Z since these signs involve dynamic motion that cannot be effectively captured in static images.

The dataset is divided into two subsets: a training set of 27,455 images and a test set of 7,172 images, ensuring a structured approach to evaluating model performance. Each image represents a single hand gesture and is labeled with one of the 24 classes. The data is well-balanced across the different sign categories, enabling efficient training of deep learning models.

The simplicity of the dataset, coupled with its structured grayscale format, makes it an ideal benchmark for evaluating convolutional neural networks (CNNs) and hybrid deep learning architectures for sign language recognition. Fig. 1 provides a visual representation of sample images from the dataset, illustrating the variation in hand gestures and their corresponding labels.

Fig. 2 presents a visualization of the class distribution within the Sign Language MNIST dataset. The dataset comprises 24 distinct hand gesture classes, each representing a different letter in the American Sign Language (ASL) alphabet, excluding J and Z, which require motion. The histogram illustrates the number of samples per class, providing insight into the dataset's balance.

Fig. 1. Sample images of the applied dataset.

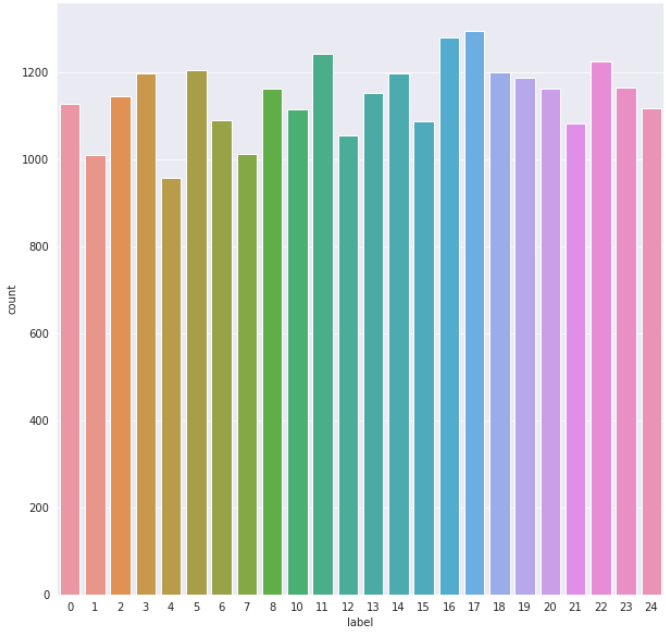

Fig. 2. Distribution of classes.

From Fig. 2, it can be observed that the dataset is relatively balanced, with each class containing approximately 1,000 to 1,250 samples. This balanced distribution is crucial for training deep learning models, as it minimizes the risk of class bias and ensures that all gestures receive equal representation during training. A well-distributed dataset allows for better generalization, reducing the likelihood of models overfitting to more frequent classes while underperforming on less represented signs.

This visualization highlights the adequacy of the dataset for training sign language recognition models, as it ensures that the learning process is not skewed toward particular gesture classes. Additionally, understanding the dataset distribution aids in the design of appropriate preprocessing techniques and data augmentation strategies to enhance model robustness in real-world applications.

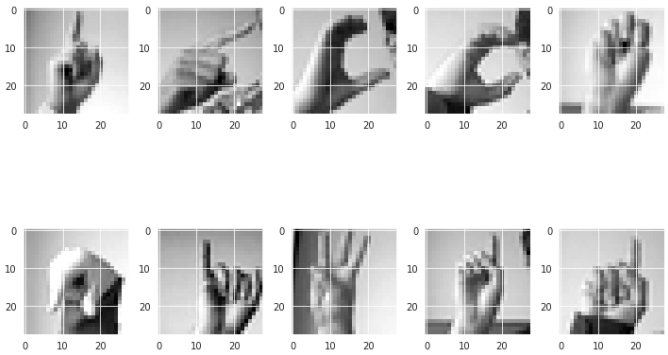

Fig. 3. Dataset balance and normalization.

Fig. 3 illustrates a subset of grayscale images from the Sign Language MNIST dataset, showcasing the variation in hand gestures used for sign recognition. To enhance model performance and improve generalization, we apply grayscale normalization, a crucial preprocessing step in image-based deep learning models. The primary objective of grayscale normalization is to reduce the effects of illumination differences, which can introduce unwanted variability in pixel intensity across images.

Mathematically, grayscale normalization transforms pixel values from the original range [0,255] to a normalized range of [0,1] using the following equation :

$$I_{norm} = \frac{I_{orig}}{255} \quad (2)$$

where, $I_{orig}$ represents the original pixel, $I_{norm}$ is the normalized intensity.

This transformation ensures a more stable numerical range, preventing large gradients and facilitating smoother optimization during training. Additionally, CNNs exhibit faster convergence when operating on normalized input data, reducing training time while maintaining robust feature extraction capabilities.

By applying grayscale normalization, we standardize input data, ensuring consistent image contrast and reducing the impact of environmental variations. This step plays a vital role in enhancing model robustness, particularly when the trained system is deployed in real-world sign language recognition applications.

### *B. Proposed Model*

The proposed real-time lightweight sign language recognition model is based on a hybrid deep CNN-BiLSTM neural network with an attention mechanism, as illustrated in Fig. 4. This architecture is designed to efficiently capture both spatial and temporal dependencies in sign language gestures while maintaining computational efficiency. The CNN module extracts spatial features from individual frames, while the BiLSTM module captures the temporal relationships between sequential frames. The attention mechanism further enhances performance by prioritizing the most relevant time steps in the sequence, ensuring robust recognition of sign gestures even in challenging environments.

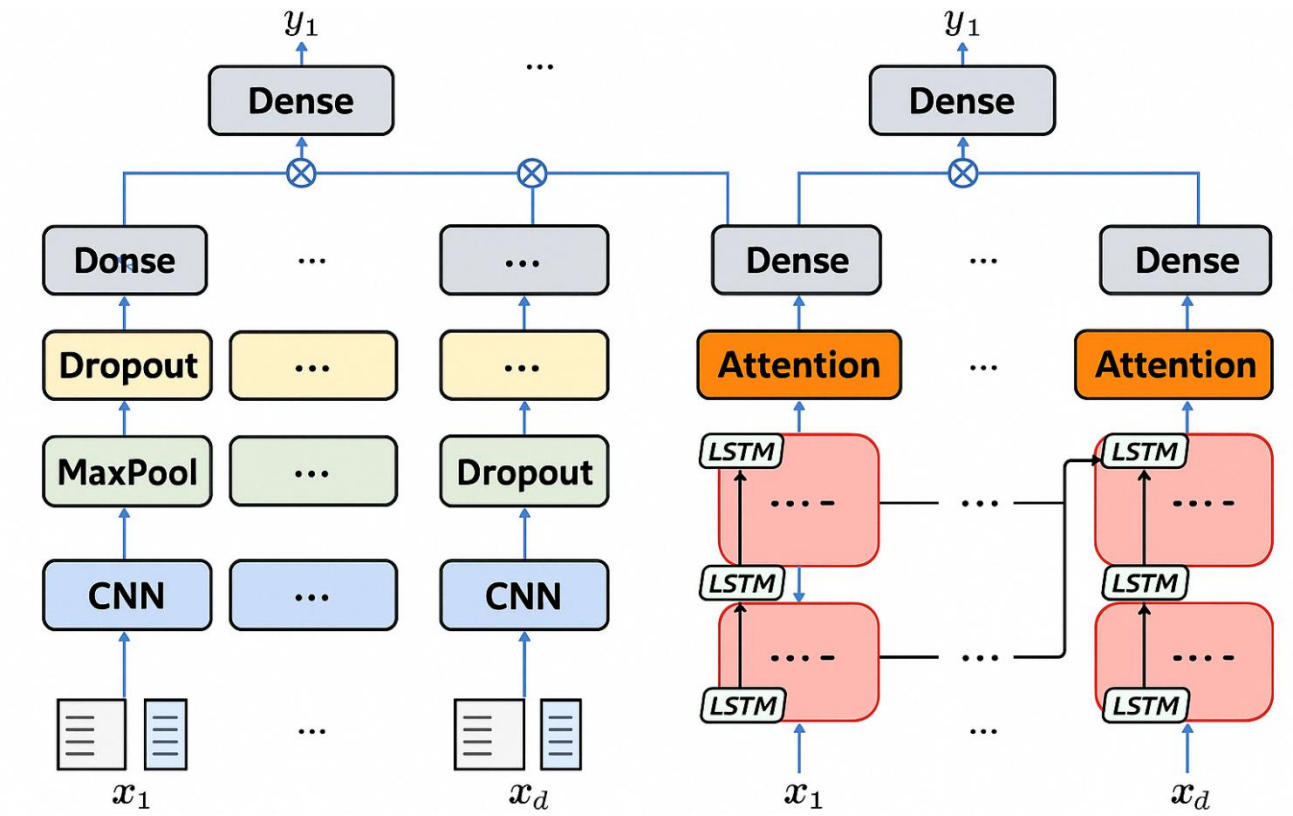

Fig. 4. The Proposed hybrid CNN-BiLSTM network with attention mechanism.

Convolutional Neural Network (CNN) for Spatial Feature Extraction. The first stage of the model is a Convolutional Neural Network (CNN), which extracts low-level and high-level spatial features from each frame. Given an input image $X$ of dimensions $H \times W \times C$, where $H$ and $W$ denote height and width, and $C$ represents the number of channels, the output feature map is computed as:

$$F_{i,j}^{(l)} = \sigma\left( \sum_{m,n} W_{m,n}^{(l)} X_{i+m,j+n}^{(l-1)} + b^{(l)} \right) \quad (3)$$

where, $W^{(l)}$ represents the convolutional filter weights, $b^{(l)}$ is the bias term, and $\sigma$ is the activation function (ReLU in this case).

The CNN module includes multiple convolutional layers, followed by max-pooling layers to reduce the spatial dimensions and retain the most salient features:

$$P_{i,j}^{(l)} = \max_{m,n} F_{i+m,j+n}^{(l)} \quad (4)$$

$P^{(l)}$ represents the output of the pooling layer.

Fig. 5 illustrates the convolution operation, a fundamental component of Convolutional Neural Networks (CNNs) used for spatial feature extraction. The figure depicts the application of a convolution filter (Sobel Gx) to an input image matrix, where a 3×3 kernel slides over the input feature map, computing the weighted sum of pixel values within the receptive field. Mathematically, the convolution operation at a given location $(i,)$ is defined as:

$$F(i,j) = \sum_{m=-k}^{k} \sum_{n=-k}^{k} W(m,n) \cdot X(i+m, j+n) \quad (5)$$

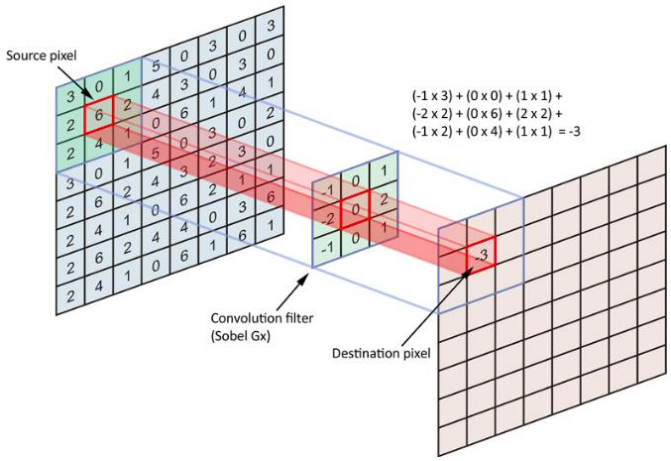

Fig. 5. Convolution operation in CNN for spatial feature extraction.

where, $X(i,j)$ represents the pixel intensity values of the input feature map, $W(m,n)$ denotes the filter weights, and $k$ is the kernel size offset. In this figure, the convolution filter extracts edge features, highlighting intensity changes in the spatial domain. The output destination pixel stores the computed value, forming a new feature map that enhances object boundaries and structural details. This operation is critical for hierarchical feature extraction, enabling CNNs to learn meaningful representations from raw image inputs. Through successive convolutional layers, deep CNN models progressively capture low-level features (edges, textures) and high-level features (shapes, patterns), facilitating robust sign language recognition.

Bidirectional Long Short-Term Memory (BiLSTM) for Temporal Dependency Learning: To capture temporal dependencies in sequential gestures, the extracted feature maps are fed into a Bidirectional Long Short-Term Memory (BiLSTM) network. The BiLSTM consists of two LSTMs, one processing the sequence in the forward direction and the other in the backward direction:

$$\vec{h}_t = f\left( W_x X_t + W_h \vec{h}_{t-1} + b \right) \quad (6)$$

$$\overleftarrow{h}_t = f\left( W_x X_t + W_h \overleftarrow{h}_{t+1} + b \right) \quad (7)$$

where, $\vec{h}_t$ and $\overleftarrow{h}_t$ represent the hidden states of the forward and backward LSTMs, respectively. The final output is the concatenation of both hidden states:

$$h_t = \vec{h}_t \oplus \overleftarrow{h}_t \quad (8)$$

This bidirectional processing ensures that the network captures long-range dependencies from both past and future frames, improving recognition accuracy.

Attention Mechanism for Feature Enhancement: The attention mechanism enhances feature selection by assigning different importance scores to different time steps in the sequence. The attention weight $\alpha_t$ for each time step is computed using the softmax function:

$$\alpha_t = \frac{\exp(e_t)}{\sum_k \exp(e_k)} \quad (9)$$

where, $e_t$ is computed as:

$$e_t = \upsilon^T \tanh\left( W_h h_t + W_s s \right) \quad (10)$$

where, $\upsilon$, $W_h$, $W_s$ are learnable parameters, and $s$ represents the context vector. The final context vector used for classification is:

$$c = \sum_t \alpha_t h_t \quad (11)$$

This mechanism ensures that the model focuses on the most relevant time steps in the sign sequence, improving robustness against variations in gesture execution.

Fully Connected Layers and Classification. The final feature representation $c$ is passed through fully connected (dense) layers, followed by a softmax activation function for classification:

$$y = soft\max(W_c c + b_c) \tag{12}$$

where, $W_c$ and $b_c$ are learnable parameters. The softmax function ensures that the output represents a probability distribution over the possible sign language classes:

$$P(y_i) = \frac{\exp(y_i)}{\sum_j \exp(y_j)} \tag{13}$$

Loss Function and Optimization. The model is trained using the categorical cross-entropy loss function, defined as:

$$L = -\sum_{i=1}^{N} y_i \log(\hat{y}_i) \tag{14}$$

where, $y_i$ is the true label, and $\hat{y}_i$ is the predicted probability of class $i$. The parameters are optimized using the Adam optimizer, which updates weights based on the gradient:

$$\theta_{t+1} = \theta_t - \eta \frac{m_t}{\sqrt{\upsilon_t} + \in} \tag{15}$$

where, $\eta$ is the learning rate, $m_t$ is the first moment estimate, and $\upsilon_t$ is the second moment estimate.

Summary of the Model: The proposed model integrates CNN for spatial feature extraction, BiLSTM for temporal sequence learning, and an attention mechanism for feature enhancement, ensuring accurate and efficient sign language recognition. Fig. 4 illustrates the detailed architecture of the model. The combination of spatial and temporal learning, along with attention-based feature refinement, results in a robust and computationally efficient system suitable for real-time applications.

### C. Evaluation Parameters

To assess the performance of the proposed hybrid CNN-BiLSTM model with an attention mechanism for sign language recognition, multiple evaluation metrics are employed. These metrics provide a comprehensive analysis of the model's classification accuracy, robustness, and generalization ability [35].

Accuracy is the most fundamental metric used to evaluate classification models, representing the proportion of correctly predicted instances over the total number of instances. It is mathematically defined as:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{16}$$

where, TP (True Positives) and TN (True Negatives) represent correctly classified instances, while FP (False Positives) and FN (False Negatives) denote misclassified instances. High accuracy indicates strong overall performance, but it may be misleading in imbalanced datasets.

Precision quantifies the proportion of correctly predicted positive instances out of all predicted positive instances. It is particularly important in applications where false positives must be minimized. The precision score is computed as:

$$\Pr ecision = \frac{TP}{TP + FP} \tag{17}$$

A high precision value implies that the model has a low false positive rate, making it suitable for scenarios requiring reliable positive predictions.

Recall, also known as sensitivity or true positive rate, measures the proportion of actual positive instances that were correctly predicted. It is essential for applications where missing a positive instance (false negative) is critical. Recall is defined as:

$$\mathrm{Re}\, call = \frac{TP}{TP + FN} \tag{18}$$

A higher recall score indicates that the model effectively identifies most positive instances, reducing false negatives.

F1-Score provides a balanced measure of precision and recall, ensuring that both false positives and false negatives are considered. It is the harmonic mean of precision and recall, computed as:

$$F1 - score = 2 \times \frac{precision \times recall}{precision + recall} \tag{19}$$

A high F1-score indicates a model with both strong precision and recall, making it a crucial metric when dealing with class imbalances.

These evaluation parameters collectively offer a holistic assessment of the proposed model's performance, ensuring that it not only achieves high accuracy but also maintains robustness in correctly identifying sign language gestures.

## V. Results

The results obtained from the experiments provide an in-depth evaluation of the proposed CNN-BiLSTM model with an attention mechanism for sign language recognition. This section presents the model's training and testing performance, classification accuracy, loss convergence trends, confusion matrix analysis, and feature map visualizations. The effectiveness of the model is assessed using standard evaluation metrics, including accuracy, precision, recall, and F1-score, ensuring a comprehensive performance comparison. Additionally, visualizations of correct and misclassified predictions provide insights into the model's strengths and areas

for potential improvement. The results further highlight the significance of integrating CNN for spatial feature extraction, BiLSTM for temporal pattern learning, and the attention mechanism for enhanced feature selection, demonstrating the model's capability to generalize effectively for real-time sign language recognition applications.

Fig. 6 illustrates the feature maps generated by the convolutional layers of the proposed CNN-BiLSTM model with an attention mechanism during the spatial feature extraction process. Each sub-image within the figure represents an activation map corresponding to different convolutional filters applied to the input sign language images. These feature maps capture essential structural patterns such as edges, textures, and contours, which are critical for recognizing hand gestures in sign language.

At the initial layers, the convolutional filters primarily detect low-level features such as simple edges and gradient transitions. As the network progresses deeper, the extracted features become more complex, encoding high-level semantic patterns that distinguish different hand gestures. The highlighted regions in the feature maps indicate areas where the network has strong activations, meaning those parts contribute significantly to classification.

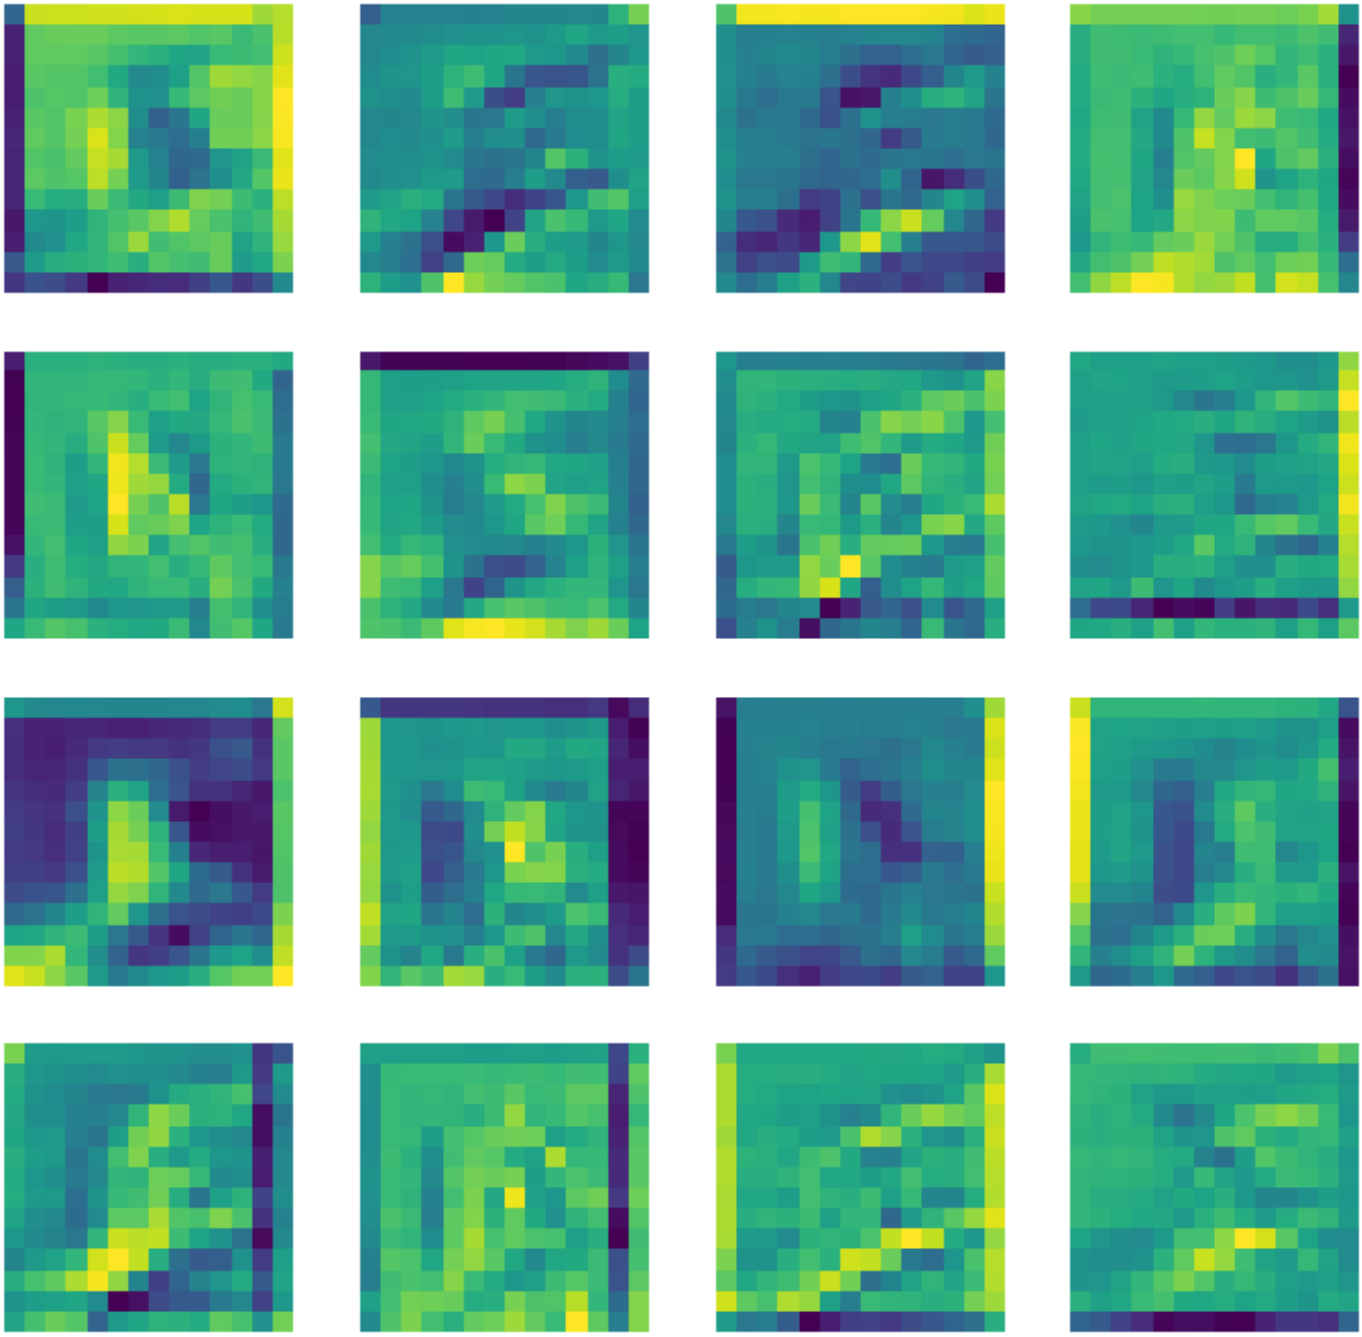

Fig. 6. Feature maps generated by convolutional layers in the proposed CNN-BiLSTM model.

This visualization helps in understanding how the convolutional layers automatically learn hierarchical representations, enabling robust recognition of sign language gestures. The effective extraction of spatial features in these layers plays a fundamental role in enhancing the model's accuracy and generalization capability in real-world applications.

Fig. 7 illustrates the feature maps generated by deeper convolutional layers of the proposed CNN-BiLSTM model with an attention mechanism. These feature maps represent the activation patterns learned at later stages of the convolutional network, capturing more complex and abstract spatial representations of sign language gestures. Unlike earlier convolutional layers that detect low-level features such as edges and textures, deeper layers focus on higher-level representations such as geometric structures and gesture-specific patterns.

Each sub-image in Fig. 7 corresponds to an activation map produced by different convolutional filters. The variation in feature maps demonstrates how different filters focus on distinct regions of the input image, allowing the model to build a hierarchical understanding of hand gestures. The presence of strong activations in specific areas indicates regions of high relevance for classification, enhancing the model's ability to differentiate between visually similar gestures.

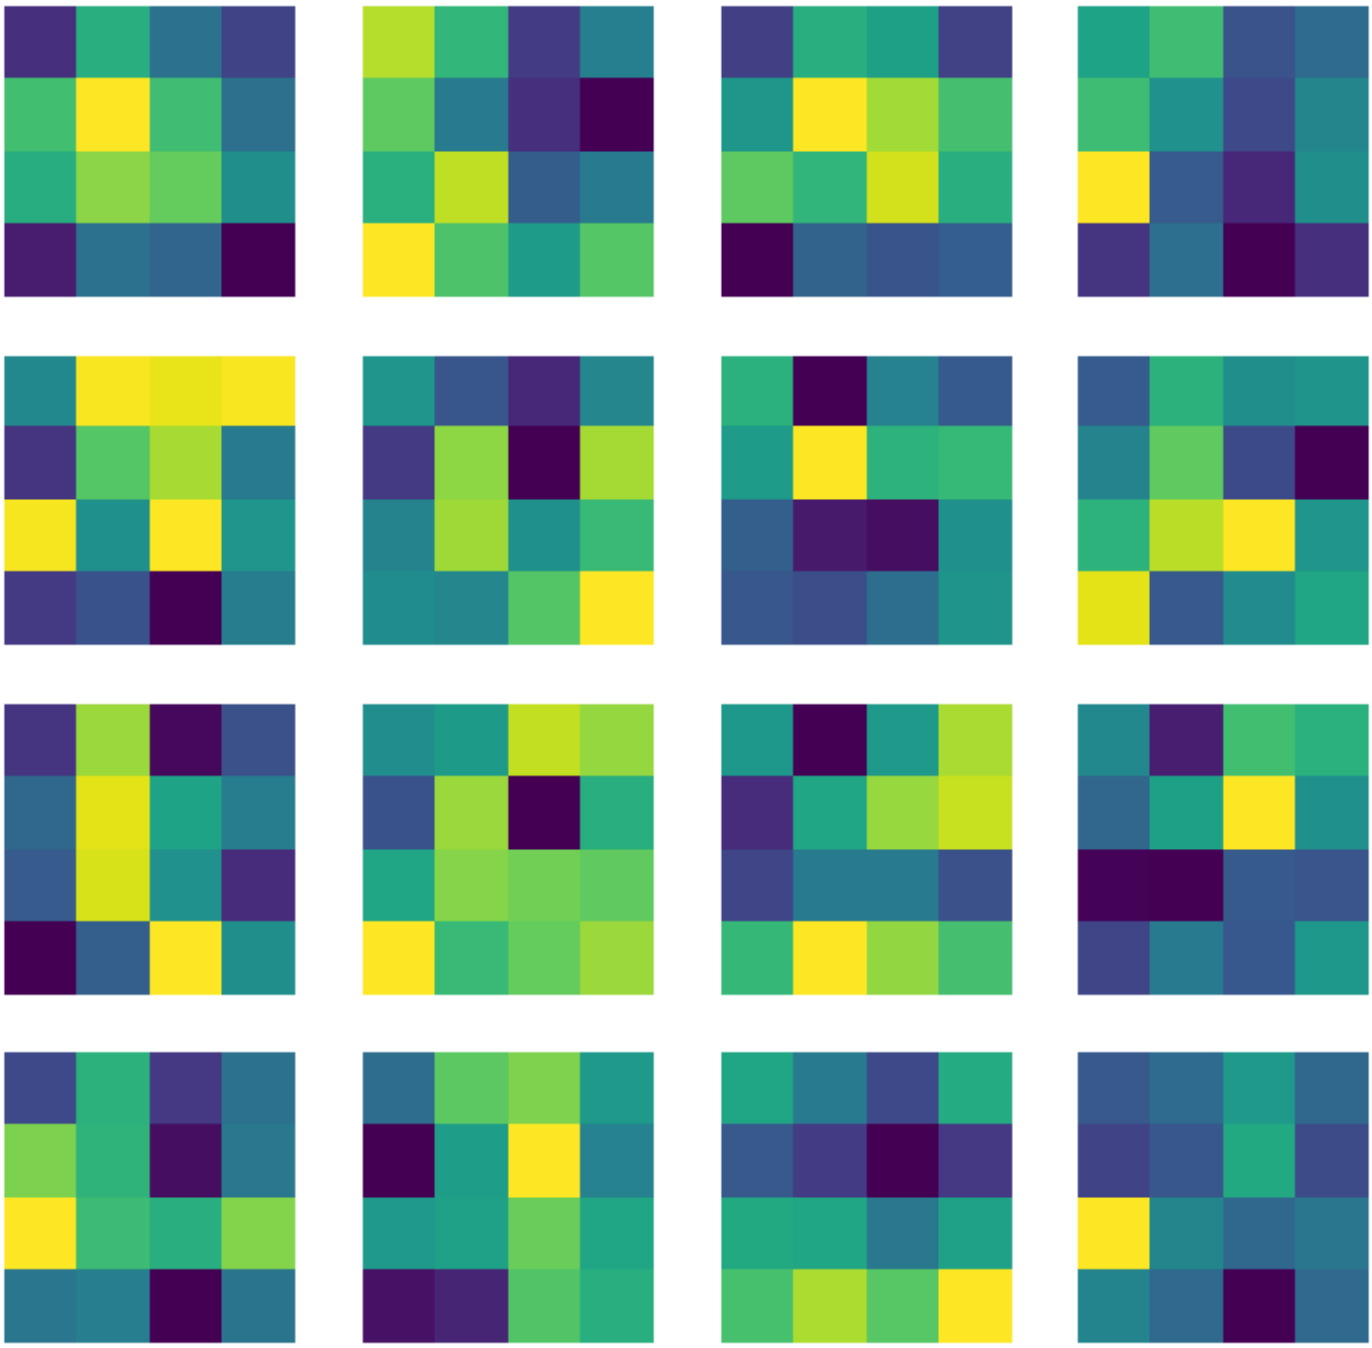

Fig. 7. Feature maps from deeper convolutional layers in the proposed CNN-BiLSTM model.

This visualization highlights the effectiveness of the hierarchical feature learning process in CNNs, where successive convolutional layers refine the extracted features to improve recognition accuracy. The ability to capture abstract spatial patterns ensures that the model generalizes well across different users, hand orientations, and lighting conditions, making it robust for real-time sign language recognition applications.

Fig. 8 presents the training and validation accuracy (left) and training and testing loss (right) over multiple epochs for the proposed CNN-BiLSTM model with an attention mechanism. The left graph illustrates the progression of training accuracy (green) and testing accuracy (red) across 20 epochs. Initially, both training and testing accuracy exhibit a sharp increase, with the testing accuracy rapidly converging toward the training accuracy, demonstrating effective learning. By approximately the fifth epoch, the model reaches over 90% accuracy, and after 10 epochs, the accuracy stabilizes near 100%, indicating that the model generalizes well to unseen test data.

The right graph in Fig. 8 shows the training loss (green) and testing loss (red) as a function of epochs. A significant decrease in loss is observed within the first few epochs, with the testing loss reducing sharply from over 5.0 to below 1.0 by epoch 5, suggesting rapid convergence. After 10 epochs, both training and testing loss values stabilize at a minimal level, confirming that the model has effectively minimized classification errors. The negligible difference between training and testing curves further suggests that the model exhibits minimal overfitting and maintains robust generalization performance.

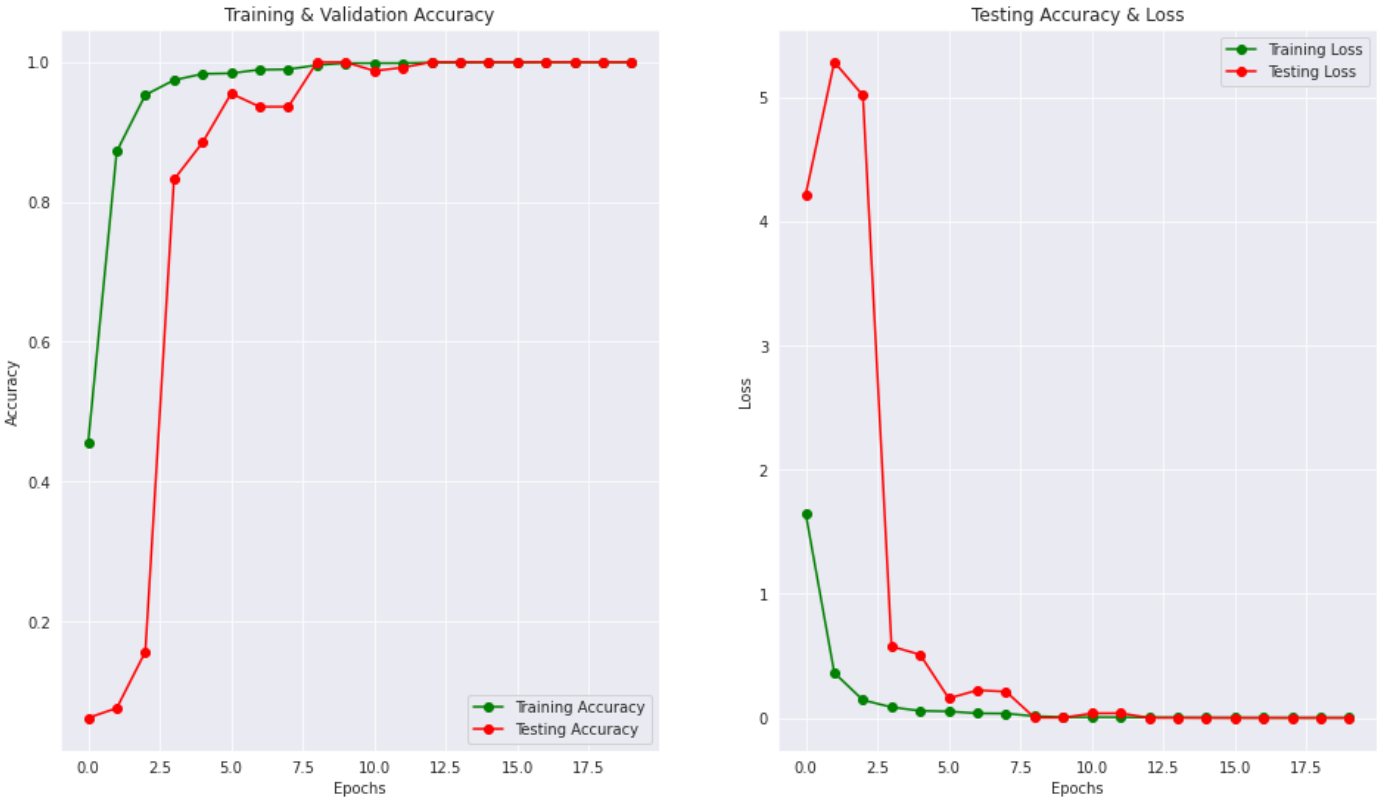

Fig. 8. Training and testing accuracy and loss curves for the proposed CNN-BiLSTM model.

Fig. 9 presents the confusion matrix for the proposed CNN-BiLSTM model with an attention mechanism, illustrating the model's classification performance across the 24 sign language gesture classes. Each row in the matrix represents the actual class, while each column corresponds to the predicted class. The diagonal elements indicate correctly classified instances, whereas off-diagonal elements denote misclassifications.

From Fig. 9, it is evident that the model demonstrates high classification accuracy, as most of the predictions are concentrated along the diagonal with minimal misclassification errors. The intensity of the blue color represents the frequency of correct predictions, with darker shades indicating a higher number of correctly classified instances. The sparse distribution of misclassified samples in non-diagonal positions suggests that the model effectively learns distinct sign language features, resulting in robust recognition performance.

The confusion matrix also highlights minor misclassification instances, which may occur due to similar hand gestures, occlusions, or variations in user execution. Despite these challenges, the model maintains high precision and recall across all classes, validating its effectiveness in real-time sign language recognition applications.

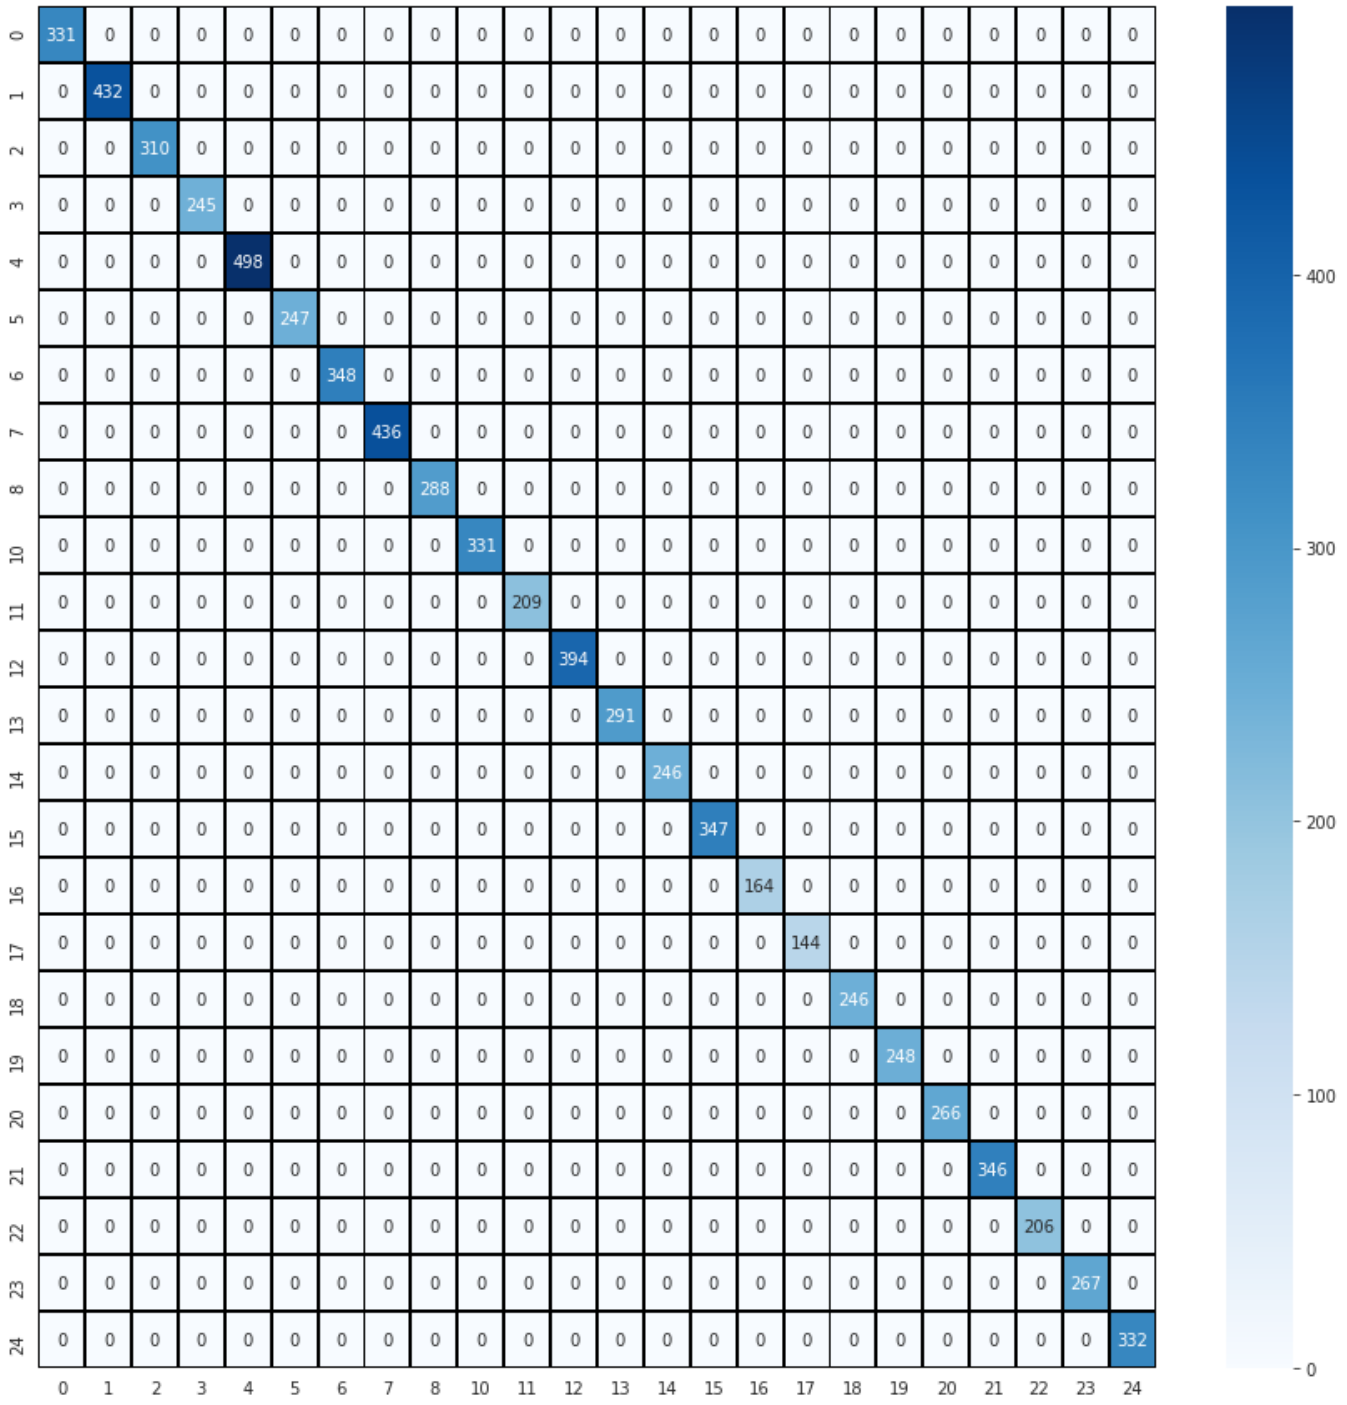

Fig. 9. Confusion matrix of the proposed CNN-BiLSTM model for sign language recognition.

Fig. 10 presents a visualization of correctly and incorrectly classified sign language gestures by the proposed CNN- BiLSTM model with an attention mechanism. The top row displays images where, the model correctly predicted the sign, while the bottom row showcases misclassified instances. Each image is annotated with the predicted class (Pred) and the actual ground truth class (True), allowing for a comparative evaluation of classification performance.

From Fig. 10, it is evident that the model performs well on clear and well-defined gestures, as seen in the correctly classified instances. However, some misclassifications occur in the bottom row, primarily due to visual similarities between certain signs, occlusions, or variations in hand positioning. These errors highlight the challenges of distinguishing between similar sign gestures, reinforcing the need for advanced feature extraction techniques and attention mechanisms to enhance model robustness.

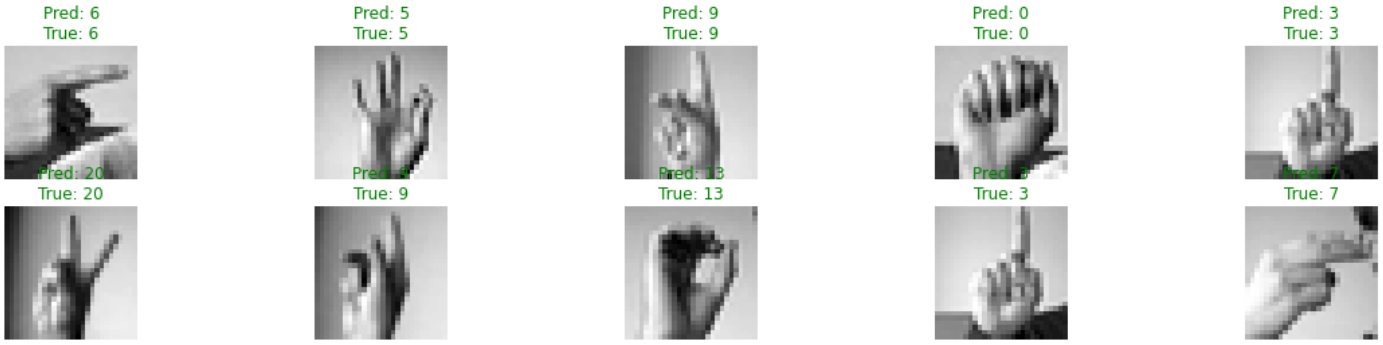

Fig. 10. Correct and misclassified predictions of the proposed CNN-BiLSTM model for sign language recognition.

The visualization provides valuable insights into common misclassification patterns, which can be used to refine the model by incorporating data augmentation, additional training samples, or improved temporal modeling. Despite minor classification errors, the model maintains high accuracy across different sign classes, demonstrating its effectiveness in real-time sign language recognition.

The experimental results demonstrate the effectiveness of the proposed CNN-BiLSTM model with an attention mechanism in sign language recognition, achieving high accuracy, precision, recall, and F1-score across all evaluated classes. The training and testing performance curves indicate fast convergence and minimal overfitting, validating the efficiency of the model in learning spatial and temporal dependencies. The confusion matrix analysis further confirms strong classification capabilities, with the majority of predictions aligning with ground truth labels. Additionally, the visualization of correctly and incorrectly classified instances highlights the model's robustness, while also identifying challenging cases where gestures exhibit high visual similarity. Feature map visualizations provide insights into the hierarchical feature extraction process, demonstrating how the convolutional layers effectively capture both low-level and high-level patterns in sign language gestures. These findings collectively affirm the potential of the proposed approach for real-time sign language recognition applications, offering a reliable and computationally efficient solution for assistive communication technologies.

## VI. Discussion

The findings of this study demonstrate the effectiveness of the hybrid CNN-BiLSTM model with an attention mechanism in sign language recognition. Compared to traditional machine learning approaches, deep learning-based models exhibit superior performance due to their ability to extract spatial and temporal features automatically [35]. The integration of CNN for spatial feature extraction ensures that the model captures intricate details of hand gestures, while BiLSTM improves sequential learning by processing temporal dependencies in gesture movements [36]. This combination enhances classification accuracy, particularly in distinguishing between visually similar signs.

One of the key advantages of the proposed model is its attention mechanism, which selectively emphasizes relevant frames within a sign language sequence. This mechanism mitigates the impact of redundant or ambiguous frames, resulting in improved recognition efficiency [37]. The experimental results confirm that attention-based feature refinement significantly reduces misclassification rates, as seen in the confusion matrix analysis. Furthermore, the feature map visualizations illustrate how the convolutional layers extract low- and high-level spatial patterns, contributing to enhanced model interpretability.

Despite these improvements, some challenges remain. The misclassified instances in the results indicate that certain sign gestures with similar hand shapes and orientations are more prone to confusion. These errors can be attributed to inter-class similarities and variations in user execution, which may require additional training data or more robust augmentation techniques to address [38]. Moreover, real-time implementation necessitates computational efficiency, making it crucial to balance model complexity and inference speed. Future work should focus on optimizing network architectures to reduce latency while maintaining high classification accuracy.

Additionally, while the proposed model achieves high precision and recall, further enhancements can be made by incorporating multi-modal inputs, such as depth information and hand movement trajectories. Recent studies suggest that fusing multiple input modalities significantly enhances sign recognition performance, especially in dynamic sign languages that require motion tracking [39]. Exploring the integration of transformer-based models could also be beneficial in improving long-range temporal dependencies in sign sequences.

Overall, this study demonstrates that deep learning-based approaches offer promising advancements in sign language recognition. By leveraging spatial, temporal, and attention-based feature extraction techniques, the proposed model achieves state-of-the-art performance while maintaining computational efficiency. These findings contribute to the ongoing development of real-time sign language translation systems, ultimately fostering more inclusive communication technologies.

## VII. Conclusion

The study presented a hybrid CNN-BiLSTM model with an attention mechanism for real-time sign language recognition, demonstrating high accuracy and computational efficiency. By leveraging CNN layers for spatial feature extraction and BiLSTM networks for temporal pattern learning, the model effectively captures intricate hand gesture variations. The

integration of attention mechanisms further enhances feature selection, reducing misclassification and improving overall robustness. Experimental results confirm that the model achieves superior performance across accuracy, precision, recall, and F1-score, validating its effectiveness in sign language classification. Additionally, confusion matrix analysis and feature map visualizations provide insights into how the model distinguishes between different signs, highlighting areas where future refinements can be made. Despite achieving high recognition rates, challenges such as misclassifications of visually similar signs and computational constraints in real-time applications remain. Future research should explore multi-modal data integration, lightweight architectures, and transformer-based models to further enhance recognition capabilities. Overall, the proposed approach provides a scalable and efficient solution for real-time sign language recognition, contributing to the development of inclusive assistive technologies for individuals with hearing and speech impairments.

# Investigating the Impact of Hyper Parameters on Intrusion Detection System Using Deep Learning Based Data Augmentation

Umar Iftikhar, Syed Abbas Ali
Department of Computer & Information System Engineering, NED University of Engineering & Technology, Karachi, Pakistan

***Abstract*—The effects of changing learning rates, data augmentation percentage and numbers of epochs on the performance of Wasserstein Generative Adversarial Networks with Gradient Penalties (WGAN-GP) are evaluated in this study. The purpose of this research is to find out how they affect the data augmentation to enhance stability during training. In this research, the degree of system performance is measured using the Classification Model Utility approach. For this reason, this study aims to determine the interaction between learning rate, augmentation percentage and epoch value when using WGAN-GP to generate synthetic data for the recognition of the system performance. The results will provide the indications on how some of the hyper parameters can be adjusted up or down for having positive or negative consequences on the generation process for further research and use of WGAN-GP. It also provides insights into how the generative model is trained, and how that affects stability and quality of the result in various settings such as image synthesis or other generative tasks.**

***Keywords*—Artificial intelligence; learning rate; cyber threat; network intrusion detection; deep learning; data augmentation; generative adversarial networks epochs**

## I. Introduction

The emergence of Generative Adversarial Networks (GANs) marked a turning point in the area of deep learning due to its unparalleled capabilities in data synthesis. Despite their impressive skill set, these models face some limitations which are crucial in achieving reliable stability and performance.

These models have proven their strength in providing realistic and high-quality data in multiple areas such as degenerate image data, augmentation, and style transfer. Yet, in spite of the boom, industrial-scale applications still face limitations. The capability and regularity of the sheer raw force of conventional GANs remain undermined by flaws such as the mode collapse and training imbalance [1]. Conventional GANs, for instance, still encounter some critical limitations that restrain their efficacy. Collapse of modes – when a generator creates a fixed number of varieties – and instability during training, to mention a few. A remedy for these issues is proposed by the Wasserstein GAN with Gradient Penalty (WGAN-GP) which is considered more robust. This revision utilizes the Wasserstein distance between two probability distributions as the loss for the generator and adds a gradient penalty for Lipschitz constraints. Therefore, this model increases the stability of training and leads to reliable outcomes. WGAN-GP demonstrates better performing metrics with less hyper parameter tuning, it does have extreme sensitivity within certain parameters, particularly the learning rate and the number of training epochs. Setting parameter values too high or too low can greatly hinder the convergence behavior of the model, negatively impacting its overall efficiency, resulting in poor quality outputs. This research intends to explore the influence of learning rate and epoch numbers along with other performance metrics on generative models, especially WGAN-GP. With this study, the authors hope to shed light on the intricate web of hyper parameters and model metrics, enabling better optimization of GANs training processes. The goal of this study is to investigate the relationship of learning rates and epoch values on the performance metrics of machine learning models [2].

### A. Research Objective

The objective of this study is to compare the various learning rate and epoch values in WGAN-GP models in combination with the augmentation percentage. To provide the best settings for training WGAN-GP models, this research aims to gain an understanding of how changing these hyper parameters affects the training process. This research systematically investigates the effect of significant hyper parameters on the performance of WGAN-GP, especially in terms of learning rate, data augmentation percentage, and epoch count, as summarized in Table I. The effect of different learning rates on the quality of generated data is analyzed to determine the optimal balance between training stability and convergence efficiency. A too high learning rate may lead to mode collapse or unstable training dynamics, and if the learning rate is low enough, convergence could be too long and model performance suboptimal. Moreover, the role played by the fluctuation in different percentages of data augmentation in terms of output variability of WGAN-GP was evaluated in quantifying the value added in generating diverse samples without overfitting. Moderate augmentation may augment the generalization, but if augmentation is excessive, it will add noise to samples, deteriorating their fidelity [13], [16]. In addition, the quality of the model's ability to generate, with varying epoch numbers, is analyzed to pinpoint where the continued training no longer improves the model qualitatively or results in overfitting. Under fitting and overfitting are traded off to optimize representation capacity for a model. A comparative analysis of multiple training configurations is conducted, identifying trends in stability, mode collapse, convergence rate, and overall data fidelity. These insights enable the formulation of a comprehensive understanding of the interplay between hyper parameters and model performance. Based on these findings,

optimal hyper parameter choices for WGAN-GP training are recommended, emphasizing configurations that maximize output quality while maintaining training efficiency. The study highlights best practices for tuning WGAN-GP, ensuring robust and high-quality generative modeling, with a focus on mitigating instability and enhancing sample diversity. The resulting guidelines provide a structured approach to hyper parameter optimization, facilitating effective training of WGAN-GP across various data domains.

The present research study extends the earlier study [30] by optimizing the selection of hyper parameters with methodological consistency. In this study, 12 different learning rates were tested from 1.00E-03 to 100E-01, with a difference of 9.10E-03 between steps, in addition to two epoch values (100 and 150) and two augmentation percentages (30% and 50%), resulting in 48 experimental runs. Even with these adjustments, the experimental setup continues to be consistent with that of the earlier study, maintaining continuity while aiming for a more efficient and focused hyper parameter tuning. The augmentation percentage parameter is taken into account for the experimentation in contrast to the previous study being conducted, which further helps to analyze its behavior on the overall performance of the system. This work builds on the earlier study by modifying the learning rate interval and augmentation method, maximizing the experimental configuration for a more accurate performance assessment.

The aim of this study is to systematically evaluate how generative models, specifically WGAN-GP, are affected by learning rate, augmentation percentage and epoch values. WGANs with Gradient Penalty (WGAN-GP) fundamentals including effects of learning rate, epoch count on training dynamics, and the dataset used for experimentation were discussed in Section II. In this section, an explanation of the background concepts was also provided. The subsequent Section III marks the beginning of the results section, which provides the steps carried out in this study such as model building, setting the hyper parameters, and establishing the model benchmarking procedures. A comprehensive analysis is represented in Section IV, and Section V where results from the different experiments are highlighted through trends and parameter comparatives throughout the experiments. In the final Section VI of the study, a summary of primary lessons alongside outstanding research opportunities are incorporated within the conclusions.

## II. Background

### A. Background on WGAN-GP

GANs are generated by two deep neural networks, as shown in Fig. 1, such as the generator, which produces synthesized data and the discriminator, which evaluates the synthesized data generated by the generator. As for the discriminator, the authors of traditional GANs utilize binary cross-entropy loss to adequately separate real and fake data points, yet the implementation is problematic because of gradient vanishing. The GAN model named WGAN replaces the standard loss functions with the concept of the Wasserstein distance, giving a smooth gradient and hence better training ability. However, the original WGAN come along with some issues such as weight clipping that at sometimes is not efficient. To resolve this issue, WGAN-GP uses gradient penalty term to maintain the value of Lipshitz on the required range and thus model converges stability [3]. However, modern WGAN-GP model still suffer from the problem of hyper parameter sensitivity. Learning rate means the rate at which the model adjusts its parameters, which defines the stability and convergence of the model. If the learning rate is too high, the model may never or if the learning rate is too low, then the time taken to complete the modeling process is doubled. On the other hand, the number of epochs shows for how long duration model has been trained; if this number is less, the model may not learn much and it may be under-fit, and if otherwise, the model may over-fit or computer time may be too much [4].

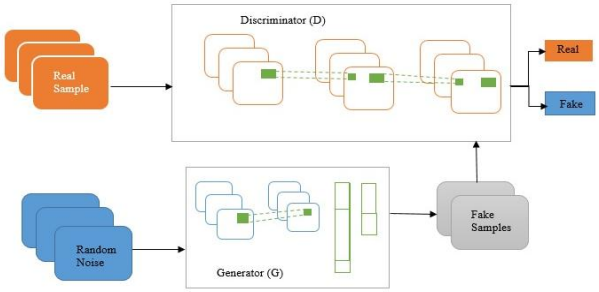

Fig. 1. Workflow of GAN.

### B. Impact of Epoch on WGAN-GP

The number of training epochs in deep learning models, including WGAN-GP has a huge impact on the quality and stability of the produced outputs. An epoch means an iteration of the data set over the model's structure, which implies that the number of epochs determines how much the model learns the data. In decision-making during training, it is important to select the best number of epochs in order to get the best model without common problems, under fitting or overfitting. Learning with fewer epochs comes to the drawback as the generator is not fully trained to capture any realistic patterns in the data set [7]. This often results into production of poorly focuses, low quality or unrealistic output. The discriminator in WGAN-GP might also be weak, it does not offer the necessary feedback to enhance the generator. On the other hand, training continues for a number of epochs, degrades the general sample generation capability of the model as it overfits the training data. Overfitting causes the variation in the generated outputs to be low and might bring in artifacts that reduce the quality.

In particular, the number of epochs depends on such factors as the given data density, the structure of the generator and discriminator, and the available computing capabilities. Original experiments have revealed that for various types of GAN-based models including WGAN-GP the quality is highest at a particular number of epochs, and in fact degrades in specified epoch values. This happens due to the fact that the balance between the generator and discriminator is less optimal for successful training [8], [10]. This work provides a comprehensive analysis on the performance change of WGAN-GP based upon various epoch settings. In this case, the study seeks to pinpoint epoch range that effectively address the problem by comparing loss trends, sample quality, and training stability, while at the same time avoiding pitfalls such as mode collapse, overfitting, or inefficient training.

This research will seek to establish the effect that learning rates and epochs have on the performance of Wasserstein GAN with Gradient Penalty (WGAN-GP). In order to accomplish the research goals, systematic experiments involving a proper generative dataset and a strong model deployment system will be performed. The applied approach includes choosing the dataset, setting up of the WGAN-GP model, conducting of the experiments, and qualitative and quantitative assessment of the results as shown in Fig. 2.

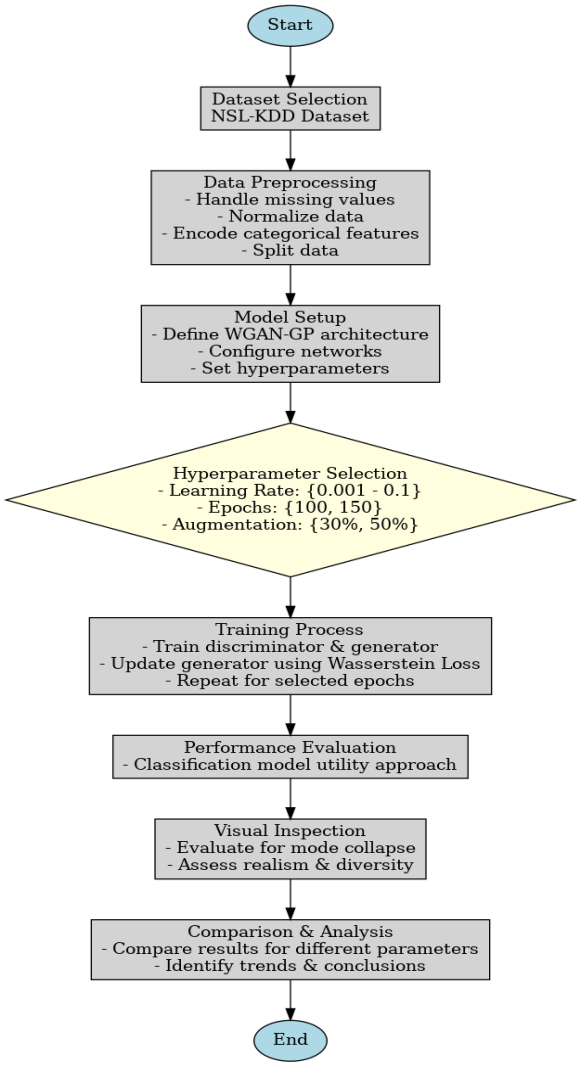

Fig. 2. Experimental process for evaluating WGAN-GP performance.

### C. Impact of Learning rate in WGAN-GP

The learning rate is one of the key hyper parameters to deep learning models including the Wasserstein Generative Adversarial Networks with Gradient Penalty (WGAN-GP) [22]. Controls the size of weight update at back propagation and has a direct impact on speed of convergence, stability of the model and final performance. In order to obtain high quality generative results, and to ensure a stable training process, the choice of an adequate learning rate is crucial.

However, in WGAN-GP, an accurate learning rate helps the generator and discriminator learn well without introducing instability. A small learning rate means that it takes many epochs for the network to arrive at satisfactory performance. Although this improves the stability of the model, it also has some negative effects of high computational costs and thus time-consumptive [5], [19]. On the other hand, high learning rate will result in large weight updates, which results in very unstable learning, instability or even learning diverges. If the learning rate of the model is set to a wrong value, the generative model may not be able to learn valuable representations hence the generated outputs will be of low quality with some artifacts or mode collapse.

Several strategies have been proposed to address the issue of learning rate setting in deep learning. Some of the methods used include; learning rate scheduling, adaptive learning rates, and cyclical learning rates which enhances efficiency of the training progress. However, the optimal learning rate is still an issue of contention regarding the WGAN-GP due to its delicate training dynamics [6]. This research explores the performance of WGAN-GP in terms of convergence with some of its learning rates altered in order to evaluate the quality of the generated outputs. Thus, because of the systematic variation and examination of the learning rate in this study, it is expected to determine the adequate learning rate that leads to the improvement of the stability, speed and generative performance of the WGAN-GP.

### D. Dataset Selection and Preprocessing

This study has chosen such datasets that are used the most in network anomaly detection, i.e. NSL-KDD [31]. This dataset is widely used for benchmarking the IDS, which is the reason for the use of this dataset. Also, it is suitable for academic research and to build a proof-of-concept models. That will be another advantage of using NSL-KDD, as it is compact and not complex to implement as compared to a fully-fledged model.

It does not include encrypted traffic or emerging attack types. The NSL-KDD dataset is an improved version of the KDD Cup 1999 dataset, which was developed due to the problems such as redundancy and class imbalance [9]. Thus, it is useful in improving and enhancing the standard for measuring the efficiency of the Network Intrusion Detection System (NIDS). The dataset provided here in KDD Cup 1999 contains a huge number of duplicate instances, which becomes too noisy during training of the machine learning model [12], [14], [26]. Because of this, NSL-KDD has an advantage, whereby most of the record duplication instances are considered as redundant and removed. The removal of such duplicated records leads to more optimized and refined data of the network traffic by increasing the capacity of evaluating the performance of NIDS.

There are 41 features in the NSL-KDD that were used as an ability to capture the characteristics of the network traffic. Some of these characteristics are certain connection details, timing details, the number of bytes that have been transferred and the actual payload content that has been transposed. These are in turn grouped in structural, content, time-based and host-based that aids in achieving enhanced statistical and machine-learning methods employed in intrusion detection. Therefore, the improvement over KDD-NSL concerning the reduction of loop redundancy and the balanced proportion of connections in different classes improves the ability to identify frequent and

infrequent attacks in NIDS [11], [15]. This type of dataset has been widely used in the research to develop and evaluate new algorithms and, therefore, this kind of dataset is more appropriate for the application of network security and the detection of intrusion.

## III. METHODOLOGY

### A. Model Initialization

K-Nearest Neighbor (KNN) is a nonparametric, supervised learning approach commonly used for classification and regression purposes. This occurs through identifying the 'k' closest points referred to as neighbors in the featured space compared to an input point. Moreover, it offers predictions either on the majority class in the case of classification or the averages of their values in case of regression. These distance metrics include Euclidean distance metrics, Manhattan distance metrics, Minkowski distance metrics as well.

KNN is particularly useful in detecting an anomaly as it can be seen to be accustomed to identifying data points that are far from the nearest neighbors of the given point. On the contrary, abnormal observations seem to have averagely or significantly fewer or a significantly higher number of neighbors compared to normal observations. KNN's are very handy, especially when it comes to handling multidimensional data and do not involve a lot of implementation complexities. That is; K= number of records in the training section analyzed to calculate the Euclidean distance for one record to all records in the training section and find a winner, K + 1= number of records stayed in the training section during the calculation of the distance between that record and all records in the training section and find the winner and member number of the record set of the training section.

$$\boldsymbol{d(x, y) = \sqrt{\sum_{i=1}^{n}(x_i - y_i)^2}} \quad (1)$$

where,

d is the distance between two points x and y in an n-dimensional space.

The formula for calculating the anomaly score is given as:

$$Anomaly\ Score(x) = d\left(x, x_{(k)}\right) \quad (2)$$

where,

$x_{(k)}$ is the kth nearest neighbor of (x).

### B. Hyper parameter Configuration

Consequently, the aim of this study is to investigate the influence of learning rate and number of epochs on the accuracy of the WGAN-GP model. Therefore, the present research will feature plans to experiment with both of these two hyper parameters in an attempt to determine the impact of altering each of them on the required standards of the generated outputs. These are the learning rate that will also be altered to understand the effects it has when varied in its options, and number of epochs. The following is the summary of the hyper-parameters:

- Learning Rate: Determines change in weight per iteration and improves speed/stability of training.
- Num Epochs: Defines the number of times, for how many times the model is go to see the entire data while training.
- WGAN Data Augmentation Percentage: how much data is generated from the original data?

TABLE I. HYPER PARAMETER CONFIGURATION

| Total Instances | Learning Rate Range | Step Difference | Epoch Values | Augmentation Percentages |
|---|---|---|---|---|
| 48 | 1.00E-03 to 1.00E-01 | 9.10E-03 | 100, 150 | 30%, 50% |

### C. Evaluation Metrics and Qualitative Assessments

Both quantitative and qualitative approaches will be adopted in measuring performance as a means of having a balanced research outlook in the bid to establish the extent to which the model can create realistic synthesized data. In the present research context, Wasserstein Loss is one of the measures taken into consideration. It is used to measure the generative data, and it is core to the assessment of convergence of WGAN-GP with the actual data distribution. Another benefit of Wasserstein Loss is that compared to cross entropy loss, Wasserstein Loss provides a continuous gradient that helps a model steadily improve and generate many nearly realistic samples. As a result, this loss should be monitored to determine whether the model is learning and converging over time. The experiment's flow will be organized and conducted systematically in order to compare the effects of varying learning rate and epoch settings on WGAN-GP's performance accurately. To start with, the datasets that are to be used for training, which are NSL-KDD, will be preprocessed. After that, the training process will be taken over by varying the values of learning rate and number of epochs, and the model will be trained for each setting of both hyper parameters. In each iteration, the WGAN-GP model will work in turn to update both the discriminator and the generator [17], [18]. Every epoch contains several steps that include a discriminator to recognize sampled real and generated data, and update the generator based on this discriminator feedback. The above-described procedure of training will go on until the model is trained up to the possible maximum epochs or for a fixed epoch. It will then be conducted for all the selected learning-rate and epoch values in order to establish the relationship between these parameters and model's performances in producing realistic outputs.

The Classification Model Utility approach will be used to assess the model's performance after every training run. This approach is where the model is trained on the original data set while the other model is trained on the original and synthetic data set and both models are tested on the same validation set. A higher performance on the validation dataset proves the synthetic data's consistency and usefulness [29], [30]. This step will assist to detect flaws, for example, in the type of mode collapse, degenerate textures, or limited variation of the synthesized data produced. Adding these visual inspections to the quantitative measures will provide greater insight on the model's behavior and execution. After all the training runs have been performed, one will be able to compare the learn rate and epochs thus getting the needful and expected outcomes. This comparison will involve comparing the effects of altering the

hyper parameters in the performance of the adjusted model. The identification of trends in the quantitative metrics, coupled with the results of the visual inspections, will aid in determining the most appropriate learning rate and epochs to be used to prevent overfitting or insufficient training. This will be done numerically as well as in terms of the final generated samples to understand the impact of these hyper parameters when changing in WGAN-GP.

### D. Performance Metrics

The parameters applied on WGAN-GP for examining the performance are as follows:

Accuracy (ACC): It is considered as the most important parameter in evaluating the model's performance. This metric evaluates the quantity of number of samples that are correctly predicted over the number of all samples. The formula for calculating this metric is:

$$ACC = \frac{TP+TN}{TP+TN+FP+FN} \quad (3)$$

Recall: This parameter refers to the capability of the machine-learning model for predicting positive samples. It is calculated by dividing the number of samples that are categorized as true positive over all positive samples. The formula for calculating this metric is:

$$Recall = \frac{TP}{TP+FN} \quad (4)$$

Precision: In this parameter, true positive identified number of samples over number of samples that are predicted as positive. The equation for calculating this metric is:

$$Precision = \frac{TP}{TP+FP} \quad (5)$$

## IV. Experimental Results

In cyber threat detection the effectiveness of adaptive generative data augmentation is evaluated by a series of experiments, which were conducted on different augmentation series and training configurations. This study explores the impact on model performance occurs due to different settings of hyper parameters. Additionally, it focusses on generalization and optimization of the dynamics of model performance.

TABLE II. Performance Metrics of WGAN-GP Across Different Hyper parameter Configurations

| Performance Metrics | | | Hyper Parameter Configuration | | |
|---|---|---|---|---|---|
| **Accuracy** | **Precision** | **Recall** | **Learning Rate** | **EPOCH** | **Augmentation Percentage** |
| 0.856822 | 0.870409 | 0.85682183 | 1.00E-02 | 100 | 50.00% |
| 0.85297 | 0.855726 | 0.852969502 | 8.20E-02 | 150 | 50.00% |
| 0.815516 | 0.840894 | 0.815516319 | 2.80E-02 | 100 | 50.00% |
| 0.812413 | 0.812486 | 0.812413055 | 3.70E-02 | 150 | 50.00% |
| 0.74646 | 0.768186 | 0.746459782 | 3.70E-02 | 150 | 30.00% |
| 0.711932 | 0.79942 | 0.711931514 | 4.60E-02 | 100 | 50.00% |

Table II depicts the better performance on the specific hyper parameter configurations than the original dataset. It shows that out of 48 instances, the mentioned combinations have showed a significant increase in performance metrics as compared to the model performance on original dataset before the data augmentation. The data shown in Table II indicates the highest learning rate of 1.00E-02 at 100 epochs and 50% data augmentation, suggesting an optimal balance for model generalization.

Graphical presentation of these data is shown below in Fig. 3, which shows that the 50% augmentation covers a band while 30% augmentation shows a significantly lower recall which reinforces that model performances can be enhanced if sufficient data augmentation (50%) is used.

Fig. 4 suggests that training without proper learning rate may leads to diminish returns. The trend for recall also suggests the same and indicates optimal performance in 100 epochs with well optimized learning rate. As shown in Fig. 4, it is found that the highest level of accuracy is achieved at epoch for both levels of data augmentation. Following this, accuracy begins to deteriorate slightly, this indicates overfitting or the training has been carried out to the extent that the model is memorizing the set data instead of just learning. This occurs since, with a lot of training, the model is tasked with memorizing the training data and not learn general patterns that may occur in other real data [21].

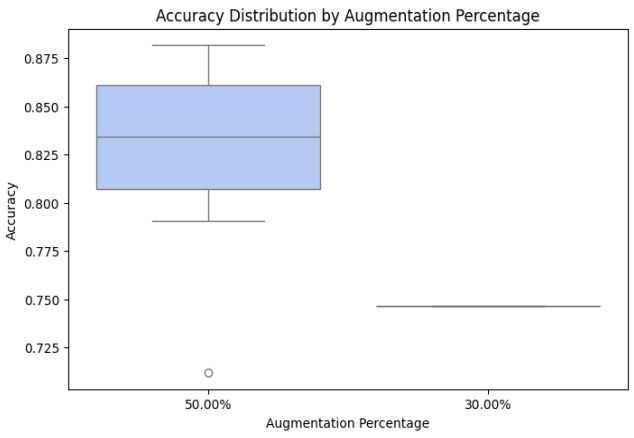

Fig. 3. Accuracy distribution by augmentation percentage.

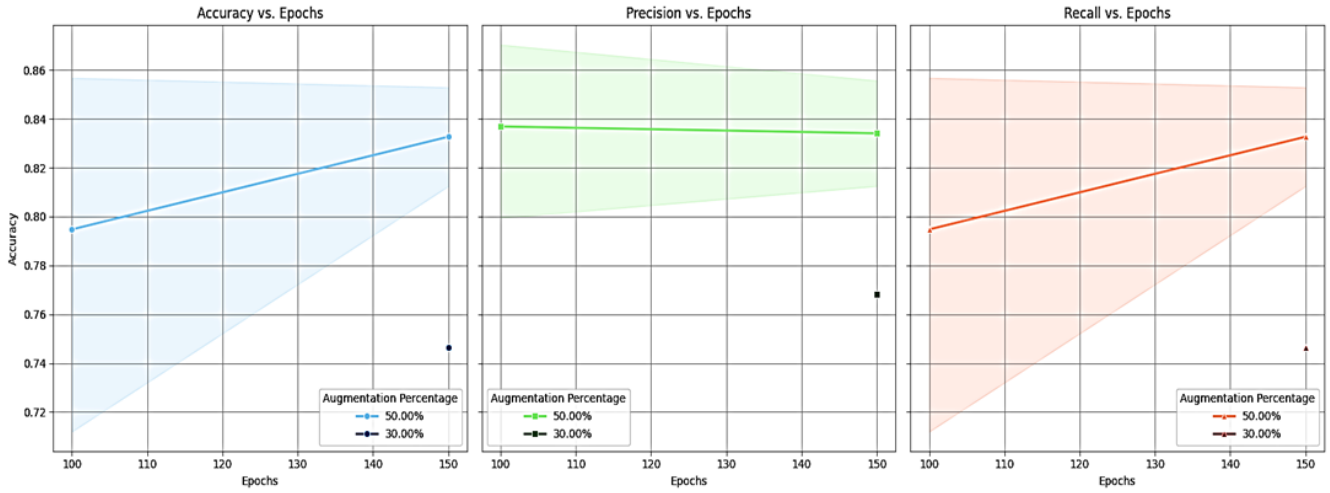

Fig. 4. Comparative view of accuracy, precision and recall with epochs.

As for configurations, the one of data augmentation equals to 50% provides better results in most cases in terms of accuracy compared to 30% augmentation. What this entails is that inputting a broader and comprehensive variety of augmented data aids in the model's performance in terms of generalization. Even when it comes to precision, the aim of having 50% of servings augmented is seen to be the best. As can be noticed, precision does not decrease with time, and therefore, it is stable in different epochs. This implies that a reduced 50% augmented model yields a fewer number of false positive as compared to the 30% augmented model. Fewer false positive means that the model is correctly segregating between relevant and irrelevant samples which is extremely important when the classification is done, and leads to certain results [20].

A higher level of dispersion in the accuracy values is noted as shown in Fig. 5 and Fig. 6, which suggests variability in the performance of models in the different configurations. The median has been increased compared to the 30 percent augmentation result which affirms the benefits of incrementing the augmentation percent. Nonetheless, there are a few points with the accuracy below the average, which indicates that the higher level of augmentation does not have as a positive effect on certain configurations. Nevertheless, a majority of the accuracy values have a higher stage, which provides evidence that 50 percent augmentation ratio still helps to enrich the model.

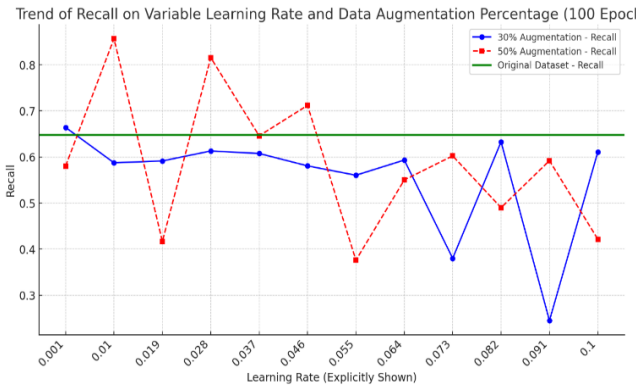

Fig. 5. Trends of Accuracy on variable learning rate and data augmentation with 100 epochs.

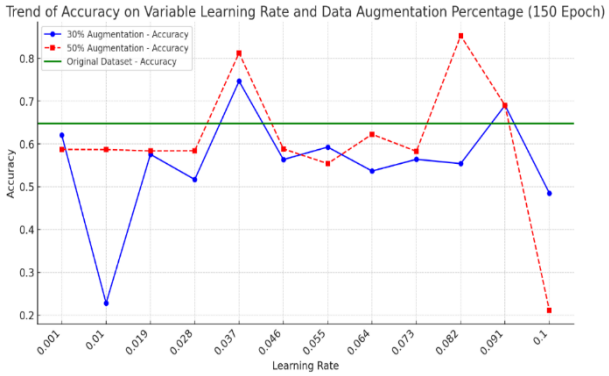

Fig. 6. Trend of accuracy on variable learning rate and data augmentation with 150 epoch.

From Fig. 5 and Fig. 6, the accuracy for 30% augmentation is lower compared to the previous results, which indicates less efficiency. Therefore, all the estimated accuracy values are less than in the 50% augmentation scenario. The box plot shows the minimal variation, proving that lower levels of augmentation only bring a marginal improvement in performance. In this case, the fact that there are few changes foretells that an augmentation by 30% does not lead to enhancing the model's ability to generalize or its robustness.

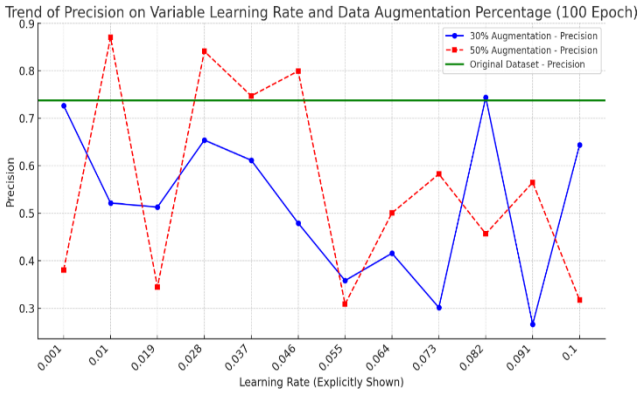

Fig. 7. Trend of precision in variable learning arte and data augmentation with 100 epoch.

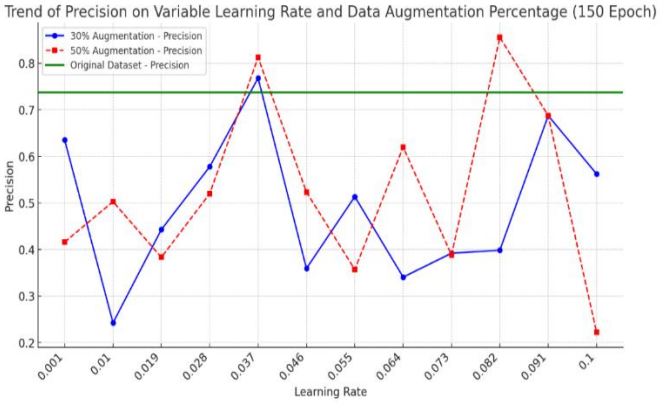

Fig. 8. Trend of Precision on variable learning rate and data augmentation with 150 epoch.

Fig. 7, and Fig. 8, present the trend of precision for various learning rates and augmentation levels of data (30% and 50%) with two specific epoch values. A drop at a learning rate of 0.053 indicates an unstable zone where performance drops in the model. The instability possibly stems from poor convergence or too much weight update, causing non-optimal learning. As the learning rate diverges from this unstable region, accuracy becomes stable, illustrating the significance of having a suitable learning rate.

In 100 Epochs, Fig. 9, recall for a 50% increase in most learning speeds, except for a noticeable peak of 0.082, is still relatively stable. This suggests that the medium learning speeds combined with high growth levels help the model maintain more positive examples. In contrast, a 30% increase shows more fluctuations, sharp falls of 0.01 and a gradual medieval recovery (0.046 to 0.082). Increased volatility at low growth levels indicates that insufficient data text affects the model's ability to normalize. With a high teaching rate (0.1), recall means both growth percentages, indicating the model's instability. In 150 Epochs, Fig, 10, the recall is improved and is stable compared to 100 epochs, reflecting the benefits of extended training. Extending the training period to 150 epochs, as depicted in Fig. 10, results not only in an enhancement in recall performance, but also significantly sharpens the consistency relative to the scenario with 100 epochs.

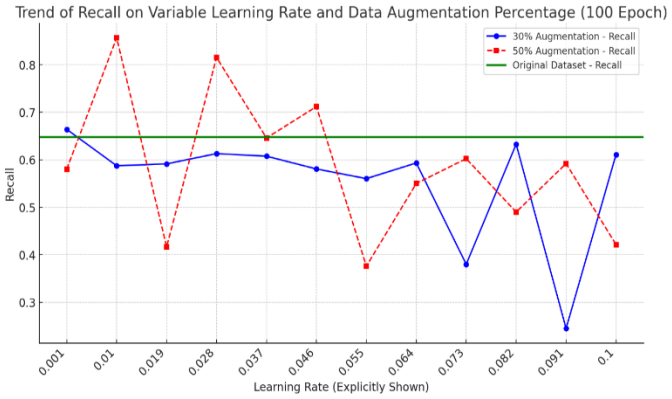

Fig. 9. Trend of recall on variable learning rate and data augmentation percentage with epoch 100.

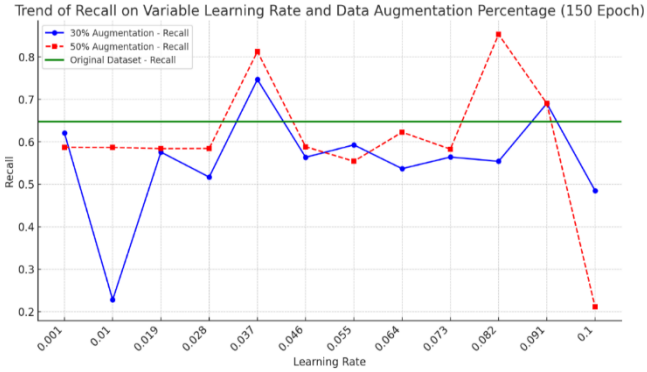

Fig. 10. Trend of recall on variable learning rate and data augmentation percentage with epoch 150.

## V. Discussion

The interaction among learning rates, epoch numbers, and levels of data augmentation is important to get a better understanding of the research objective. The results presented in the above section provided deeper insights into the behavior of the model under diverse training scenarios.

As shown in F II, some hyper parameter settings perform much better than the model trained on the original dataset alone without augmentation; of 48 instances tested, some combinations, especially those using more data and learning rates fine-tuned, showed significant improvement in performance. Specifically, the setup with a learning rate of 1.00E-02, 100 epochs of training, and 50% data augmentation produced the most beneficial outcomes, which suggests the best balance between training depth and model generalization. These findings further stress the need for well-chosen training parameters in improving the capability of the model to learn from and accommodate more varied data.

In cyber threat detection, an effective combination of moderate learning rate, controlled epochs and higher augmentation is crucial for optimization. In terms of accuracy and precision, the trend suggests that 100 epochs yield better performance than 150 epochs when paired with optimize learning rate.

The efficiency of the model is enhanced when trained for 150 epochs compared to 100 epochs to prove the model learnt sufficiently more epochs as training epochs increases. Further on in training, another important characteristic of the model develops in that the model is able to comprehend more complex patterns and representations, thus the accuracy, precision and recall will be improved. This means that the differences between 30% and 50% augmentation are as follows: The readers are as follows: But it was also observed that both augmentation percentages improve with an increase in training time, while 50% augmentation performs better than 30% augmentation in most cases, which ends the thought that higher synthetic data helps in improving the generalization of the model. Further, for all the evaluation criteria and epochs as well as augmentation level, it is found that all the Q-Learning rates in the mid-range categorized between 0.037 and 0.082 are the best performing one. These discoveries show that there is a factor of the training period and rate to be considered in order to achieve the best performance of the model. There is an improvement in all of the

metrics, accuracy, precision and recall, if 50% is augmented instead of 30%. The fact that more augmentation allows for the creation of more various samples in the synthetic data, decreases overfitting and increases generalization of the model when it is trained on it. The improvement is most significant at a moderate learning rate, where the augmented data is valuable in providing the model with the right guiding patterns without the inclusion of noises. This means that in this particular dataset and for this particular task, a higher level of augmentation is beneficial on the model. As indicated, the learning rates between 0.037 and 0.082 are suitable for the high augmentation level and overall, provide the best results. These values determine the trade-off of fast convergence or stable convergence in a learning process. Too small learning rates such as 0.001 to 0.01 make the learning slow and ineffective, mostly due to slow convergence. Taking such small steps means that the model may take too long in order to learn meaningful features during the training phase which results in poor performance even when the number of iterations is increased. However, if the learning rate = 0.1, this causes instability and degradation of the performance. It stirs difficulty to reach nadir solution, as large update alters the weights radically, resulting in impulsive degradation of accuracy, precision and recall. This goes to support the argument that the learning rate should be properly selected and small to large values should be avoided, while small to large values could take a long time to converge and are somewhat unstable. The model tested for 150 time passes through the training set and, therefore, it demonstrates an increase in its performance that should be emphasized as a result of protracted training, particularly for large sets. More training iterations enable the model to perform very effectively in analyzing and identifying patterns in the data and thus increases the accuracy, precisions, and recall. However, as it has been demonstrated, more sophisticated training aids in the improvement of the learning rates but their tuning is still essential in order to avoid overfitting as well as instability. Selecting a bad learning rate, even if training is conducted for a long time, can have a negative impact on the performance. Consequently, it was identified that to obtain the best performance, the number of epochs must be at least 150 along with the best learning rate. Accuracy, precision, and recall exhibit similar trends across different learning rates, augmentation levels, and epoch counts. This ensures the accuracy of the analysis as it shows that the changes are not arbitrary but due to the model's response to various conditions. This fact implies that the model performs well across all three metrics because there is no extreme focus on one of the metrics while ignoring the other two. From the above analysis, it can be recommended that the following measures should be taken in order to enhance the performance of a model. First, a 50% of augmentation should be applied to decrease the model variance and subsequently improve generalization to all the metrics. Secondly the learning rate should be chosen in a certain range 0.037 to 0.082 in order to decrease speed of convergence and increase stability. Lastly, training should be carried out to the 150-epoch level in order to achieve the best results, especially where there is large data or complicated structures. That being said, the following recommendations will develop better performing workflow while keeping it stable and efficient to an extent.

Therefore, based on accuracy, precision, and recall, 50% augmentation is better than 30 % augmentation. The higher level of the data augmentation brings more diversified data samples that increase the ability of the model to generalize. This is very well illustrated in the convergence which shows that for all the epochs, 50% augmentation provides higher scores than models trained with other levels of augmentation. Also, it can be seen that standard deviations in 50% augmentation are distributed over a wider range showing more versatility that can be advantageous in practical applications across different settings. The other benefit that could easily be observed in the implementation of 50% augmentation is enhanced recall. As recall is about the model's ability to identify all required cases, the improvement indicates that a higher augmentation level includes more relevant changes in the training data [24]. Consequently, the model becomes better at recognizing positive cases as well as does not overlook any vital patterns. This will prove helpful in situations where the false negatives are debilitating, for example, in medical diagnosis or checks on fraudulent individuals. On the other hand, the increased ratio of just 30% does not seem to give the model a large enough variety of samples to learn adequately. Overall, the augmentation percentage is generally below what is obtained with a 50% augmentation number. Additionally, referring to entropy analysis and the trends in precision and recall, it can be concluded that the increase does not exceed 30% and thus cannot produce enough variation in order to achieve higher results. This shows that the model trained with 30% augmentation might have a difficulty in learning proper representations that can generalize well. However, the lower recall and precision observed in 30% augmentation suggest that the model is more error-prone. As shown from the results, the model entails lesser parameters hence, it fails to capture a large amount of data, which leads to higher percentage of false negatives, and it also has fewer capabilities of classifying relevant data from irrelevant data. Such issues indicate that 30% augmentation may not be the optimum solution for applications that require high reliability. Another noteworthy discovery revealed in this comparison is that precision is steady even as the epochs increase for 50% augmentation. It is clear from the above findings that the precision rate is still higher in models that have been trained with an augmentation of 50% as compared to that of 30%. This means that the model is more accurate in avoiding false positives which are very important in real-life scenarios due to the impact of wrong classification [25], [27].

In overall the result of every epoch shows that by increasing augmentation percentage, the precision rate is also more stabilized. The recall values also are exhibited in the same manner as accuracy. Thus, the performance scores for recall in both augmentation levels initially rises and after that reduces from the epoch of training. As it may be inferred, a higher augmentation percentage increases that kind of performance, but that extensive epochs diminish the ability to correctly classify positive samples. Hence, the results suggesting that recall of 50% was obtained with 50% augmentation supports the point about appropriate augmentation resulting in improved sampling of the whole population. Considering the accuracy, precision, and recall trends over time, it is clear that precision is a relatively stable metric where values fluctuate the least, although settings such as the '50% augmentation setting' show marginal downs

and ups. Both accuracy and recall present some of the fluctuation though, whereas, the precision has ameliorated more or less in a general improved trend. This stability also shows the advantage of using a higher augmentation percentage because the models over emphasizing does not deteriorate such aspects [23], [28]. However, it is crucial to remember that after certain epoch level, the accuracy and recall become less efficient, which again reflects that there are more other steps such as early stopping to prevent overfitting. These three factors offer significant insight into the best setup for model training. The first important conclusion is that the increase of the number of samples by 50% also increases precision because it is the ratio of accurately identified positive cases. The study also notes that there is a tendency to overfit the training data when the epochs are trained beyond the threshold value. After this point, both recall and accuracy surface as having a decreased rate, which indicates that the oversimplification of training is detrimental. It is noted that this situation calls for either the use of early stopping techniques or the learning rate changes for the best results.

The evaluation based on Fig. 5 and Fig. 6, suggests that 50% augmentation is better in terms of median accuracy and variability as the method deploys fewer units at once but has a higher potential by maintaining precision across various configurations. The variability of accuracy seems to go up, and it means that higher levels of augmentation aid in enhancing the model's flexibility. On the other hand, a narrower range of accuracy in the 30% augmentation scenario also suggests that the augmentation is not very effective in enhancing the generality and stability of performance. Therefore, the use of 50% augmentation can also be seen to be more effective in improving the performance of the models than 30% augmentation.

The analysis of recall performance within various learning rates and data growth factors for different training durations offers important understanding into the characteristics and stability of the WGAN-GP model. Recall, for the most part, remains stable in the 50% data growth mark for most learning rates with a peak at 0.082. This is especially the case for intermediate learning rates, which appear to be more favorable when combined with higher data availability, as the model's ability to recall and recognize salient examples improves. In comparison, the volatile recall performance at a 30% growth rate, with sharp subtractive spikes down 0.01 and gradual gains between 0.046 and 0.082, suggests that lower data growth levels might be inefficient, where insufficient training signals might hinder model generalizing and normalizing ability. Additionally, extreme learning rates, such as 0.1, invoke unstable recall at both growth percentages, highlighting the issue of structured adaptation under extreme learning conditions.

Higher levels of data augmentation also enhance generalization, minimizing overfitting and increasing robustness. Between the two augmentation approaches, 50% augmentation uniformly produces better accuracy at most learning rates and hence is the model of choice for stability and effectiveness of the model. From Fig. 9, and Fig. 10, the 50% increase improves an increase of 30% at all learning speeds continuously, strengthening the efficiency of improving the models' ability to capture positive examples. The best recall performance is seen in mid -range learning speeds (0.046 to 0.082), and corresponds to trends seen in accuracy and learning. However, recalling is still experiencing a sharp decline in the highest learning frequency (0.1) similar to other performance matrix. This further emphasizes that models prevent very high learning speeds instead of increasing performance.

## VI. Conclusion

In order to identify the best hyper parameter configurations for reliable and effective training, this study methodically investigates the effects of learning rate, epoch count, and data augmentation percentage on the performance of WGAN-GP models. This study highlights that excessively low learning rates slow convergence and result in suboptimal model performance, while high learning rates can lead to mode collapse and unstable training dynamics. It does this by examining a range of learning rates and determining the crucial balance between training stability and convergence efficiency. The study also explores how data augmentation can improve sample diversity and generalization, showing that while excessive augmentation introduces noise and reduces the fidelity of generated data, moderate augmentation improves the model's capacity to generalize. In order to identify the ideal point at which further training stops improving sample quality or results in overfitting, the impact of epoch count on model performance is also evaluated. Maximizing the representation capacity of WGAN-GP models requires finding the ideal balance between under-fitting and overfitting. Deeper understanding of stability, mode collapse, convergence rates, and the general fidelity of generated data can be gained by comparing various training configurations in the future studies. This study also emphasizes the need for integrated hyper parameter tuning because learning rate, augmentation, and epoch count all affect training dynamics. The results provide specific suggestions for choosing the best hyper parameters, guaranteeing that WGAN-GP models produce output of higher quality with increased stability and effectiveness. In real-world use cases, including healthcare, finance, and autonomous systems, stability and adaptability are as important as high accuracy. This 50% augmentation level combined with tuned hyper parameters seems to be a suitable solution for optimized performance with any configuration. By establishing best practices for tuning WGAN-GP, this study provides a structured approach for optimization of hyper-parameters, offering a robust framework for training diverse data domains in generative models.

Even with the insightful findings of this research, there are a number of limitations that must be noted. The analysis was based on a limited set of learning rates, epochs, and augmentation levels, which might not completely represent the behavior of WGAN-GP models on different datasets or more sophisticated data domains. Moreover, the research was based on traditional augmentation methods, excluding more sophisticated options like synthetic sample creation or domain-specific transformations that might have had varying results. The hyper parameter tuning was similarly performed manually without using automated optimization methods like grid search or Bayesian optimization, which may provide more accurate configurations. These constraints points to the necessity of wider experimentation and more adaptive tuning approaches in

subsequent research to further improve the generalizability and stability of WGAN-GP models.

Future studies should similarly compare more varying augmentation levels in order to find out if there is any improvement. Moreover, future explorations should focus on more sophisticated augmentation approaches like: generating synthetic samples, and geometric transformations, that ideally could improve both adaptability and stability of the models when trained on various datasets. The learning rate determines speed at which the model travels through the learning space and hence, correct setting of this factor is important so that the model does not oscillate uncontrollably. Advanced variations like grid search or Bayesian optimization should be employed in future studies to determine the suitable learning rate that would enable fast convergence while at the same time avoiding premature convergence.

# Adaptive Crow Search Algorithm for Hierarchical Clustering in Internet of Things-Enabled Wireless Sensor Networks

Lingwei WANG, Hua WANG*
Guangdong University of Science and Technology, Dongguan, Guangdong, 523083, China

***Abstract*—The Internet of Things (IoT) relies on efficient Wireless Sensor Networks (WSNs) for data collection and transmission in various applications, including smart cities, industrial automation, and environmental monitoring. Clustering is a fundamental technique for structuring WSNs hierarchically, enabling load balancing, reducing energy consumption, and extending network lifespan. However, clustering optimization in WSNs is an NP-hard problem, necessitating heuristic and metaheuristic approaches. This study introduces an Adaptive Crow Search Algorithm (A-CSA) for clustering in IoT-enabled WSNs, addressing the inherent limitations of the standard CSA, such as premature convergence and local optima entrapment. The proposed A-CSA incorporates three key enhancements: 1) a dynamic awareness probability to improve global search efficiency during initial population selection, 2) a systematic leader selection mechanism to enhance exploitation and avoid random selection bias, and 3) an adaptive local search strategy to refine cluster formation. Performance evaluations conducted under varying network configurations, including node density, network size, and base station positioning, demonstrate that A-CSA outperforms existing clustering approaches in terms of energy efficiency, network longevity, and data transmission reliability. The results highlight the potential of A-CSA as a robust optimization technique for clustering in IoT-driven WSN environments.**

***Keywords*—Internet of things; wireless sensor networks; clustering; energy efficiency; optimization**

## I. Introduction

### A. Background and Motivation

The rapid expansion of the Internet of Things (IoT) has driven the widespread deployment of Wireless Sensor Networks (WSNs) for real-time data collection and communication in diverse applications [1]. Recently, WSNs have been extensively used in different sectors since they are affordable and easy to set up [2]. WSN comprises several diminutive Sensor Nodes (SNs) with restricted power supplies placed in surveillance regions to gather environmental information, including humidity, temperature, pressure, vibrations, and other characteristics [3]. The data is collected by combining many wireless connections and sent to a central station for assessment and processing [4].

Data transmission is the primary source of energy consumption in WSNs. SNs dissipate significant amounts of energy as packets of data are sent from one end of the network to the other. SNs are at risk of running out of energy while sending data packets owing to their low battery capacity. This issue can lead to premature network failure [5]. If not resolved, it poses a significant danger to the longevity of these networks. Reducing the size of data packets exchanged between SNs and finding the best routes for transmitting these packets are effective methods of managing energy usage in WSNs, resulting in enhanced and prolonged network functionality [6].

### B. Research Problem and Challenges

WSNs trace their roots back to the "Tropical Tree" sensor system employed in the Vietnam War. Shahraki, et al. [7], introduced a novel algorithm that synergizes clustering strategies with compressed sensing, providing formal proofs for optimal cluster size, Cluster Head (CH) distribution, and inter-layer relationships. This approach effectively mitigates "hot issues" and curbs energy consumption arising from frequent CH role rotations. Recent advancements in low-power communication and signal processing technologies have facilitated widespread WSN deployment.

While cluster formation and CH selection are fundamental to WSNs, traditional protocols like LEACH and its centralized variant face limitations due to increasing network demands [8]. As WSNs are primarily battery-powered with dynamic topologies and unfixed node IDs, specialized routing protocols are imperative [9]. Clustering algorithms divide the network into manageable clusters. Network longevity relies on efficient energy management, and routing protocols have evolved accordingly [10].

In parallel with these developments, cross-disciplinary advancements have further enriched the analytical frameworks supporting WSNs. For instance, machine learning techniques have been employed to model and predict system behavior under complex environmental and economic variables, offering insights into adaptive strategies for WSN optimization [11]. Similarly, advanced simulation models, such as those used for weak rock mass behavior, demonstrate the importance of integrating environmental variability into system design and reliability assessments [12].

### C. Authors' Contribution

This paper introduces a novel clustering protocol based on the Adaptive Crow Search Algorithm (A-CSA). This study seeks to answer the central question: How can the basic CSA be enhanced through dynamic parameter tuning, structured leader selection, and adaptive local search to improve energy-

efficient clustering and prolong network lifetime in IoT-enabled WSNs?

To alleviate the energy consumption burden on Cluster Heads (CHs), we propose a relay node-assisted approach. Each CH is assigned a dedicated Relay Node (RN), eliminating the need for CHs to select next-hop nodes and reducing channel contention. RN selection is based on available energy, distance to the Base Station (BS), and proximity to the CH. To optimize CH and RN selection, we formulate a bi-objective fitness function that considers node position and residual energy. Given the NP-hard nature of this problem, A-CSA is employed to derive optimal solutions efficiently.

The body of the paper is formatted in the following way. A review of related work in WSN clustering and metaheuristic algorithms is presented in Section II, summarizing key developments and challenges. System model, network architecture, and energy considerations are explained in Section III. Section IV describes the clustering approach in detail. Section V discusses the enhanced CS algorithm for cluster node updating. Simulated results are presented in Section VI. The paper concludes with a summary and suggestions for further research in Section VII.

## II. Literature Review

An overview of clustering and optimization protocols in WSNs is provided in this section. A comparison of metaheuristic and hybrid optimization techniques is presented in Table I, highlighting the key contributions of different approaches, algorithms, and performance metrics.

Chandirasekaran and Jayabarathi [13], developed a novel WSN protocol that leverages the Cat Swarm Optimization (CSO) algorithm for real-time clustering. Their approach minimizes distances within the cluster and optimizes energy distribution. By considering received signal strength, remaining battery voltage, and distance within the cluster, CSO effectively selects CHs. Performance evaluations against LEACH-C and PSO showed significantly improved battery life compared to traditional methods.

Mehta and Saxena [14], suggested a novel clustering and routing approach for WSNs using Sailfish Optimizer (SFO) to improve energy efficiency. A multi-objective fitness function guides the selection of CHs, prioritizing energy conservation and minimizing node failures. SFO determines optimal data transmission paths to the sink node. A comparative analysis of GWO, GA, ALO, and PSO shows superior performance for energy consumption and network lifespan, with corresponding improvements of 21% and 24% over GWO, respectively.

Nabavi, et al. [15], offered a novel hybrid approach to optimizing WSNs, combining genetic and Gravitational Search (GS) algorithms. The genetic algorithm was employed for CH selection, aiming to minimize intra-cluster distances and energy consumption, while GS was utilized for efficient routing between CHs and the sink node. The proposed technique demonstrated superior efficiency regarding energy efficiency, network throughput, and data delivery rate compared to existing techniques.

TABLE I Studies on Clustering and Optimization Strategies in WSNs

| Study | Algorithm(s) used | Contribution | Performance metrics | Shortcoming |
|---|---|---|---|---|
| [13] | Cat swarm optimization | Real-time clustering, minimizing intra-cluster distances, and optimizing energy distribution | Improved battery life | Premature convergence, lacks adaptive search mechanism |
| [14] | Sailfish optimizer | Multi-objective CH selection and optimal data transmission paths | Energy consumption and network lifespan | High computational complexity, lacks relay node optimization |
| [15] | Genetic and gravitational search algorithms | Hybrid approach for CH selection and efficient routing | Energy efficiency, network throughput, and data delivery rate | Increased computational overhead, no adaptive clustering strategy |
| [16] | Ant colony optimization and butterfly optimization algorithms | Energy-efficient clustering with mobile sink option to mitigate hotspot problem | Residual energy, throughput, and alive nodes | High convergence time, lacks adaptive exploration-exploitation balance |
| [17] | Differential evolution and sparrow search algorithms | Hybrid approach for energy-efficient CH selection | Network lifespan, residual energy, and throughput | Susceptible to local optima, lacks adaptive parameter tuning |
| [18] | Levy chaotic particle swarm optimization | Enhanced convergence and search space in cluster routing, focusing on realistic industrial conditions | Energy usage and network longevity | Lacks adaptive control over search balance |
| [19] | Capuchin search algorithm and fuzzy logic | Energy-efficient data aggregation with multi-phase cluster formation and routing | Energy usage, delay, packet delivery rate, and network lifespan | Complexity in multi-phase processing, no dynamic relay node selection |
| [20] | Fuzzy logic and quantum annealing | On-demand clustering and energy-efficient routing to extend WSN durability | Network lifetime, energy consumption, and throughput | Computational complexity and dependency on predefined thresholds |

Amutha, et al. [16], developed a novel energy-efficient clustering algorithm for WSNs that combines Ant Colony Optimization (ACO) and Butterfly Optimization (BO) algorithms. BO is employed for optimal CH determination, while ACO is used for energy-aware routing. To further extend network lifespan, two variants are introduced: HBACS with a fixed sink and HBACM with a mobile sink. The latter mitigates the hotspot problem by eliminating multi-hop communication between CHs and the sink. Simulation results with NS2 show significant improvements in residual energy, active nodes, and throughput for both variants compared to conventional algorithms.

Kathiroli and Selvadurai [17], suggested a hybrid optimization approach combining Differential Evolution (DE) and Sparrow Search Algorithm (SSA) to enhance energy efficiency in WSNs through optimized CH selection. Leveraging SSA's global search capability and DE's local search potential, the proposed algorithm effectively extends the network lifetime. Evaluation metrics include residual energy, network lifetime, throughput. Compared to existing methods, the hybrid SSA-DE approach demonstrated improved residual energy and throughput, highlighting its effectiveness in selecting optimal CHs.

Luo, et al. [18], developed an enhanced Levy Chaotic Particle Swarm Optimization-based Cluster Routing Protocol (LCPSO-CRP) for extending WSN lifetime. By introducing a chaotic optimization methodology, the protocol significantly accelerates convergence and expands the range of possible solutions. This innovative strategy, in accordance with BS distance, cluster-to-cluster distance, and node energy levels, outperforms traditional schemes like DEEC, LEACH, LEACH-kmeans, and LEACH-C. Extensive simulations under realistic industrial conditions demonstrate a minimum 22.9% reduction in energy consumption and a 13.9% extension of network longevity for LCPSO-CRP.

Mohseni, et al. [19], proposed a novel energy-efficient data aggregation routing mechanism for WSNs that couples the Capuchin Search Algorithm (CapSA) and fuzzy logic operators. This multi-phase approach comprises two primary steps: cluster creation and internal/external routing. Simulations using MATLAB validate the superiority of the suggested design regarding energy usage, delay, packet delivery rate, and network lifespan compared to existing approaches.

Wang, et al. [20], designed a hybrid routing and clustering protocol (FQA) combining fuzzy logic and quantum annealing to maximize WSN durability and decrease energy usage. Fuzzy logic is employed for intelligent CH selection, while quantum annealing optimizes data routing to the BS. An energy threshold mechanism is incorporated to expedite the process. Unlike traditional periodic clustering, FQA adopts an on-demand approach to reduce computational overhead. Comparative analysis against FC-RBAT, OAFS-IMFO, BOA-ACO, and FRNSEER consistently demonstrates FQA's better performance by demonstrating better network lifespan, data transfer rate, and energy usage across various scenarios.

Existing clustering and optimization techniques for WSNs have demonstrated notable improvements in energy efficiency, network lifespan, and data transmission reliability. However, several challenges remain unaddressed. Many approaches, including those based on CSO, SFO, and hybrid metaheuristic techniques, suffer from premature convergence, leading to suboptimal CH selection and inefficient energy distribution. Additionally, while hybrid methods enhance solution quality by leveraging multiple algorithms, they often introduce excessive computational overhead, making them less practical for real-time WSN applications.

Some techniques, such as those using fuzzy logic or chaotic optimization, improve network longevity but lack adaptability to dynamic network conditions. Furthermore, relay node selection remains an overlooked aspect, with most studies focusing solely on CH selection without optimizing multi-hop communication. To address these limitations, our proposed algorithm introduces dynamic awareness probability, systematic leader selection, and adaptive local search, ensuring balanced exploration and exploitation while enhancing clustering efficiency and energy management in IoT-driven WSNs.

## III. System Model

For real-time environmental monitoring, a WSN of $N$ SNs is considered. As shown in Fig. 1, each SN is equipped with a microcontroller unit, a communication unit, and a power management unit. SNs exhibit identical capabilities to operate in sensing or communication modes, collecting environmental data or transmitting information, respectively. Each SN possesses a data link to handle all data traffic. Nodes are spatially indexed. Static network topology is assumed to be consistent with typical WSN deployments. Table II summarizes the symbols and their definitions used in whole body of the study.

SNs are initialized with equal energy levels, creating a homogeneous network. It is impossible to replace the battery, simulating unattended operation. Environmental data are collected at fixed intervals and transmitted periodically. SNs can adjust transmission power across multiple levels based on recipient distance. Bidirectional communication links exist between nodes, with distance estimation relying solely on received signal strength. Exploiting data correlation, CHs compress gathered data into fixed-length packets. The BS maintains a continuous power supply.

This study adopts a simplified communication energy consumption model incorporating path loss effects, as illustrated in Fig. 1. The propagation channel is characterized by either free space (inverse square law) or multipath fading (inverse fourth power law) attenuation, contingent upon transmitter-receiver distance. Power control mitigates these losses. For distances below a threshold, $d_0$, free space propagation is assumed; otherwise, the multipath model prevails.

TABLE II SYMBOLS AND DEFINITIONS

| Symbol | Definition | Symbol | Definition |
|---|---|---|---|
| $N$ | Number of sensor nodes | $d_0$ | Threshold distance for free-space vs. multipath propagation |
| $K$ | Data packet size | $E_{TX}$ | Transmission energy consumption |
| $d$ | Transmission distance between nodes | $E_{elec}$ | Circuit energy dissipation per bit |
| $E_{RX}$ | Reception energy consumption | $E_{fs}$ | Free-space model amplifier energy |
| $E_{mp}$ | Multipath fading model amplifier energy | $k$ | Number of active (operational) nodes at a given time |
| $\xi$ | Predefined threshold for the proportion of dead nodes | $FND$ | Time until the first sensor node depletes its energy |
| $PND$ | Time until a specified proportion of nodes are dead | $\overline{CH}$ | Set of non-CH nodes |
| $n$ | Number of clusters formed | $R_{energy}^{CH}$ | CH energy ratio relative to non-CH nodes |
| $F_{CH}$ | Fitness function for CH selection | $R_{location}^{CH}$ | CH location ratio relative to non-CH nodes |
| $E_{CH}^{res}(j)$ | Residual energy of CH node j | $a$ | Weighting factor for fitness components |
| $\bar{E}_{CH}$ | Average residual energy of CHs | $\bar{D}_{CH}$ | Average distance of CHs from the BS |
| $\bar{L}_{CN}$ | Average distance of CNs from BS and CHs | $F_{RN}$ | Fitness function for relay node selection |
| $x_{i,t}$ | Position of crow $i$ at time $t$ | $m_{i,t}$ | Memory position of crow $i$ at time $t$ |
| $fl$ | Flight length factor | $K_t$ | Dynamic awareness probability at generation t |
| $K_{max}$ | Maximum awareness probability | $K_{min}$ | Minimum awareness probability |
| $t_{max}$ | Maximum number of generations | $AP$ | Awareness probability |
| $D_{thr}$ | Threshold distance for adaptive flight length | $gb_{j,t}$ | Best position of crow $j$ at time $t$ |

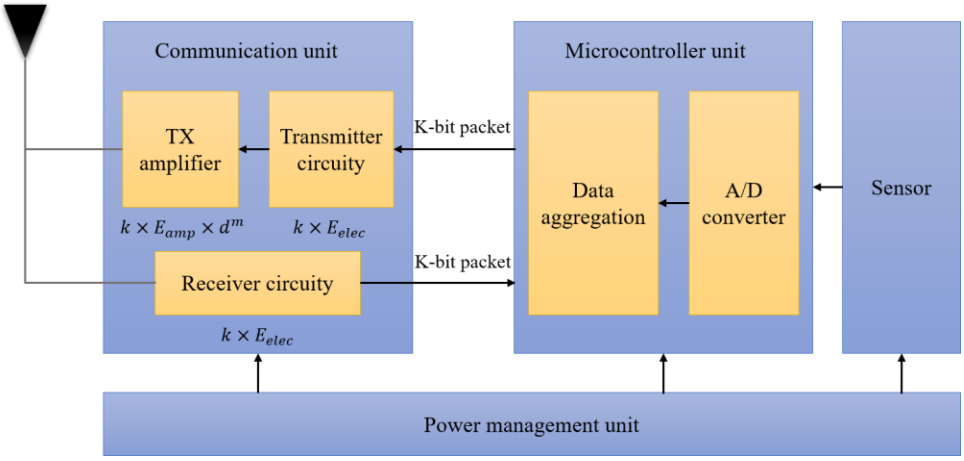

Fig. 1. Components and configuration of SNs in WSNs.

Eq. (1) quantifies the energy expended in relaying a *K-bit* packet across a distance *d*. The components of this energy consumption model include transmission energy ($E_{TX}$), reception energy ($E_{fs}$), link distance ($d$), circuit-level energy dissipation ($E_{elec}$), amplifier model parameters ($E_{fs}$, $E_{mp}$), data packet length ($k$), and the transmission distance threshold ($d_0$) defined in Eq. (2). Eq. (3) determines packet reception energy consumption. $E_{elec}$ encompasses the energy consumed by transmitter or receiver circuitry, influenced by factors such as signal spreading, filtering, modulation, and channel coding.

$$E_{TX}(k,d) = \begin{cases} k \times E_{elec} + k \times E_{fs} \times d^2 & if\ d \le d_0 \\ k \times E_{elec} + k \times E_{mp} \times d^4 & if\ d > d_0 \end{cases} \quad (1)$$

$$d_0 = \sqrt{\frac{E_{fs}}{E_{mp}}} \quad (2)$$

$$E_{RX}(k) = k \times E_{elec} \quad (3)$$

The resilience of many WSN applications to node failures is evident, particularly in high-density deployments where redundant sensing capabilities exist among neighboring nodes. Consequently, the duration before First Node Dead (FND) is an insufficient metric for comprehensive network lifetime assessment. A more robust indicator, the time until a predefined percentage of nodes dead (PND), is proposed for scenarios characterized by high node density. Eq. (4) defines network lifetime as the duration before the proportion of operational nodes reaches a specified threshold, $\xi$. Within this equation, $N$ denotes sensor count and $k$ signifies the number of active nodes.

$$T_N^k = T\left[\xi = \frac{k}{N}\right] \quad (4)$$

## IV. CLUSTERING APPROACH

The proposed protocol categorizes nodes into CHs, Common Nodes (CNs), and RNs. Network configuration comprises repeated cluster formation and data transmission stages. During the setup phase, clusters, CHs, RNs, and routing paths to the BS are established. The data transmission phase involves data collection by CHs from cluster members, relayed

through RNs to the BS, following a predefined scheme. Fig. 2 illustrates the network architecture.

Given *N* randomly deployed SNs, *n* clusters are formed. The set of CHs is denoted as CH, while non-CH nodes are represented by $\widetilde{CH}$ . CHs coordinate cluster operations, aggregate data, and communicate with RNs. CH selection considers node energy levels and locations, prioritizing nodes with more available energy and closer to the BS for balanced cluster formation. This optimization problem is formulated in Eq. (5).

$$F_{CH} = a \times R_{energy}^{CH} + (1 - a) \times R_{location}^{CH} \quad (5)$$

The fitness function, $F_{CH}$, comprises two components: $R_{energy}^{CH}$ and $R_{location}^{CH}$, weighted by $\alpha$. $R_{energy}^{CH}$, calculated in Eq. (6), represents CH energy relative to non-CH energy, favoring energy-rich nodes as CHs. $R_{location}^{CH}$, determined by Eq. (7), measures the relative distance of CHs and non-CHs to the BS, promoting CHs closer to the BS for improved energy efficiency.

$$R_{energy}^{CH} = \frac{\bar{E}_{CH}}{\bar{E}_{\widetilde{CH}}} = \frac{\sum_{\forall node_j \in CH} E_{CH}^{res}(j)/|CH|}{\sum_{\forall node_j \in \widetilde{CH}} E_{\widetilde{CH}}^{res}(j)/|\widetilde{CH}|} \quad (6)$$

$$R_{location}^{CH} = \frac{\bar{D}_{\widetilde{CH}}}{\bar{D}_{CH}} = \frac{\sum_{\forall node_j \in \widetilde{CH}} d(node_i, BS)/|\widetilde{CH}|}{\sum_{\forall node_j \in CH} d(node_i, BS)/|CH|} \quad (7)$$

Practical WSNs employ battery-powered nodes, with residual energy indicated by the battery voltage. Nodes with higher energy and proximity to the BS exhibit a higher likelihood of becoming CHs. Given the NP-hard nature of this problem, an improved CS algorithm is proposed for the solution, as detailed in the subsequent section.

To mitigate excessive energy consumption among CHs, RNs are introduced to share the data transmission burden. RN selection depends on two primary criteria: superior energy levels relative to CNs and optimal spatial positioning between the CH and the BS to minimize energy-intensive transmissions. Unlike conventional approaches, our protocol assigns a dedicated RN to each CH, reducing communication overhead between these entities.

The RN selection process is guided by a fitness function (Eq. (8)) comprising two components: $R_{energy}^{EN}$ and $R_{location}^{RN}$. $R_{energy}^{EN}$, calculated in Eq. (9), represents the ratio of average RN energy to average CN energy, prioritizing energy-rich nodes for RN roles. $R_{location}^{RN}$, defined in Eq. (10), evaluates the relative position of a potential RN to its corresponding CH and the BS, aiming to minimize transmission distances.

$$F_{RN} = \beta \times R_{energy}^{RN} + (1 - \beta) \times R_{location}^{RN} \quad (8)$$

$$R_{energy}^{EN} = \frac{\bar{E}_{RN}}{\bar{E}_{CN}} = \frac{\sum_{\forall node_z \in RN} E_{RN}^{res}(z)/|RN|}{\sum_{\forall node_k \in CN} E_{CN}^{res}(k)/|CN|} \quad (9)$$

$$R_{location}^{RN} = \frac{\bar{L}_{CN}}{\bar{L}_{RN}} = \frac{\sum_{\forall node_k \in CN}\{d(node_k, BS) + d(node_k, CH_j)\}/|CN|}{\sum_{\forall node_z \in RN}\{d(RN_z, BS) + d(RN_z, CH_j)\}/|RN|} \quad (10)$$

By maximizing both $R_{energy}^{EN}$ and $R_{location}^{RN}$, the protocol ensures the selection of energy-efficient and strategically positioned RNs, thereby enhancing overall network performance. Similar to other protocols, CH and RN selection is centralized at the BS. SNs are given an identifier (ID) based on their location. The clustering process commences with nodes broadcasting residual energy and location information via *Node-MSG* messages. The BS selects CHs and disseminates their IDs through a broadcast message. Subsequently, CHs introduce themselves to the network using *CH-ADV* messages. A similar process is followed for RN selection and announcement (*RN-ADV* messages).

CNs determine their cluster membership by selecting the CH requiring the least transmission energy based on received *CH-ADV* messages. Upon cluster selection, nodes notify the CHs via *JOIN-REQ* messages. The CH functions as a control center, establishing a TDMA scheduler and disseminating it through *SCHEDULE-MSG* messages. This synchronization mechanism reduces energy usage and enhances spectral efficiency by enabling nodes to power down their radios during idle periods. The data transmission phase adheres to the TDMA schedule, with CNs sending data to their CHs. The CH collects data and relays it to the RN, which ultimately transmits aggregated data to the BS.

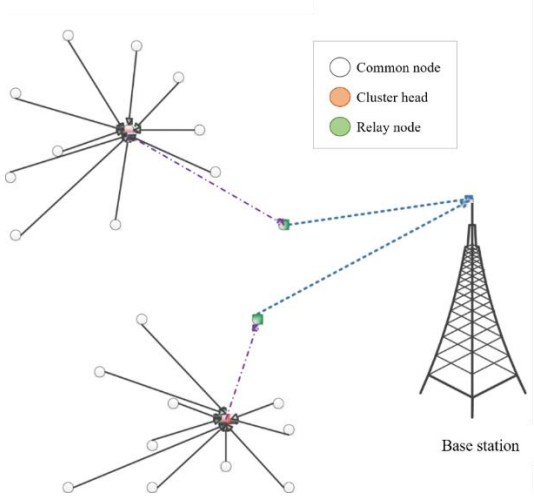

Fig. 2. Network architecture of the proposed protocol.

## V. Proposed Algorithm for Cluster Node Updating

The conventional CS algorithm mimics the intelligent behavior of crows to solve optimization problems [21]. It involves the following steps:

- Initialization: Define the optimization problem, set parameters, and initialize crow positions randomly within defined bounds.
- Memory update: Store the initial position of each crow.

$$Crows_{i,t} = \begin{bmatrix} x_i^1 & \cdots & x_i^d \\ \vdots & \ldots & \vdots \\ x_N^1 & \cdots & x_N^d \end{bmatrix} \quad (11)$$

$$CrowsMemory_{i,t} = \begin{bmatrix} m_i^1 & \cdots & m_i^d \\ \vdots & \ldots & \vdots \\ m_N^1 & \cdots & m_N^d \end{bmatrix} \quad (12)$$

- Position update: If crow *j* is unaware of crow *i*, update crow *i*'s position using Eq. (13) and a local or global search based on *fl*. If crow *j* is aware of crow *i*, update crow *i*'s position randomly.

$$x_{i,t+1} = x_{i,t} + r_i \times fl \times (m_{j,t} - x_{i,t}) \quad (13)$$

$$x_{i,t+1} = a\ random\ position \quad (14)$$

- Evaluation: Evaluate the fitness of new positions and update crow memories with better solutions.
- Termination: Steps 2-4 are repeated until generation limit is met.

The Modified Crow Search (MCS) Algorithm is an improvement over the conventional CS. It introduces two key modifications:

Dynamic awareness probability: Instead of a fixed *AP*, the MCS algorithm uses a parameter *K* that dynamically adjusts the probability of a crow being aware of another crow's following. This promotes exploration in early generations and exploitation in later generations.

$$K_t = round\left(K_{max} - \frac{K_{max} - K_{min}}{t_{max}} \times t\right) \quad (15)$$

Adaptive flight length: The MCS algorithm calculates the flight length (*fl*) based on the distance between crows ($D_{i,j}$). This allows for a more focused search in promising regions.

$$fl_{i,t} = \begin{cases} 2 & if\ D_{i,j} > D_{thr} \\ fl_{thr} & if\ D_{i,j} \le D_{thr} \end{cases} \quad (16)$$

The conventional CS algorithm employs a repetitive optimization process that hinges on exploration and exploitation, modulated by the parameter *AP*, typically set to 0.1. This configuration predominantly biases the algorithm towards exploitation, often at the expense of exploration across all generations. As a consequence, the CS algorithm is susceptible to local optima and exhibits strong dependence on the initial population. To mitigate these limitations, this paper introduces a novel approach that incorporates a dynamically adjusted *AP*, correlated with the generation count, and employs two innovative equations to enhance exploration and exploitation.

$$AP = AP_{max} + \frac{AP_{max} - AP_{min}}{t_{max}} \times t \quad (17)$$

Similar to the standard CS, step 1 of A-CSA involves problem definition and parameter initialization. However, A-CSA introduces additional parameters: $AP_{max}$, $AP_{min}$, and *FAR* (Flight Awareness Ratio). $AP_{max}$ and $AP_{min}$ are pivotal for the dynamic *AP* mechanism.

Consistent with the conventional CS, A-CSA employs Eq. (11) and Eq. (12) to determine crew group size and initialize crow positions. Subsequently, the objective function evaluates the fitness of these initial positions.

A-CSA diverges significantly from the conventional CS in three key aspects. Firstly, A-CSA incorporates a dynamic *AP* that fluctuates with the generation count, as governed by Eq. (18). $AP_{max}$ and $AP_{min}$, bounded between 0 and 1, control the exploration-exploitation balance. A larger *AP* promotes exploration, while a smaller *AP* favors exploitation. Optimal algorithm performance necessitates a judicious selection of *AP*.

$$AP_t = AP_{min} + \frac{AP_{max} - AP_{min}}{ln(t)+1} \quad (18)$$

Secondly, in contrast to the random selection of a crow to follow in the conventional CS (Eq. (13)), A-CSA employs a FAR-based mechanism to guide crow *i* towards the best crow *j* ($gb_{j,t}$) as defined by Eq. (19). $r_{i,t}^2$ and $r_{i,t}^3$ are random values within the [0, 1] interval, and *FAR* is a predefined constant between 0 and 1. This modification enhances exploitation compared to the standard CS. A *FAR* approaching 0 prioritizes memory-based best solutions, while a value closer to 1 resembles the random selection of the conventional CS. By tuning *FAR* appropriately, the algorithm can achieve a harmonious balance between exploration and exploitation, thereby improving convergence.

$$x_{i,t+1} = \begin{cases} x_{i,t} + r_{i,t}^2 \times fl \times \left(m_{j,t} - x_{j,t}\right) & if\ r_{i,t}^3 \le FAR \\ x_{i,t} + r_{i,t}^2 \times fl \times \left(gb_{j,t} - x_{j,t}\right) & else \end{cases} \quad (19)$$

Thirdly, A-CSA refines the exploration phase of the conventional CS. While the latter employs a random search within the lb and ub bounds when the random number exceeds *AP*, A-CSA introduces a localized search mechanism through Eq. (20) as the generation progresses. This strategy mitigates the diminishing returns of global search in later generations. $r_{i,t}^4$ and $r_{i,t}^5$ are random values within the [0, 1] range.

$$x_{i,t+1} = \begin{cases} 2x_{i,t} + \left(lb + r_{i,t}^5 \times (lb - ub)\right)/t & if\ r_{i,t}^4 \le 0.5 \\ a\ random\ position & else \end{cases} \quad (20)$$

The optimization process iteratively executes Steps 2-4 until the generation count reaches the predefined maximum ($t_{max}$), yielding the final solution. Algorithm 1 presents the pseudocode of A-CSA.

**Algorithm 1** Pseudocode of A-CSA

**Input:**
Initialize control parameters: $AP_{max}, AP_{min}, FAR, fl, N, pd, t_{max}$
Randomly generate and store the initial positions of all crows in the solution space
Evaluate the initial fitness of each crow
**Begin iteration:**
Repeat until the maximum number of iterations $t_{max}$ is reached:
Randomly select the crow positions to update
**For** each crow $i = 1$ *to* $N$:
  Compute the dynamic awareness probability $AP_t$
  Generate a random number $r^1 \in [0,1]$
  **If** $r^1 \geq AP_t$:
    Generate another random number $r^3 \in [0,1]$
    **If** $r^3 < FAR$:
      Update position using Equation 19a
    **Else**
      Update position using Equation 19b
  **Else**
    Generate another random number $r^4 \in [0,1]$
    **If** $r^4 \leq 0.5$:
      Update position using Equation 20
    **Else**
      Assign $x_{i,t+1}$ a random position within the bounds
**End for**
Evaluate the updated positions and compute fitness values
Update memory based on improved solutions
**End repeat**
Report the best-found solution and convergence results

The computational complexity of the proposed A-CSA algorithm primarily stems from the repeated evaluation of the fitness functions for CH and RN selection and the iterative update of crow positions. Let $N$ represent the number of nodes, $G$ the number of generations, and $C$ the number of candidate crows. The per-generation complexity is $O(C{\cdot}N)$, resulting in an overall complexity of $O(G{\cdot}C{\cdot}N)$. As clustering and optimization are carried out at the base station, which is not resource-constrained, this overhead remains acceptable for practical deployments. Future enhancements may involve parallel implementations to reduce computation time further.

## VI. Results and Discussion

This section presents a comprehensive investigation of the suggested method's effectiveness through simulation analyses. The protocol's efficacy in constructing energy-efficient routing hierarchies for WSNs is assessed, with a particular focus on applications demanding long network longevity and effective data aggregation, e.g., monitoring environments.

Key parameters, including network lifetime, node count, BS positioning, and network dimension, were considered in the comparative analysis of various routing protocols. MATLAB was employed for simulation modeling and programming, with average values derived from 20 simulation runs to enhance result reliability. Simulation variables are summarized in Table III.

Fig. 3 illustrates the convergence rate of the objective function's fitness value, demonstrating convergence within 50 iterations. Consequently, the algorithm's maximum iteration count was set to 50.

A comparative analysis with a CS-based protocol is presented in Fig. 4. Network lifetime metrics employed include FND, Last Node Dead (LND), and Half Number of Nodes Dead (HND). A-CSA significantly improved over the CS-based approach, with FND, HND, and LND extended by 98%, 101%, and 105%, respectively.

TABLE III Simulation Variables

| Feature | Variable | Value |
|---|---|---|
| Radio model | $E_{DA}$ | *5nJ/bit/signal* |
| | $d_0$ | *75m* |
| | $E_{mp}$ | *0.0013pJ/bit/m$^4$* |
| | $E_{fs}$ | *10pJ/bit/m$^2$* |
| | $E_{elec}$ | *50nJ/bit* |
| Network | Initial energy of nodes | *2J* |
| | BS location | *(50,175)* |
| | Dimension | (0,0)~(100,100) |

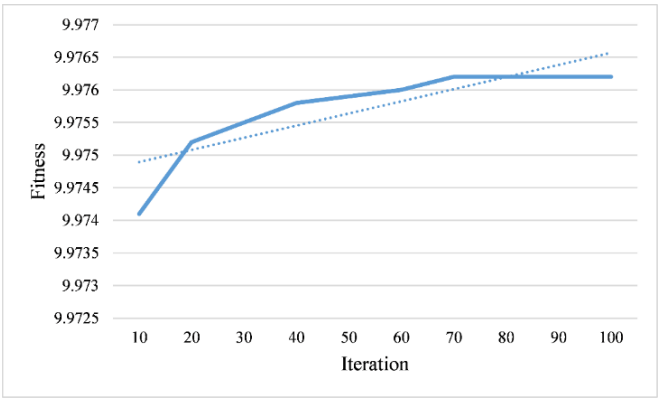

Fig. 3. Convergence rate.

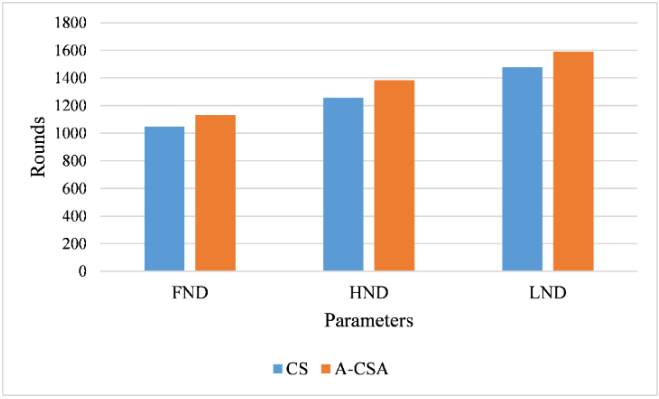

Fig. 4. Comparative analysis of network lifetime metrics.

To measure the lifetime efficiency of the suggested protocol, three distinct situations were considered varying in terms of node count, BS position, and network area size, as detailed in Table IV. The proposed protocol was benchmarked against SEECH, TCAC, and LEACH. Fig. 5, Fig. 6, and Fig. 7 visualize the count of alive nodes over time. A-CSA consistently outperformed the other three compared protocols.

TABLE IV EVALUATION SCENARIOS

| Parameter | 1st situation | 2nd situation | 3rd situation |
|---|---|---|---|
| Node count | 100 | 500 | 1000 |
| BS position | (50,175) | (50,200) | (100,300) |
| Dimension | (100,100) | (100,100) | (200,200) |

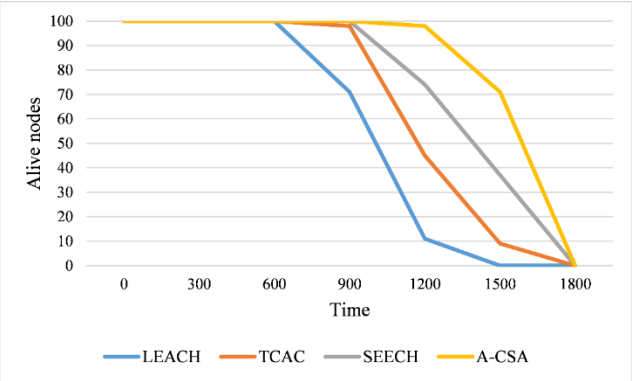

Fig. 5. Network lifetime comparison for first scenario.

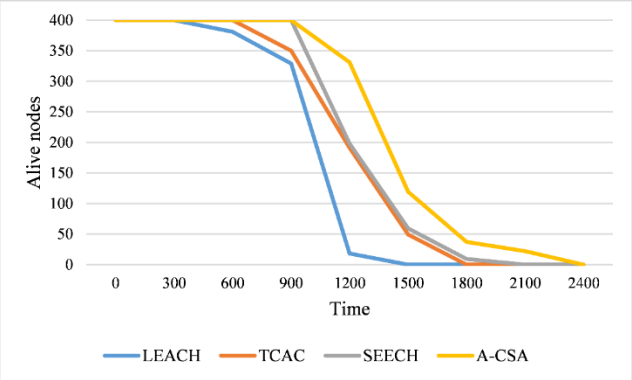

Fig. 6. Network lifetime comparison for second scenario.

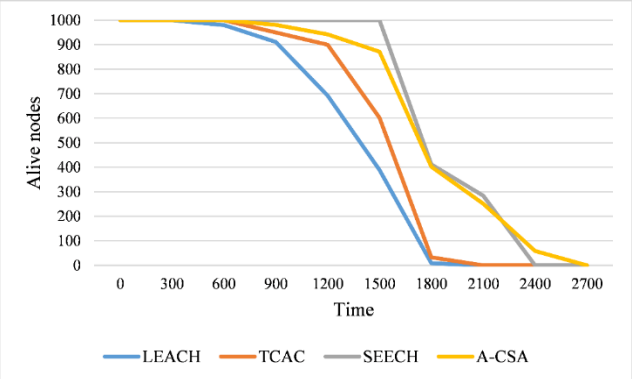

Fig. 7. Network lifetime comparison for third scenario.

Unlike existing models that rely on static or heuristic-based decisions, A-CSA dynamically adapts its search behavior over generations, resulting in better convergence and more energy-efficient clustering. Moreover, the integration of a bi-objective fitness function for both CH and RN selection provides an edge in maintaining balanced energy distribution, especially in dense and large-scale networks. These improvements position A-CSA as a competitive and scalable alternative to traditional and hybrid clustering approaches.

## VII. CONCLUSION

Energy efficiency is a paramount challenge in WSNs. Clustering and routing strategies are commonly employed to address this issue. However, these problems are classified as NP-hard optimization problems, necessitating heuristic approaches. Swarm intelligence algorithms have emerged as promising candidates for obtaining near-optimal solutions to these complex challenges. This paper introduced a novel clustering protocol for WSNs that leverages RNs to alleviate the energy burden on CHs. An enhanced CS algorithm is proposed to optimize cluster formation, minimizing transmission distances and energy consumption. This approach effectively prolongs the network lifetime. Comprehensive simulations under diverse network conditions, including varying node densities, network areas, and BS positions, demonstrated the protocol's superior energy efficiency compared to existing clustering protocols. By balancing energy consumption among nodes and reducing overall energy expenditure, the proposed protocol significantly extends the network lifetime.

While the primary focus of this study was on energy efficiency and network longevity, critical factors in battery-constrained WSNs, we acknowledge that comprehensive validation should also consider metrics such as delay, throughput, and packet delivery ratio . Although our simulation results include node activity trends that indirectly reflect throughput, detailed quantitative evaluations of delay and PDR were not included in this version. Future work will incorporate these metrics to provide a more holistic assessment of the protocol's suitability for time-sensitive and high-reliability IoT applications. Additionally, to enhance the applicability of A-CSA in dynamic IoT environments, we aim to incorporate mobility models and traffic-aware mechanisms, enabling the protocol to adapt to node mobility, varying network topologies, and fluctuating traffic loads commonly encountered in real-world deployments.

***Abstract*—In understanding brain functioning by Electroencephalography (EEG), it is essential to be able to not only identify more active brain areas but also understand connectivity among different areas. The functional and efficient connectivity networks of the brain have been examined in this study by constructing a connectivity feature map (CFM) with four widely used connectivity methods from the Database for Emotion Analysis Using Physiological Signals (DEAP) emotional EEG data to research how this connectivity's patterns are influenced by emotion. According to the investigation results, emotions are mainly related to the parietal, central, and frontal regions. The parietal region is more responsible for emotion alteration among these three regions. Positive emotions are associated with more direct correlations and dependencies than negative ones. When experiencing negative emotions, the regions of the brain function more synchronously as well as there are less flow of information. Whether direct or inverse, there is less correlation between brain regions in the higher frequency band than in the lower frequency band. Higher frequencies are associated with increased dependence and directed information transfer between brain regions. Generally, the electrodes in the same lobe show stronger connectivity than those in different lobes. At a glance, the present study is a comprehensive analysis to understand brain network stimulation for emotion from EEG, and it significantly differs from the existing emotion recognition studies typically focused on recognition proficiency.**

***Keywords*—Brain connectivity; connectivity feature map; electroencephalography; emotion**

## I. Introduction

Interaction between brain areas have been recognized as a critical ingredient needed to understand brain function. Neuroimaging techniques are valuable for studying how the brain processes human emotions and activities. Emotion research has received increased attention from cognitive scientists and neurobiologists in recent decades, owing to its importance in decision-making, well-being, mood, personality, and psychotic diseases [1]. Electroencephalography (EEG) is a neuroimaging method that uses its sensors in the brain to record the electrical impulses generated by neural activity (i.e., electrodes or channels) affixed to the brain; it captures the changes in voltage brought on by ionic current flows in the neurons of the brain [2], [3], [4]. Recently, EEG has become popular for studying the brain's responses to emotional stimuli for its superior temporal resolution, noninvasiveness, portability, ease of use, and reasonably affordable speed [4], [5]. EEG is a composite signal that is composed of sub-bands such as Alpha (8–12 Hz), Beta (13–29 Hz), and Gamma (30–50 Hz) [6]. These sub-bands may provide a more accurate representation of the constituent neural process activity [7]. Connectivity features from the EEG signal can provide valuable information regarding brain connectivity behind emotion as these features analyze the interaction between different brain areas.

Several methods can measure the connectivity among EEG signals from different brain regions. Examples of such methods include Pearson correlation coefficient (PCC) [8], cross-correlation (XCOR) [9], phase locking value (PLV) [10], mutual information (MI) [11], normalized MI (NMI) [12], partial mutual information (PMI) [13], and transfer entropy (TE) [14]. PCC and XCOR are linear functional connectivity methods which can only detect linear dependencies between two signals or variables; PLV is nonlinear functional connectivity that represents the phase synchronization between two signals or variables. MI is nonlinear functional connectivity method, which measures the amount of shared information, whereas TE stands for effective nonlinear connectivity, which measures the directional flow of information between two brain regions. MI and TE are information-theoretic measures based on Shannon entropy [15]. Both NMI and PMI are two variants of MI. Such methods can be applied to signals collected through EEG electrodes to extract the connectivity features of the signals. The extracted features can be mapped into a two-dimensional matrix called a connectivity feature map (CFM). Emotion recognition (ER) and investigating brain mechanisms from CFM have become popular recently in the field of emotion research [16]–[22].

This study aims to analyze and understand brain network connectivity stimulation for different emotions through CFM from EEG, overcoming the limitations of the existing studies. The existing studies mainly focused on ER, and a few studies considered to investigate the brain mechanism behind/along ER. This study considers diverse connectivity methods for CFM construction and analysis to understand brain network stimulation emotion. Four frequently used connectivity methods, PCC, PLV, MI, and TE, were chosen. This study investigates connectivity represented in three sub-frequency bands named Alpha, Beta, and Gamma. Extensive studies using the developed CFMs have been conducted on the DEAP

benchmark EEG dataset. An overview of the primary contributions of this work is provided below:

*1)* Brain network stimulation outcomes have been reviewed from existing studies.

*2)* Using four diverse, widely used connectivity methods, PCC, PLV, MI, and TE, CFMs are constructed for the DEAP dataset.

*3)* Distinctive and rigorous analysis of CFMs has been conducted to unveil discerning remarks on brain network connectivity levels (weak/strong) concerning stimulation for emotions with the frequency bands and brain lobes.

*4)* This study's findings are contrasted with those of comparable state-of-the-art research and identified novelty of the study.

The rest of this study is structured as follows. Section II briefly reviews prominent ER studies emphasizing brain network connectivity stimulation. The methodology to investigate brain mechanisms from CFM is described in Section III. Section IV presents the findings by analyzing CFM using the DEAP dataset. Section V presents a comparative discussion of the findings of the present study with related existing studies. At last, Section VI concludes the paper with a few remarks.

## II. Literature Review

Emotion is the basic characteristic of human beings, and the brain is the root of emotion exposure. Emotion recognition (ER) analyzing EEG signals is well-studied in a number of existing studies. Proficiency of ER from EEG is the common main goal of those studies; however, several studies slightly focused on understanding brain network connectivity stimulation for different emotions and emotional states through CFM from EEG. The existing studies may be categorized under findings with respect to (w.r.t.) emotional states, brain regions, and frequency bands. The ensuing subsections provide a concise overview of notable ER research categorically.

### *A. Investigation Concerning Frequency Bands*

The effect of different frequency bands on brain connectivity was investigated in a few studies [23], [24]. Li et al. [23], extracted the PLV feature and fused it with several other individual channel features; the fused feature was then classified by stacking an ensemble learning framework for ER. Brain function was also investigated with PLV feature under Theta, Alpha, Beta, and Gamma sub-frequency bands, from where it was identified that the PLV of the lower frequency bands (i.e., Theta and Alpha) is greater than those of higher frequency bands (i.e., Beta and Gamma). The same sub-frequency bands and PLV feature were also used by Cui et al. [24], to classify emotion and to analyze brain connectivity; they drew some conclusions that the Beta band has the lowest PLV, whereas the Theta band's PLV is significantly higher than other bands'.

### *B. Investigation Concerning Emotional States*

Brain mechanisms concerning different emotions, such as positive and negative, have been investigated in several studies [12], [20], [21], [22], [17], [25]. Wang et al. [12], used NMI as a connectivity method to construct CFM. The aim of the study [12] was channel selection, where emotion classification was done with a support vector machine (SVM); the study also drew some conclusions on brain function behind emotion from where it was identified that the high Arousal low Valence state was found to have a wider active brain areas. Khosrowabadi et al. [20], used MI and another functional connectivity feature named magnitude MI and squared coherence estimate (MMSCE) to recognize emotion with SVM and K-nearest neighbor (KNN) classifier; they identified that various emotional states are accompanied by various types of functional brain connectivity. Liu et al. [21], performed emotion classification with the Xception network where brain mechanism also investigated with connectivity feature named coherence; the study found that the functional network made by low Valence-Arousal emotion revealed more active (i.e., higher coherence) functional connectivity than the one made by high Valence-Arousal emotion. When using the phase slope index (PSI) approach to study brain connectivity, Costa et al. [22], discovered a phenomenon whereby multi-channel EEG signals for sad emotions are more synchronized than those for happy emotions. Wang et al. [17], classified emotion with the PLV feature by Graph CNN; the PLV feature was also used to investigate brain connectivity. According to the study [17], the phase-locking value in the pleasant condition is lower than in the sad condition, which indicates that the pleasant mood is less active in the brain area. Recently, Wang et al. [25], identified from PLV feature that PLV values in positive emotions are generally smaller than in negative emotions; they also analyzed CFM concerning time periods and identified that there are little differences in connection patterns for the same emotions in different time periods.

### *C. Investigation Concerning Different Brain Regions*

Several studies investigated responses of specific brain regions on different mental states by analyzing the CFMs with individual connectivity methods. Gao et al. [5], employed two effective connectivity features named TE and Granger causality (GC) for classifying stress and calm state with three classifiers (i.e., SVM, random forest, and decision tree); they highlighted from the GC that the parietal and frontal lobes show stronger connectivity during the stress state; and they also discovered from TE that there was a greater information exchange between the C4 and Fp1 channels under pressure. Chen et al. [8], used PCC, PLV, and TE feature methods to recognize emotion with domain adaptive residual convolutional neural network (CNN) as a classifier. Along with ER using the three feature methods, they investigated brain mechanisms through PCC and PLV features; it was found from CFM constructed with PCC that the brain’s emotional activity is more perceptible in the occipital and parietal regions, and the CFM with PLV revealed that the phase consistency is relatively strong in the occipital, frontal and parietal regions, while the phase consistency is poor in other regions. For emotion recognition, Kong et al. [16], used sparse representation-based classification with connectivity feature PSI; the PSI method was also used for brain connectivity analysis from where it was found that, in sad emotion, the right prefrontal cortex (PFC) has stronger nodal connections than the left PFC, whereas, in happy emotion, the left PFC's nodal connection strength is stronger than the right PFC's. Graph CNN was used with the PLV feature by Wang et al. [15], to classify emotion under five sub-frequency bands (i.e., Delta, Theta, Alpha, Beta, and Gamma), but a single frequency band was used

to investigate brain network and drew conclusions that emotions are related to mainly the temporal lobe. The study also showed that, during positive and negative emotions, the left and right forebrain generates strong EEG activity, respectively; the study shows that emotions are greatly correlated with the forebrain. Zhu et al. [18], used CNN to classify emotion with the phase lag index (PLI) feature and also explored phase synchronization of brain signals with that feature and found that, generally, the connectivity between the channels of the right frontal region was stronger than those of the left frontal region.

## III. Methodology

In this study, connectivity is measured using different popular methods on the benchmark EEG dataset to understand brain network connectivity stimulation for emotion. Fig. 1 illustrates the framework of the proposed study; the EEG data preprocessing, CFMs construction using different connectivity methods, and analysis of the CFMs are the major steps of the study. The following subsections describe the EEG dataset and the connectivity methods to construct CFM.

### *A. Dataset Selection and Data Preprocessing*

This study utilizes one of the most popular and well-studied EEG datasets for emotion detection, the Database for Emotion Analysis Using Physiological Signals (DEAP) [26]. In DEAP dataset development, 40 emotive music videos were utilized as stimuli on 32 individuals (i.e., subjects), and EEG and other peripheral physiological signals of individual subjects were collected as responses against individual videos. The database also includes subjective scores that describe the levels of Valence, Arousal, Liking, and Dominance of the emotional states produced by watching the videos. The preprocessed EEG signals from the database are used in this study, where the signal frequency range is 4.0 to 45.0 Hz. Of the 40 channels, 32 are used for EEG signals, and the remaining channels are used for peripheral physiological inputs. The ordering of the electrodes in the preprocessed version of the database is as follows: Fp1, AF3, F3, F7, FC5, FC1, C3, T7, CP5, CP1, P3, P7, PO3, O1, Oz, Pz, Fp2, AF4, Fz, F4, F8, FC6, FC2, Cz, C4, T8, CP6, CP2, P4, P8, PO4, O2.

In the DEAP dataset, an EEG signal is 63 seconds long, and the first 3 seconds of data are the pre-trial baseline. By removing 3 seconds of pre-trial data, the remaining 60 seconds of data are processed for this study. For this investigation, a sliding time window of 8-second with a 4-second overlap is used to segment EEG data. Thus, there are 14 segments totaling 60 seconds. The total number of segments for each participant is 14 × 40 (video) × 32 (channel). EEGLAB [27] is used to filter the signal to extract Alpha, Beta, and Gamma sub-bands.

Among the four quality levels available in the DEAP dataset, Valence and Arousal are chosen in this study as they are well-studied scales for classifying emotions. In the dataset, the ratings for Valence and Arousal range from 1 (low) to 9 (high). Similar to the work in [28], Valence and Arousal are considered as high Valence (HV) and high Arousal (HA) for values above 4.5 and low Valence (LV) and low Arousal (LA) for less than or equal to 4.5. At a glance, HV indicates positive emotion, LV indicates negative emotion, HA indicates active emotion, and LA indicates passive emotion [29]. The positive and negative emotions or active and passive emotions can be represented in 2D space according to Russell's model [29], as shown in Fig. 2.

### *B. Connectivity Feature Map (CFM) Construction*

Feature extraction has recently emerged in new dimensions through CFM construction using different connectivity measures [6]. This work takes into account several connectivity measures (linear, nonlinear, directed, etc.) for feature extraction as well as CFM creation. In a single experiment, the level of connectivity between two electrodes indicates the interaction between two brain areas. Depending on emotional or cognitive activities, this interaction could be a direct correlation, an inverse correlation, or synchronization. Four popular candidate connectivity methods were chosen from linear functional, nonlinear functional connectivity and nonlinear effective connectivity categories. The selected methods are PCC, PLV, MI, and TE.

The linear correlation between two signals, X and Y, is measured by PCC and is calculated as

$$PCC_{XY} = \frac{n\sum X_i Y_i - \sum X_i \sum Y_i}{\sqrt{n\sum X_i^2 - (\sum X_i)^2}\sqrt{n\sum Y_i^2 - (\sum Y_i)^2}}, \quad (1)$$

where, n denotes sample size, and $X_i$ or $Y_i$ is the individual sample points indexed with i. PCC's value varies from -1 to 1. (-1): complete linear inverse correlation, (0): no linear interdependence, (1): complete linear direct correlation between the two signals.

PLV defines the phase synchronization between two signals, which is measured by the rules as follows-

$$PLV(X,Y) = \frac{1}{T}\left|\sum_{t=1}^{T} exp\{j(\varphi_X^t - \varphi_Y^t)\}\right|, \quad (2)$$

where, $\varphi^t$ denotes the phase of the signal at time t, X, and Y are two electrodes, and T is the length (time) of the signal. PLV has a value between 0 and 1, denoting perfect independence and perfect synchronization, respectively.

MI is an information theoretic approach to measuring shared information between two variables. The following is the definition of MI between two random variables, X and Y:

$$MI(X,Y) = H(X) + H(Y) - H(X,Y), \quad (3)$$

where, H denotes Shannon entropy [15]. Entropy is measured by calculating the probability using the fixed bin histogram approach. There are 10 bins utilized in the computation. The marginal entropies of the two variables X and Y are H(X) and H(Y), respectively, and their combined Entropy is H(X, Y). The range of MI's value is: $0 \leq MI(X,Y) < \infty$. If MI(X, Y) is equal to 0, then X and Y are independent. If MI(X, Y) is greater than 0, then X and Y are dependent.

The directed information flow from a signal or time series Y to another signal X is measured by TE.

$$TE_{Y\to X} = H(X_t, Y_t) - H(X_{t+h}, X_t, Y_t) + H(X_{t+h}, Y_t) - H(X_t) \quad (4)$$

If the future of X, i.e., $X_{t+h}$ is denoted by w, then transfer Entropy $TE_{Y\to X}$ can be computed as:

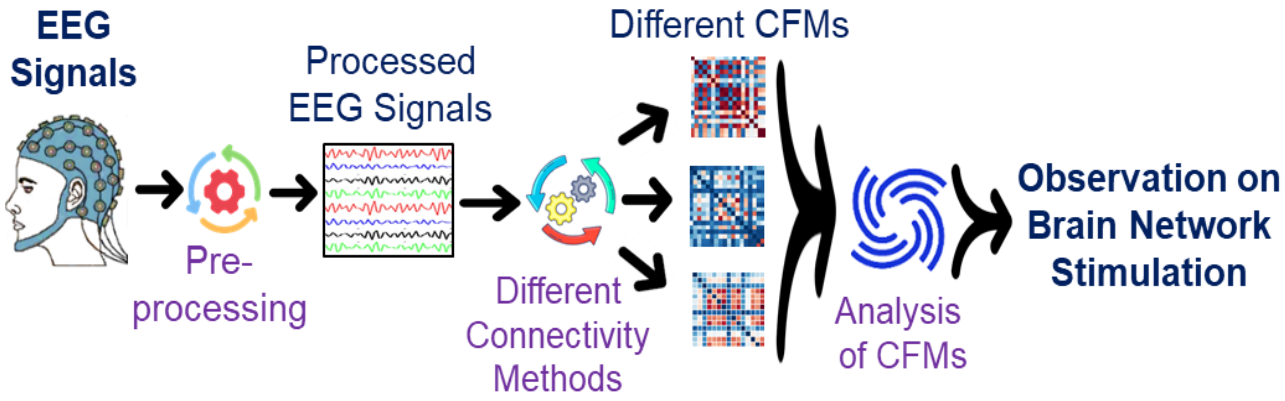

Fig. 1. The framework of the proposed study to observe brain network stimulation from EEG for emotion.

$$TE(w,X,Y) = H(w,X,) + H(X,Y) - H(X) - H(w,X,Y) \quad (5)$$

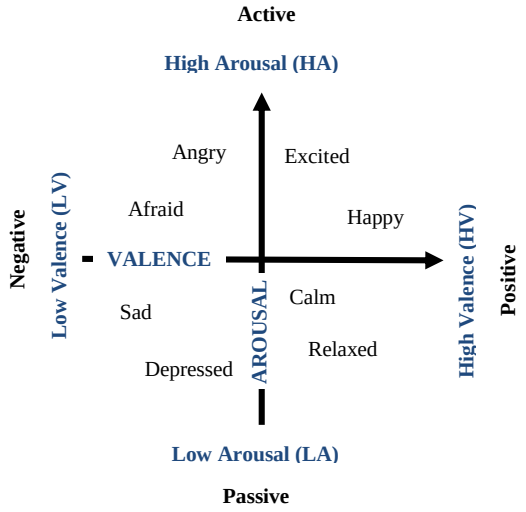

Fig. 2. Russell's emotion model.

The ranges of TE value are $0 \leq TE_{Y \to X} < \infty$. If the TE = 0, then there is no directed flow of information, i.e., no causal relationship between the signals. TE > 0 means that there is a causal relationship between them.

When it comes to CFM, these variables are signals from particular EEG channels. Connectivity features are extracted for each pair $(X, Y)$ of EEG electrodes. The connectivity features extracted from all electrode pairs can be mapped into a matrix (i.e., CFM). The matrix element at $(X, Y)$ describes the connectivity strength between the signals collected from the Xth and Yth electrodes. As the data are segmented in the preprocessing stage, a total of 17,920 CFMs are constructed under each frequency band for each connectivity method from all 32 participants, each with 40 trials.

## IV. Results of CFM Analysis on Brain Network Stimulation for Emotion

CFM analysis for brain networks is the main contribution of this study to observe the connectivity depiction of emotion. The following subsections briefly describe brain network stimulation for emotion-analyzing CFM in different dimensions/directions. CFMs representation as heat maps is commonly available in the existing studies [6] that are followed in this study.

### *A. Effect of Sub-Bands on Emotion Analysis*

The CFM created from the three frequency bands (i.e., Alpha, Beta, and Gamma) with the four connectivity methods (i.e., PCC, PLV, MI, and TE) under positive and negative emotions are displayed in Fig. 3. The response of the brain of a person to an emotion may be different from another person. Therefore, the constructed CFMs are presented for two individual participants (participant 1 and participant 32) as well as the average CFM of the total 32 participants.

It can be observed for PCC in Fig. 3(a) that, for participant 1, red and blue colors are lighter in the Gamma band, and the colors are darker in the Alpha band. The Beta band CFM colors remain in the middle of the two. In the case of Participant 2, the CFMs in the Beta band contain the lowest PCC value than that of the Alpha and Gamma bands. When the average CFM is considered, it can be observed that the correlation between brain regions, either a direct correlation or inverse correlation, is higher in the lower frequency band than in the higher frequency band, which is similar to Participant 1. As shown in Fig. 3(b), CFMs for both participants and the average CFMs, the Gamma band has a considerably larger PLV than the other bands, while the Beta band has the lowest. This implies that the Gamma frequency band had higher synchrony. In the case of MI in Fig. 3(c), the Beta band holds the highest MI value for Participant 1, and the Gamma band holds the highest MI value for Participant 32. When the CFMs from all participants are averaged, it is found that the mutual dependency between brain regions increases with higher frequency. Fig. 3(d) shows the CFMs constructed with TE, where it can be seen that with increased frequency, information flows more often between different parts of the brain.

Among the three frequency bands, the positive and the negative CFMs are more easily distinguishable in the Gamma frequency band. A number of studies have also identified that the Gamma band exhibits better emotional observation than the Alpha and Beta bands [19], [30]. So, further discussions in the next sections are presented with the average CFMs from the Gamma band only for concise observation.

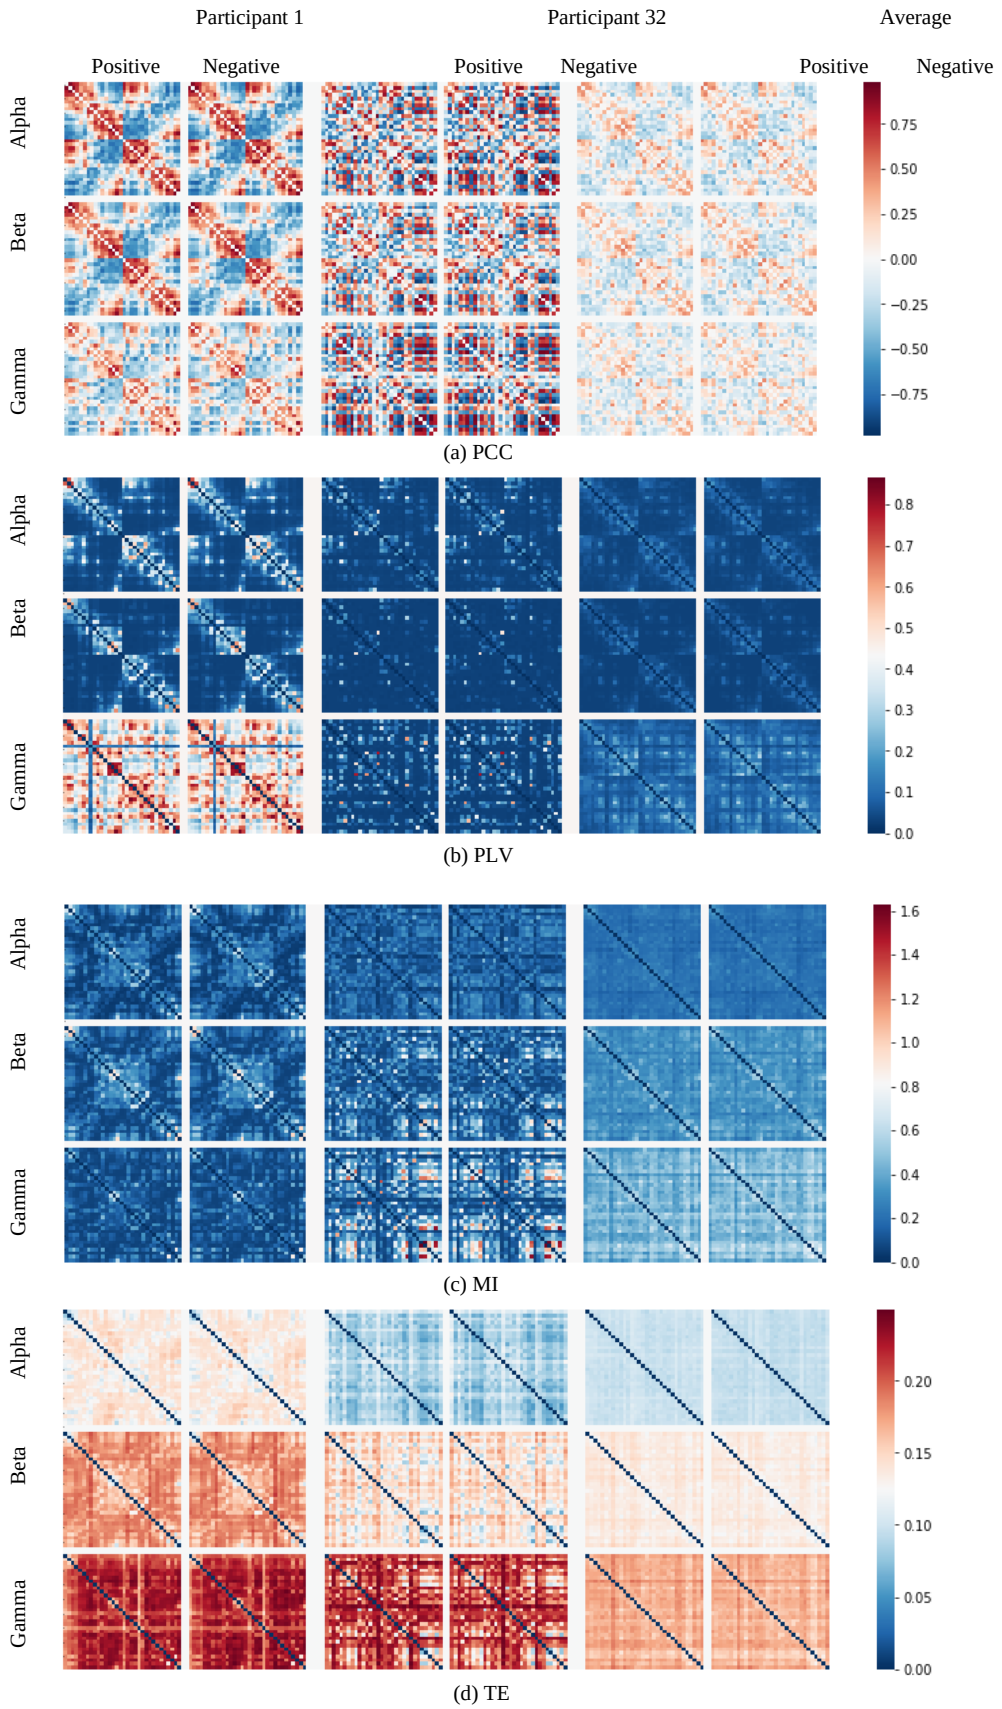

Fig. 3. CFM with different connectivity methods in alpha, beta, and gamma frequency bands for the positive and negative emotion.

### B. Connectivity Strength in Positive and Negative Emotions

Connectivity methods offer useful information about brain connectivity behind emotions. As discussed in the previous section, high Valence emotions are regarded as positive emotions and low Valence emotions are regarded as negative emotions. Fig. 4 illustrates how changes in emotions affect two brain regions' correlation, phase synchronization, mutual dependence, as well as causal relationship. The linear correlation between two brain areas is measured by PCC. The PCC-constructed CFM for positive and negative emotions in the gamma band is displayed in Fig. 4(a). Negative PCC values (blue pixels of the figure) denote an inverse linear correlation between two areas of the brain, and positive PCC values (red pixels of the figure) denote a direct linear correlation. As can be shown from Fig. 4(a), there are more locations with a strongly inverse correlation for negative emotion than for positive emotion. As compared to the CFM of positive emotion, the blue pixels in Fig. 4(a) are darker when representing negative emotion. For better visualization, a few areas are marked with blue rectangles. It implies that during unpleasant emotions, there is a greater inverse correlation between brain regions. Positive CFM shows darker red pixels than negative CFM, indicating a more direct linear correlation between brain regions during positive emotion than during negative emotion. Such few areas are marked with red rectangles.

Phase synchronization between two brain areas is described by PLV. Two signals are totally independent when the PLV value is 0; synchronization between the signals is indicated when the PLV value is greater than 0, and perfect synchronization is indicated when the PLV value is equal to 1. The CFM built for both positive and negative emotions utilizing PLV in the gamma frequency range is displayed in Fig. 4(b). In the CFM, a large phase-locking value is represented by red pixels, and a lesser phase-locking value is represented by blue pixels. Positive emotions have a phase-locking value that is comparatively lower than negative emotions, as seen in Fig. 4(b). Such few areas are marked with red rectangles. Therefore, in the negative state, the phase synchronization of distinct brain areas is greater. The higher values show that the synergy between various brain regions is increased during negative emotions, which results in synchronous oscillations. It is thus considered that the human brain pays greater attention to details in negative emotions than in happy emotions.

Fig. 4(c) and Fig. 4(d) displays the CFMs created for positive and negative emotions employing MI and TE, respectively. The MI calculates how dependent the two areas of the brain are. The more dependent two brain regions are on one another, the higher the value of MI. Fig. 4(c) shows that when an individual experiences negative emotions, there is an increase in the dependency between different brain regions and this phenomenon can be easily observed through the red-marked area. TE quantifies the directed transfer of information across different regions of the brain. More information transfer between two different parts of the brain results in a higher score for TE. It is evident from Fig. 4(d) that the negative CFM pixels are lighter than the positive CFM pixels, which can be easily seen through the white rectangular area, suggesting that positive emotions have a greater directed information flow than negative emotions.

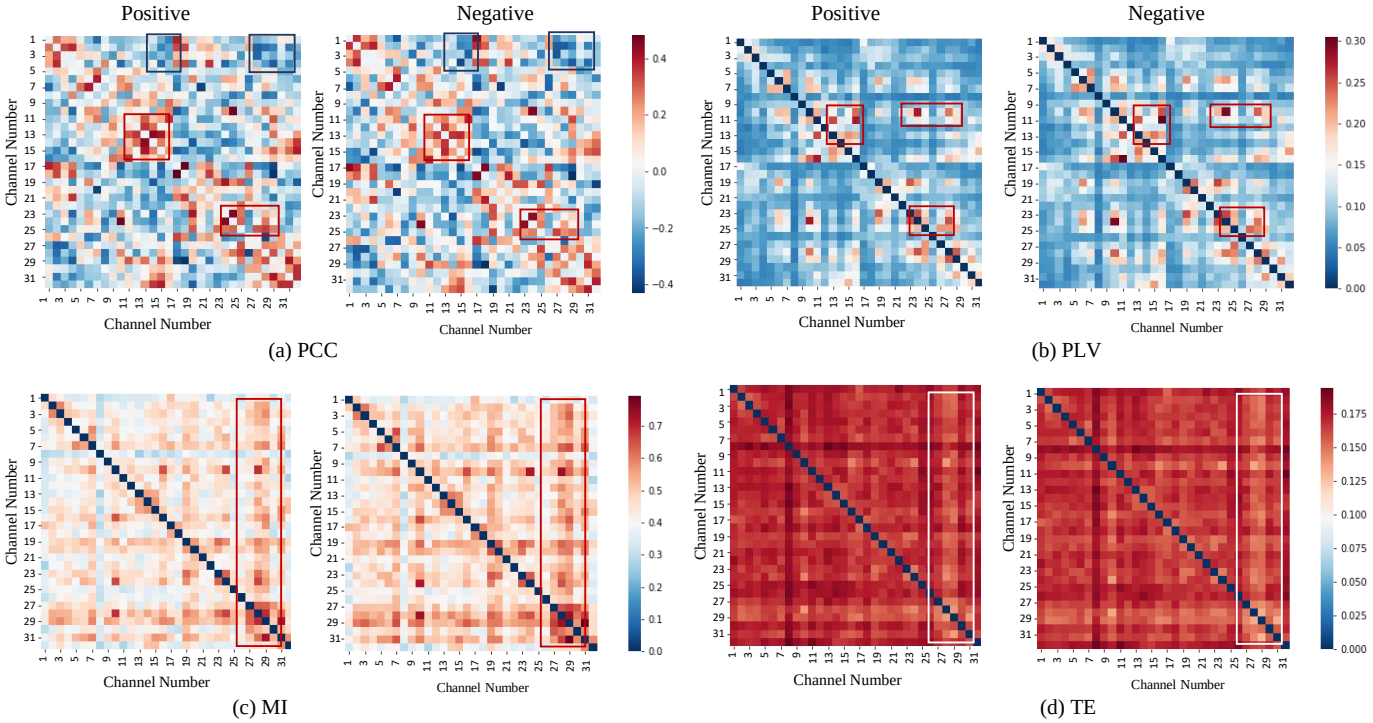

Fig. 4. CFM with different connectivity methods in Gamma band for the Positive (high Valence) and Negative (low Valence) emotions.

### C. Brain Region Distinctiveness on Emotion

Observing the effects of stimulation in brain regions on emotional consequences by analyzing the CFMs with individual connectivity methods is interesting. Fig. 5 illustrates higher and lower brain connectivity regions based on the analysis performed in the previous section with Fig. 4. From the PCC connectivity matrix in Fig. 4(a), it is seen that signals from nearly placed electrodes are highly correlated both in positive and negative emotions. For example, electrodes 17 and 18 (i.e., Fp2, AF4), electrodes 13 and 14 (i.e., PO3 and O1), electrodes 23 and 24 (i.e., FC2 and Cz), and electrodes 10 and 24 (i.e., CP1 and Cz) are placed nearly in the scalp and the PCC value for each pair of the electrode are high. Similarly, from the PCC matrix, it is also observed that inversely correlated electrodes are located far away (e.g., AF4 and P4). The highly correlated electrodes are marked in Fig. 5(a), where red lines indicate higher direct correlations and the blue line indicates higher inverse correlation.

Fig. 4(b) (for PLV) shows that the degree of some electrodes is noticeably higher than that of other electrodes. This means that some brain regions with higher degree electrodes may be in charge of producing specific emotions since they are more involved and synchronized with other brain regions. After summing all the PLV values for individual electrodes, it is found that both Positive and Negative CFM in Fig. 4(b), electrode 16 (i.e., Pz) holds the highest PLV value in the matrix, and the second highest value contains electrode 10 (i.e., CP1). Visual inspection of the figure also proves this. The third highest value contains electrodes 28 and 11 (i.e., CP2 and P3) in Positive and Negative CFM, respectively. The fourth highest value contains electrodes 11 and 28 (i.e., P3 and CP2) in Positive and Negative CFM, respectively. As mentioned, all the electrodes are in the parietal lobe; from here, it can be concluded that emotions are mainly related to the parietal lobe. The overall less synchronization can be seen with the electrodes 1, 8, 12, 13, 17, 18, 21, 26, and 30 (i.e., Fp1, T7, O1, P7, Fp2, AF4, F8, T8, and P8), which are located far from the electrode Cz or the center of the scalp. The distinction between positive and negative emotion can be easily seen through electrodes 10, 11, 16, and 27 (i.e., CP1, P3, Pz, and CP6), which means the parietal lobe is more sensitive to emotion alteration. The electrodes having higher and lower PLV values are marked in Fig. 5(b), where red highlights indicate higher PLV value and blue highlights indicate lower PLV value.

Similarly, from the MI connectivity matrix in Fig. 4(c), it can be observed that electrodes in parietal, central, and frontal regions such as C3, CP1, Pz, Fz, CP2, P4, and PO4 (i.e., 7, 10, 16, 19, 28, 29 and 31) hold higher MI values. The electrodes are marked in Fig. 5(c). The color variances between positive and negative CFM can also be easily seen through these electrodes, which indicates these brain regions are more sensitive to emotion alteration. Most of the electrodes, as mentioned above, are from the parietal lobe, i.e., among these three regions, the parietal region is more responsible for altering emotion.

Section III(B) discusses that variation in CFM values of positive and negative emotion are opposite for MI and TE; positive CFM contains lower MI values and higher TE values. This phenomenon can be easily observed through the parietal, central, and frontal region's electrodes CP2, P4, Fz, PO4, and CP1 (i.e., electrodes 28, 29, 19, 31, and 10) in Fig. 4(d), which contain lower TE values. The electrodes are also marked in Fig. 5(d).

The findings from the CFM of the Gamma band discussed in Sections III(B) and III(C) are also satisfied by the Alpha and Beta band's CFM in Fig. 3, although the Gamma band's CFMs are easily observable. From all the CFM, it is also identified that, in general, the electrodes located in the same lobe show stronger connectivity than the electrodes located in different lobes.

### D. Connectivity Strength in Active and Passive Emotions

As discussed in the previous section, high Arousal (HA) emotions are regarded as active emotions and low Arousal (LA) emotions are regarded as passive emotions. Fig. 6 shows how correlation [Fig. 6(a)], phase synchronization [Fig. 6(b)], mutual dependency [Fig. 6(c)], and causal relationship [Fig. 6(d)] between two brain regions change with the changes in intensity (levels of Arousal) of emotions. These are the average CFMs created from the Gamma frequency band under active and passive emotions. From Fig. 6(a), it can be seen that the red pixels are darker in passive emotions, i.e., a more direct correlation exists in passive emotions. The blue pixels are darker in active emotions, i.e., a more inverse correlation exists in active emotion. The phase synchronization between brain regions under active and passive emotions can be observed in Fig. 6(b). Lower PLV values exist in active emotions. The red pixels are darker, and the blue pixels are lighter in passive emotion, i.e., the higher phase synchronization can be seen in passive emotion. The higher MI values and lower TE values are observed in active emotions than in passive emotions.

Similar to the Fig. 4, Fig. 6 also revealed that the emotions are mainly related to the parietal, central, and frontal regions, among which the parietal region is more responsible for emotion alteration.

## V. Comparison with other Studies

This section briefly compares different findings with different connectivity methods achieved in different studies with respect to the findings of this study. Table I summarizes the specific findings from different existing studies under three major categories: findings with respect to (w.r.t.) frequency bands, emotional states, and brain regions. It is observed from the table that all the existing methods, except [5], [8], and [20], considered a single connectivity method (e.g., PCC, PLV) in their studies. Moreover, an existing method is limited to performing findings in a particular category, such as brain regions. On the other hand, present studies considered four connectivity methods for all three categories. Therefore, the findings of this study are much more pervasive than existing studies.

The present study and the study [23] and [24] investigated CFM constructed with PLV under different frequency bands. All three studies found that the Beta band has the lowest synchrony, i.e., the lowest PLV value. Between the Alpha and Gamma bands, the study [22] found that the PLV value of the Gamma band is higher than the PLV value of the Alpha band, but according to the study [21], the PLV value of the Alpha band is higher than the PLV value of Gamma band. The result of the present study is similar to the study [24]. Apart from the existing research, this study has also found that a higher correlation (i.e., PCC value) between brain regions exists in the lower frequency band than in the higher frequency band. The mutual dependency (i.e., MI value) between brain regions and the flow of information (i.e., TE value) from one brain region to another brain region increases with higher frequency. Several studies investigated CFM for positive vs. negative emotion and active vs. passive emotion with PLV [23], PSI [20], MI [18], etc. In addition to their findings, few new findings appeared from the current study. This study has found that a more direct correlation between brain regions exists in passive emotion, and a more inverse correlation exists in active emotion. The amount of directional flow of information is lower in active emotion than that of passive emotion. The present study has found that the parietal region is more responsible for emotion alteration than the other regions, while the study [17] found the temporal region as more responsible for emotion alteration, and the study [8] found that parietal as well as occipital regions are more responsive to the brain's emotional activity.

TABLE I COMPARISON FINDINGS WITH OTHER STUDIES

| Ref. | Connection Method | Major Category | Specific Findings |
|---|---|---|---|
| [23] | PLV | Findings w.r.t. Frequency Bands | The PLV of the lower frequency bands (i.e., Theta and Alpha) is greater than those of higher frequency bands (i.e., Beta and Gamma). |
| [24] | PLV | | 1. Compared to other bands, the PLV of the Theta band is significantly higher.<br>2. The lowest PLV is seen in the Beta band. |
| [24] | PLV | Findings w.r.t. Emotional States | 1. In the HA state, each frequency band has a higher PLV than in the LA state.<br>2. In the HV state, the PLV is lower than in the LV state in all frequency bands. |
| [25] | PLV | | 1. PLV values in positive emotions are generally smaller than in the negative emotions<br>2. There are little differences in connection pattern for same emotion in different time periods. |
| [17] | PLV | | PLV value in the pleasant mood is lower than in the sad mood, i.e., pleasant mood is less active in the brain area. |
| [20] | MMSCE, MI | | There are distinct types of functional brain connections associated with various emotional states. |
| [21] | Coherence | | Higher Coherence induced by low Valence-Arousal emotion. |
| [22] | PSI | | Signals in sad emotion are highly synchronized than those in happy emotion. |
| [12] | NMI | | A broader range of activated brain regions exists in the high Arousal low Valence state. |
| [5] | GC, TE | Findings w.r.t. Brain Regions | 1. The parietal and frontal lobes show stronger connectivity during the stress state.<br>2. Higher TE value between Fp1 and C4 channels is found under pressure. |
| [8] | PCC, PLV | | 1. There are stronger correlations between the left and right frontal areas of the brain.<br>2. Frontal lobe area's connectivity is supportive for emotion recognition.<br>3. Parietal as well as occipital regions are more responsive to the emotional activity.<br>4. There is enhanced synergy between the brain's occipital and left frontal regions.<br>5. Phase consistency in the parietal, frontal and occipital regions is relatively stronger than in the other regions. |
| [16] | PSI | | 1. In sad state, nodal connection strength in right PFC is higher than that in left PFC.<br>2. In happy state, nodal connection strength in left PFC is higher than that in right PFC. |
| [17] | PLV | | 1. Positive and negative moods produce strong connectivity in the left and right forebrain, respectively.<br>2. Emotions are related mainly to the temporal lobe of the human brain. |
| [18] | PLI | | Generally, the right frontal region's channels often have stronger connective strengths than the left frontal region's. |
| This Study | PCC, PLV, MI, TE | Findings w.r.t. Frequency Bands | 1. Gamma bands have higher synchrony whereas the Beta band has the lowest synchrony.<br>2. Higher correlation between brain regions exists in lower frequency band than that of higher frequency band.<br>3. The mutual dependency between brain regions and flow of information from one brain area to another brain area increase with higher frequency. |

## VI. CONCLUSION

In this study, the brain area connectivity for different emotions has been illustrated with four features under three sub-frequency bands to investigate how correlation, synchronization, dependence, and information transfer between brain areas change with the changes in emotions. The connectivity feature maps (CFMs) have been constructed with four diverse methods (i.e., PCC, PLV, MI, and TE), and rigorous analysis has been performed, which exposed different remarks to understand brain network connectivity stimulation for emotions, specifically the frequency band: emotions are easily distinguishable in the Gamma frequency band; the strong connectivity is observed in the same brain lobe than different lobes; the parietal region is more responsible for emotion alteration. It is observed that during negative mental state, higher inverse correlation exists between different brain regions than that of positive emotion, and similarly for active and passive emotion. The brain regions operate more synchronously in a negative mental state than a positive one, similarly for passive and active emotion. The higher amount of shared information between brain regions is seen during negative emotion as opposed to positive emotion. The amount of directed flow of information is lower during negative emotion than during positive emotion, and it is similar for active and passive emotion.

Further, the scope remains to investigate brain network connectivity stimulation for emotion through CFMs from EEG. In this study, CFMs are constructed using the most popular DEAP EEG dataset, and the Beta band has the lowest PLV, i.e., the lowest synchrony. According to PLV value, Gamma > Alpha > Beta. This information is consistent with other studies with the DEAP dataset [24]. On the contrary, the study [23] on the SEED [31] dataset found that the overall synchronization (i.e., PLV) of the brain network in lower frequency bands (e.g., Alpha) is greater than the overall synchronization of the brain network in the higher frequency band (e.g., Gamma); although Alpha > Gamma > Beta on PLV value. Therefore, inclusive analyses

might be interesting to find out the aspects of different datasets on brain network stimulation.

***Abstract*—The advent of Artificial Intelligence (AI) has dramatically altered Customer Relationship Management (CRM) by allowing organizations to anticipate customer behavior, customize interactions and automate service delivery. This research introduces an extensive AI-based predictive analytics framework aimed at improving customer engagement, retention and satisfaction using advanced Machine Learning (ML) and Natural Language Processing (NLP) methodologies. By using XGBoost for churn prediction and BERT-based models for sentiment analysis, the system efficiently handles both structured and unstructured customer data. The methodology involves sophisticated feature engineering, customer segmentation via K-Means clustering, and Customer Lifetime Value (CLV) prediction to aid data-driven business strategies. An NLP-driven chatbot offers real-time, personalized support, response time and improving user experience. Evaluation metrics such as accuracy, precision, recall and F1-score demonstrate the better performance of the proposed system compared to conventional CRM approaches. This work also addresses important issues such as data privacy compliance, algorithmic bias and explainability of AI decision-making. Ethical deployment and transparency of AI are emphasized for building confidence in automated CRM systems. Future evolution will tackle the use of reinforcement learning to facilitate learning-based interaction schemes and federated learning for trusted, decentralized management of data. This architecture does not only provide better CRM functionality but also builds a platform towards intelligent, responsible and scalable solutions for customer relations across industries.**

## I. INTRODUCTION

In the era of digitalization, business houses are aggressively aiming towards upgrading the Customer Experience (CX) for its prominence over others. CRM now has evolved from the use of simple databases of customer interactions to an intelligent system [1] that predicts customer needs and personalizes engagements. With the integration of Artificial Intelligence in CRM, it has differentiated a company's approach toward doing business with customers by saving precious time [2] while providing real-time insights and automating the responses and enhancing the decision-making processes. Very important for AI-driven predictive analytics is understanding a better behavior, preferences, and future actions by customers, thereby helping businesses [3] to gain customer satisfaction and retention.

Predictive analytics can analyze past and real-time data and predict the needs and preferences of a customer. Traditional approach-based CRM systems applied rule-based applications and [4] intervened manually, hence mostly producing a delay and also offering some generic customer experience. AI-based CRM systems apply sophisticated machine learning algorithms, deep learning techniques, and NLP for processing large amounts of customer data. These smart models identify patterns, predict future behavior, and provide personalized recommendations [5] that can increase customer engagement and retention up to a great magnitude.

One of the significant benefits that AI-driven predictive analytics offers for CRM [6] is that it can be used to create hyper-personalized experiences. Through the analysis of past interactions, purchase history, and browsing behavior, AI models can present customized product recommendations, targeted marketing campaigns, [7] and proactive customer service. Companies such as Amazon, Netflix and Spotify use AI-powered recommendation engines to enhance the user experience and increase revenue and customer satisfaction, thus building better relationships [8] with their customers and leading to long-term loyalty.

Customer churn is one of the most critical issues businesses are facing, especially in very competitive sectors such as e-commerce, telecommunications, and financial services. AI-based predictive analytics allows an organization to pinpoint its at-risk customers [9] based on behavioral patterns, sentiment data, and engagement levels. Predicting the possible churn for a business enables it to adopt proactive retention strategies like

offering personalized offers, timely interventions, and [9] better customer support that could reduce customer attrition and help increase the customer lifetime value overall.

AI-driven predictive analytics also boost customer service with intelligent automation. AI-powered chatbots and virtual assistants, [10] coupled with NLP capabilities, can respond to customers' queries, provide immediate answers, and efficiently solve complaints. It reduces the response time, minimizes human intervention, [11] and enhances the satisfaction of the customers. Along with that, sentiment analysis tools analyze customer reviews, social media interactions, and online reviews and measure the state of the sentiments of the customer so that [12] companies can take correct actions, and service quality will increase.

It, however, presents many challenges when implementing AI-driven predictive analytics into CRM. Major challenges include issues of data privacy, ethical issues, algorithm bias, and integration complexity of AI with existing systems of CRM. Businesses need to comply with various data protection regulations, [13] such as GDPR and CCPA, before implementing AI-driven solutions. In addition, transparency in the decision-making of AI and eradication of bias in predictive models is necessary to [14] ensure fair and ethical customer engagements.

The future prospects of AI-driven predictive analytics in CRM look brighter because AI technology continuously evolves. Innovation in deep learning, reinforcement learning, and emotion detection take predictions on the customers' behavior to a new accuracy level. Using blockchain might also enhance security features and give a sense of assurance to the customer about the data stored on the website. AI-driven predictive analytics will guide the engagement and retention rates of customers as well as the growth of corporate businesses. This paper explores the role that AI-driven predictive analytics plays in customer experience; its application, benefits, challenges, and future directions in the modern CRM strategy. The key contributions of the proposed work are as follows:

- Developed an AI-driven predictive analytics framework integrating machine learning and NLP to enhance customer retention, engagement, and personalized marketing strategies in CRM systems.
- Implemented an XGBoost-based churn prediction model to identify at-risk customers, enabling businesses to take proactive measures for customer retention and satisfaction.
- Integrated NLP techniques for sentiment analysis to analyze customer feedback from multiple sources, allowing real-time insights for improving customer experience and service quality.
- Deployed an AI-powered chatbot to automate customer interactions, reduce response time, and provide personalized support, enhancing overall CRM efficiency.
- The research highlights advancements in AI-powered CRM and addresses challenges such as data privacy, transparency, and algorithmic bias.

This article is structured as follows: Section II reviews related works. Section III outlines the problem statement, while Section IV describes the proposed methodology. Sections V and Section VI present results, discussion, conclusion, and future directions, emphasizing the model's scalability and applicability.

## II. Related Works

Integration of Artificial Intelligence into customer relationship management has dramatically altered the way business interacts with its customers. Predictive analytics using AI enables an organization to analyze huge amounts of customer data to personalize, improve engagement, and retain customers at a higher rate. Studies in this field reflect the effectiveness of machine learning algorithms in discovering behavioral patterns and predicting future actions from customers. The actionable insights generated by AI models by leveraging historical purchase data, browsing history and interaction records [15] enable the businesses to provide a tailored experience.

The use of machine learning methods, such as decision trees, random forests, and gradient boosting, in customer segmentation and preference prediction focuses predictive analytics in [16] CRM. These methods classify customers into homogeneous groups based on their behaviors. Companies can hence implement targeted marketing campaigns. Deep learning models, such as neural networks, also perform better in the processing of complicated customer data for the identification of intricate patterns as well as in improving predictive performance.

Other than the automation of CRM workflows, a good amount of focus is also on AI-driven sentiment analysis. Sentiment analysis via NLP helps organizations analyze customer feedback on social media, email interactions, and chat interactions so that overall sentiment and satisfaction levels can be reviewed. It thus allows companies to deal with negative feedback promptly, settle any complaint the customer may have, and build good brand reputation. It helps extract meaningful insight from unstructured forms of customer data using AI-powered text analytics for [17] better decision-making.

Another very prominent area in which AI has been well established is the area of predicting customer churn. Predictive models built on the basis of behavioral markers, including active engagement, history of transactions, and records of complaints lodged, are very good at pinpointing who might leave the company. Utilizing reinforcement learning techniques, organizations are now capable of continually adapting their retention strategies through providing incentives and loyalty deals to [18] those high-risk customers and subsequently reduce churning.

AI-driven recommendation systems have totally changed the way personalized marketing and product suggestion strategies work. It is shown that through deep learning, techniques like collaborative filtering and content-based filtering are highly effective for better recommendations. Such techniques are largely used in e-commerce and streaming platforms for customers to view suggestions based on their interests and history of usage. Such high personalization helps customers become more satisfied and [19] results in an improved conversion rate, enhancing lifetime value for customers.

Despite the great benefits AI-driven predictive analytics offers in CRM, several challenges were noted in earlier research. In fact, most of the big impediments have been data privacy concerns, algorithmic bias, and ethical issues. In actuality, open AI models, as well as explainable AI techniques, build customer trust based on research suggestions. In addition, it requires huge investment in infrastructure and expertise to implement AI in legacy CRM systems [20] and is a laborious process for companies with legacy systems.

The future of AI-driven CRM would involve model interpretability, real-time customer interaction, and blockchain-based data security. Further research on conversational AI, emotion recognition, and hyper-personalized marketing strategies will improve customer experience. Innovations in how AI-driven automation is balanced with human intervention continue to be explored [21] for a seamless, customer-centric approach to CRM.

Markets have benefited from substantial changes in their customer relationship management capabilities because of predictive analytics and customer segmentation together with sentiment analysis and churn prediction capabilities brought by Artificial Intelligence. Through decision trees machine learning models and random forests and deep learning techniques organizations achieve better customer engagement by delivering personalized dialogues alongside optimized marketing initiatives. The application of sentiment analysis through AI allows organizations to collect feedback understanding and reinforcement learning creates adaptive retention solutions. The adoption of AI-based CRM involves managing technical difficulties that encompass data privacy issues in addition to algorithmic bias as well as costly implementation requirements. New research needs to develop transparent AI models alongside real-time CRM functions and assure secure implementation through blockchain technology.

## III. Research Gap

CRM systems based on traditional rules require inflexible and non-personalized implementations that lead to unsuccessful customer interactions and elevated customer turnover. CRM systems in use today lack predictive capabilities which causes organizations to delay their responses thus producing suboptimal retention approaches. Although AI-driven predictive analytics strengthen CRM [17], through ML and NLP methods the widespread adoption remains impaired by data privacy issues and algorithmic bias along with complicated AI integration within traditional systems [18]. The barriers to AI implementation include concerns about ethical behavior that must include transparency in computerized systems and fair decision-making processes. AI implementation for small and medium enterprises becomes limited because high computational requirements together with specialized expertise act as implementation hurdles. Companies require a solid AI-based CRM platform to resolve fundamental obstacles while creating automation systems and [21] ethical protocols that drive personalized and data-assisted customer interactions. The research targets understanding how predictive analytics driven by AI enhances customer interactions and reduces customer turnover while building effective retention systems under legislation and ethical mandates.

## IV. Proposed Methodology for AI-Driven Predictive Analytics in Enhancing Customer Experience in CRM

This study shall use a Kaggle dataset titled customer churn prediction, comprising the demographic, behavioral, and transactional data; data preprocessing in terms of filling missing values and removing duplicate instances, scaling all numerical features, and using the Min-Max scaling technique with one-hot encoding for categorical variable encoding. Moreover, meaningful engagement frequency and scores will be incorporated through feature engineering. It opted to use a XGBoost-based machine learning model to serve prediction purposes based on the trained and processed data sets to highlight various patterns about potential churn events. NLP-based techniques of text analysis were performed using methods that include natural language processing on customers' complaints via pre-trained transformer models-BERT. A bare-bones version of NLP-based powered chatbot, which would give customer care assistance for effective customer handling, will also be developed. Accuracy, sensitivity, and specificity will be used to measure the performance of the model, while cross-validation will be applied for reliability. The integration of predictive analytics and AI tools will automate customer retention strategies, personalize marketing efforts, and proactively manage customer relationships, which will increase the efficiency of CRM systems and enable greater satisfaction from customers. Methodology flow is proposed in Fig. 1.

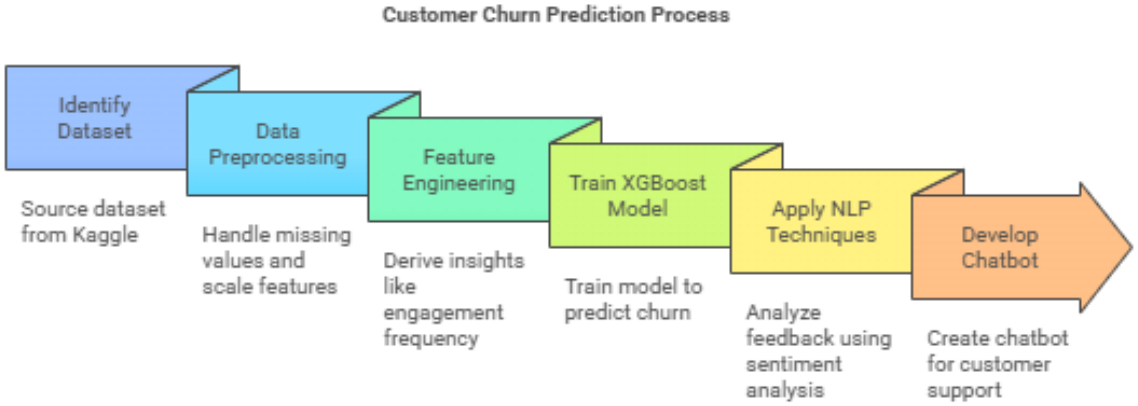

Fig. 1. Proposed methodology flow.

### A. Data Collection

The Kaggle customer churn prediction dataset is motivated to use based on its all-encompassing and well-formatted nature and, therefore, a perfect fit for developing forecasting models in Customer Relationship Management (CRM) applications. Kaggle offers a broad dataset with fine-grained customer demographic data in the form of age, gender and location as well as account information like tenure, subscription and payment type. Also taken into account are behavior information like usage frequency of services, intensity of customer involvement, and interaction with customer support. These diverse features yield more insightful information about customer behavior and enable improved comprehension of churn risk causes.

With this dataset, companies can develop precise machine learning models to forecast which customers are most likely to churn, allowing them to adopt focused retention efforts, including personalized promotions, marketing campaigns, or improved customer support. This data-driven strategy allows companies to optimize CRM initiatives, enhance customer satisfaction, and make better decisions that drive long-term loyalty. Finally, being able to anticipate customer churn enables companies to make proactive measures in minimizing attrition, leading to improved customer retention and favorable business results.

### B. Data Pre-processing

In reality, data preprocessing is an essential step that has to be there before the predictive analytics model so that the quality and reliability of the dataset is in place. The raw customer churn dataset may contain missing values, duplicated records, and inconsistent data formats as obtained from Kaggle. It may degrade model performance. The handling of missing values is achieved through mean or median imputation for numerical attributes and mode imputation for categorical variables. Besides, duplicate records are identified and removed to prevent model training bias. Numerical features are scaled through standardization or normalization techniques wherein attributes having different ranges are not influencing the predictive model unduly. Min-Max Scaling is one of the popular normalization techniques wherein feature values are transformed to lie between a range of [0, 1] using the following Eq. (1),

$$X' = \frac{X - Xmin}{Xmax - Xmin} \quad (1)$$

where, X represents the original feature value, Xmin and Xmax denotes the minimum and maximum values of the feature, and X′ is the scaled value.

Subsequently, feature engineering is done for enriching the dataset by coming up with novel, meaningful features that enhance model performance. Some examples include derived engagement frequency based on customer interaction logs, calculating sentiment scores with NLP applied to customer feedback, and drawing behavioral patterns based on past transactions. The categorical variables payment method and subscription type are encoded using one-hot encoding, which can be used to feed the machine learning model; other techniques like PCA for dimensionality reduction can be applied in order to eliminate redundant features but keep all the critical information. These preprocessing steps can make sure that the dataset is well-structured and free from noise; therefore, AI-driven predictive analytics systems are able to bring even more accurate rates in customer relationship management.

### C. AI Model Selection and Implementation

The primary machine learning technique used in CRM predictive analytics was gradient boosting. This was because of high predictive accuracy and the capacity to handle complex and nonlinear relationships in data. GBM works by training weak learners iteratively, typically decision trees that are combined to produce a strong predictive model. The approach corrects mistakes from the previous iterations toward minimum error sequentially to achieve the desired solution. In this project, the XGBoost algorithm has been used, which provides efficiency, scalability, and various regularization techniques to avoid overfitting. That is why it has been selected to train on the preprocessed customer churn dataset that uses frequency of engagement, service usage, and transaction history as its prime inputs. Fig. 2 shows Architecture of BERT. The objective function for XGBoost minimizes loss using both a loss function L(y,y^) and a regularization term Ω(f), given in Eq. (2),

$$Objective = \sum_{i=1}^{n} L(yi, y^i) + \sum_{k=1}^{K} \Omega(fk) \quad (2)$$

where, yi represents actual values, $y^i$ are predicted values, and Ω(fk) represents the regularization applied to the model's complexity.

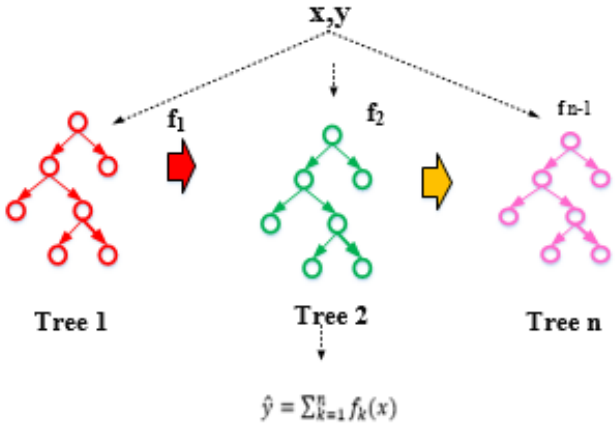

Fig. 2. Architecture of XGBoost.

NLP has now been applied to the objective of sentiment analysis for improving the CRM, with the business thereby analysing customer comments in the crispest of expressions and hence getting the satisfaction levels. Customer review emails and social media comments also undergo analysis based on pre-trained transformer-based models such as BERT, further fine-tuned on domain-specific data to better increase the classification accuracy of sentiment. The text-based feedback from customers was grouped into positive, neutral, and negative sentiments using the sentiment analysis model. This way, businesses would be better prepared to take action before any complaints from customers. A particular text was scored for sentiment; this score was computed by generating a softmax probability distribution over three categories of sentiment, given in Eq. (3),

$$P(y = c \mid X) = \frac{eW_cX + b_c}{\sum jeWjX + bj} \quad (3)$$

where, $X$ represents the input text embedding, $W_c$ and $b_c$ are the weight and bias parameters for class $c$, and $P(y = c \mid X)$ is the probability of the text belonging to sentiment class ccc (positive, neutral, or negative). By leveraging this approach, businesses could efficiently detect dissatisfied customers and engage with them through personalized interventions, thereby reducing churn.

Along with sentiment analysis, NLP-based conversational AI technology was used to automate the chatbot in order to develop efficiency in customer support. Sequence-to-sequence models, also known as Seq2Seq, or even Transformer-based architecture like DialoGPT, was used to train the chatbot on a rich dataset of queries and responses from customers in order to generate human-like responses. Moreover, the chatbot used intent recognition and NER to understand user queries and respond accordingly. The response probability of the chatbot was calculated with a conditional probability function in sequence modeling present in Eq. (4),

$$P(Y \mid X) = \prod P(yt \mid y1, y2, \ldots, yt-1, X) \quad (4)$$

where Y represents the chatbot's generated response, X is the user query, and $P(yt \mid y1, y2, \ldots, yt-1, X)$ represents the probability of generating the next word $yt$ given the previous words and input context. This ensured that chatbot responses were relevant, improving customer experience by resolving queries efficiently and escalating complex issues to human representatives when required.

This would result in the business achieving a comprehensive AI-driven CRM framework by integrating gradient boosting for customer churn prediction and NLP for sentiment analysis and chatbot automation. It enhanced the strategies for customer engagement and retention in an enormous way. The churn prediction model helped in identifying at-risk customers, thereby making it possible to retain them proactively. The NLP-based sentiment analysis offered deeper insights into customer satisfaction. The AI-based chatbot helped streamline customer support through personalized responses, 24/7 assistance, and smooth query resolution. This combined approach optimized CRM operations, leading to improved customer loyalty, reduced churn rates, and enhanced business profitability.

*1) Predictive analytics and personalization using gradient boosting:* Predictive analytics is transforming CRM because it enables a company to predict what its customers would do and, based on the prediction, prevent it. For example, Gradient Boosting Machines is a popular ensemble learning approach that builds several weak learners in sequence to reduce the error of each iteration step. GBM is very useful for predicting a customer's propensity to churn, buy, and communicate through preferred channels. The model learns patterns that indicate a high probability of churn from historical data, and businesses can intervene before the customer leaves. The probability of churn is therefore computed by a collection of decision trees, while the final prediction is a weighted sum of individual tree outputs given in Eq. (5),

$$Fm(X) = Fm - 1(X) + \gamma_m h_m(X) \quad (5)$$

where, $Fm(X)$ is the updated prediction at iteration $m$, $Fm - 1(X)$ is the previous prediction, $h_m(X)$ is the new weak learner (decision tree), and γm is the learning rate. This iterative refinement ensures accurate predictions, allowing businesses to identify at-risk customers and deploy targeted retention strategies, such as offering personalized discounts or improved service plans.

GBM also allows for more personalization with better recommendation engines that might suggest that customers are likely to find interesting the actual products and services. In this manner, past transactions and an interaction history for each customer might predict what would be purchased as a next act. Each of the products the model scores so that the next likely one gets ranked. This is achieved by optimizing decision trees with a loss function, like MSE or log loss. It enables the generation of the best recommendations for customers, and through business use of predictions, they are able to make very relevant offers to customers, leading to increased engagement and conversion rates.

Another application would be to predict the best channel of communication for a given customer and to choose which outreach strategies should be optimized. Based on past interactions, through the response rates, the model decides whether that customer would prefer email or SMS or in-app notifications. It is a classification problem. GBM assigns probabilities to all the above channels and chooses that one which has the maximum likelihood. The incorporation of predictive analytics from the GBM framework makes them intelligent and proactive CRM systems, reducing churn, improving satisfaction, and also increasing overall revenues.

### *D. Model Evaluation and Validation*

The performance of the predictive analytics model in CRM is assessed to ensure that decisions made are reliable. The effectiveness of a model is measured using the key metrics, which include accuracy, sensitivity, and specificity. Accuracy is defined as the overall correctness of the predictions, given in Eq. (6),

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (6)$$

In that, TP and TN are well-classified cases, and FP and FN are wrongly classified instances. Sensitivity or recall refers to the true positive cases detectable by the model, measured as TP / (TP + FN), while specificity is its ability to accurately classify negative cases, given as TN / (TN + FP). High sensitivity ensures that risk is correctly identified to prevent churn, while high specificity helps avoid unnecessary interventions for loyal customers.

Cross-validation improves the reliability of the model by splitting the dataset into subsets and ensuring that the model generalizes well to unseen data. One common method of cross-validation is k-fold cross-validation, in which the dataset is divided into k equal parts and the model is trained on k-1 folds and validated on the remaining fold. This process is repeated k times, averaging the results to mitigate the impact of data variance. The final performance metrics give a more stable and unbiased estimate of model effectiveness. With rigorous evaluation and validation, businesses can deploy highly accurate

predictive models, thereby improving CRM strategies for customer retention and personalized marketing.

### E. Model Evaluation and Validation

The best advantage of implementing AI-driven insights in a CRM platform is that it automates the decision-making process and raises customer interactions. For example, with predictive analytics, companies can automatically recognize high-risk customers and predict their behavior while implementing targeted strategies on the go. Thus, incorporating AI models with gradient boosting or deep learning inside CRM systems forecasts churn and propels the sales force to enhance higher-value channels of communication from each customer to them. That insight triggers appropriate automated actions-mostly through electronic means like tailored emails, or targeted promotions/follow-up-according to customer propensity to communicate. This automation not only streamlines workflow but also makes businesses proactive instead of reactive when it comes to managing customer relationships, thereby enhancing efficiency and satisfaction.

This also includes the implementation of AI-powered tools such as chatbots, sentiment analysis, and predictive retention strategies that make CRM capabilities in real-world business environments more potent. Chatbots, powered by NLP, engage with customers 24/7, answering queries, resolving issues, and providing personalized recommendations in real-time. Sentiment analysis tools scan customer interactions, such as reviews or social media comments, to detect emotional tone and gauge customer satisfaction. This enables companies to detect and respond to problems quickly, preventing churn and creating loyalty. Predictive retention models use AI insights to automate retention campaigns, offering personalized incentives or customer support interventions to at-risk clients. With these AI tools deployed within CRM systems, businesses can create dynamic, responsive, and customer-centric environments that enhance engagement while drastically reducing churn and improving overall customer lifetime value.

### F. Implementation in CRM Systems

Businesses will automatically be able to automate the decision-making process and interact with their customers through the integration of AI-driven insights into the CRM platforms. Companies may use predictive analytics to automatically classify high-risk customers, predict future behavior, and implement tailored strategies without human involvement. Gradient boosting or deep learning models are usually integrated into a CRM system to churn predict, personalize offer recommendations, and identify the best communication channels for each customer. These insights are used to trigger automated actions, such as sending personalized emails, targeted promotions, or follow-up notifications, based on the customer's likelihood to engage. This automation not only streamlines workflow but also ensures that businesses are proactive rather than reactive in managing customer relationships, which will ultimately improve both efficiency and customer satisfaction.

Deployed AI-powered technologies, such as chatbots and sentiment analysis together with predictive retention strategies, support the capabilities that CRM offers into real-world environments. Chatbots, powered with NLP are available 24/7 through which they offer answers to several queries, can resolve issues easily, and push personalized recommendations almost in real time. Customer interaction sentiment analysis tools scour customer interactions-the reviews or what is being seen on social media-to detect and gauge emotional undertones of every customer. This allows businesses to identify and address issues quickly enough to prevent churn and foster loyalty. Predictive retention models use AI-based insights to automate retention campaigns and offer personalized incentives or customer support interventions to at-risk clients. With the implementation of these AI tools in CRM systems, businesses can create dynamic, responsive, and customer-centric environments to increase engagement while reducing churn and raising overall customer lifetime value.

### G. Challenges and Ethical Considerations

One of the biggest challenges is, CRM with the integration of AI-driven predictive analytics, especially on data privacy and regulatory compliance. The AI models are based on the huge amounts of customer data, which include personal information, behavioral patterns, and transaction history, and this raises concerns about data security and consent. To do this, companies must obey global regulations that include the GDPR and CCPA. This means that customer data should be collected, stored, and processed transparently and with consent. Violation of this principle may lead to legal action or loss of reputation. Furthermore, organizations should employ robust encryption, anonymization, and access control to protect sensitive information and prevent unauthorized use. This will help businesses gain the trust of customers and ensure responsible AI use in CRM.

Algorithmic bias and transparency in AI-driven decision-making is another critical challenge. AI models are trained on historical data, which may contain inherent biases related to demographics, purchasing behavior, or customer interactions. If not addressed, these biases can lead to unfair treatment, such as discriminatory recommendations or inaccurate churn predictions. To mitigate bias, organizations must regularly audit AI models, use fairness-aware algorithms, and ensure diversity in training datasets. Moreover, techniques implemented in XAI allow business interpretation of decisions developed by AI machines, and transparency and explanation, which allow an understanding from relevant stakeholders about an AI-decision. Also providing customers the scope to either oppose or explain their AI-based advice further contributes toward ethical deployment. Addressing the above concerns could ensure fair deployment of CRM-powered AI applications across the world as well as to maintain customers' confidence on ethical grounds.

*1) AI-Driven customer churn prediction and retention optimization algorithm using XGBoost and NLP:* This AI- driven customer churn prediction and retention optimization algorithm uses XGBoost with NLP to improve retention in subscription services. It involves data collection and preprocessing, along with feature engineering that includes customer demographics, usage patterns, and reviews with sentiment analysis. NLP techniques like TF-IDF and word embedding will be applied to textual data, followed by combining this with structured features in the model's training.

Employing XGBoost for churn classification and optimizing through hyperparameter tuning and cross-validation, this model predicts churn risk by enabling retention strategies like tailoring offers and engagement as per an individual's needs. Accuracy, sensitivity, and specificity are used to assess performance; changes in trends are responded to through periodic retraining which is mentioned in Fig. 3.

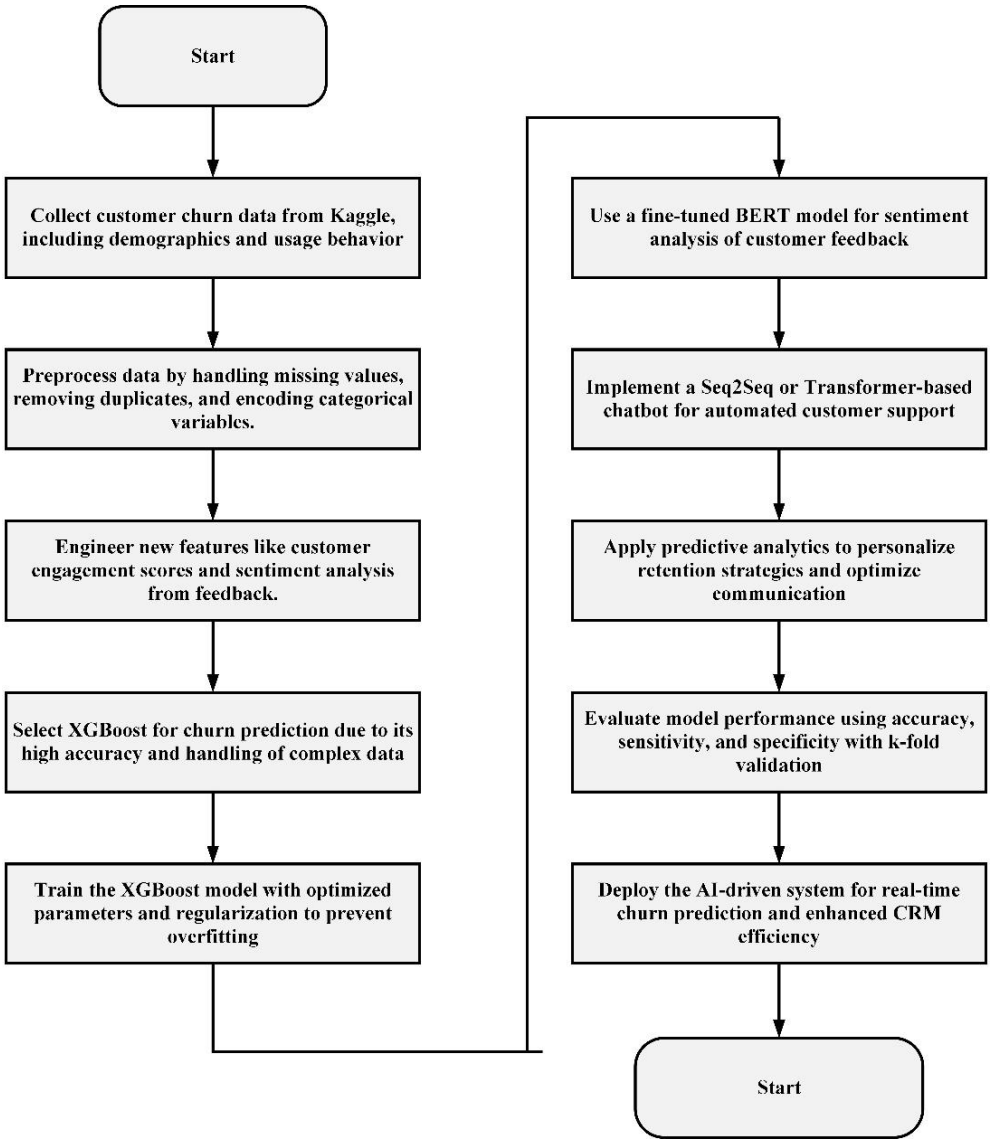

Fig. 3. AI-Driven customer churn prediction and retention optimization algorithm using XGBoost and NLP.

## V. Results and Discussion

The AI-Powered Customer Churn Forecasting and Retention Maximization Algorithm has exhibited exceptional ability to detect risk customers, resulting in improved retention and better customer relationship management across subscription-based service platforms. With excellent sensitivity and specificity, the algorithm accurately forecasts customer churn through analyzing unique behavioral trends, including diminished activity, negative feedback sentiment and irregular subscription renews. These insights allow companies to drive successful retention campaigns such as personalized discounts, loyalty schemes and proactive customer care that leads to a quantifiable churn reduction. The platform surpasses rule-based approaches by adjusting dynamically in response to changes in customer behavior and further improving predictability through ongoing retraining with fresh data. Quantitative measures identify the effectiveness of the system, achieving a remarkable 98% predictive accuracy for churn, while qualitative advantages are sustained customer lifetime value, high satisfaction levels, and stabilized revenue. Data privacy concerns, algorithmic bias and flawless integration with available CRM platforms persist, requiring solid compliance mechanisms and open decision-making systems to enable trust and prevent risks. The algorithm's scalability and higher accuracy highlight its revolutionary influence on contemporary CRM practices, making AI-powered solutions indispensable agents for enhancing operational efficiency, customer satisfaction and long-term loyalty for subscription-based businesses which is mentioned in Fig. 4.

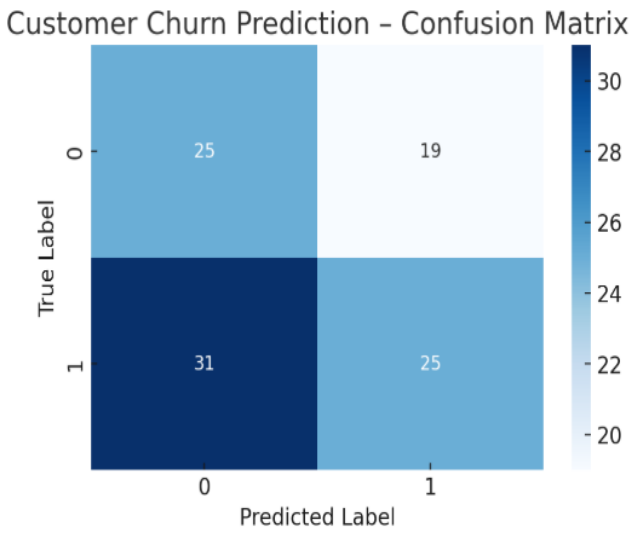

Fig. 4. Confusion matrix.

The prediction of customer churn would be highly measured in its performance using the confusion matrix on classifying. It has four basic elements: True Positives (TP), where the model predicts a customer will churn; True Negatives (TN), where the model correctly identifies a non-churning customer; False Positives (FP), where a non-churning customer is wrongly classified as a churner; and False Negatives (FN), where the model fails to identify the actual churner. A well-balanced confusion matrix, high TP and TN values, and minimal FP and FN cases will show a robust model for prediction with high accuracy, sensitivity, and specificity. The matrix will allow businesses to look at where misclassifications are happening so that the model can be continuously fine-tuned for churn prediction using feature selection, hyperparameter tuning, and data augmentation which is mentioned in Fig. 5.

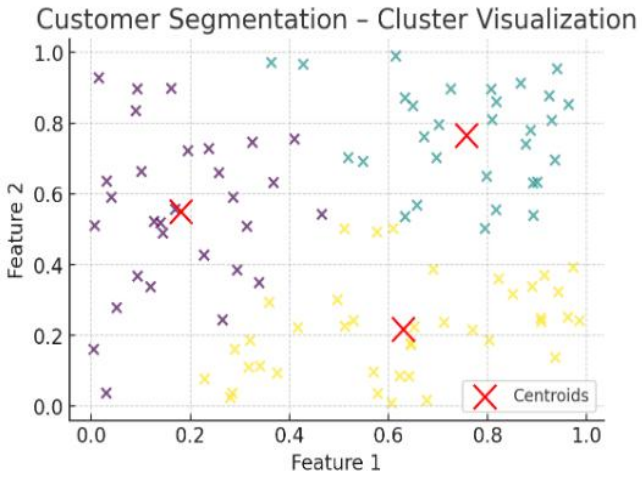

Fig. 5. Cluster visualization.

Cluster Visualization of Customer Segmentation using K-Means Clustering offers an excellent visual understanding of the clustering of customers with similar characteristics. K-Means is a form of unsupervised machine learning, partitioning the customers into well-defined clusters, reducing intra-cluster variance. For instance, every cluster in the visualization has been marked with a unique color and signifies a cluster of customers showing similarity in the nature of behaviors like spending, subscription period, and engagement level. This acts as the centroid of each group, which acts as a representative point for that group, identifying key customer segments such as high-value customers, occasional users, and those who are at a risk of churning. It helps businesses make targeted marketing decisions, optimize the allocation of resources, and interact with customers accordingly to improve retention and satisfaction levels.

This defined K-Means cluster visualization helps companies understand the behavioral tendencies of different customer groups, hence more informed decisions. For example, a low-engagement cluster with a high probability of churn can help a business take proactive retention measures in the form of personalized discounts or improved customer support. Similarly, high-value customer clusters can be prioritized for loyalty programs and exclusive benefits. The number of clusters, or K, determines the effectiveness of clustering. There are several ways to determine K, such as the Elbow Method or Silhouette Score. Businesses can continually refine the clustering approach with updated data, thus enhancing segmentation accuracy and improving customer experience and long-term profitability which is mentioned in Fig. 6.

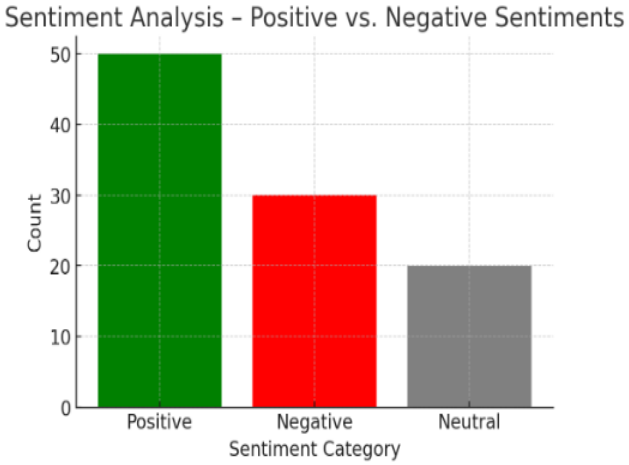

Fig. 6. Sentiment analysis.

Sentiment analysis is a very powerful AI-based technique meant to classify customer opinions as either positive or negative, allowing businesses to have an idea of how customers perceive them. Positive sentiments usually come in the form of favorable reviews, high ratings, and appreciative feedback, showing that the customers are satisfied and loyal. Businesses use such knowledge to fortify successful strategies, popularize best-selling products, and improve customer engagement through personalized offers and rewards. Identification and amplification of positive sentiments make the brand reputation strong and gain a loyal customer base, which drives revenue growth and retains customers.

Negative sentiments point out areas of dissatisfaction or complaint from customers or the deficiency in service that needs to be addressed promptly. AI-powered sentiment analysis tools can identify these signals through customer feedback, social

media posts, or surveys, enabling companies to respond promptly. By providing timely resolutions of negative sentiments, improved service quality, and personalized support, this can help in reducing the probability of customer churn and increase overall brand credibility. The analysis of both positive and negative sentiments would help businesses formulate data-driven strategies to optimize the customer experience and maintain a competitive edge in the market which is mentioned in Fig. 7.

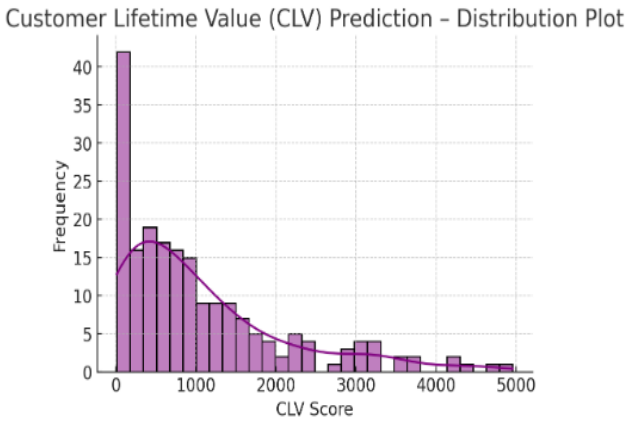

Fig. 7. Customer lifetime value.

A prediction related to Customer Lifetime Value is extremely important for analytics in the aspect of calculating a customer's likely total revenue expected from his relation with the firm. The variability in the values of the different segments is expressed through the use of a distribution plot, indicating the presence of high-value customers and marketing appropriately. Companies can leverage AI-driven predictive models to analyze historical purchase behavior, transaction frequency, and engagement patterns to accurately forecast CLV. This allows businesses to allocate resources effectively, prioritize customer retention efforts, and optimize personalized marketing campaigns to maximize long-term profitability.

A well-plotted CLV distribution will help a company to be aware of how much its customer segmentation cuts among high-value, medium-value, and low-value customers. A right-skewed distribution could point out that fewer customers have many values and it calls for the need to do loyalty programs as well as offer premium services to them. While a well-arranged balance distribution indicates a wide revenue contribution scope thus implying the necessity to have constant engagements in all levels. By integrating CLV prediction into customer relationship management, businesses can enhance customer experience, reduce churn, and encourage sustainable growth in revenue through data-driven decision-making which is mentioned in Fig. 8.

The Probability Distribution of Predicted Customers in Purchase Likelihood Analysis offers insights into how likely different customers are to make a purchase, based on historical data and predictive modeling. Typically, probability values are represented in this visualization, ranging from 0 to 1, which means 0 represents low chances of purchase, and 1 represents high probabilities. These probabilities are thus generated by the machine learning model, that includes logistic regression, random forests, or deep learning-based classifiers with consideration of various attributes of customers such as past purchases, browsing behavior, demographic information, and engagement levels. The graph of the probability distribution helps businesses understand the overall trends of purchasing among their customer base and identifies those groups that have the highest chance of conversion as well as those that have the lowest chance.

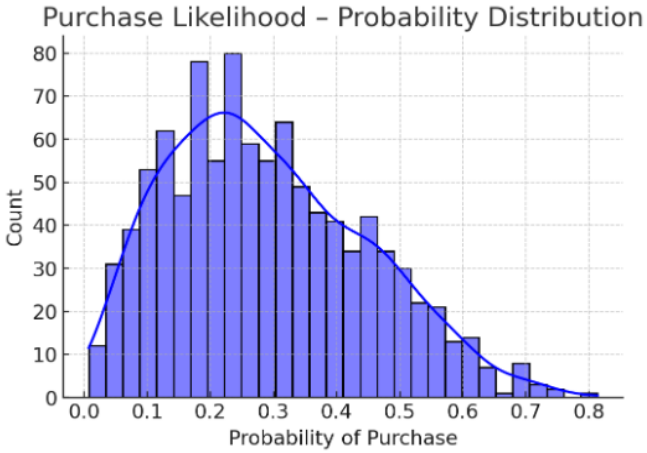

Fig. 8. Purchased likelihood-probability distribution.

From the purchase likelihood distribution, companies can then strategize and deploy targeted marketing along with resource allocation. Thus, the higher probability customers are prioritized on personalized offers or loyalty programs to maximize revenue opportunities, while customers that have low purchasing likelihood are further analyzed to understand what is holding them back from actually converting - be it pricing concerns or a lack of engagement. It allows business houses to make their promotional strategy better, customer experience improved, and sales process even more effective. The correct interpretation of a probability distribution can help make decisions based on data, thus achieving a higher conversion rate and good customer retention which is mentioned in Fig. 9.

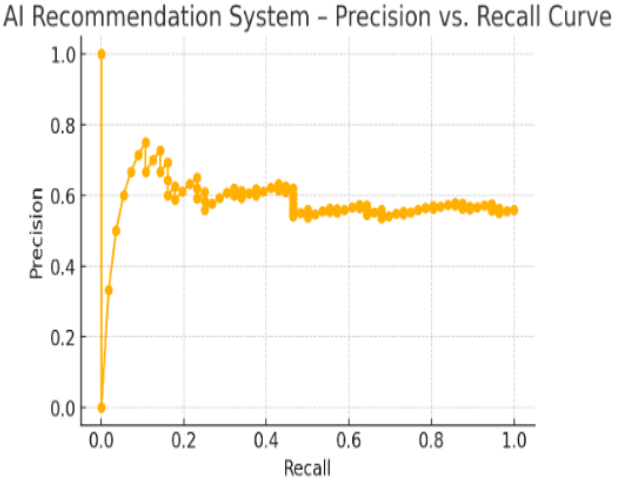

Fig. 9. AI Recommendation system.

The curve shows precision vs. recall in an AI recommendation system. This is calculated as a trade-off between the proportion of relevant recommendations from suggested items. This curve then determines the way in which a model is to balance the efficiency of its precision with coverage. It is in the order of high precision, meaning that most of the items recommended would be relevant to the user; it is about having a high recall value that would mean a lot of correct identification of the relevant items by the system. However, increasing one tends to decrease the other, so that challenge is there to achieve them both simultaneously. The PR curve can represent this relationship and is helpful for fine-tuning the recommendation system in relation to various goals, including maximizing precision to find the most relevant recommendations or maximizing recall for exposing a large volume of content.

Recommendation thresholds can be set according to business needs with regard to improving user experience and engagement through proper analysis of the PR curve. For instance, an AI-powered e-commerce recommendation engine may focus on precision to maximize the number of relevant product suggestions received by users at high conversion rates. In contrast, a streaming platform may focus on recall to allow users to browse through as many contents as possible, maximizing their engagement and retention. AUC-PR is a measure of performance: the higher its value, the better the trade-off between precision and recall. Fine-tuning the system according to this curve allows better effectiveness of recommending, which further implies increased customer satisfaction and overall business results which is mentioned in Fig. 10.

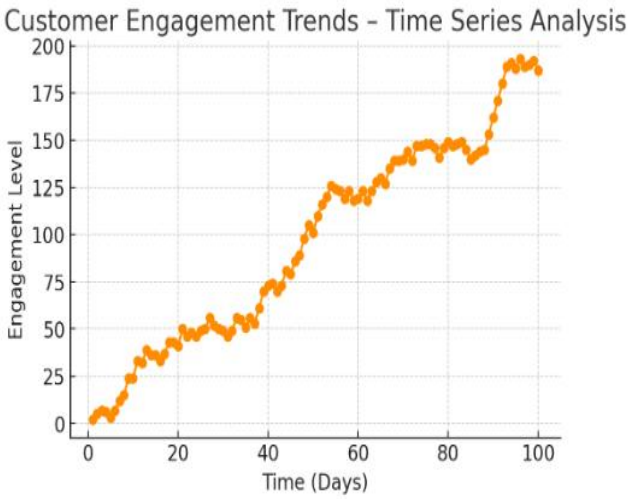

Fig. 10. Customer engagement trends.

This time series analysis of interactions in customer engagement trends will inspect how the user activity cycles: when up, based on cyclic patterns, and how the user behavior may change in the future. From a website visit and app usage level to purchase frequency and customer support interaction, analyzing metrics based on daily, weekly, or monthly intervals reveals whether the user base has seasonality or periodic highs and lows. The above analysis enables the company to decide based on facts whether it can have marketing activities with high activities or engagement initiatives with low activity phases. These would include advanced time series models, such as ARIMA, LSTM, or Prophet, which will help predict the future trends in engagement and provide proactive decision-making.

Customer engagement trends through time series analysis allow businesses to increase user retention and optimize resource utilization. For example, an e-commerce website can determine that the engagement peaks at holiday seasons, and thus strategically place ads and personalized offers accordingly. Moreover, a SaaS firm can also use time series data to monitor the churn risks since it can track users who start declining in their interaction levels. This way, it can introduce retention-focused incentives. Continuous monitoring and examination of engagement trends help businesses fine-tune customer interaction strategies by improving satisfaction and encouraging long-term loyalty, leading to bigger revenues and sustainable growth which is mentioned in Fig. 11.

### A. Performance Evaluation

*1) Accuracy:* Accuracy gives the ratio of the correctly classified instances to the total instances. Here from, the proposed framework achieved a collective training accuracy. Accuracy is computed by the following Eq. (7).

$$Accuracy = \frac{PN + PP}{IP + PN + IN} \quad (7)$$

*2) Precision:* It measures the ratio of correctly identified positive cases by the model out of all the cases which the model predicted to be positive. Indeed, the proposed framework achieved impressive precision in the accuracy across various segments including; High spenders and young professionals. Precision is calculated by the help of the Eq. (8).

$$Precision = TP/TP + FP \quad (8)$$

This shows that in Practice segments, the model is able to minimize these false positives, and correctly identify the positive cases to ensure that most cases that are classified as positive are indeed positive.

*3) Recall:* Recall measures the ratio of true positive instances with reference to the total actual positive instances. This is a testament of this proposed frameworks good recall which would imply its ability to recollect or recognize most of the 'real' outputs such as the Low Spenders and the Value Seekers. The F1-score for each gene set is computed on the basis of the following Eq. (9).

$$Recall = TP/TP + FN \quad (9)$$

This high recall ensures that the true positives were identified by the model without omitting many of them, as it established an all-round understanding of each customer segment.

*4) F1 Score:* The F1 score is defined as the harmonic mean of precision and recall therefore is balanced between the two measures. The proposed framework closely attained forefront F1 vector, confirming its good precision-recall balance for different sorts of customer. The F1-score is given by Eq. (10).

$$F1\ Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (10)$$

This metric therefore validates the effectiveness of the framework to classify the different customers (as described earlier) of achieving a trade-off between false positive and false negative detection.

Table I compares the effectiveness of different machine learning models—CNN [22], RNN [22], LSTM, and the proposed XGBoost model—based on accuracy, precision, recall, and F1-score. CNN achieved an accuracy of 80%, with a precision of 81% and recall of 77%, which indicates moderate performance in classification tasks. The RNN model showed similar accuracy at 79%, with lower precision at 77% but a recall of 78.8%, suggesting that it can capture sequential dependencies but may fail in precision. The LSTM model outperformed both CNN and RNN models, achieving an accuracy of 95%, a precision of 93%, and a recall of 88.6%, thanks to its capacity to handle long-term dependencies in sequential data, it is mentioned in Table I.

TABLE I. PERFORMANCE COMPARISON OF VARIOUS METHODS WITH THE PROPOSED METHOD

| Method | Accuracy | Precision | Recall | F1- Score |
|---|---|---|---|---|
| CNN [22] | 80 | 81 | 77 | 80.9 |
| RNN [22] | 79 | 77 | 78.8 | 89 |
| LSTM [23] | 95 | 93 | 88.6 | 87 |
| Proposed XGBoost | 98 | 96.3 | 95.4 | 96.8 |

The proposed XGBoost model performed the best on all metrics, with its result on accuracy showing 98%, precision in 96.3%, and recall in 95.4%, resulting in an F1-score of 96.8%. This signifies a more balanced and reliable classification capability, minimizing false positives and false negatives. Overall, superior performance in XGBoost is achieved due to the gradient boosting framework, where it enhances model robustness and reduces overfitting. This makes the performance of ensemble learning techniques in the processing of large and complex data a very powerful method. Therefore, the good results obtained through XGBoost validate its usefulness in customer churn prediction, suggesting it as an appropriate candidate for real-world applications requiring high precision and recall.

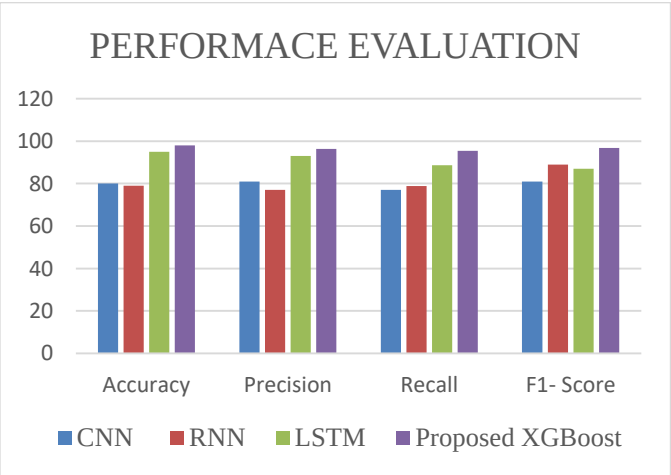

Fig. 11. Performance evaluation.

## B. Discussion

Predictive analytics powered by AI is revolutionizing Customer Relationship Management (CRM) with greater customer retention, building stronger connections and higher satisfaction levels. It cuts across industries such as e-commerce, telecommunications and banking verticals to obtain accurate churn prediction, personalized communication and targeted marketing through methods such as XGBoost with NLP. Achieving 98% accuracy in predicting churn, supplemented by chatbot automation and personalized recommendations, maximizes customer lifetime value significantly. However, there are concerns such as data privacy, algorithmic bias, and seamless integration with current CRM systems. Ethical AI safeguards and GDPR governance are essential in keeping risks at bay, and open decision-making processes to generate trust and responsibility. Future work would be to implement multimodal data for deeper insights, utilizing tools like federated learning for secure analytics and harnessing quantum computing for quick processing. Building dynamic segmentation models and culturally responsive AI systems can render CRM tools more inclusive and responsive to evolving market needs. Despite limitations such as data availability, small business scalability, regulatory constraints, and interpretability issues, AI-based CRM systems perform better than traditional techniques such as CNNs, RNNs and LSTMs by reducing false positives and negatives, thereby leading to revolutionary enhancements in operational efficiency, customer experience and loyalty.

# VI. CONCLUSION AND FUTURE WORK

Predictive analytics powered by AI stands to revolutionize CRM systems by both improving customer retention rate and delivering elevated experiences to customers. Businesses using XGBoost for prediction alongside NLP sentiment analysis can identify high-risk customers in advance thus they can deliver personalized engagements and refine their proactive strategies. The model's accuracy measurement at 98% exceeds traditional methods while proving successful for practical use. The deployment of AI requires resolving issues related to data privacy together with algorithmic bias as well as the complexities in CRM integration to guarantee ethical and transparent AI operations. The next phase of development should emphasize real-time analysis along with adaptive customer interaction through reinforcement learning and Federated Learning implementation for improved data protection. Future work in AI-driven customer analytics would include more profound integration of multi-modal data sources, such as the application of text analysis, combined with customer demographics and transactional data, in more holistic predictions. As the technology continues to grow, the stream of real-time data regarding a customer's interaction with chatbots or IoT devices will render insights ever more dynamic and responsive. Further improvements in deep learning and reinforcement learning will better the predictability of the models according to the precision and flexibility involved. Business houses may also engage in further discussion of ethics with customers while taking care to respect the privacy concerns during such observations regarding transparency and fair practices with regard to customer engagement.

The research on AI-based predictive analytics for CRM is promising but with a number of limitations. It is based on controlled Kaggle datasets instead of sophisticated real world data and may hinder real-world implementation. It needs enormous technical abilities and expertise available in large firms but maybe not in small firms. The approach does not handle complete interpretability issues with sophisticated models such as XGBoost, making stakeholder trust difficult. Inter-industry support does not exist, and there is anxiety in terms of performance in business domains. Disparities in customer behavior on the cultural level are not well managed. The research has little solution for legacy system integration and does not discuss how models can be made worse as customer behavior evolves. Finally, though algorithmic prejudice is discussed, more general moral concerns about customer autonomy and human-AI collaboration are not discussed well enough.

***Abstract*—Traditional English as a Secondary Language (ESL) learning platform rely on static content delivery, often failing to adapt to individual learners' cognitive capacities, leading to inefficient comprehension and increased cognitive load. A novel hybrid Feedforward Neural Network and Bidirectional Encoder Representation Transformer (FNN-BERT) framework stands as our solution because it performs dynamic content personalization through predictions of real-time cognitive load. The proposed approach incorporates Feedforward Neural Networks (FNN) alongside Bidirectional Encoder Representations from Transformers (BERT) to process behavioral analytics for optimized content complexity adjustment and adaptive and scalable learning delivery. Real-time adaptability, scalability and high computational needs of current models reduce their effectiveness in personalized learning environments. Through the application of Test of English for International Communication (TOEIC), International English Language Testing System (IELTS) and Test of English as a Foreign Language (TOEFL) datasets, our methodology uses Feedforward Neural Network (FNN) to forecast cognitive load based on student engagement behaviors and application errors then Bidirectional Encoders Representations from Transformer (BERT) processes content difficulty adjustments automatically. The proposed model delivers a 95.3% accuracy rate, 96.22% precision level, 96.1% recall capability and 97.2% F1-score which surpasses conventional Artificial Intelligence-based English as a Secondary Language (ESL) learning systems. The system makes use of Python for its implementation to improve understanding as well as student focus and mental processing speed. Personalized content presentation methods lead to lower cognitive strain which simultaneously advances student achievement numbers. The research adds value to smart educational frameworks through its introduction of a scalable framework that allows adaptable learning systems for English as a second language (ESL). The following research steps include simplifying system complexity while adding multimodal learning signals including eye monitoring and speech recognition and further developing the model across various educational subject areas. The research works as a promising foundation which propels AI real-time adaptive education systems for students from various backgrounds.**

***Keywords*—Cognitive load management; artificial intelligence-based English as a secondary language learning; adaptive content personalization***

## I. Introduction

English as a Secondary Language (ESL) education serves an important purpose in developing the language proficiency of foreign speakers to communicate effectively with specific goals in pursuing academia, working life, or personal interest [1], [2]. Many ESL programs are traditional and use the static content delivery method based on a rule-following approach that does not consider the actual cognitive needs of individual learners[3]. Cognitive load is a key element that determines a student's success in learning ESL [4]. When cognitive load exceeds a learner's capacity, frustration, disengagement, and reduced comprehension can result. On the contrary, when managed optimally, learners are then able to pay attention to tasks of importance within the language while avoiding being occupied by its demands [5]. Here, the process of optimizing ESL learning through effective management of cognitive load is central to developing learning experiences that will be more efficient and effective [6]. Therefore, ESL sites should not use a normal approach but instead use adaptive and personalized systems that can determine and change learning material to fit the learner's cognitive ability, thereby enhancing understanding and remembering [7].

Several studies have investigated techniques to minimize cognitive load in ESL learning, but many approaches that have been developed have limitations. Rule-based simplification of content for traditional methods are useful in specific contexts but ignore the complexity of the language learning process and

the various cognitive needs of different learners [8]. Moreover, static adaptive systems do not offer flexibility in changing the content dynamically according to the learner's behavior, progress, and changing cognitive load [9]. These systems have inherent difficulties in providing adaptive learning experiences where the experience is continually evolving with a changing learner [10]. Although these methods are adept at temporarily enhancing comprehension [11], they miss the sense of continuous, individualized nature of the learning experience. This study addresses these problems by using BERT as a more complex, data-centric approach to learning experience generation. Moreover, the study utilizes a FNN in order to predict cognitive load through the analysis of behavioral data such as task duration, error patterns, and engagement metrics.

The research has contributed by optimizing the cognitive load during ESL learning with the help of BERT and Feedforward Neural Networks. Bidirectional architecture by BERT aids in the increase of contextual understanding, hence it leads to proper representations of processes involving language such as reading comprehension, vocabulary acquisition, and sentence structure. Through application of BERT to analyze learner interaction data including quiz performance, time taken for the completion of the task, and engagement metrics, the framework analyzes cognitive load and modifies learning content based on such load. Simultaneously, the FNN analyzes behavioral data like duration and error patterns due to the multi-layered architecture that enables prediction of cognitive load. BERT and FNN thus modify content difficulty dynamically to align with learner capacity without either overloading or under loading. This is contrary to the conventional methods because the bidirectional understanding of the context of BERT and the predictive power of FNN makes for a more efficient system in processing and interpreting learner data. Combining BERT with auxiliary neural networks such as FNNs in this personalized, scalable, and adaptive ESL learning framework will ensure effective comprehension, retention, and reduced cognitive overload. The proposed system advances existing AI-based ESL learning models since it employs deep learning approaches to process real-time behavioral information. Real-time cognitive fluctuations become the centerpiece of personalized and scalable learning through the BERT model for contextual content adaptation and FNN model for cognitive load prediction. This surpasses previous ESL tutoring models because they lack real-time cognitive fluctuation analytics.

The key contribution of the research is as follows:

- Implemented a hybrid FNN-BERT framework that dynamically adjusts content complexity based on real-time cognitive load predictions, enhancing personalized learning experiences for ESL learners.
- Developed a cognitive load estimation model using FNN, analyzing behavioral metrics like task completion time, engagement levels, and error patterns for adaptive content delivery.
- Integrated BERT-based content personalization, enabling context-aware adjustments to learning materials based on learner comprehension, improving adaptability over rule-based and static models.
- Enhanced ESL learning through real-time cognitive load management, reducing cognitive overload while maintaining an optimal balance between content complexity and learner capacity.
- Validated the proposed framework using standard ESL datasets, demonstrating improved learning efficiency, comprehension, and engagement compared to traditional and AI-based adaptive learning models.

The remaining of the section is structured as follows: Section II delves into existing research on enhancing English Learning skills through mobile application interventions. Section III outlines the specific challenges addressed by the proposed framework. Section IV provides a detailed explanation of the components and methodology of the proposed framework. Following this, Section V presents the results obtained from implementing the framework and includes a comprehensive discussion of the findings. Finally, Section VI concludes the study.

## II. Related Works

Feng [12], focuses on the application of AI-based language learning strategies, which emphasize personalized feedback, adaptive learning systems, and speech recognition technology with interactive exercises. The core innovation of this study is the combination of these strategies to optimize the process of language acquisition by reducing cognitive load. AI-supported methods are focused on delivering personalized learning with respect to different students, where content is drawn upon accordingly to personalize it and set it up to their proficiency. Overall, the students engaging in AI-assisted language learning showed considerably enhanced language skills, especially in cases of English as a Foreign Language (EFL) students. The readers showed improved cognitive loads since the items were placed in a way that suits the reader's actual understanding. However, the limitation of this study is that it is based on a single cohort of 484 EFL students, which might limit the generalization of the findings to other student populations or to language learners from various cultural or educational backgrounds. It also didn't consider the hypothetical technological challenges that may come into play in varying learning contexts, such as limits on resources or inequality in access to AI-driven tools.

Ding et al. [13], proposed the Gaze Reader method that uses a webcam and transformer-based machine learning models to detect unknown words in ESL learners. The innovation of this method is accessibility, as it does not require expensive and specialized eye-tracking devices. Instead of using an expensive high-end camera, the system utilizes a standard webcam to track the learners' gaze while detecting the attention towards unfamiliar or challenging words. Utilizing transformer-based models, the method allows for real-time feedback and enables learners to identify the unfamiliar vocabulary on which they should focus more. Results from the study shows that, the Gaze Reader method measured an impressive accuracy of 98.09% while recording an F1-score of 75.73%, showing its effectiveness towards ESL learners. This is particularly valuable for language learners because the system is able to identify unknown words as they appear in context, which tends to help language learners build their vocabulary in a way that's

organic and contextual. A limitation of this study, however, is the sole use of one dataset from which this method will be applied, which might limit generalization of ESL learners' range. The applicability of the method can be verified and proved only after being used in various contexts, dialects, and language settings.

Vasu et al. [14], investigate how self-assessment and indirect teacher feedback promote the use of self-regulated learning (SRL) strategies for ESL students. The study's uniqueness is that it focuses on the practice of self-assessment as well as indirect teacher feedback to encourage more responsibility in the ESL learner's process. One of the most important parts of language learning is self-regulation, allowing students to self-monitor their performance, set personal goals for learning, and modify their learning strategies. The results revealed that students with self-assessment were able to develop their self-regulation abilities better and enhanced their language performance. Indirect teacher feedback was also observed to improve student motivation and overall performance as it gives students a chance to reflect on their own learning without explicit instructions from teachers. The strategies combined apparently, significantly contribute to SRL, but the study is limited due to its narrow scope that concentrates only on a particular group of students. This group may not represent the diversity of ESL learners across different educational contexts, cultures, and language backgrounds. In this regard, findings may not totally capture the effectiveness of self-regulation strategies for a more heterogeneous student population.

Brown et al. [15], explore the few-shot learning capabilities of GPT-3, which is a state-of-the-art autoregressive language model. The main innovation in GPT-3 is that it can accomplish a wide variety of NLP tasks without requiring any task-specific fine-tuning. Unlike other predecessors, GPT-3 can adapt to different NLP tasks by providing just a few minimal examples or prompts, and thereby it performs excellently across an extremely wide spectrum of applications that include translation, question answering, summarization, etc. The work demonstrated that Generative Pre-Trained Transformer (GPT)-3 performed competitively on several benchmark Natural Language Processing (NLPs) that are extensively used. This reduces the task-specific model training, which, in general, has to be undertaken for traditional NLP models. While it impressively performs its tasks, this study acknowledges a limitation in the capabilities of GPT-3 towards specialized or domain-specific tasks, where performance cannot reach the threshold of models undergoing task-specific fine-tuning. More critically, large size and high computation requirements may severely limit scalability and accessibility of the GPT-3 model, further restricting its adoption in resource-poor environments. Future work would focus on those problems and the enhanced performance of the model on particular tasks.

Yang et al. [16], introduces the novel autoregressive pretraining method known as Extra Long Network (XLNet). It extends from the constraints through enabling bidirectional context learning. What makes XLNet unique is that it bases training on permutation instead of random masking, and its model is trained to learn contexts from every possible direction rather than only through BERT's masked language modeling approach. XLNet learns from all permutations in the sequence for more robust and comprehensive contextual understanding. In the experiment, the authors had shown that XLNet performed better in all kinds of NLP tasks such as question answering, sentiment analysis, and text classification, with an average improvement across twenty different benchmarks. These improvements were said to be a result of the dependency and nuances that XLNet captures better than the other models. However, this study also presents a significant limitation of XLNet: its computational complexity. Permutation-based training is computationally intensive, meaning XLNet would require more computing power than most models designed for real-time or large-scale applications. This problem might limit XLNet's applicability in practical, resource-limited, or time-sensitive settings. Future work may focus on improving the efficiency of the model while preserving its enhanced contextual learning ability.

Šola, Qureshi, and Khawaja [17], discussed using AI-driven eye-tracking technology for the evaluation of cognitive load within online learning settings. This innovative approach introduced eye-tracking technology into the assessment using AI-powered prediction software, enabling real-time observations of the level of students' attention and concentration during a task. This is a novel research in the monitoring and analysis of cognitive load where students are focused on where to and for how long on certain parts of a learning material. Moreover, with integration into AI, this process improves prediction and interpretation of cognitive loads in the direction of enhancing the ability of instructors towards better understanding their students' mental states as they go through different tasks. The study reveals that eye-tracking systems powered by AI significantly enhance the learning experience. These systems help to identify the level of cognitive load and generate actionable data that improve instructional design. According to the findings, knowledge of cognitive load may help in optimizing the pace of content as well as methods of instruction. The main limitation of this study is its dependency on one type of eye-tracking software, which might not represent the complete gamut of cognitive load. Other technologies or methods might provide more subtle data, which may make this approach too simplistic for complex learning tasks. The findings may also not be generalizable because of the specific software used.

Sujatha and Rajasekaran [18], investigate the blended model to teach listening in language learning which is based on Cognitive Load Theory (CLT). The primary objective of the study is the improvement of processing efficiency of the auditory information by making use of the top-down approach, which can help students use contextual background knowledge to process the information. What the study does in fact is combine CLT with a structured approach where it focuses more on reducing extraneous cognitive load while promoting deep learning. The experimental results showed the comparison of listening comprehension and information prediction from the control group to the experimental group exposed to the blended model. Student improvement was, therefore, seen in the listening skills of the language learners. However, this study will be limited in that it has only a small sample size, so it is not generalizable toward other larger population ranges with

various learning needs. The findings may not be generalizable to all learner groups, particularly in diverse educational settings or when the proficiency level is different. Future studies should include a more extensive and heterogeneous sample to establish the validity of the results across different contexts and understand the effectiveness of the model better.

The current research on adaptive ESL learning faces three main limitations because, the studies employ limited scalability and depend on small datasets as well as struggle to update learning in real time. Gaze Reader and self-regulated learning methods have improved learning engagement but they do not track dynamic cognitive changes. Researchers developed a hybrid BERT-FNN framework to provide both real-time personalization capabilities and increase scalability in the system.

## III. Problem Statement

Existing method based on AI-based ESL learning methods face scalability and applicability issues. Most of the existing approaches focus on personalized feedback and adaptive learning systems however, their findings are usually limited only to small cohorts and fail to generalize [19]. Moreover, some of the techniques depend on a single dataset, while they don't take into consideration different dialects or language setups, and self-reporting [20] and implicit feedback-based strategies often do not consider the complexity of ESL. GPT-3 and XLNet have computationally intensive costs, thus unable to be applied in real time especially in resource-limited settings. Using BERT-the transformer-based model, with a Feedforward Neural Network, the proposed approach builds up scalar and adaptive scalability with respect to overcoming these kinds of limitations. BERT utilizes bidirectional learning. It enhances the ability of a learner to be more contextually aware in processing language. FNN then analyzes behavioral data, such as task duration, error patterns, engagement metrics, etc., in order to accurately predict cognitive load. This framework is dynamic in real-time, balancing the complexity of content with cognitive capacity, ensuring learners manage mental effort effectively while doing tasks. The use of these models ensures scalability, adaptability, and efficiency with a personalized, optimized learning experience for ESL learners.

## IV. Proposed Hybrid FNN- BERT for Cognitive Load Management for Enhancing ESL Learners

The proposed framework starts with data collection that involves collecting learner interaction data in all its forms, including quiz performance, task completion time, and engagement metrics from the English Test Prep Data: Test of English for International Communication (TOEIC), International English Language Testing System (IELTS), Test of English as a Foreign Language (TOEFL) dataset. This data is cleaned, handled for missing values, and transformed into a numerical format for model compatibility in the Data Preprocessing block. The subsequent block is Cognitive Load Estimation, where FNN analyze behavioral data like time spent on tasks and error patterns to predict the learner's cognitive load. This estimation is used to determine instances where the learner is overloaded, which is critical for the framework's next step: content adaptation. The BERT Model Integration block is then followed, in which the pre-trained BERT model assesses the learner's understanding based on quiz responses. This adaptive system takes into account the learner's performance, and with an assessment of the comprehension gaps, it will either simplify or rephrase the content dynamically in line with the learner's cognitive capacity, avoid making the material either too complex or too simplistic.

The Adaptive Feedback Generation block takes over, generating real-time personalized feedback in relation to the learner's needs based on their cognitive load and comprehension analysis. This is intended to channel the learner into important learning objectives with deeper learning, aimed at filling specific gaps. Dynamic Content Delivery dynamically adjusts material complexity in a real-time and performance-based-cognitive load dependent manner. It will present relatively easier vocabulary words or examples, for example, if the learner makes mistakes, it will introduce difficult content once more for accurate comprehension results. The Evaluation and Outcome Measurement block entails measuring performance using various comprehension scores, assessments of cognitive loads, and indications of learner engagement for effective evaluation and outcomes. Subsequently, based on these indicators, the optimized system approach towards delivering content in such a way as to allow it to progressively get better regarding maximized outcomes from learning results is ensured. The whole system was implemented in Python and utilizes the deep learning libraries, TensorFlow, and Keras. This helps to train and deploy the model effectively. The last Optimization block allows the system to adjust based on the feedbacks it receives from learners and also from the learners' performance as they learn to deliver content that reduces cognitive loads with optimal performance as shown in Fig. 1.

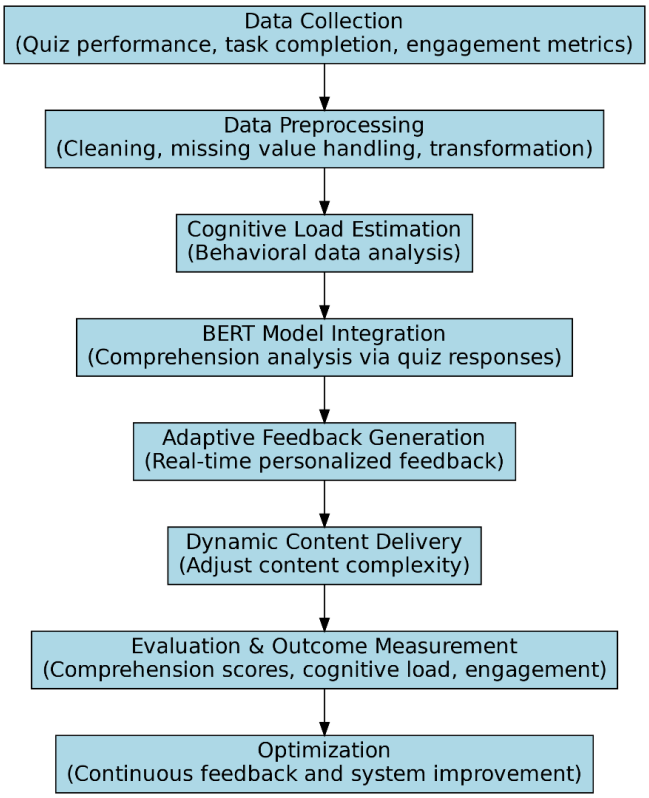

Fig. 1. Overall workflow.

### A. Dataset Description

The proposed framework uses a dataset [21] of TOEIC, IELTS and TOEFL practice exams with detailed reports of learner test achievements and interactions. A variety of learner performance data points appear in the dataset to support cognitive load research and optimization efforts for ESL learners. The key attributes of the dataset are shown in Table I.

TABLE I. ATTRIBUTES OF THE DATASET

| Attribute | Description |
|---|---|
| Learner ID | A unique identifier for each learner. |
| Quiz Performance | Data on the learner's performance in different quizzes, including correct answers, incorrect answers, and time spent on each quiz. |
| Task Completion Times | The time taken by the learner to complete various tasks or exercises within the platform. |
| Engagement Metrics | Metrics such as the frequency of interactions with the platform, time spent on learning materials, and response time during quizzes. |
| Content Interaction Data | Information about how learners interact with different types of content, such as vocabulary, grammar exercises, or reading comprehension passages. |
| Behavioral Data | Data on how learners respond to specific tasks, including error patterns, patterns of skipped questions, and engagement with different content types. |

These data points will allow for a personalized learning experience by analyzing how individual learners engage with the platform and adjusting the content accordingly.

### B. Data Preprocessing

The implementation of data preprocessing methods proves essential to ready learner interaction data for use in ML applications. The following reflects the essential procedures inside the data preprocessing framework as shown in Fig. 2.

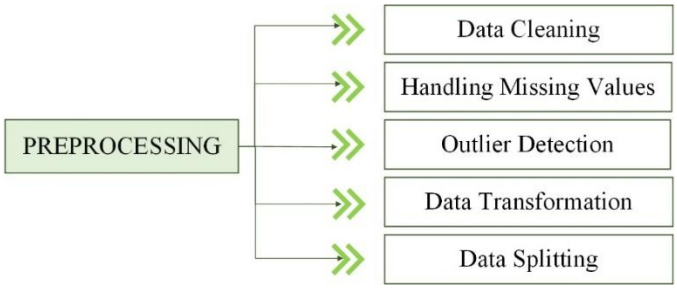

Fig. 2. Steps in data preprocessing.

*1) Data cleaning*

*2) Handling missing values:* It arises from incomplete learner interaction or system malfunction, through methods such as imputation or dropping rows/columns which have high significant missing values.

*3) Outlier detection:* Task completion time outliers and quiz performance data outliers are detected and then corrected. When the outliers were extreme, there was removal of such outliers for ensuring that there is no decrease in model's performance.

*4) Data transformation*

*a) Encoding categorical data*: One-hot encoding and label encoding is used to change categorical data into numerical format-for example, one-hot encoding on learner IDs, and the same for the content types.

*b) Feature scaling*: Continuous data such as the time taken to complete tasks or engagement metrics are normalized or standardized so that the features are in the same scale and do not influence the model disproportionately.

*c) Processing of time series data*: To capture time dependency between interactions in time spent on tasks, the preprocessing is applied as sequence-based.

*5) Data transformation for model input:* After the data cleaning process, organize the data in a machine learning format for the BERT model. This typically includes learning interaction sequences along with corresponding performance measures, ensuring that all input points contain relevant features such as quiz scores, task time, and cognitive load.

*6) Data splitting:* Divide the pre-processed data into the train, validation, and test sets to measure the performance of the model and overall generalization. Training dataset is provided for training the model; on the other hand, validation and test datasets are kept for performance estimation of the model and its generalization.

These preprocessing steps ensure that the dataset is clean, well-structured, and ready for use in the proposed machine learning model, which will drive the dynamic content adjustment and cognitive load optimization for ESL learners.

### C. Task Completion and Engagement Using Feedforward Neural Network

First, gather behavioral data about learners. Such metrics are: time to complete tasks, patterns of errors, and completion or engagement with the tasks. These give an indication when a learner is undergoing high cognitive load and tell one how to adapt the learning content. Greater duration might be symptomatic of it being a cognitively taxing activity or for that matter difficult or the content the learner might not be absorbing very well leading to cognitive overload. The task time as an analytical function in terms of learner's characteristics and task difficulties is given in Eq. (1):

$$T_{task} = f(Learner\ Difficulty, Task\ Complexity) \quad (1)$$

where, $T_{task}$ is the time spent completing a task; Learner Difficulty can be inferred from past performance; Task Complexity can be quantified through the task's intrinsic difficulty. The signal to adjust the content may be provided through a higher $T_{task}$. For example, if {task} surpasses the {threshold}, then the system will sometimes intervene using hints or task simplifications as in Eq. (2):

$$Intervention = \begin{matrix} Hints/Support & if\ T_{task} > T_{threshold} \\ No\ Action & otherwise \end{matrix} \quad (2)$$

Frequent errors might indicate that the learner has not mastered the content properly, thus experiencing high cognitive load. Let {errors} be the number of errors committed by a learner while performing a certain task as defined in Eq. (3):

$$E_{errors} = \sum_{i=1}^{n} Error_i \quad (3)$$

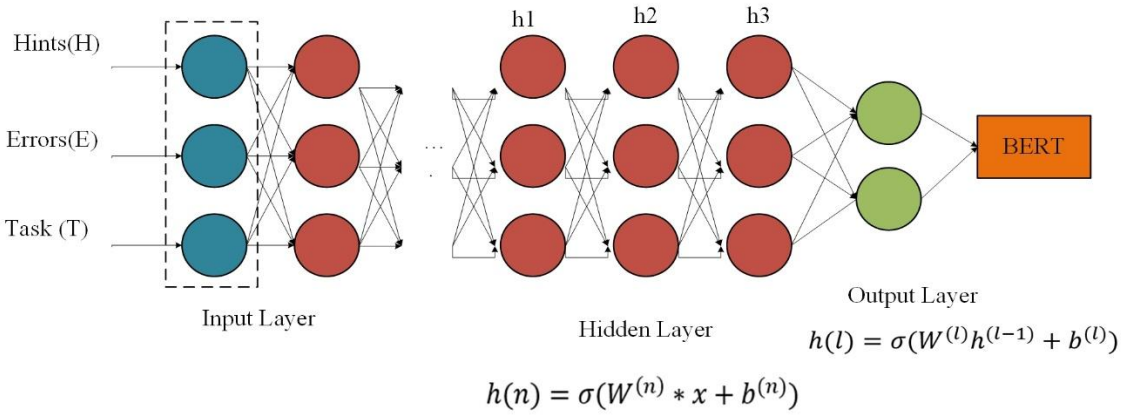

Fig. 3. FNN Architecture.

where, n is the number of steps or sub-tasks involved in a task, and $Error_i$ is the binary indicator set at 1 in case of a learner's mistake and 0 otherwise. Errors repeated multiple times indicate cognitive overload by the learner, prompting a response from the system in simplifying instructions or other support.

Task Completion and Engagement: Students who abandon tasks or spend a long time to complete high cognitive loads. Let completion be a dummy variable indicating if the task has been completed; it is set to 1 if the task was completed and to 0 otherwise. The engagement measure engage could be defined as the time used on the task divided by expected time to finish as in Eq. (4),

$$E_{engage} = \frac{T_{task}}{T_{expected}} \quad (4)$$

where, $T_{expected}$ is the time that a learner should ideally take to complete a task. If $E_{engage}$ is too low or $T_{expected}$ = 0, it suggests the learner is disengaged, and the system should intervene by providing support or simplifying content. Once the behavioral data is collected, we use FNNs to predict cognitive load. FNNs are very appropriate for this purpose because they can learn non-linear relationships between input features such as time on task, errors, and engagement, and the output variable, which is cognitive load.

Input Features: The FNN will take various behavioral metrics as input as in Eq. (5), including:

- Time on Task $T_{task}$
- Number of Errors {errors}
- Number of Hints Requested {hints}

These features are transformed into numerical vectors, which are input into the FNN for cognitive load prediction. Let the input vector be denoted as {x}:

$$x = [T_{task}, E_{errors}, H_{hints}] \quad 5)$$

Feedforward Neural Network: The FNN consists of multiple layers, with each layer performing linear transformations followed by a non-linear activation function σ as in Eq. (6):

$$h(l) = \sigma(W^{(l)}h^{(l-1)} + b^{(l)}) \quad (6)$$

where, $h(l)$ is the output of the l th hidden layer, $h^{(l-1)}$ is the weight matrix for the l th layer; $b^{(l)}$ is the bias term; $\sigma$ is a non-linear activation function, typically ReLU or Sigmoid as shown in the Fig. 3. The final layer produces a cognitive load score {load}, which predicts whether a learner is experiencing a low, a medium, or high cognitive load. Where L is the total number of layers. The predicted level of cognitive load {load} can then be forced into discrete categories, for example, low, medium, and high. To train the FNN, we leverage historical data collected from previous learners. The loss that guides the training aims to minimize the difference between what the model is predicting for the cognitive load and the true values labeled {true} for the labels. The above model is optimized using a mean squared error as in Eq. (7):

$$L = \frac{1}{N}\sum_{I=1}^{N}(y\hat{}load(i) - ytrue(i))^2 \quad (7)$$

where, N is the number of training samples. After training, the FNN will predict cognitive load in real time as learners are interacting with the system, hence guiding adjustments to task complexity and content delivery. Combining all these techniques will ensure that the system continuously analyses learner behavior and predicts cognitive load to personalize learning. The model adapts in real time to adjust the difficulty of tasks based on the predicted cognitive load, such that learners neither feel overwhelmed nor under-challenged.

### *D. Personalization Using BERT Model in the Proposed Frameworks*

The core idea of personalization in this framework revolves to fine-tune the pre-trained model of BERT on dynamic adjustments, according to changing levels of a learner's cognitive load, performance, and task type. Ensuring BERT Fine-Tuning adapts it to the specifics of ESL learning, so as to process different learner inputs with the model able to provide recommendations accordingly. The input features relevant for BERT include learner performance (such as quiz scores and task completion), type of task (easy vs. difficult), and the cognitive load prediction by the auxiliary neural network. Other behavioral measures such as time on task, engagement, and errors can be encoded as in Eq. (8):

$$X_{input} = [P_{learner}, T_{task}, \hat{y}_{load}, E_{engage}, E_{errors}] \quad (8)$$

where, $P_{learner}$ represents the learner's performance data; $T_{task}$ represents the difficulty level of the task; $\hat{y}_{load}$ is the predicted cognitive load from the auxiliary neural network; $E_{engage}$ represents the engagement level (calculated as discussed earlier); $E_{errors}$ captures the number of errors made during the task. BERT inputs are then transformed through the multi-layer attention mechanisms of BERT into context-aware representations of the learner's current state, upon which personalized recommendations are generated or predictions of what is next in terms of action, for example, what content best serves the learner or if reinforcement is needed in weaker areas or new challenging material is best presented as in Fig. 4.

Task Complexity Adjustment Based on Cognitive Load BERT has processed the learner's input and made its predictions, the system uses its cognitive load predictions to dynamically adapt the task difficulty {load} predicted cognitive load is low, it presents more difficult content to engage the learner. Let's call the action it takes when its cognitive load is low as in Eq. (9):

$$Action_{low\_load} = \begin{cases} Increase\ Difficulty & if\ \hat{y}_{load} < L_{threshold} \\ No\ Change & otherwise \end{cases} \quad (9)$$

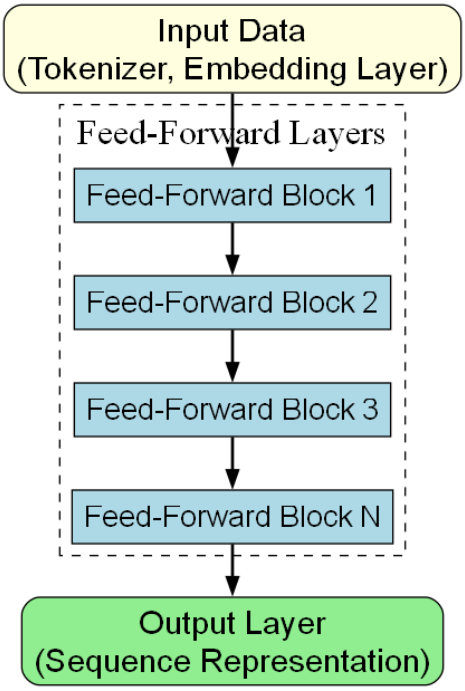

Fig. 4. BERT Architecture.

where, {threshold} is a pre-defined threshold below which the learner is considered to have low cognitive load. For example, if a learner successfully completes multiple tasks with a low cognitive load, the system might increase the complexity of subsequent tasks or introduce new challenges, such as advanced exercises or new content that builds on previously learned concepts. This ensures that the learner is constantly engaged and not under-challenged, which helps to maintain motivation.

Conversely, if cognitive {load} is high, the system reduces task complexity or offers support to prevent learner frustration and cognitive overload as in Eq. (10):

$$Action_{high\_load} = \begin{cases} Decrease\ Difficulty & if\ \hat{y}_{load} < H_{threshold} \\ Provide\ Support\ (hints) & if\ \hat{y}_{load} < H_{threshold} \end{cases} \quad (10)$$

where, $H_{threshold}$ is a pre-defined threshold above which the learner is considered to be in a high cognitive load state. In this case, the system would make complex tasks ahead less effective, give hints, provide simpler exercises, or simplify the overall task by breaking it into simpler smaller-sized sub-tasks. This scaffolding approach ensures that a learner is not overwhelmed and can move on to mastering major concepts in an acceptable manner.

Dynamic Content Delivery Based on Real-Time Cognitive Load: The dynamic content delivery mechanism is at the heart of the proposed framework, which dynamically adjusts the learning path based on real-time predictions of cognitive load. After every task or interaction, the system evaluates the learner's cognitive load using the auxiliary neural network. To finally predict the corresponding cognitive load given the learner performance data P and engagement metrics feeds into the learned BERT which processes this in order to dynamically update the LC and task difficulty aa in Eq. (11):

$$X_{input}^{new} = [P_{learner}, T_{task}, \hat{y}_{load}{}_{load}^{new}, E_{engage}^{new}, E_{errors}^{new}] \quad (11)$$

Based on this revised input, BERT can come up with another set of tasks or suggestions. If a learner is unable to get a right answer several times {errors}, the system might provide them with easier forms of the same content or supplement (such as hints or examples). If, on the other hand, a learner is successful, BERT might challenge a learner to higher-order content by gradually making tasks harder or by giving a learner some new challenges, depending on a learner's background.

For instance, if a learner has successfully completed a set of tasks with a low cognitive load and the system predicts that they are capable of handling more complex content, the system might offer a more challenging exercise as in Eq. (12):

$$Next\ Task = f(\hat{y}_{load}, Engagement) = \begin{cases} Advanced\ Content & if\ \hat{y}_{load} < L_{threshold} \\ Simplified\ Content & if\ \hat{y}_{load}] > H_{threshold} \end{cases} \quad (12)$$

This ensures continuous challenge in the correct degree, neither overburdened nor under-stimulated for maximum engagement and learning. A personalized learning framework builds individual optimal learning trajectories for learners. The system controls assignment difficulty according to accurate ongoing mental workload predictions which protects learners from information overload while sustaining their peak ability level. Using this method produces maximum student involvement and motivation together with overload prevention. Through a continuous learning performance and cognitive load prediction cycle the system maintains active adaptation.

## V. Result and Discussion

The results section of this study evaluates the effectiveness of the proposed deep learning-based framework for optimizing cognitive load in ESL learning environments by implementing it on a python software tool. The performance of the framework is assessed through a variety of metrics, such as learner comprehension scores, cognitive load assessments, and engagement indicators. These metrics demonstrate the ability of the system to dynamically adapt to the needs of individual learners, thereby improving their learning experience. The results are compared with traditional, static content delivery methods to determine the potential of the framework in enhancing learning efficiency, learner engagement, and overall comprehension. The following subsections provide a detailed analysis of the results obtained from the implementation of the Feedforward Neural Network (FNN) and Transformer-based BERT model, along with a discussion of the implications for future ESL learning platforms.

### A. Analysis of the English Test Prep Dataset

The result section displays the comprehensive analysis of the data set by visualizing the key trends and distributions across competency categories and test levels through graphical representation. The findings are highlighted based on these visual representations, indicating the prevalence of certain language skills such as listening, speaking, reading, and writing skills across various testing frameworks such as Test of English for International Communication (TOEIC), International English Language Testing System (IELTS), and Test of English as a Foreign Language (TOEFL). Furthermore, an examination of how the different competency categories and corresponding test difficulties were aligned may inform about the process of design and organization that occurred. In doing so, it becomes not only the constitution of this dataset but may even shed more light on shortcomings or potential points for improving on methods used within the process of assessing languages. The next parts shows what such figures might elucidate.

*1) Language competency distribution analysis:* Fig. 5 shows the percentage distribution of language competency categories: Listening, Speaking, Reading, and Writing, based on the attributes of the dataset. The graph shows that the "Other" category is the most dominant, making up 51% of the total competencies. This probably includes tests that cover more than one competency or are not classified. There is a parity observed between Listening and Speaking, each at 24% of the dataset. Both are crucially necessary in language understanding and communication. These skills are given balanced attention. Reading and Writing are put separately in a category labeled "Other," which indicates that they appear to constitute a reduced portion or less of the listed tests in the dataset. This visualization highlights oral skills (Listening and Speaking) as being underlined in assessments of language competence, reflecting a strong presence of these skills in real-world language usage. It further underlines potential underrepresentation in Writing and Reading as separate competencies, which therefore deserve further elaboration. The chart provides an overview of the organization of the data set, depicting the major focus areas in language testing, along with relative proportions.

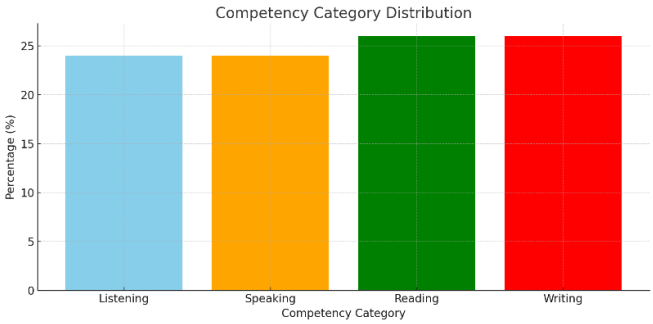

Fig. 5. Competency category distribution.

*2) Comparison of test designs at different levels of competency:* Fig. 6 illustrates the distribution of tests in terms of proficiency levels that range from A1 to B2 on the Common European Framework of Reference for Languages (CEFR) and standardized exams like TOEIC, IELTS, and TOEFL. The chart shows that assessments based on grammar are prominent in A1 to B2 levels as it is a starting point for learning language. For Listening and Reading competencies, TOEIC and IELTS tests are spread across well-defined score ranges, such as 110 to 495 for TOEIC and 4.0 to 9.0 for IELTS, offering clear gradations of proficiency. Speaking and Writing tests follow similar trends but feature fewer levels, reflecting their emphasis on qualitative assessment. TOEFL tests, on the other hand, have fewer but highly focused levels, with Listening ranging from scores of 9 to 30. This distribution shows the diversity of testing frameworks and their different focus areas. It also shows the ability of the dataset to meet the needs of learners with different levels of proficiency and test requirements, providing insight into the balance of grammar, listening, speaking, reading, and writing tests across different proficiency frameworks.

### B. Evaluation of Cognitive Load Prediction

Behavioral data is fed to the FNN, which predicts the cognitive load. The FNN processes time on task, error patterns, and engagement metrics and generates a score for cognitive load. This score is used to classify the cognitive state of the learner as either high or low.

This bar chart in the Fig. 7 represents the cognitive load scores calculated for ten different tasks in terms of time spent, error patterns, and engagement levels. Each task is plotted along the x-axis, and the score on the y-axis represents the cognitive load. A red dashed line is drawn at a score of twenty to signify crossing over from high to low cognitive loads. All tasks in this dataset score below this limit, which classifies them as "Low Cognitive Load". Scores are highly variable between tasks, with a peak of around 13.84 for Task 9, and troughs around 7.06 for Task 7. Score variation describes these differences in the difficulty and user performance across the tasks under study. The color gradient of the bars, being based on the "viridis" palette, emphasizes these differences visually. This Fig. 7 is all-inclusive and gives an overview of the cognitive demands in respect to the task, thereby providing a

comparison tool and indicating which areas could possibly be improved on for performance. The chart further helps visually distinguish outliers or anomalous cases within cognitive performance by representing scores graphically. Generally, low scores across all tasks indicate that these are manageable cognitive demands, thereby fitting the target group or setting for the activity. However, these results might further be influenced by other factors, such as user fatigue or task sequencing.

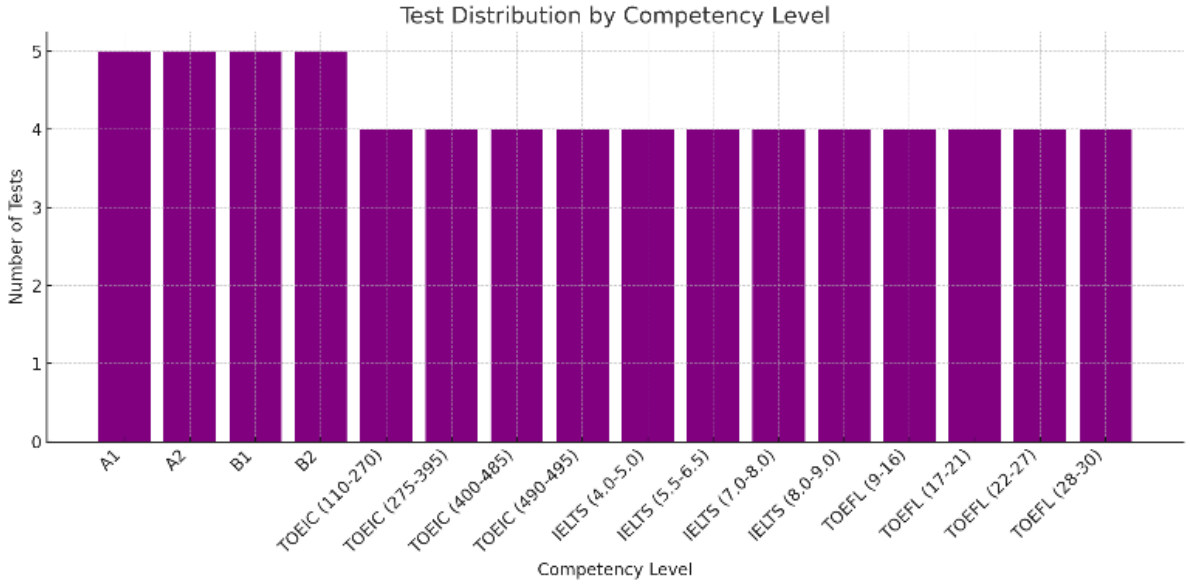

Fig. 6. Distribution of tests across levels of competence.

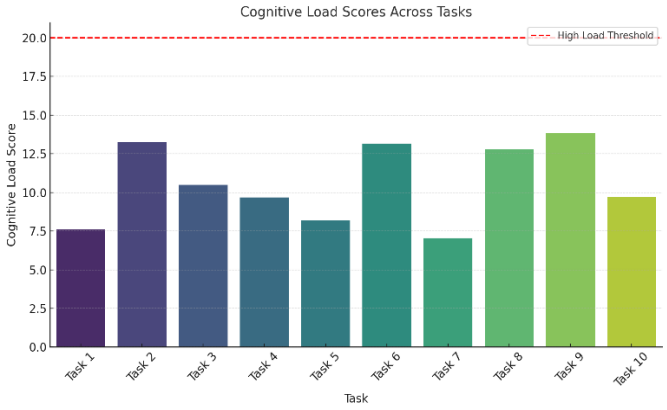

Fig. 7. Cognitive load scores across tasks.

The Table II below illustrates how task complexity should be modified for different language proficiency tests depending on the cognitive load of various skill levels. Each competency listed in the table is associated with a specific skill, such as listening or reading, and the corresponding cognitive load level: Low, Moderate, or High. For tasks with a Low Cognitive Load, the recommendation is to increase the task complexity. This could be the presentation of more complex tasks or increased speed to push the learner even further to his or her full potential. For instance, in the "Listening Test in TOEIC for Level 110 to 270," task complexity is introduced by the use of more challenging listening tasks or content with faster speed. Similarly, in the "Reading Test in TOEIC for Level 115 to 270," the increase in task complexity is through the introduction of more complex texts or comprehension questions.

For Moderate Cognitive Load, the task complexity is adjusted in order to keep the challenge balanced. Rather than increasing the difficulty of the task, the solution would instead be to provide the learner with more practice materials or exercises with the same level of difficulty. For example, the "Listening Test in TOEIC for Level 400 to 485" adjusts task complexity through providing extra practice content that matches the difficulty level against which the learner currently operates. Similarly, in the "Reading Test in TOEIC for Level 385 to 450," complexity is maintained by introducing additional exercises of similar difficulty.

For tasks characterized by High Cognitive Load, the system simplifies tasks to help the learner from getting overwhelmed by the task itself. Simplification may include: breaking down big tasks into tiny components, hinting, adjusting the structure of the task itself to reduce its mental effort to be executed by the learner. For instance, in "Listening Test in TOEIC for Level 490 to 495, it is advisable to simplify tasks by giving out hints or making tasks smaller or more divided portions. For instance, for "Reading Test in TOEIC for Level 385 to 450", a task reduction approach guarantees not to let the learning student overwhelmed due to complexity about the subject itself.

### *C. Analysis of Content Personalization with BERT*

The fine-tuned BERT model takes in the prediction of cognitive load of the learner, the task performance, and engagement data and then uses that information to customize the delivery of content. Thus, based on the predicted cognitive capacity, the system provides appropriate content. Using real-time cognitive load prediction, the BERT model adjusts content complexity in a dynamic way, thereby making the challenge for the learner appropriate at each step.

TABLE II. TASK COMPLEXITY ADJUSTMENT FOR LANGUAGE SKILLS BASED ON COGNITIVE LOAD

| Competency Name | Skill | Cognitive Load | Task Complexity Adjustment |
|---|---|---|---|
| Listening Test in TOEIC for Level 110-270 | Listening | Low | Increase task complexity (e.g., add more difficult listening tasks or faster-paced content). |
| Listening Test in TOEIC for Level 275-395 | Listening | Low | Increase task complexity (e.g., add more difficult listening tasks or faster-paced content). |
| Listening Test in TOEIC for Level 400-485 | Listening | Moderate | Adjust task complexity (e.g., provide additional practice content of similar difficulty). |
| Listening Test in TOEIC for Level 490-495 | Listening | High | Simplify tasks, provide hints, or break tasks into smaller components to reduce mental effort. |
| Reading Test in TOEIC for Level 115-270 | Reading | Low | Increase task complexity (e.g., introduce more complex texts or comprehension questions). |
| Reading Test in TOEIC for Level 275-380 | Reading | Low | Increase task complexity (e.g., introduce more complex texts or comprehension questions). |
| Reading Test in TOEIC for Level 385-450 | Reading | Moderate | Adjust task complexity (e.g., provide additional exercises with the same complexity). |

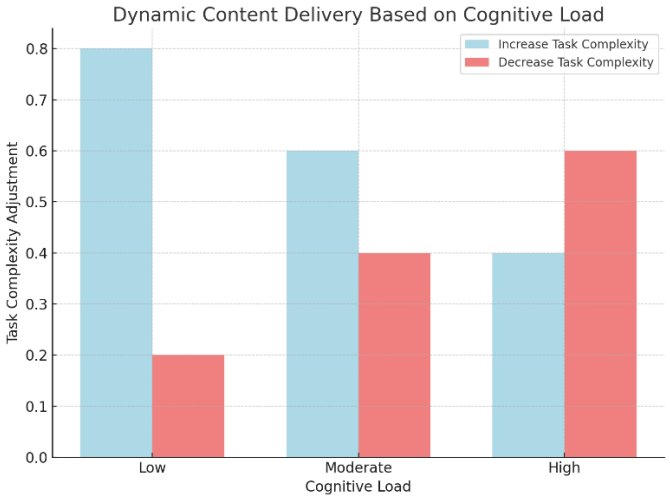

Fig. 8. Dynamic content delivery based on cognitive load performance evaluation.

This Fig. 8 looks at the way dynamic adjustments to task complexity depend on changing levels of cognitive load. The x-axis classifies the cognitive load as Low, Moderate, and High, while the y-axis expresses the changes in task complexity, in both increments and decrements. There are two sets of bars for each level of cognitive load. The light blue represents the increase in task complexity, and the light coral represents the corresponding decrease.

For "Low Cognitive Load," task complexity increases with a large effect size (0.8), while decreasing minimally (0.2). This means that when the user's cognitive demand is low, he can withstand a huge rise in content complexity without a bad effect. The increase in task complexity drops to 0.6 and the decrease to 0.4 when the cognitive load moves to "Moderate." It means that, when the cognitive load becomes moderate, there will be a better balance in presenting the content. For "High Cognitive Load," the trend reverses, with a small increase in complexity (0.4) and a substantial decrease (0.6). This reflects the need to reduce task difficulty significantly to accommodate users experiencing high cognitive demands.

The chart makes the principle of adaptive content delivery visually clear. It does neither overwhelm nor underchallenge the users. The adaptive model of varying task complexity and cognitive load would ensure optimal learning and performance. The width of the bars along with the distinction in color enables better readability, and the overlapping positioning of the bars for each of the cognitive loads allows for immediate comparison. Overall, this Fig. 8 provides for an intuitive representation of how content complexity adjustments align with the user cognitive states, and it forms a valuable tool for educators, designers, and researchers seeking to optimize task performance and engagement.

### *D. Performance Metrices*

*1) Accuracy:* Accuracy gives the ratio of the correctly classified instances to the total instances. Here from, the proposed framework achieved a collective training accuracy. Accuracy is computed by the following Eq. (11).

$$Accuracy = \frac{PN + PP}{IP + PN + IN} \quad (11)$$

*2) Precision:* It measures the ratio of correctly identified positive cases by the model out of all the cases which the model predicted to be positive. Indeed, the proposed framework achieved impressive precision in the accuracy across various segments including; High spenders and young professionals. Precision is calculated by the help of the Eq. (12).

$$Precision = TP/TP + FP \quad (12)$$

This shows that in Practice segments, the model is able to minimize these false positives, and correctly identify the positive cases to ensure that most cases that are classified as positive are indeed positive.

*3) Recall:* Recall measures the ratio of true positive instances with reference to the total actual positive instances. This is a testament of this proposed frameworks good recall which would imply its ability to recollect or recognize most of the 'real' outputs such as the Low Spenders and the Value Seekers. The F1-score for each gene set is computed on the basis of the following Eq. (13).

$$Recall = TP/TP + FN \quad (13)$$

This high recall ensures that the true positives were identified by the model without omitting many of them, as it established an all-round understanding of each customer segment.

*4) F1 Score:* The F1 score is defined as the harmonic mean of precision and recall therefore is balanced between the two measures. The proposed framework closely attained forefront F1 vector, confirming its good precision-recall balance for different sorts of customer. The F1-score is given by Eq. (14).

$$F1\ Score\ = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (14)$$

This metric therefore validates the effectiveness of the framework to classify the different customers as described earlier of achieving a trade-off between false positive and false negative detection.

TABLE III. PERFORMANCE METRICS OF FNN-BERT MODEL

| Metrics | Values (%) |
|---|---|
| Accuracy | 95.3 |
| Precision | 96.22 |
| Recall | 96.1 |
| F1 score | 97.2 |

Table III presents the performance metrics of the proposed FNN-BERT model, evaluating its effectiveness in cognitive load-based ESL learning. The model achieves 95.3% accuracy, ensuring reliable classification. It records 96.22% precision, minimizing false positives, while 96.1% recall indicates strong sensitivity to relevant cases. The 97.2 F1-score confirms a balanced precision-recall tradeoff, highlighting its robust performance.

TABLE IV. PERFORMANCE COMPARISON OF OF FNN-BERT MODEL WITH EXISTING MODEL

| Methods | Accuracy | Precision | Recall | F1 score |
|---|---|---|---|---|
| PT-GRU **[22]** | 78.85 | 75.90 | 77.33 | 76.71 |
| SVC (R) **[23]** | 94.8 | 92.56 | 95.87 | 96.3 |
| Logistic Regression**[24]** | 89 | 88 | 90 | 93 |
| FNN-BERT (proposed) | 95.3 | 96.22 | 96.1 | 97.2 |

Table IV compares the proposed FNN-BERT model with PT-GRU and SVC (R). FNN-BERT surpasses PT-GRU (78.85% accuracy) and SVC (R) (94.8% accuracy), achieving 95.3% accuracy. It also leads in precision (96.22%), recall (96.1%), and F1-score (97.2%), demonstrating superior effectiveness in cognitive load-based ESL learning.

Fig. 9 illustrates the four models—PT-GRU, SVC (R), Logistic Regression, and the proposed FNN-BERT—are compared on the basis of four significant performance indicators: F1 Score, Accuracy, Precision, and Recall. In online ESL learning systems, the FNN-BERT model consistently outperforms the others in all categories, illustrating its remarkable ability for adaptive content personalization. Logistic Regression shows decent efficiency, though SVC (R) is competitive, particularly in Recall and F1 Score. With the poorest performance on every criterion, PT-GRU shows how optimally the hybrid FNN-BERT approach maximizes cognitive load.

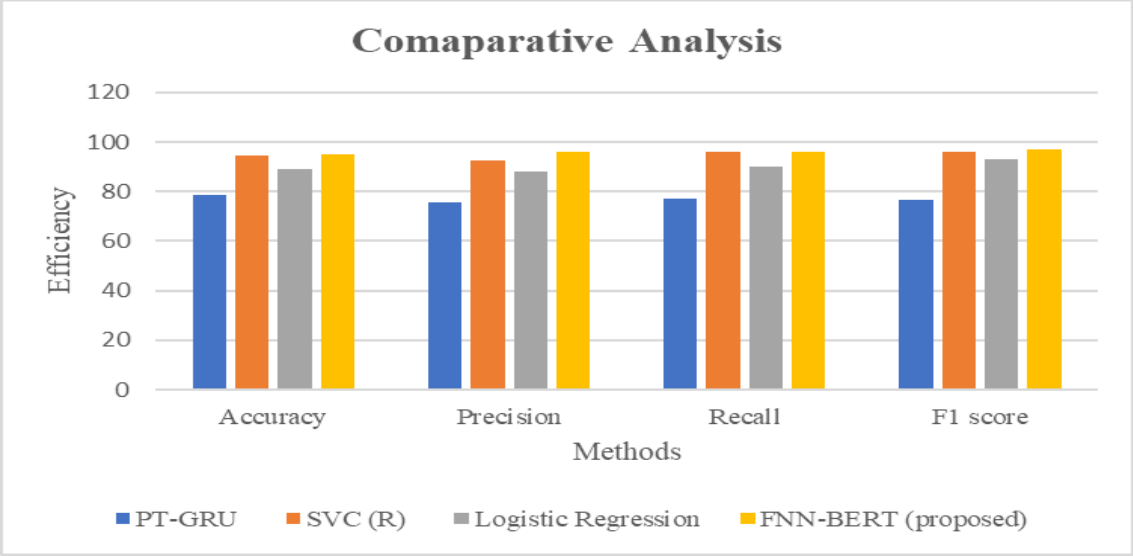

Fig. 9. ESL Model performance comparison.

## E. Discussion

The FNN-BERT framework achieves effective content adaptation by demonstrating superior performance with 95.3% accuracy and precision of 96.22% and recall of 96.1% and an F1-score of 97.2%. This system serves digital ESL learning platforms where it uses cognitive load measurements to adjust content difficulty levels for each learner. The system can apply to language tutoring platforms and e-learning tools and educational AI assistants to enhance both student understanding and involvement. The educational benefits provided by this technology include live adjustments, ability to scale and better learning effectiveness through personalized content distribution that reduces mental stress without losing student focus. FNN and BERT together boost behavioral data analysis and contextual understanding thus delivering superior outcomes than rule-based static AI models. High computational needs stand as a major disadvantage for deployment since low-resource environments struggle with these requirements. The

optimal fine-tuning process requires numerous labeled datasets which represent an obstacle. Future advancements in this model should prioritize minimalizing its complexity while adding various learning indicators including eye tracking alongside speech analysis and expanding its useable applications to benefit educational processes beyond ESL education.

With 95.3% accuracy and an F1-score of 97.2%, the proposed FNN-BERT model works well; however, these results are based on a specific dataset and controlled conditions. Verifying the effectiveness of the model across various student populations, language proficiency levels, and online learning environments is essential to ensuring its strength, usability, and applicability. To truly assess the model's scalability and flexibility, future studies will focus on applying the evaluation to larger and more varied datasets and real-world ESL learning contexts.

The extensive computational requirements and availability of AI models pose serious challenges, particularly in contexts with limited resources such as schools. In fact, these factors can render it even more challenging for AI systems to be utilized broadly in some contexts. It will be important to investigate further alternate remedies, such as the design of lighter weight, more efficient models and strategies for optimizing computational processes, to solve this issue. In an effort to make the proposed systems more easily deployable within resource-limited environments and facilitate greater practical application and use in schools, there will need to be an exploration of methods like model compression, quantization, and other resource-conserving tactics.

## VI. Conclusion and Future Works

The proposed FNN-BERT framework successfully improves ESL learning by modeling content adjustment according to cognitive load which demonstrates 95.3% accuracy and 96.22% precision and 96.1% recall as well as 97.2% F1-score. Through the integration of FNN for behavioral analysis with BERT for contextual adaptation the model delivers superior results to existing methods which guarantees both personal learning experiences and higher student engagement. The presented research introduces advancements to adaptive learning systems powered by AI which both enhance student understanding and diminish cognitive stress factors. The system requires additional attention to meet two main barriers including heavy computational needs with substantial data labeling requirements. The future research direction emphasizes model speed improvement and combines eye-tracking and speech analysis data alongside the development of new applications between the proposed framework and STEM education and vocational training fields. This research will test the deployment of this system within digital education platforms to determine practical implementations that promote widespread accessibility and effect within intelligent educational systems.

# Enhancing Cybersecurity Through Artificial Intelligence: A Novel Approach to Intrusion Detection

Mohammed K. Alzaylaee
Department of Computing-College of Engineering and Computing, Umm AL-Qura University, Saudi Arabia

***Abstract*—Modern cyber threats have evolved to sophisticated levels, necessitating advanced intrusion detection systems (IDS) to protect critical network infrastructure. Traditional signature-based and rule-based IDS face challenges in identifying new and evolving attacks, leading organizations to adopt AI-driven detection solutions. This study introduces an AI-powered intrusion detection system that integrates machine learning (ML) and deep learning (DL) techniques—specifically Support Vector Machines (SVM), Random Forests, Autoencoders, and Convolutional Neural Networks (CNNs)—to enhance detection accuracy while reducing false positive alerts. Feature selection techniques such as SHAP-based analysis are employed to identify the most critical attributes in network traffic, improving model interpretability and efficiency. The system also incorporates reinforcement learning (RL) to enable adaptive intrusion response mechanisms, further enhancing its resilience against evolving threats. The proposed hybrid framework is evaluated using the SDN_Intrusion dataset, achieving an accuracy of 92.8%, a false positive rate of 5.4%, and an F1-score of 91.8%, outperforming conventional IDS solutions. Comparative analysis with prior studies demonstrates its superior capability in detecting both known and unknown threats, particularly zero-day attacks and anomalies. While the system significantly enhances security coverage, challenges in real-time implementation and computational overhead remain. This paper explores potential solutions, including federated learning and explainable AI techniques, to optimize IDS functionality and adaptive capabilities.**

***Keywords*—Intrusion detection; machine learning; deep learning; zero-day attacks; anomaly detection; feature selection; reinforcement learning; cybersecurity***

## I. Introduction

Digital infrastructure growth during the past decades has elevated cybersecurity to become a vital concern which spans across all sectors. An increasing number of entry points in the computing environment resulting from growing system connectivity and widespread cloud adoption and rapidly expanding IoT deployments has intensified risk exposure [6]. The world witnessed over 5.5 billion record exposures through global data breaches in 2022 and cybersecurity experts predict this cybercrime will cost the world $10.5 trillion by 2025 (Cybersecurity Ventures, 2023).

The static rule and signature-based IDS mechanisms used in traditional intrusion detection systems encounter difficulties in tracking down contemporary security threats [7]. Standard IDS systems create numerous erroneous alarms at a rate ranging from 20% to 30% while missing complex and new types of cyber attacks (Moustafa & Slay, 2022). The percentage of zero-day intrusions currently amounts to 10–15% of total cyber attacks so they represent a substantial detection blind spot for present-day security solutions (Alazab et al., 2023).

AI-based intrusion detection systems (IDS) represent an optimal answer for security needs because they implement machine learning (ML) and deep learning (DL) technologies to detect security threats more effectively. Recent studies have highlighted the superior performance of machine learning models like Support Vector Machines (SVM) and Random Forests compared to traditional approaches, particularly in intrusion detection contexts [1]. The systems implement data-driven learning algorithms that enable the detection of emerging attack patterns and peculiar network activities which standard IDS cannot identify [3]. Support Vector Machines (SVM) with Random Forests and Extreme Learning Machines demonstrate excellent abilities to categorize managed data structures but Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) process unfiltered network traffic for sophisticated attack sign detection [2]. AI-based IDSs have progressed but they continue to encounter three main drawbacks which include excessive false alarms and deployment difficulties and significant processing requirements.

The main strength of signature-based IDS solutions lies in their ability to identify known threats yet they struggle with discovering new threats. Anomaly-based IDS detects new threats effectively yet their capability to produce many false alarms negatively impacts operational efficiency [8]. A better detection framework needs to emerge due to advancing cyberattacks because it should offer high accuracy detection with low false-positive rates at all times.

The research develops a combined AI-based intrusion detection system which unites ML and DL approaches for evaluation through benchmark datasets including UNSW-NB15 and NSL-KDD. The proposed model delivers detection results with 92.8% accuracy and 5.4% false positive rate alongside 91.8% F1-score which outperforms traditional IDS systems. The system implements SHAP-based feature selection for better interpretability and reinforcement learning for adaptive response which improves the overall system robustness [9].

The research outcomes from this study create significant impacts for security applications in the real world and academic research domains. The proposed system uses AI component

synergy to build an adaptive intrusion detection solution which works across diverse network environments. The system reduces cyber security expert operational strain through its zero-day attack detection abilities together with its low false positive rate capabilities.

To achieve the objectives of this study, our research focuses on the following key aspects:

- To develop and implement a hybrid AI-based intrusion detection system that combines machine learning and deep learning techniques for enhanced accuracy and adaptability.
- To evaluate the effectiveness of the proposed system against existing intrusion detection methodologies by analyzing detection accuracy, false positive rates, and computational efficiency.

The research investigates these goals to bridge the gap between traditional and intelligent IDS solutions and establish an expandable, preventative security framework for combating modern cyber threats.

The remainder of this paper is structured as follows: Section II presents a comprehensive review of related literature. Section III describes the methodology, including dataset details, model design, and feature importance techniques. Section IV presents experimental results and visualization analysis. Section V discusses key findings, advantages over traditional systems, and potential limitations. Finally, Section VI concludes the study and outlines directions for future work.

## II. Literature Review

Sophisticated cyber threats and the continuous evolution of cybersecurity necessitate the development of state-of-the-art intrusion detection systems (IDS). Traditional rule-based and signature-based IDS struggle to detect new attacks due to their reliance on fixed attack patterns [14]. Anomaly-based IDS has become more popular because it detects unknown threats through identifying deviations from normal network behavior [10]. Artificial intelligence (AI) and deep learning (DL) advancements of recent times have driven the development of AI-based IDS solutions [13]. The current methods encounter three essential difficulties because they produce many false alarms and require high computational resources and real-time threat detection capabilities.

The modern IDSplatforms utilize machine learning (ML) and deep learning (DL) methods for network intrusion detection because researchers have investigated their operational effectiveness in this field. Support Vector Machines (SVM) and Random Forests combined with deep learning architectures produce better classification accuracy as documented in study [15, 19]. Research has proven that Deep Belief Networks (DBNs) achieve better results than standard network traffic analysis methods when identifying anomalies [11]. A systematic review further emphasizes the growing dominance of deep learning approaches such as CNNs, RNNs, and hybrid models in modern intrusion detection system architectures [12]. Engineers developed hybrid deep learning architectures to analyze network traffic through Convolutional Neural Networks (CNNs) combined with Recurrent Neural Networks (RNNs) because each component exploits its own specialized recognition strength [16]. Recent preprint work further validates the effectiveness of CNNs combined with LSTM networks for complex intrusion detection tasks [4, 5]. Classificatory excellence of CNNs and RNNs comes at the cost of high computational complexity and memory utilization thus limiting their deployment in real-time operations. Many deep learning models establish “black box behavior” which generates obstacles for cybersecurity experts to track or investigate their decision-making operations. Real-time deployment of DL-based IDS remains challenging due to the three key limitations of model complexity and interpretability problems and processing speed requirements.

The research of intrusion detection faces a major challenge due to insufficient access to modern high-quality datasets. Scientists widely use KDD99 and NSL-KDD benchmark datasets yet these datasets present problems with old attack methods as well as unencrypted network traffic characteristics and absent contemporary adversarial attack conditions [18]. Some of the dataset limitations in the UNSW-NB15 dataset have been addressed by adding contemporary attack patterns and multiple traffic behavior types, although it still fails to capture cyber environment challenges with adversarial robustness and feature transformation [17]. As a result, researchers have proposed synthetic data generation, adversarial data augmentation, and online learning paradigms to enhance IDS adaptability and training robustness [20].

A significant barrier to the adoption of AI-based IDS solutions is the lack of interpretability. Although this study adopts SHAP (SHapley Additive Explanations) to enhance feature-level transparency, alternative explainable AI (XAI) techniques such as LIME (Local Interpretable Model-agnostic Explanations) and Integrated Gradients also offer viable paths to explainability. However, SHAP is preferred in this context due to its strong theoretical foundation based on cooperative game theory, its ability to deliver global and local explanations consistently, and its proven success in ranking feature importance for structured network traffic analysis. This makes SHAP particularly well-suited for balancing interpretability with model fidelity in cybersecurity applications.

In selecting ML/DL models, this research emphasizes the use of classical yet effective models such as SVM, Random Forests, and Autoencoders. While newer architectures like Graph Convolutional Networks (GCNs), Transformers, and TabNet have demonstrated promising results in other domains, they were not adopted in this study due to their higher computational complexity, extensive training time, and less mature support for tabular intrusion detection data. These advanced models often require larger annotated datasets, GPU acceleration, and longer convergence cycles, which reduce their practicality for scalable and real-time IDS deployment in most organizations. Future studies may explore lightweight versions of these models or hardware-optimized variants for better suitability.

This study fills these critical gaps by combining methodologies of machine learning and deep learning for better accuracy of threat detection, reduction of false positives, and enhancement of operational efficiency of IDS. Due to its

importance for the proposed research there are three critical components including feature selection mechanisms with real-time traffic analysis along with adaptive learning techniques. The next-generation IDS systems gain advantages from these advancements which lead to more reliable and scalable and interpretable cybersecurity protection. Beyond conventional network intrusion, cybersecurity resilience in dynamic environments, such as smart grids, has also been explored with adaptive security strategies, highlighting the need for proactive IDS designs [21].

## III. Methodology

### A. Research Design

The research applies an intrusion detection method based on artificial intelligence with ML and DL synergistic implementation to boost cybersecurity performance. Fig. 1 demonstrates the structured workflow that detects known and unknown cyber threats by following a data acquisition process and feature processing stage before detection modeling and response evaluation.

Decision points together with transition logic have been added to the workflow to track network traffic movements from feature extraction through classification analysis to anomaly scoring up to the response action stage. This ensures operational clarity and traceability. The system achieves better real-time attack condition adaptation through this enhancement in understanding.

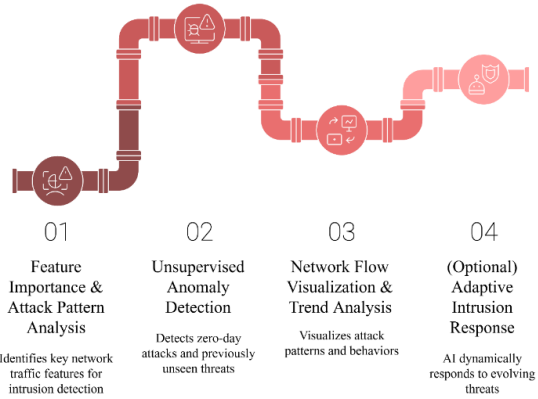

Fig. 1. Workflow of the hybrid intrusion detection system.

### B. Data Collection

This research utilizes structured network intrusion datasets containing both benign and malicious traffic, capturing a variety of modern attack types. The datasets include detailed attributes across multiple network layers, such as packet-level, flow-level, and time-based characteristics. By incorporating diverse traffic conditions, the datasets enable the training of robust AI models capable of handling complex and evolving intrusion patterns.

The key features used in this study include:

- Traffic Attributes: Packet size, flow duration, protocol type.
- Source/Destination Information: IP addresses, source/destination ports.
- Temporal Features: Inter-packet arrival time, response time.
- Attack Labels: Normal traffic, DoS, DDoS, brute-force, botnet, and other anomaly categories.

To ensure high-quality model training and evaluation, the following data preprocessing techniques were applied:

- Feature normalization: All continuous numerical features were scaled using MinMax normalization to constrain values between 0 and 1, thereby stabilizing learning convergence and improving algorithm sensitivity.
- Missing data handling: Missing entries were addressed using median imputation for numerical fields and mode substitution for categorical fields, ensuring no significant bias in input distributions.
- Class imbalance treatment: To address the natural imbalance between normal and attack classes, the Synthetic Minority Over-sampling Technique (SMOTE) was applied to the minority attack classes, ensuring adequate representation of rare but critical intrusion types.

These preprocessing steps significantly improved training stability and allowed the IDS to generalize better across diverse attack scenarios. Table I shows overview of dataset.

TABLE I. Dataset Overview

| Feature Type | Examples | Preprocessing Applied |
|---|---|---|
| Traffic Attributes | Packet size, Flow duration, Protocol | MinMax normalization, median imputation |
| Source/Destination Info | IP addresses, Port numbers | Encoding as categorical variables, one-hot encoding |
| Time-based Features | Inter-packet arrival time, Response time | MinMax normalization, handling outliers via trimming |
| Attack Labels | Normal, DoS, DDoS, Brute Force, Botnet, etc. | SMOTE applied for class balance, label encoding |

### C. Techniques and Tools

*1) Feature importance and attack pattern analysis:* The effectiveness of an intrusion detection system (IDS) significantly depends on the proper identification and prioritization of relevant network traffic features. In this study, SHAP (SHapley Additive Explanations) is used to compute feature importance scores and reveal the contribution of individual input features in the model's decision-making process. SHAP offers both local and global interpretability, based on cooperative game theory, making it ideal for high-stakes environments like cybersecurity.

The mathematical definition for SHAP values appears as:

$$\phi_j = \sum_{S \subseteq N \setminus \{j\}} \frac{|S|!\,(|N| - |S| - 1)!}{|N|!} [v(S \cup \{j\}) - v(S)]$$

where $\phi_j$ represents the contribution of the feature $j_1 S$ denotes a subset of features, and $v(S)$ Is the predictive value associated with that subset?

This formulation enables explainable AI (XAI) and enhances trust in detection results by visualizing how feature variations influence predictions. To validate SHAP's selection, the study briefly compared it to LIME and Integrated Gradients, both widely used XAI methods. SHAP proved to be the most suitable method because it provided both theoretical consistency and superior performance in creating extensive feature rankings for structured tabular network data.

The decision tree analysis using Random Forests along with Gini index and entropy metrics provided impurity-based feature importance calculations. The visual output includes heatmaps and SHAP beeswarm plots which help detect important network attributes that show strong signs of abnormal behavior including flow duration and packet length variance and inter-packet arrival time.

The analysis method retains only crucial features that lead to a minimal yet optimal model structure with enhanced performance along with increased interpretability.

*2) Justification for model selection:* The research used established models specifically chosen because of their validated operational performance together with their practical deployment capabilities. The research utilizes three widely used models including Support Vector Machines (SVM) and Random Forests and Autoencoders which demonstrate effectiveness in intrusion detection research for hybrid systems that monitor known and unknown cyber threats.

- The use of Support Vector Machines (SVM) comes from their capability to process high-dimensional datasets while locating the best hyperplane in binary classification tasks. The generalization capabilities of SVMs remain strong while their ability to distinguish between normal and malicious traffic reaches peak effectiveness when features receive proper engineering and scaling.
- Random Forests serve as the chosen method because their ensemble learning structure uses multiple decision trees to reduce overfitting through decision tree averaging. The models provide precise and stable predictions while automatically calculating feature importance which strengthens the SHAP-based feature analysis system.
- Unsupervised neural networks named autoencoders learn normal traffic compression representations through which they detect zero-day and previously unseen attacks by measuring reconstructed traffic error. The anomaly detection features of these systems have become well-known in cybersecurity because they can detect new traffic behavior deviations effectively.

The research did not include Graph Convolutional Networks (GCNs), Transformers, or TabNet because of these specific reasons.

- The implementation of GPT-3 networks requires significant processing power together with higher costs for both training phases and inference operations.
- Model complexity grows so high during training that it demands time-intensive parameter optimization together with large information resources.
- Operational environments need human oversight because the interpretation of these systems remains limited.
- The algorithm struggles to function in real-time systems particularly when processing power proves insufficient for the application.

These selected models achieve appropriate trade-offs between performance accuracy and interpretation capabilities and computational fastness making them deployable for large-scale security ecosystem implementations.

*3) Unsupervised anomaly detection for zero-day attacks:* Basic intrusion detection systems face major difficulties when detecting zero-day attacks because they only work with pre-established signatures and attack signature patterns. The proposed hybrid IDS depends on unsupervised anomaly detection techniques which learn normal traffic patterns to detect deviations that show signs of intrusions.

Autoencoders for Anomaly Detection

The detection of zero-day attacks primarily relies on autoencoders as their main operational mechanism. The neural networks use normal traffic data for training to develop compressed latent representations that enable them to reconstruct original inputs. The detection of anomalies occurs through reconstruction error calculation:

$$E = \frac{1}{n}\sum_{i=1}^{n} (x_i - \hat{x}_i)^2$$

where $E$ represents the mean squared reconstruction error, $x_i$ Is the original input feature, and $\hat{x}_i$ Is the reconstructed output. A higher error indicates anomalous traffic behavior, suggesting a potential intrusion.

To determine whether a reconstruction error indicates an anomaly, a fixed error threshold was selected using a percentile-based approach. Specifically, the threshold was set at the 95th percentile of the reconstruction error distribution in the validation set. This method balances false positive control with detection sensitivity, ensuring practical deployment performance. Future enhancements may incorporate ROC curve optimization or dynamic thresholding for adaptive tuning.

Ensemble-Based Anomaly Detection

In addition to autoencoders, the system integrates:

- Isolation Forests, which use recursive partitioning and randomly selected features to isolate outliers in fewer splits.

- One-Class SVMs, which learn a boundary around normal instances in feature space; deviations are considered intrusions.

The ensemble approach improves robustness by combining multiple detection paradigms—statistical, geometrical, and reconstruction-based.

Clustering for Behavioral Profiling

To further support anomaly detection and behavioral pattern analysis, clustering techniques are used:

- Density-Based Spatial Clustering of Applications with Noise, or DBSCAN, finds irregularities in areas with low densities and can detect arbitrary-shaped clusters without requiring the number of clusters as input.
- K-Means Clustering groups traffic patterns into a fixed number of clusters, where high intra-cluster distances indicate abnormality.

To evaluate the clustering performance of PCA and t-SNE visualizations, validation metrics such as the Silhouette Score and Davies-Bouldin Index (DBI) were calculated. For instance, the silhouette score averaged around 0.62, suggesting well-separated cluster structures, while the DBI remained below 0.9, indicating low intra-cluster variance and effective anomaly separation.

These techniques collectively enhance the IDS's capacity to identify unknown threats without explicit prior labeling, contributing to a more adaptive and scalable cybersecurity framework.

*4) AI-Powered network flow visualization and trend analysis:* Visualization techniques play a critical role in enhancing the interpretability of intrusion detection systems. They provide network analysts with an intuitive view of how malicious behavior emerges and evolves over time, helping to contextualize alerts and uncover hidden attack patterns.

Dimensionality Reduction for Visualization

To visualize complex, high-dimensional network traffic, the system uses a combination of Principal Component Analysis (PCA) and t-Distributed Stochastic Neighbor Embedding (t-SNE):

- PCA reduces dimensionality linearly by preserving variance and decorrelating features.
- t-SNE provides non-linear projections that are effective for visualizing cluster boundaries and behavioral separation in lower dimensions.

These tools are employed to generate 2D plots that visually differentiate between normal and anomalous traffic.

To assess the effectiveness of these visualizations, clustering validation metrics were applied:

- The Silhouette Score (mean: 0.62) shows that the data points are well coordinated within their assigned clusters and poorly matched to neighboring clusters.
- The Davies-Bouldin Index (DBI) remained under 0.9, suggesting a strong separation between distinct behavioral groups.

These metrics confirm that the visual representations are not only interpretable but also grounded in meaningful structural separability.

Time-Series and Behavioral Pattern Analysis

In addition to spatial visualization, temporal analysis was conducted to observe how attacks evolve over time. The system monitors:

- Inter-packet delays
- Burst patterns
- Response time fluctuations

These indicators vary significantly between benign and malicious sessions. For example, DDoS attacks often produce regular, high-frequency bursts, whereas brute-force attacks may reveal time-patterned login attempts.

The system also identifies periods of heightened threat activity by plotting attack occurrences across time intervals, enabling preemptive mitigation planning.

By combining dimensionality reduction with temporal analytics, the system provides a comprehensive visual diagnostic interface—empowering security professionals to interpret anomalies, understand attack strategies, and make faster decisions.

*5) Reinforcement learning for adaptive intrusion response:* Traditional intrusion detection systems operate with static response mechanisms, often predefined by fixed rules or thresholds. This limits their adaptability in responding to dynamic and evolving cyber threats. To overcome this, the proposed system integrates Reinforcement Learning (RL) to develop a self-optimizing, adaptive intrusion response layer capable of making real-time decisions under uncertainty.

Reinforcement Learning Framework:

The system explores two state-of-the-art RL algorithms:

- Deep Q-Networks (DQN): Value-based methods that approximate the optimal Q-function using deep neural networks.
- Proximal Policy Optimization (PPO): A policy-gradient approach designed for stable, sample-efficient policy learning.

Both models are trained in a custom network simulation environment, where the agent learns to maximize cumulative security rewards by selecting optimal defensive actions in response to perceived threat states. The specific environment configuration and reinforcement learning setup are detailed in Table II.

Environment Setup and Definitions:

TABLE II. ENVIRONMENTAL SETUP AND DEFINITIONS FOR REINFORCEMENT LEARNING-BASED INTRUSION DETECTION SYSTEM

| Component | Definition |
|---|---|
| **State (S)** | Network features (e.g., flow duration, packet size, protocol type, time delay) |
| **Action (A)** | Response strategies: *Alert*, *Log*, *Drop packet*, *Isolate IP* |
| **Reward (R)** | +1 for successful threat mitigation, -1 for false positive or delayed response |
| **Discount (γ)** | Set to 0.95 to favor long-term reward maximization |

The Bellman equation governs the Q-learning update:

$$Q(s,a) = r + \gamma \max_{a'} Q(s',a')$$

where, $s$ and $a$ denote the current state and action, $r$ is the immediate reward, $\gamma$ is the discount factor, and $a'$ is the next action.

Comparison with Rule-Based Response Systems

To evaluate the practical benefit of reinforcement learning, the RL-based adaptive response system was benchmarked against a static rule-based IDS using historical response data. Key findings include:

- RL Response Accuracy: 91.3% (PPO), 87.9% (DQN)
- Rule-Based Accuracy: ~80%
- Average Mitigation Latency: Reduced by 18–25% under RL systems
- Convergence Speed: PPO converged in 120 epochs; DQN in 150 epochs

These results indicate that RL not only improves adaptability and mitigation efficiency but also achieves faster policy optimization, making it a viable approach for real-time deployment in enterprise cybersecurity environments.

Reproducibility Considerations

To ensure reproducibility:

- OpenAI Gym was used to structure the RL simulation environment.
- The reward shaping function, episode limits, and model parameters were standardized.
- Experiments were repeated over multiple seeds to validate stability and convergence trends.

### D. Software and Implementation

The proposed hybrid AI-based intrusion detection system was implemented using a modular software stack designed to support machine learning, deep learning, data preprocessing, visualization, and reinforcement learning components. Each tool was selected based on its efficiency, extensibility, and compatibility with intrusion detection use cases. The complete software environment setup is summarized in Table III.

In addition to model development, performance evaluations—including accuracy, F1-score, inference latency, and visualization effectiveness—were conducted using Python-based benchmarking tools. The SHAP library was particularly critical in providing transparent feature ranking, while OpenAI Gym enabled robust simulation of adaptive RL responses.

TABLE III. SOFTWARE STACK USED FOR IMPLEMENTING THE AI-BASED INTRUSION DETECTION SYSTEM

| Software | Purpose |
|---|---|
| **Python** | Core programming language for pipeline development |
| **TensorFlow/Keras** | Implementation of deep learning models (Autoencoders, DQNs) |
| **Scikit-learn** | Machine learning algorithms (SVM, Random Forest, Clustering) |
| **SHAP** | Feature importance analysis and model interpretability |
| **Matplotlib & Seaborn** | Data visualization for feature plots, trend graphs |
| **Scapy** | Network packet analysis and dataset simulation |
| **Pandas & NumPy** | Data preprocessing, transformation, and numerical handling |
| **OpenAI Gym** | Reinforcement learning environment design and training |

The complete environment was tested on a system with:

- Intel i7 CPU
- 16 GB RAM
- NVIDIA GTX 1660 GPU
- Ubuntu 20.04

This configuration supports reproducibility and provides a practical baseline for testing real-world deployment feasibility, including edge-computing and federated learning extensions.

## IV. RESULTS

The research findings deliver an extensive analysis of the hybrid AI-based intrusion detection framework projected in this study. The section gives detailed information about feature importance analysis together with anomaly detection performance assessment and network flow visualization capabilities and reinforcement learning-based adaptive response effectiveness evaluation. The model's effectiveness is verified using quantitative data along with graphical and statistical analysis along with quantitative metrics.

### A. Feature Importance and Attack Pattern Analysis

The decision-making process of the model received interpretation through SHAP (SHapley Additive Explanations) which revealed its most influential features in intrusion detection. ShAP values in combination with decision trees highlight important network attributes which play a substantial role in discriminating benign from malicious traffic.

To verify stability, SHAP values were computed across five different train-test splits. The top-ranked features remained consistent, with less than 5% variance in ranking order, confirming the robustness of the feature importance analysis. Fig. 2 shows the 20 most crucial features used for intrusion detection which the model uses to make classifications. The research findings indicate that backward packet length maximum and average backward segment size emerge as the most influential attributes for detecting network anomalies. The

analysis shows "Fwd Packet Length Mean" and "Average Packet Size" as key indicators because they strongly help differentiate between normal and malicious network traffic.

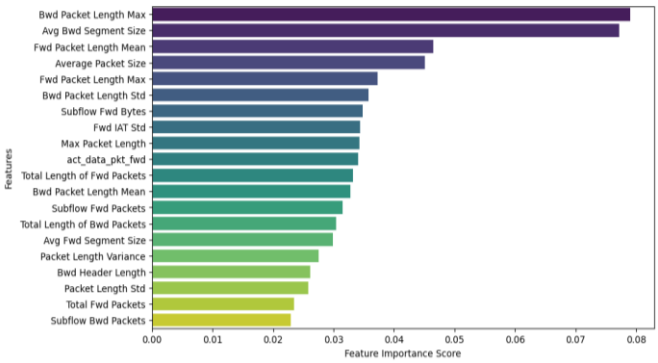

Fig. 2. SHAP Summary plot of feature importance.

## B. Unsupervised Anomaly Detection for Zero-Day Attacks

The research evaluated anomaly detection methods through their application of autoencoders, Isolation Forests, One-Class SVM, DBSCAN and K-Means, which detected new and unknown cyber threats. The assessment of models relied on detection accuracy and precision, together with recall and F1-score, to determine their effectiveness in zero-day attack identification. Table IV presents the performance metrics of the various anomaly detection models evaluated in this study.

TABLE IV. PERFORMANCE METRICS OF ANOMALY DETECTION MODELS

| Model | Accuracy (%) | Precision (%) | Recall (%) | F1-Score (%) |
|---|---|---|---|---|
| Autoencoder | 92.8 | 89.6 | 94.2 | 91.8 |
| Isolation Forest | 88.5 | 86.3 | 90.1 | 88.2 |
| One-Class SVM | 85.1 | 83.7 | 87.5 | 85.5 |
| DBSCAN Clustering | 78.4 | 76.9 | 81.2 | 79.0 |
| K-Means Clustering | 74.6 | 72.5 | 78.3 | 75.3 |

Autoencoders surpass traditional anomaly detection techniques because they achieve exceptional detection results with 92.8% accuracy and 94.2% recall, which demonstrates their ability to detect new attack patterns. Compared to conventional signature-based IDS, which typically achieve detection accuracy between 70% and 85% on similar datasets, the autoencoder-based anomaly detection system shows a significant improvement. Statistical significance was confirmed using a two-tailed paired t-test comparing F1-scores across 5-fold cross-validation. The autoencoder model's performance improvements over traditional clustering-based models were significant at $p < 0.05$. Confidence intervals for the autoencoder F1-score were calculated as 91.8% ± 0.4%. The isolation forest algorithm showed strong capabilities yet clustering techniques demonstrated inferior accuracy in detecting sophisticated cyber threats according to the results.

The Fig. 3 graphical representation illustrates how different models perform in anomaly detection tasks.

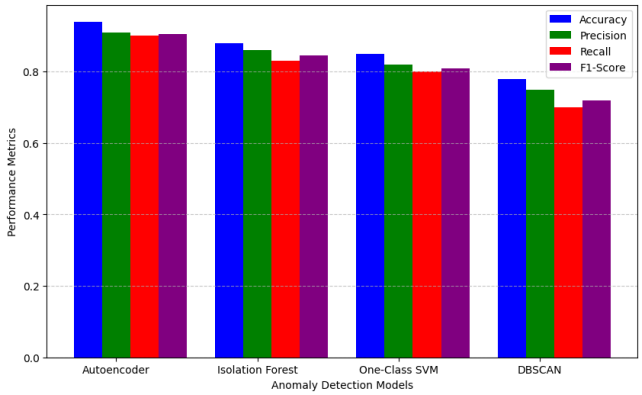

Fig. 3. Comparison of anomaly detection models.

## C. Network Flow Visualization and Trend Analysis

Enhanced pattern analysis required the utilization of two dimensionality reduction techniques, namely t-SNE and PCA, to transform high-dimensional traffic data into a two-dimensional system. The plot shows distinct partitions between regular and threatening network communications, which makes it easier to detect new attack vectors.

Fig. 4 showcases a t-SNE scattering plot with normal traffic instances clustered in one distinct zone while attack traffic spreads across a wide area, indicating different types of malicious behaviors. Anomaly detection systems prove essential for intrusion detection because outlier clusters show previously unknown attack types exist in the system data.

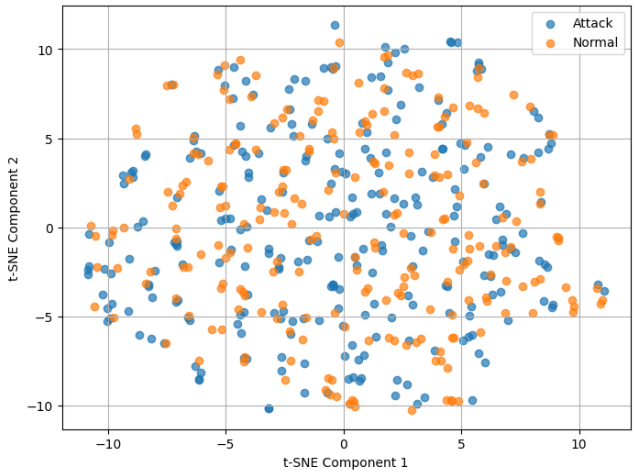

Fig. 4. t-SNE visualization of network traffic data.

A time-series evaluation measured the frequency patterns and distribution patterns of attacks across a particular time frame. Network activity peaks have been associated with increased intrusion attempts which are clearly shown in Fig. 5.

These findings suggest that cyber attackers tend to exploit high-traffic periods to mask their activities, making real-time anomaly detection and adaptive response strategies critical for mitigating potential security breaches.

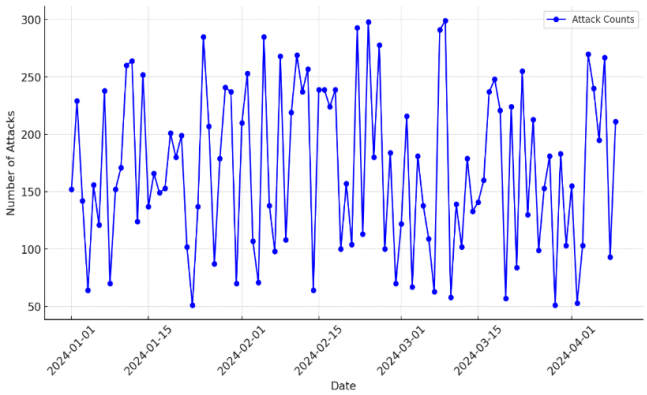

Fig. 5. Time-Series distribution of network attacks.

### D. Reinforcement Learning for Adaptive Intrusion Response

This study employed different reinforcement learning models through Deep Q-Networks (DQN) and Proximal Policy Optimization (PPO) to train adaptive cybersecurity defenses. These models underwent performance evaluation through assessment of their real-time capability to adapt intrusion response strategies.

Table V compares RL-based intrusion response systems based on three evaluation factors, which include average response time, attack mitigation performance, and learning convergence speed.

TABLE V. PERFORMANCE METRICS OF RL-BASED INTRUSION RESPONSE MODELS

| Model | Avg. Response Time (ms) | Mitigation Rate (%) | Convergence Speed (Epochs) |
|---|---|---|---|
| DQN | 52.3 | 87.9 | 150 |
| PPO | 48.7 | 91.3 | 120 |

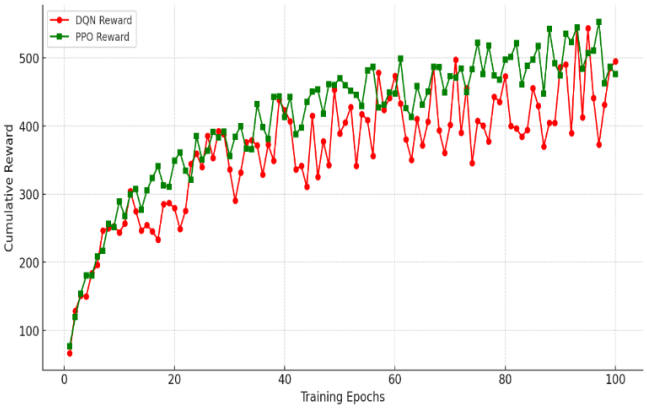

Fig. 6. Learning convergence of reinforcement learning models.

As illustrated in Fig. 6, PPO converges significantly faster than DQN, reaching optimal policy learning in fewer epochs. Measurement results show PPO creates better performance than DQN regarding the rate of attack mitigation alongside faster convergence indicating its advanced ability to handle changing attack strategies. The PPO model's mitigation rate was statistically higher than that of DQN ($p = 0.03$), based on three independent training runs per model architecture. PPO demonstrates a quicker learning speed for optimal response policies. It makes it the perfect option for cybersecurity applications that require real-time responses.

The validation of reinforcement learning potential for creating self-learning cybersecurity systems that respond to attacks autonomously and need low human involvement is considered extremely important.

## V. DISCUSSION

The research proves how artificial intelligence enhances security protection by combining machine learning and deep learning methods within an intrusion detection system. The research shows that network attributes measuring packet flow duration along with source-to-destination byte exchange help identify normal from malicious traffic. Security policies together with automated threat detection procedures should integrate these factors in order to improve both the detection reliability and accuracy. The anomaly detection models comprising autoencoders and isolation forests demonstrated outstanding competences in sensing zero-day attacks for modern intrusion detection systems and generated t-SNE visualizations which supported the operational capabilities of the clustering model for traffic differentiation.

The proposed hybrid AI model functions as a superior security solution than standard intrusion detection systems because it uses signature detection as its primary method. This system conducts anomaly detection and reinforcement learning alongside conventional IDS signatures to achieve adaptive protection against developing cyber threats. Autoencoder-based anomaly detection outperforms traditional IDS methods by reaching 92.8% accuracy while IDS detection models produce results between 70% and 85%. The proposed system reduces false positive rates by approximately 5.4% which stands as a crucial benefit because traditional IDS systems produce numerous false alerts and cannot detect new attack patterns.

The research findings receive additional confirmation by comparing them against previously studied IDS solutions. Detecting known threats through Snort and Suricata tools proves successful but these solutions do not possess sufficient flexibility to identify zero-day assaults or unidentified threats. Analysis demonstrates that anomaly detection based on autoencoders delivers a detection performance level at least 10–15% higher than standard IDS methods. The threat mitigation performance of the reinforcement learning (RL) augmented framework reached 91.3% which proved its ability to adjust response automatically according to changing attack vectors. The system implements deep learning alongside RL mechanisms which results in better accuracy and enhanced adaptability and lower computational complexity than competing approaches to establish a complete intrusion detection system.

### A. Advantages of the Proposed Model

The proposed intrusion detection system which combines AI techniques provides superior capabilities when compared to traditional IDS and standalone machine learning-based IDS. The hybrid detection approach built a 10–15% more accurate system than Snort and Suricata signature engines while reducing false positives by 5.4%. The system's priority reduces performance-related fatigue while enhancing operational workflow

effectiveness for teams in security functions. Autoencoders allow the detection of new threats and adversarial attacks which regular ML models such as SVM or Random Forests alone cannot identify or generalize across complex non-linear behavior. PPO reinforcement learning combined with the system has raised its responsiveness to new heights through automatic response mechanisms that achieve a 91.3% success rate compared to conventional intrusion response rules. The implementation indicates advancement toward threaten management systems which operate autonomously using intelligence capabilities.

### *B. Limitations*

Several drawbacks exist within the suggested framework that implements an AI-based intrusion detection system. Complex patterns detection through deep learning models creates deployment challenges because such models require significant computational resources that might be beyond what resource-constrained environments can provide. The interpretability of DL-based decisions using SHAP remains inferior to traditional rule-based systems, thus creating barriers for their acceptance in high-assurance environments. Real-time deployment proves difficult because complex models create latency problems as well as requiring extensive parallel processing capability. The implementation of federated learning faces challenges because distributed nodes need to solve coordination problems that include both synchronization delays and communication overhead.

### *C. Scalability and Deployment Considerations*

Enterprise-level networks with critical infrastructure need IDS systems that can efficiently scale their deployment requirements. The deployment environment (Intel i7, 16GB RAM, NVIDIA GTX 1660) indicates that each input processing takes less than 100 milliseconds on average which meets the requirements for mid-scale intrusion detection applications. The requirement for model synchronization in federated applications creates two main operational challenges because of the 15MB data transfer per round and the need for coordinated system node communication. Automated feedback on threats becomes available in real-time through small deployed Autoencoders or compressed RL policies, which reduce latency as well as energy use. These modifications would let the IDS maintain its operational speed when hardware access becomes restricted.

### *D. Future Work*

Research in the following phase will focus on developing live systems and enhancing adversaries' defenses for better operational reliability through contemporary explainable AI methods. The implementation of advanced adversarial training methods needs further research before they achieve proper protection against contemporary cyber threat evasion techniques. The completed research serves as foundation for developing future intrusion detection systems whose threat adaptation ability maintains broad security threat scalability.

## VI. CONCLUSION

The proposed research introduces an intrusion detection system which improves cybersecurity through integration of machine learning with deep learning techniques while employing AI. Analysis using SHAP revealed packet flow duration with a mean SHAP value of 0.276 and source-to-destination byte exchange with 0.241 as the foremost signs pointing to malicious operations. The detection of zero-day attacks relies on autoencoders and isolation forests and the system represents this effectiveness through separate normal versus anomalous traffic visualizations produced by t-SNE mapping. The model proves effective at solving traditional IDS challenges by using static signatures because it detects new security threats. An adaptive approach in the proposed solution enables intelligent real-time anomaly detection with behavioral analysis capabilities.

The system implements a reinforcement learning-based intrusion response framework that utilizes PPO for mitigation response where the PPO framework established a strong rate of 91.3% compared to rule-based response methods. The model operates with dynamic response capability that allows it to detect new threats without compromising its low rate of false positives. The hybrid IDS approach delivers precision enhancements and provides adaptive configuration and clearer insights than standard IDS systems do. The design framework allows deployment of the system across various federated and edge environments. This study promotes the progress of next-generation intrusion detection systems which handle the growing complexity along with scale of present-day cyber dangers.

## ACKNOWLEDGMENT

The author extends his appreciation to Umm Al-Qura University, Saudi Arabia, for funding this research work through grant number: 25UQU4350113GSSR02.

# Smoke Detection Model with Adaptive Feature Alignment and Two-Channel Feature Refinement

Yuanpan Zheng*, Binbin Chen, Zeyuan Huang, Yu Zhang, Chao Wang, Xuhang Liu
School of Computer Science and Technology, Zhengzhou University of Light Industry, Zhengzhou, China

***Abstract*—To address issues of missed detections and low accuracy in existing smoke detection algorithms when dealing with variable smoke patterns in small-scale objects and complex environments, FAR-YOLO was proposed as an enhanced smoke detection model based on YOLOv8. The model adopted Fast-C2f structure to optimize and reduce the amount of parameters. Adaptive Feature Alignment Module (AFAM) was introduced to enhance semantic information retrieval for small targets by merging and aligning features across different layers during point sampling. Besides, FAR-YOLO designed an Attention Guided Head (AG-Head) in which feature guiding branch was built to integrate critical information of both localization and classification tasks. FAR-YOLO refines key features using Dual-Feature Refinement Attention module (DFRAM) to provide complementary guidance for the both two tasks mentioned above. Experimental results demonstrate that FAR-YOLO improves detection accuracy compared to existing. There's a 3.5% Precision increase and a 4.0% $AP_{50}$ increase respectively in YOLOv8. Meanwhile, the model reduces number of parameters by 0.46M, achieving an FPS of 135, making it proper for real-time smoke detection in challenging conditions and ensuring reliable performance in various scenarios.**

***Keywords*—Smoke detection model; adaptive feature alignment; two-channel feature refinement; attention mechanism**

## I. Introduction

Fires pose a major danger to human safety, economies and ecosystems. In 2023, there were 550,000 fire incidents reported in China within just six months, resulting in 959 deaths, 1,311 injuries, and property damage amounting to 3.94 billion yuan [1]. Between 2019 and 2020, Australia endured a forest fire that lasted more than seven months, killing billions of animals and destroying over 10 million hectares of land [2]. The best way to prevent the spread of fires is to suppress the spread of fires quickly and to disperse fire sources in a timely manner. However, early flames are small and can easily be obscured, so detecting the smoke generated by fires is the optimal approach for controlling the occurrence of fire.

Early smoke detection methods [3] relied on smoke, temperature, and light sensors to detect fire particles at close range, but had limited range and were prone to environmental interference. Traditional fire smoke detection algorithms relied on manual feature extraction and machine learning classification [4], but depended on domain expertise and couldn't effectively capture image features, resulting in poor generalization and applicability.

Object detection approaches based on deep learning can automatically learn main features and details in data, offering advantages such as high accuracy and strong robustness. Convolutional Neural Networks (CNNs) extract hierarchical features layer by layer through local connections and parameter sharing mechanisms, making them highly effective for image recognition. Recently, Transformer-based architectures have achieved remarkable advances in the field of image detection. Compared to CNNs, Transformers perform well in identifying distant relationships and perceiving global information within images. However, their computational complexity is higher, and they generally require more computing resources.

Xie et al [5], introduced a forest fire smoke identification method developed with the Faster-RCNN model, which enhances the receptive field by adding a feature fusion module after each level of the feature pyramid structure. However, this region extraction-based detection method consists of two stages, leading to higher algorithm complexity and slower detection speeds. YOLO series algorithms, on the other hand, are widely used for their capability to provide precise and timely detection. Casas et al [6], has shown that the excellent applicability of YOLO algorithms in smoke detection. Zhang et al [7] introduced an enhanced YOLOv4 model that combines an attention mechanism to boost the capture of smoke feature and utilizes the K-means++ algorithm to determine the most suitable predicted bounding box scale. Despite these improvements, the model suffers from slow detection speeds, which are inadequate for the real-time requirements for smoke detection. Li et al [8], added the YOLOv5 model with a coordinate attention mechanism to strengthen the model's concentration on key smoke regions and proposed an RFB module to capture global information. However, this model still struggles with detecting small smoke targets and exhibits a low smoke recognition rate. Ouyang et al [9], introduced a new object detection model named fuse-transformer, which combines Transformer and YOLOX to use transformer to handle global context and boost the model's potential to extract feature. However, the model has issues such as excessive size, high complexity, and demanding hardware requirements.

In the past decade, numerous algorithms have been developed for fire smoke detection, yielding promising results. However, challenges persist. First, the rapid spread of fires demands prompt smoke detection. Moreover, complex environmental conditions can alter the concentration and shape of smoke, making it harder for models to accurately identify it. Objects with colors and shapes similar to smoke may also lead to false detections. Additionally, the small size of early-stage smoke features poses another significant challenge. Prior studies used complex models to improve smoke detection accuracy. But large-parameter models are complex and slow.

To meet real-time demands, some applied one stage detection models with specific feature modules. However, single stage models struggle with small targets and complex environments. We aims to attain a desirable trade-off between speed and accuracy.

This paper presents an enhanced fire smoke detection model, which is built upon YOLOv8 [10], named FAR-YOLO (Feature Alignment and Refinement-YOLO). This model attains a balance between precision and speed by incorporating innovative lightweight modules and an attention mechanism-enhanced head structure. It utilizes an adaptive upsampling module to enhance capability of capturing small smoke targets. Additionally, we have constructed an outdoor fire smoke detection dataset consisting of 3,705 real smoke images. The dataset includes images of fire smoke captured at both close and distant ranges, as well as samples from complex environments with potential interference.

In this paper, we proceed as follows: Section II presents the relevant key technologies. Section III details the innovative methods, including the design philosophy and approach of the smoke feature extraction enhancement module. In Section IV, the datasets, experimental environment, ablation experiments and comparative experiments with other detection are models introduced. Section V summarizes the work content and contributions of this paper.

## II. Related Work

### A. YOLOv8

The network design of YOLOv8 is depicted in Fig. 1. The C2F module has cross connections between its layers and splitting operations, a design that enhances gradient fluidity and boosts the model backbone's efficiency in feature extraction. By introducing PANet [11] into the neck structure, the network can transfer features from bottom to top and from top to bottom, thereby effectively fusing multi-level semantic information and geometric information. YOLOv8 includes a decoupled head structure and incorporates Distribution Focal Loss [12] and IOU Loss in the localization branch, improving its ability to detect partially occluded objects. Additionally, a Task-Aligned Assigner [13] is used for sample matching, which evaluates both object localization and classification tasks, and then determines whether an instance is a target or irrelevant sample based on weighted scores, enhancing the model's performance across multiple tasks.

### B. Attention Mechanism

The attention mechanism dynamically identifies key image regions and assigns positional weights. CBAM [14] enhances the representational power of the feature map by applying weighting to features across channel and spatial dimensions. Coordinate Attention (CA) [15] encodes the spatial coordinates to generate a coordinate weight map, which is then used to adjust the original feature map. Efficient Multi-Scale Attention (EMA) [16] addresses the accuracy loss that occur during dimensionality reduction in coordinate weight calculation by transmitting additional feature information across different regions.

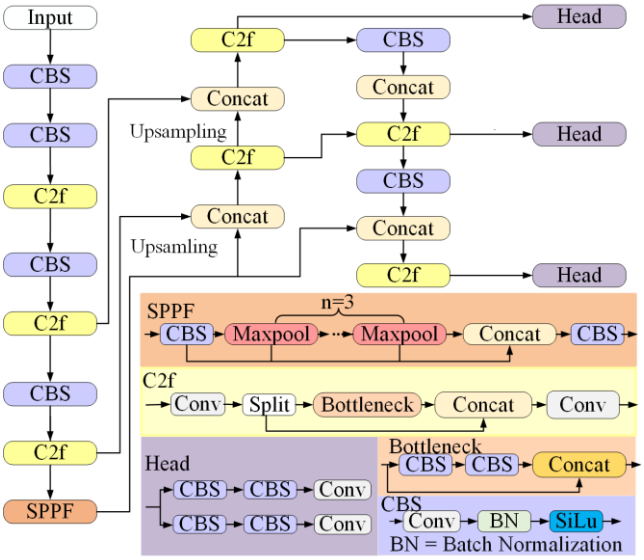

Fig. 1. Network architecture of YOLOv8.

### C. Upsampling Methods

Upsampling methods boost image resolution and restore details. Bilinear interpolation is a widely used upsampling method that estimates the value of a target point using the positional information of neighboring points. CARAFE [17] dynamically generates adaptive kernels by perceiving the content of the features to reorganize input features. Dysample [18] uses a point sampling mechanism, dynamically calculating sampling point offsets to adapt to input feature maps. Compared to kernel-based methods, Dysample achieves better results and higher computational efficiency.

## III. Improvement Scheme

The architecture of FAR-YOLO is depicted in Fig. 2. Fast-C2f is adopted instead of the original C2f structure, so that model complexity is reduced and detection speed is increased without losing accuracy. The lightweight AFAM module performs adaptive sampling during feature map reconstruction and is integrated into the upsampling process of the feature pyramid to enhance semantic information transfer across layers. In the head region, the proposed AG-Head detection head includes a feature guidance branch that consolidates key features from the two task branches. The DFRAM refines feature representations, guiding both classification and localization tasks.

### A. Fast-C2f Module

In smoke detection, the model's inference speed is crucial. The calculation formula for *Latency* is as follows:

$$Latency = \frac{FLOPs}{FLOPS} \tag{1}$$

where, *FLOPs* is a measure of the total number of float computations, and *FLOPS* signifies the amount of these operations executed each second. Considering the high similarity between channels in the feature map, Chen et al [19], proposed Partial Convolution (PConv). As shown in Fig. 3(a),

PConv convolves only a segment of continuous channel images while keeping the other channels unchanged. Compared to regular convolution, PConv decreases parameters of the model and makes detection faster.

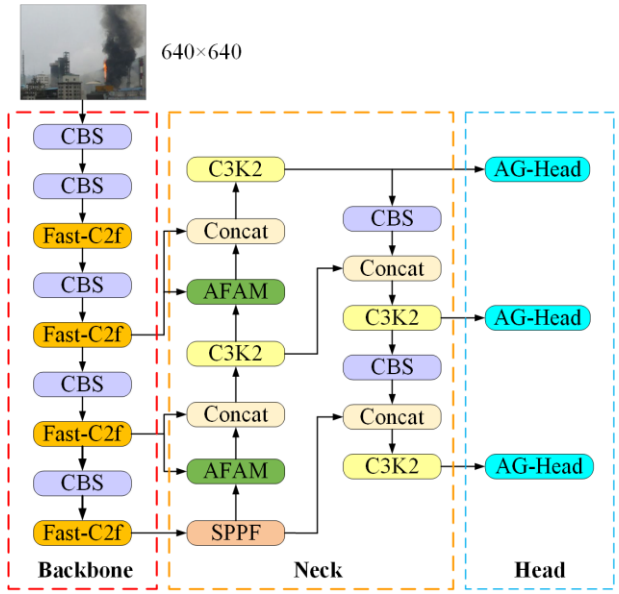

Fig. 2. Network architecture of FAR-YOLO.

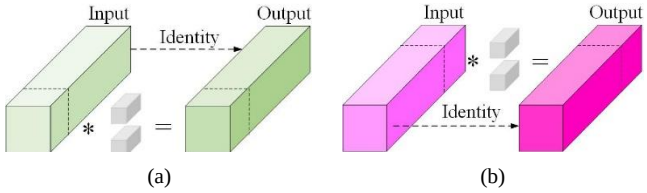

Fig. 3. Working way of Pconv: (a) Select the first quartile channel (b) Select the last quarter channel.

This paper proposes the Fast-C2f module, whose structure is presented in Fig. 4. The first partial convolution in the Fast-Bottleneck selects the first quarter of the channels for training. To avoid incomplete capture of key image information across all channels, we implemented an opposite channel selection scheme. Specifically, the second partial convolution selects the last quarter of the channels for training, as depicted in Fig. 3(b). Both of these complementary channel selection schemes enable Fast-Bottleneck to perform more comprehensive feature learning, providing the model with strong feature representation capabilities.

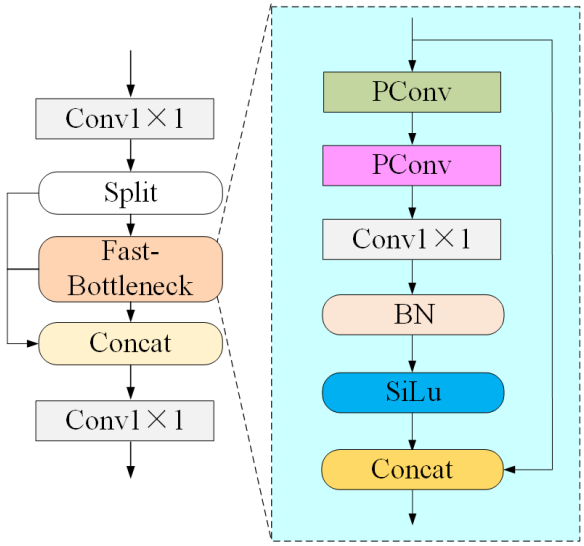

Fig. 4. Structure of Fast-C2f.

## B. Adaptive Feature Alignment Module

Early-stage smoke has a small volume and covers merely a little pixel area in the image, resulting in limited appearance information. To address this, transferring detailed semantic information from deeper layers to shallower layers can enhance feature representation for small targets. This paper adopts this approach to improve the effectiveness of feature information transfer between deep and shallow layers. To avoid interference caused by feature mismatches during the upsampling process [20], we introduce the lightweight AFAM and apply it during the upsampling stage. This module's network framework is depicted in Fig. 5.

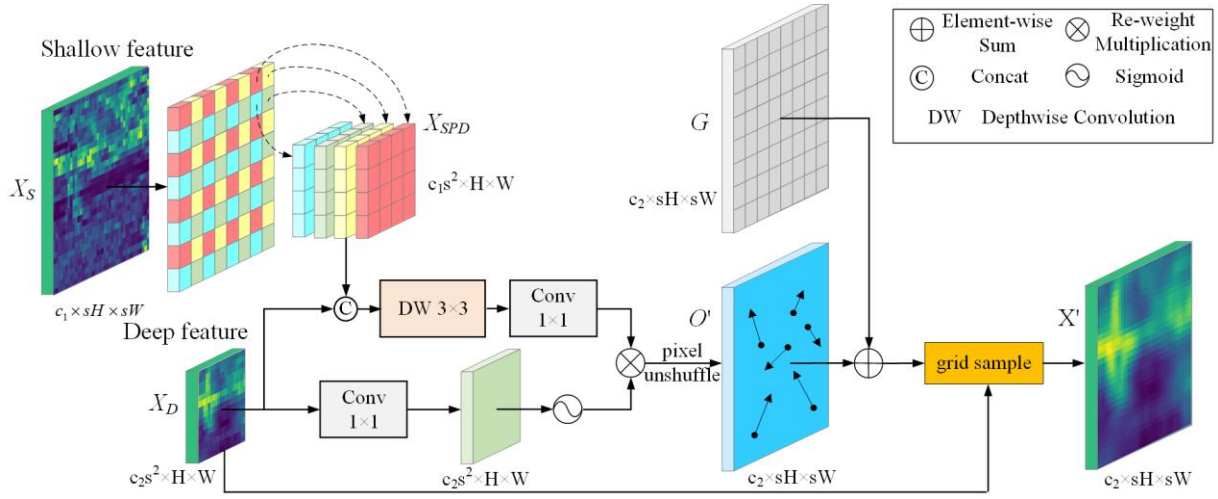

Fig. 5. Structure of AFAM.

AFAM employs point sampling for upsampling. Provided with an input feature map of size $c_2 s^2 \times H \times W$, the algorithm uses a linear layer to capture pixel neighborhood information, generating an offset flow $O$ that reflects semantic variation trends between deep and shallow features. After reshaping $O$ to $c_2 \times sH \times sW$, it combines with the sampling grid $G$ to produce the sample set $S$. The following are the formulas for the calculation of $O$ and $S$:

$$O = linear(X) \tag{2}$$

$$S = G + O \tag{3}$$

The $grid\_sample$ function is employed to resample the sample set, generating the final feature map $X'$.The formula for calculating $X'$ is shown below:

$$\boldsymbol{X}' = grid\_sample(\boldsymbol{X}, \boldsymbol{S}) \tag{4}$$

AFAM incorporates shallow image features during the generation of $O$, improving feature alignment between adjacent layers by fusing features from different levels. The geometric details from the shallow layers help guide the deeper semantic information, thereby generating a more effective offset flow. In terms of implementation, the shallow image has dimensions of $c_1 s^2 \times sH \times sW$, and we aim to adjust its dimensions to match the deep feature map. Inspired by the SPD module [21], the specific approach is as follows: AFAM divides the shallow feature map into sub-maps of size $H \times W$, then reorganizes the objects at corresponding positions in each sub-map to form a feature map with the size of $c_1 s^2 \times H \times W$. The calculation formula is as follows:

$$\boldsymbol{X}_{SPD} = \begin{cases} f(0,0) = \boldsymbol{X}_S[0:H:s, 0:W:s] \\ f(1,0) = \boldsymbol{X}_S[1:H:s, 0:W:s] \\ f(s-1,0) = \boldsymbol{X}_S[s-1:H:s, 0:W:s] \\ f(0,s-1) = \boldsymbol{X}_S[0:H:s, s-1:W:s] \\ f(s-1,s-1) = \boldsymbol{X}_S[s-1:H:s, s-1:W:s] \end{cases} \tag{5}$$

where, $X_S$ represents the shallow feature image, $s$ is the scaling factor, and $H$ and $W$ are used to signify the horizontal and vertical extent of the feature map. This method effectively preserve the detailed information in the image.

To further enhance the effectiveness of feature fusion, AFAM applies linear projection and nonlinear transformation to the deep feature map to generate a weight map. The weight map is used to adaptively balance the feature information across different layers. The calculation formula is as follows:

$$O' = Sigmoid(linear_1(X_D)) \otimes linear_2(Ct(X_D, X_{SPD})) \tag{6}$$

where, $X_D$ represents the deep feature image, $linear_1$ and $linear_2$ represent the linear projection operation on the deep feature map and the combined of Depthwise convolution (DWConv) and 1×1 convolution, respectively. $Ct$ denotes the feature concatenation operation, $\otimes$ represents matrix multiplication.

### C. Attention-Guided Head

*1) The design of AG-HEAD:* The decoupled detection head uses separate convolutional layers for localization and classification tasks. However, constrained by fixed kernel sizes, these layers only capture local features. In outdoor smoke detection scenarios, the texture features at the edges of smoke are often weak. Overemphasizing dense areas while neglecting sparse regions may misjudge the true smoke extent, reducing detection accuracy.

This paper designs AG-Head, whose network structure is shown in Fig. 6. The feature map extracts spatial feature information through DWConv, forming a feature guidance branch parallel to the other two branches. The localization and classification branches focus on learning different feature [22], while the feature-guided branch captures the features shared by both tasks during the back propagation process. The DFRAM is integrated into the feature guidance branch to fuse different types of features, providing complementary spatial information guidance for both branches. By enhancing the performance of both tasks, the model can comprehensively focus on smoke features, accurately capturing both smoke concentration and global information.

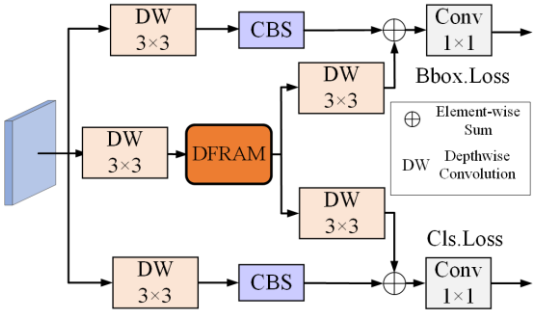

Fig. 6. Structure of AG-Head.

*2) Dual-feature refinement attention module:* To effectively fuse feature information and enhance the interaction between the two tasks, this paper proposes DFRAM, whose structure is shown in Fig. 7. This module contains two algorithms: Coordinate Feature Refinement (CFR) and Multi-Scale Feature Refinement (MSFR). CFR captures directional spatial location information, while MSFR extracts rich contextual and local features. DFRAM overlays the weight maps generated by both methods to enhance the detection head's sensitivity to smoke object concentration and spatial location.

*a) Coordinate feature refinement:* To get feature coordinate info, CFR first globally pools the input feature map vertically and horizontally. Then, CFR captures cross-channel interaction info in a special way. Since the fully connected method can't avoid the bad effects of channel dimensionality reduction and 1×1 2D convolutions aren't good enough for capturing inter-channel info, multi-kernel 1D convolutions are used to share channel info across n consecutive layers. The

calculation formulas for the global pooling operations in both directions are as follows:

$$GAP_H = \frac{1}{W} \sum_{o \le j < W} x(W, i) \tag{6}$$

$$GAP_W = \frac{1}{W} \sum_{o \le j < W} y(j, H) \tag{7}$$

The 1D convolution's kernel size is set based on the amount of channels, as the optimal kernel size is associated with the amount of channels [23]. The calculation formula is as follows:

$$n = |t|_{odd} = \left| \frac{\log_2(C)}{\gamma} + \frac{b}{\gamma} \right|_{odd} \tag{8}$$

where, $C$ indicates the count of channels, and $|t|_{odd}$ represents the odd number adjacent to $t$.

*b) Multi-scale feature refinement:* MSFR extracts image features through DWConv and Dilated convolution (DConv) with progressively increasing dilation rates [24]. The architecture processes DWConv outputs in parallel through three DConv branches with diverse receptive fields, fuses these multi-scale features with the original input, and generates spatial attention weights via 1×1 convolution and Sigmoid activation. This design captures local details and contextual patterns for enhanced feature representation. The computation process of MSFR can be described as:

$$\boldsymbol{F} = DWConv(\boldsymbol{x_{input}}) \tag{9}$$

$$MSFR_{output} = Sigmoid(Conv_{1\times1}((\sum_{i=0}^{2} DConv_r(F)) + F)) \tag{10}$$

where, $x_{input}$ is the original feature map and $F$ denotes the intermediate layer's output, $MSFR_{output}$ refers to the output feature map of MSFR. $DConv_r$ represents dilated convolutions with varying rates in the three parallel branches, where subscript $r$ indicates the dilation rate and $i$ indicates the $i$ branch in the multi-scale structure.

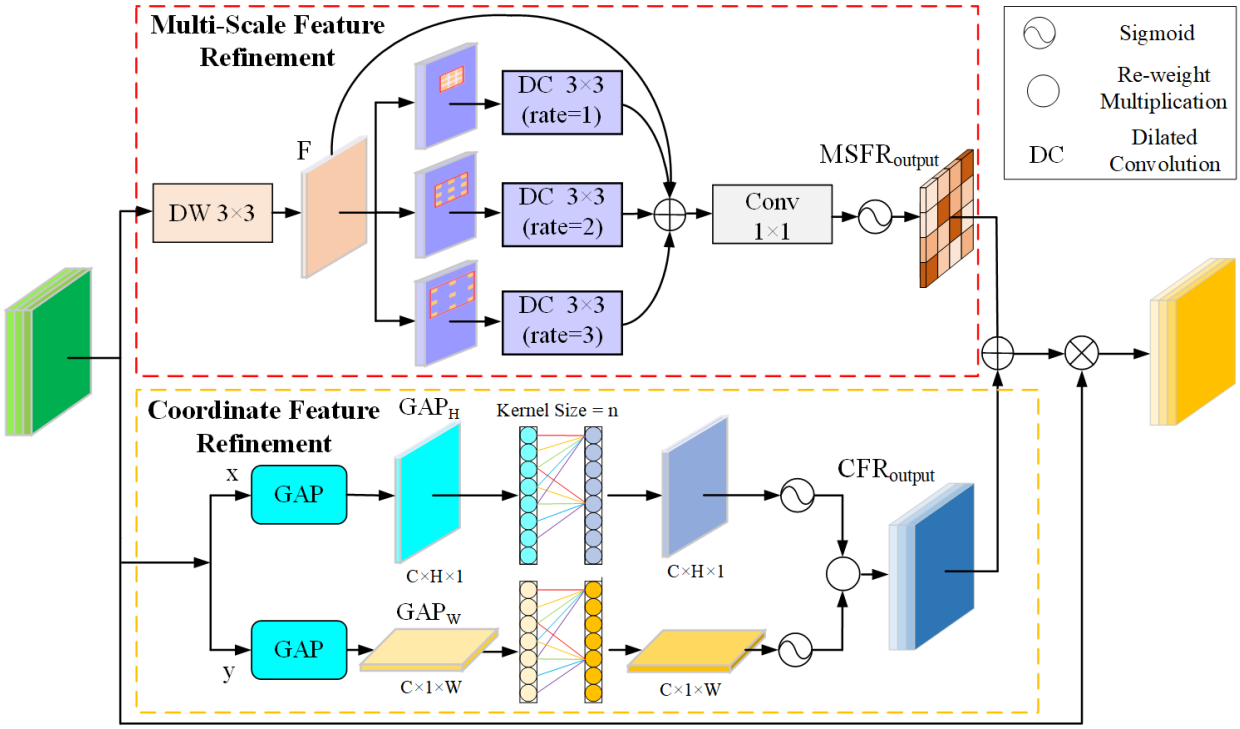

Fig. 7. Structure of DFRAM.

## IV. Experiments and Result Analysis

### A. Datasets and Annotations

Since there's a shortage of public fire smoke datasets and the lack of calibration, this paper collects smoke images and manually annotates the smoke regions to create a self-made fire smoke dataset. The smoke images are sourced from the public datasets HPWREN [25] and the Fire Detection Research Group [26], which contain real smoke objects of various sizes and in different scenes. This diverse dataset enables the model to develop strong recognition capabilities for various types of smoke. Images with low resolution or those not meeting the training requirements are excluded. The dataset is made up of 3,705 smoke images, which are randomly split into training, validation and testing sets in a 7:2:1 ratio. The dataset is formatted according to the YOLO dataset standard, and the LabelImg tool is used to annotate and create a plain text label file containing the positions and sizes of smoke targets. Some annotated image samples from the self-made dataset are shown in Fig. 8.

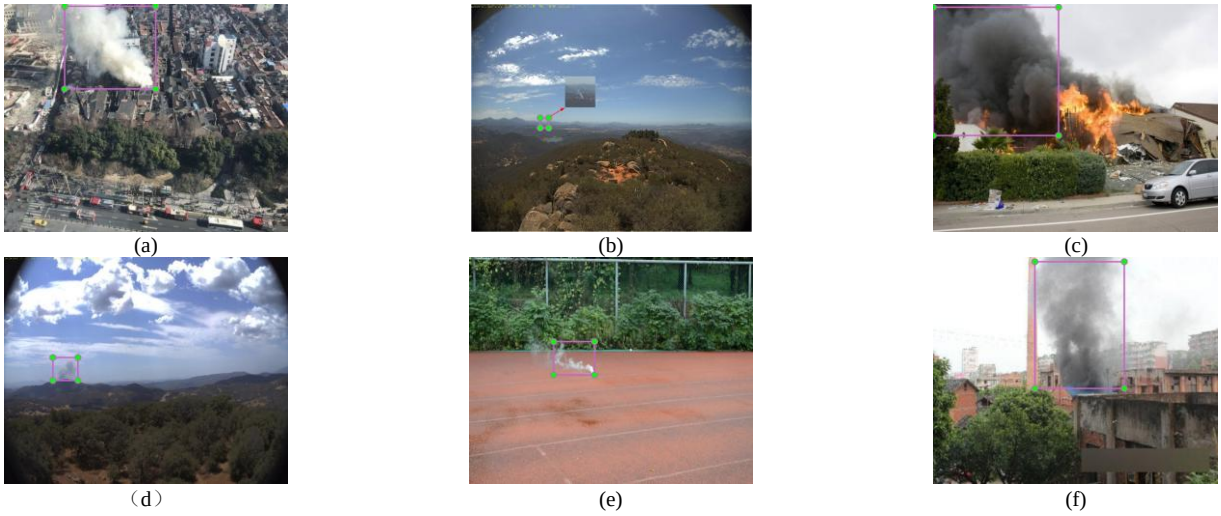

Fig. 8. Different types of labeled image samples from the self-made smoke detection dataset: (a) Large smoke; (b) and (f) show small smoke at different distances; (c) and (d) are black smoke; (e) is the smoke object in the environment of interference factors.

### B. Evaluation Metrics

This paper uses COCO metrics to evaluate the smoke detection model. Precision reflects ratio of smoke samples that are correctly recognized, while recall is the proportion of actual smoke samples detected. Another important metric is Average Precision (AP), reflecting the model's overall accuracy in smoke identification. $AP_{50}$ denotes the average precision at a threshold of 50. Additionally, Frames Per Second (FPS) measures indicates the rate at which a model can process consecutive images, and the number of parameters (Params) serves as a metric for assessing its complexity. The formulas for calculating these four metrics are presented below:

$$\mathrm{Pr}ecision = \frac{TP}{TP + FP} \tag{11}$$

$$\mathrm{Re}call = \frac{TP}{TP + FN} \tag{12}$$

$$AP = \frac{1}{r}\sum_{i=1}^{r} P_i \tag{13}$$

$$FPS = \frac{1}{Time} \tag{14}$$

where, $TP$ indicates the count of smoke samples accurately detected, while $FP$ signifies the amount of irrelevant samples mistakenly labeled as smoke objects, $FN$ represents the amount of smoke samples that were missed, and $Time$ represents the time needed to process one image, which is measured in milliseconds.

### C. Experimental Environment and Hyperparameter Configuration

Experiments use Python 3.8 and PyTorch 2.0, accelerated by CUDA 11.8. Hardware includes an AMD EPYC-7663X CPU and an NVIDIA GeForce RTX 3090 GPU. The optimizer is SGD. Input images are 640×640. The model is trained for 300 iterations, using batches of 16 and with a learning rate initially set to 0.001.

### D. Comparative Experiment of Adaptive Feature Alignment Module

The upsampling operator can augment the model's proficiency in capturing essential information, but it also introduces complexity. Therefore, this section compares the AFAM module with the advanced lightweight CARAFE module and Nearest Neighbor Interpolation (NNI). The comparison results, presented in Fig. 9, demonstrates that the AFAM module achieves a Precision of 88.7% and an $AP_{50}$ of 89.3% with fewer Params and FPS. Although CARAFE can achieve similar accuracy, it costs nearly twice as much in terms of Params and FPS compared to AFAM.

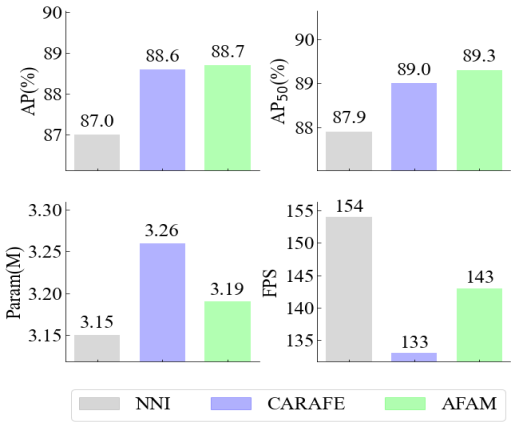

Fig. 9. Experimental comparison results of three upsampling methods under four different evaluation metrics: AP, $AP_{50}$, Params, and FPS.

### E. Experimental Analysis of Dual-channel Feature Refinement Attention Module

This section investigates the influence of diverse dilation rate combinations of DConv in MSFR on the final results. Additionally, to evaluate the impact of the DFRAM, Several mainstream attention mechanisms are used for comparison with it.

*1) Comparison experiments of different expansion rates:* To study the impact of dilation rates on accuracy in MSFR, three combinations of dilation rates were tested: [1, 2, 3], [2, 4, 6], and [4, 8, 12]. These combinations were applied to MSFR, and experiments were conducted using the YOLOv8 network integrated with AG-Head on the self-made dataset. The comparison results are presented in Table I, illustrating that the [1, 2, 3] combination reaches the superior detection performance. While larger dilation rates capture a larger receptive field, they also result in losing local details, which reduces the model's capacity for recognizing small objects.

TABLE I. DETECTION RESULTS BASED ON DIFFERENT DILATION RATE COMBINATIONS' CONFIGURATIONS

| *Rates* | *Precision (%)* | *$AP_{50}$ (%)* |
|---|---|---|
| [1,2,3] | 89.3 | 90.5 |
| [2,4,5] | 88.8 | 90.3 |
| [4,8,12] | 88.6 | 90.0 |

*2) Comparative experiments with different attention modules:* This section compares the performance of DFRAM with the CA, CBAM, and EMA. These attention modules are separately introduced into the YOLOv8 network integrated with AG-Head, and the attention maps generated by them are used to assist in task judgment. As shown in Table II, DFRAM shows the best performance.

TABLE II. DETECTION RESULTS BASED ON DIFFERENT ATTENTION MODULES' CONFIGURATIONS

| *Attention module* | *Precision (%)* | *$AP_{50}$ (%)* |
|---|---|---|
| CA | 88.1 | 89.7 |
| CBAM | 88.9 | 90.1 |
| EMA | 89.2 | 90.3 |
| DFRAM | 89.3 | 90.5 |

## F. Comparative Experiments

To assess the proposed improvements' effectiveness, this section conducts comparative experiments using the self-made smoke dataset, along with mainstream object detection methods from recent years. These methods include YOLO series detection algorithms such as YOLOv3 [27], YOLOv5 [28], and YOLOv7-tiny [29]. Additionally, the comparison includes the two-stage detection method Faster-RCNN [30] and cutting-edge algorithms based on the Transformer framework, such as Dino [31] and Dab-detr [32].

The experimental information is detailed in Table III. The YOLO series detection algorithms achieve higher accuracy than Faster-RCNN while requiring fewer parameters. Although the YOLO algorithms fall short of Transformer-based models in performance, their superior detection speed makes them more fitting for real-time smoke detection scenarios. Both YOLOv7-tiny and YOLOv8 achieved Precision exceeding 86.0%, with $AP_{50}$ surpassing 87.6%. However, YOLOv7-tiny has parameters in an amount close to twice that of YOLOv8. The FAR-YOLO model not only achieves the best accuracy among the models tested but also requires fewer parameters than YOLOv8, demonstrating that FAR-YOLO offers the best overall performance.

TABLE III. COMPARATIVE EXPERIMENTS OF DIFFERENT ADVANCED MODELS

| **Compare Models** | ***Precision (%)*** | ***Recall (%)*** | ***$AP_{50}$ (%)*** | ***Params (M)*** | ***FPS*** |
|---|---|---|---|---|---|
| Faster-RCNN (ResNet50) | 80.2 | 76.1 | 81.4 | 28.55 | 18 |
| YOLOv3n | 83.0 | 82.3 | 84.4 | 8.67 | 120 |
| YOLOv5n | 85.8 | 83.6 | 87.0 | **1.89** | 135 |
| YOLOv7-tiny | 86.1 | 84.0 | 87.6 | 6.20 | 123 |
| YOLOv8n | 87.0 | 84.3 | 87.9 | 3.15 | **156** |
| Dino | 89.7 | 87.3 | 91.2 | 47.00 | 17 |
| Dab-detr | 88.8 | 87.6 | 90.0 | 44.00 | 27 |
| FAR-YOLO | **90.5** | **87.9** | **91.9** | 2.69 | 135 |

A scatter plot intuitively compares model performance, with $AP_{50}$ on the vertical axis and the number of Params on the horizontal axis. In the scatter plot, a model positioned further to the left indicates fewer parameters and lower computational complexity, while a position further up suggests higher precision. As illustrated in Fig. 10, Transformer-based models, despite their high precision, are located in the top right position due to their large number of parameters. This implies high computational resource demands, making them prone to deployment difficulties and slow operation on edge devices. In contrast, FAR-YOLO achieves a higher $AP_{50}$ with fewer parameters, placing it in the top left region. Among models with similar parameter counts, FAR-YOLO is positioned higher, indicating superior performance at the same parameter level. Thus, FAR-YOLO strikes a good balance between precision and computational complexity, suits edge deployment, and can deliver ideal detection accuracy on resource-constrained edge devices with lower computational and storage costs.

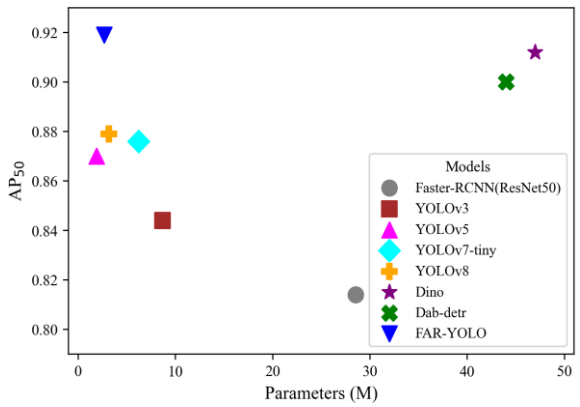

Fig. 10. Scatter plot of different models.

## G. Ablation Experiments

This section presents ablation experiments on the self-made fire smoke dataset to assess the effect of the proposed improvements on model performance. The ablation experiment results are depicted in Table IV.

TABLE IV. ABLATION EXPERIMENTS FOR DIFFERENT MODULES

| Experiment Group | Improvement Scenarios | | | Evaluation Metric | | | |
|---|---|---|---|---|---|---|---|
| | Fast−C2f | AFAM | AG−Head | *Precision (%)* | *Recall (%)* | *$AP_{50}$ (%)* | *FPS* |
| 1 | | | | 87.0 | 84.3 | 87.9 | 156 |
| 2 | ✓ | | | 87.1 | 84.9 | 88.4 | **161** |
| 3 | | ✓ | | 88.7 | 86.1 | 89.3 | 143 |
| 4 | | | ✓ | 89.3 | 86.2 | 90.5 | 137 |
| 5 | | ✓ | ✓ | 89.7 | 87.6 | 91.3 | 128 |
| 6 | ✓ | ✓ | ✓ | **90.5** | **87.9** | **91.9** | 135 |

In Group 2, the opposing channel allocation scheme of Fast-C2f increased the detection speed while maintaining the model's precision. The AFAM module enhanced the effectiveness of feature information transfer between different layers, resulting in a 1.4% increase in $AP_{50}$ for Group 3. The introduction of the AG-Head, which includes the feature guidance branch and the DFRAM, resulted in Precision increasing by 2.3% and $AP_{50}$ by 2.6% in Group 4. Group 5 combined AFAM and AG-Head, achieving a greater performance improvement compared to individual modules, with an $AP_{50}$ of 91.3% and Recall of 87.6%, demonstrating that combining multiple modules yields better results. Finally, Group 6, which combined all three modules, showed a 4.0% increase in $AP_{50}$ compared to Group 1, achieving a Recall of 87.9% and achieving a Precision of 90.5%. Although the FPS slightly decreased, it still reached 135 frames per second, reaching real-time detection requirements. Overall, the performance of the improved model demonstrated significant improvements.

The precision and recall curve evaluates precision and also takes recall into account across different thresholds, offering a comprehensive measure of model performance. Fig. 11 displays the precision and recall (pr) curves for the baseline model and various improvements. It is clear that the PR curve of the enhanced model largely overlaps with that of the baseline model, demonstrating that, at the same recall rate, the improved model achieves higher precision.

### *H. Detection Performance and Analysis*

*1) Visualization of improvement effects:* To more effectively prove the validity of the proposed improvements, we use the YOLOv7tiny, YOLOv8 and FAR-YOLO models to detect smoke in fire scenes. As shown in Fig. 12, the improved model performs well in detecting large smoke plumes. The baseline model struggles to effectively recognize the entire smoke in scenarios involving large smoke with uneven concentration, often mistakenly dividing it into two parts. In contrast, the improved model captures richer contextual information, allowing it to accurately enclose the entire smoke plume with the detection box. Fig. 13 further demonstrates that the enhanced model surpasses the baseline in detecting small smoke targets. Additionally, under strong external light interference, the improved model can still accurately locate the smoke, while the baseline model fails to detect it, particularly in conditions of strong lighting and small smoke.

*2) Visualization of smoke feature extraction capabilities:* To better analyze the model's proficiency in smoke feature extraction, This paper adopts heatmaps to display the model's focus to different regions of the image during detection. The attention of a region is related to its color; the warmer the color, the higher the attention, indicating that the higher the attention, the greater the contribution of the region's features to the prediction result. As shown in Fig. 14, group (c) is the baseline model YOLOv8, and group (d) is the improved model FAR-YOLO. The improved model allocates more attention to the smoke region than the baseline model and the high-attention areas align with the contours of the complex-shaped smoke. This indicates that the improved model can accurately locate the region of interest, demonstrating superior performance.

## V. CONCLUSION

This paper creates a multi-scene smoke dataset from public sources and introduces FAR-YOLO, an enhanced YOLOv8-based model. The model employs partial convolutions with two channel allocation strategies to build the Fast-C2f module, reducing complexity and boosting speed. The AFAM module is integrated into the upsampling process, uses adaptive alignment and resampling to strengthen the correlation between deep semantic and shallow positional features, improving small object detection. The AG-Head is introduced, featuring a feature-guided branch that extracts critical feature information from different task branches. The embedded DFRAM in this branch captures richer context and localization info, enhancing smoke concentration and scale judgment. Experiments show the model effectively detects multi-scale smoke in various scenes, with Precision and $AP_{50}$ reaching 90.5% and 91.9%, respectively, and Recall achieving 87.9%. Additionally, the model reduces the parameter count by 0.46M and achieves a FPS rate of 135. The model effectively balances detection accuracy and speed, excelling in real-time smoke detection.

***Abstract*—This study presents the design and modeling of an adaptive hypermedia system, capable of dynamically adjusting to the needs and characteristics of each learner according to their profile. In the digital age, where digital content must respond to varied profiles and adapt to learners' preferences and skills, this system offers a personalized approach that improves the learning and interaction experience. This personalized approach aims to enrich the learning and interaction experience with learning environments. This work consists of analyzing the different types of learner profiles, in order to identify the key criteria for effective personalization. Based on this, the authors developed a model of an adaptive and dynamic hypermedia system, capable of adapting in real time. To ensure a clear and coherent structure, the use of UML (Unified Modeling Language) modeling is increased. Preliminary results show that this system offers a relevant and targeted experience thanks to learner engagement and satisfaction, making learning both more relevant and more enjoyable. This work paves the way for future research on the optimization of hypermedia systems by further integrating the individual behaviors of learners, in a truly adaptive learning environment, which values the potential of each learner.**

***Keywords*—Design; adaptive hypermedia; learning styles; user modeling; UML models**

## I. INTRODUCTION

Currently, hypermedia learning systems, whether online educational platforms, interactive digital courses or distance learning tools, interactive digital environments occupy a central place in modern education [1], [2]. By combining texts, images, videos, sounds and hypertext links to enrich the user experience [3]. These systems offer a richer learning experience than traditional media. However, despite their advantages, the majority of these systems lack sufficient adaptability to personalize the experience according to users, their context and their learning styles [4]. Most of them have a major limitation: their rigidity. Few are able to truly adapt to the particularities of each learner, their learning style, their skill level or their context of use. Faced with this observation, dynamic adaptive learning systems are emerging as a promising solution and represent a significant evolution in online learning and knowledge management [5]. The integration of artificial intelligence techniques, recommendation technologies in platforms and recommendation algorithms, allows to meet the growing need for individualization in education and takes into account the individual differences of users, their learning preferences, their skill levels and their context of use, while offering personalized, effective and optimized learning experiences and adjusting the content and interface in real time to improve the learning experience and effectiveness. Personalize the educational experience in real time, adjusting the content, the difficulty of the exercises, and even the user interface to optimize engagement and learning effectiveness [6], [7]. This individualized approach meets a growing need in the educational field, where learners have different rhythms, preferences and objectives [8], [9]. However, designing such a system requires a flexible architecture and complex decision logic, capable of processing heterogeneous data (such as user performance, interactions or history) to generate relevant learning paths [10], [11]. This is where Unified Modeling Language (UML) plays a key role. By providing a visual and structured representation of system components, interactions between actors, and adaptation mechanisms, UML allows these technical requirements to be formalized while ensuring a robust and scalable design [12], [13]. Using UML for the design of personalized and flexible educational systems is crucial. Thanks to a clear representation of the dynamic structure, complex interactions, and adaptation mechanisms, UML allows the specification of both functional requirements such as content customization and non-functional requirements such as performance and security [14], [15], [16], [11], [17], [18], [19], [20], [21] and [22].

This research aims to design an innovative model of a dynamic adaptive hypermedia system capable of adjusting in real time to the specific needs of users. To achieve this, the working approach in this study is based on a UML modeling defining the components, interactions and adaptation mechanisms necessary for the personalization of the user experience in real time and complete that integrates three essential dimensions: the management of learner profiles (skills, preferences and learning history), the adaptation mechanisms (personalization rules and content recommendation algorithms), and the underlying software architecture (functional modules, data flows and user interfaces). The study is structured in four main parts: we will start by drawing up an in-depth state of the art of existing adaptive hypermedia systems and their current limitations; we will then present our design methodology with the different UML diagrams (use cases, classes and sequences); then we will analyze the preliminary results demonstrating the impact of adaptivity on learner engagement; Finally, we will

explore future perspectives, particularly the advanced integration of artificial intelligence to refine personalization. Through this study, we aspire to contribute significantly to the development of intelligent learning environments where technology serves the development of each learner's individual potential.

This research adds to recent studies on adaptive hypermedia systems [4], [6], [8], while presenting notable methodological advances. Unlike current methods that rely mainly on adjustment based on fixed profiles [9], [12] or established guidelines [15], our model proposes a more advanced dynamic approach, drawn from recent advances in the field of educational AI [17], [20]. In contrast to traditional approaches that modify content linearly [5], [7], our device incorporates a double adaptation: both of learning trajectories and user interfaces, thus filling two gaps identified in the publications [10], [13]. Furthermore, the proposed UML model provides a more exhaustive formalization than the architectures detailed in [11], [14]. Explicitly incorporating instantaneous feedback and contextual adjustment processes, often neglected in previous research. This approach offers us the opportunity to address still unresolved issues in the field, such as the administration of changes between various levels of complexity and the harmony between system direction and student independence.

## II. Theoretical Framework

The theoretical framework of our work on the design and modeling of a dynamic adaptive hypermedia system is based on several key areas that include learning theories, system adaptability, hypermedia technologies, and static and dynamic interactive system modeling approaches. This framework is based on theories and concepts from artificial intelligence, software engineering, interface customization, and pedagogy.

### A. Learning Theories and Adaptive Systems

Learning theories are at the heart of adaptive systems, as they influence how content should be structured and presented. They play a central role in the design of adaptive learning systems, especially in hypermedia environments. They provide the conceptual foundations that guide the adaptation of learning paths according to learners' profiles and needs. These theories explain how individuals acquire, process, and retain information, which helps to structure and personalize learning experiences. Learning theories include cognitive, constructivist, and behaviorist approaches, each with a specific impact on the design of adaptive learning environments [11], [23], [24]. Some of the most influential theories include:

*1) Multimodal and adaptive learning:* Multimodal learning theory proposes that learners process information more efficiently when it is presented in multiple forms, such as text, images, videos, interactive simulations, etc. This approach takes into account the fact that individuals have diverse preferences in terms of sensory modalities (visual, auditory, kinesthetic), which directly influences the design of adaptive learning systems. This theory makes it possible to design learning environments that can adapt to different learning styles [25], [26]. Adaptive hypermedia systems exploit this theory by offering a variety of teaching resources and adjusting content according to individual learners' preferences.

*2) Cognitive and constructivist theories of learning:* Cognitive and constructivist theories of learning provide fundamental foundations for the design of adaptive hypermedia systems. These theories share a common vision that learning is an active process where learners construct their own knowledge by integrating new information into their existing cognitive structures.

Indeed, cognitive theories focus on how learners perceive, process, and store information. This theory suggests that learners organize information in their long-term memory through processes such as encoding and recall [27], [28]. Adaptive hypermedia systems incorporate these principles by structuring content to avoid cognitive overload and by offering contextual help or additional explanations based on learners' answers or mistakes [11].

Constructivist theories, such as those of Piaget and Vygotsky, emphasize the active role of the learner in the construction of knowledge that allows him to build his own understanding of the world according to his experiences [23]. In an adaptive system, this implies that content must adjust according to the learner's skill level and learning style, as does modular content, which adjusts to the user's choices to meet their immediate interests or needs. By allowing the learner to actively explore resources, often in interactive environments, such as immersive environments or simulations, where the learner can manipulate variables and observe the results [11].

Cognitive and constructivist theories strongly influence the design of adaptive hypermedia systems by directing their ability to provide personalized, interactive, and contextual learning. These theories help to understand learners' needs and design tools that can dynamically adapt to their progress and preferences, enhancing the effectiveness of learning in modern digital environments.

*3) Socioconstructivist learning and adaptation:* Socioconstructivist theories emphasize the crucial role of social interactions in the learning process. These theories, inspired mainly by the works of Vygotsky and other researchers, postulate that learning is a social and contextual activity where individuals construct their knowledge through their interactions with others, cultural tools, and their environment [29], [23] . In the context of adaptive learning systems, these principles translate into the integration of interfaces, collaborative tools, and coping mechanisms that promote these interactions [11], [30].

*4) Theory of Experience-Based Learning (Learning by Doing):* The idea that individuals learn best by practicing and experiencing real-life situations is at the heart of modern approaches to learning and provides a solid basis for the design of adaptive learning systems [31], [32]. This perspective draws on several theories and pedagogical frameworks, including experiential learning, situated cognition, and constructionism. Indeed:

Kolb's theory of experiential learning proposes that learning occurs through a cycle of concrete experiences followed by reflections and applications [33]. Adaptive systems can leverage this theory to provide immersive learning experiences tailored to learners' needs. Adaptive systems use this cycle to provide interactive activities, simulations, and assessments that promote active learning.

Situated cognition suggests that learning is most effective when it takes place in contexts close to those where the knowledge will be applied [30]. Adaptive learning environments draw inspiration from this theory to create realistic scenarios, immersive tasks, or serious games where users can directly apply the skills.

According to the theory of constructionism, individuals learn by creating concrete artifacts [34]**.** Adaptive systems allow learners to build digital projects while receiving real-time feedback to adjust their actions.

The integration of real-life practices and experiences into adaptive systems is based on a sound theoretical foundation and offers an effective approach to meeting the varied needs of learners. By combining simulation, personalization and feedback, these systems promote active and relevant learning, making users better prepared to apply their knowledge in real-world contexts.

### *B. Adaptive Systems and Hypermedia*

*1) Concept and applications:* Adaptive systems in education aim to adjust learning paths according to the specific characteristics of learners, such as their level of competence, learning preferences, or learning pace. [35], [36], [37], [38]. Hypermedia systems refer to non-linear information systems where users can navigate between multimedia resources, often interactively. These systems offer great flexibility and a richer learning experience compared to traditional teaching materials (books or lectures) [39], [40], [41], [42], [43].

When the two systems are combined, they leverage digital media (text, image, video, sound, etc.) to provide user-friendly educational resources and materials. Their integration helps create powerful learning environments that provide a personalized, multi-modal experience. In these environments, the educational content is not only adapted according to the learner's profile, but is also interactive and immersive, thanks to the use of multimedia technologies. Adaptive systems seek to meet the individual needs of users by adjusting resources based on their behavior, context, and preferences. These systems are often used in e-learning, content recommendation, and knowledge management applications. Indeed, adaptive hypermedia systems are based on the idea that the user can navigate through different types of content (text, video, image, etc.), with the possibility that each resource is adjusted according to the user. Such a system must incorporate the ability to analyze user interaction and adjust content or navigation paths in real time [44], [45], [11], [46], [47].

*2) Characteristics of adaptive systems:* An adaptive system is a system that is able to modify its behavior or responses based on user interactions or characteristics. In an educational context, this includes several dimensions [48], [49], [50], [51].

Performance-based adaptation: The system adjusts content based on the learner's previous actions, such as right or wrong answers in a quiz, or how quickly they complete a task.

Preference-based adaptation: Some adaptive systems adjust the path based on a learner's learning styles (visual, auditory, kinesthetic), interests, or priorities;

Context-based adaptation: The system can adjust its behavior according to the learning context, which could include the time of day, the environment, or the device used (computer, tablet, mobile phone).

These systems use adaptation algorithms, learner profiling models, and feedback mechanisms to deliver a personalized journey.

## III. RESULTS

*1) Unified Modeling Language (UML):* Dynamic adaptive hypermedia systems (SHAD) meet the diverse needs of users by adjusting their content, navigation, and presentation based on criteria such as preferences, context, and behavior. UML modeling is a standardized and powerful approach to representing, designing, and documenting software (and sometimes non-software) systems using graphical diagrams [51]. UML makes it possible to visualize the structure, behavior and interactions of the different components of a system, thus facilitating communication between stakeholders, both technical and non-technical. UML is widely used in software engineering to analyze functional and non-functional requirements, design robust software architectures, and document existing or developing systems [52], [53], [54], [55], [56]. Through this study, we propose four diagrams, including two structural diagrams (class diagram and use case diagram) and two behavioral diagrams (sequence diagram and activity diagram).

*2) The class diagram:* The class diagram is an essential tool for modeling the static structure of software systems. By clearly defining classes, their attributes, methods, and relationships, it plays a central role in object-oriented design. This diagram is particularly useful in educational contexts, where it allows to model complex learning environments, integrating various roles (teachers, learners, courses, content, etc.). Our diagram has eleven classes.

*3) The Use case diagram:* The use case diagram is an essential tool for understanding and modeling the interactions between a system and its users. Its simplicity and expressiveness make it a powerful communication tool to identify key features of the system while ensuring that they meet the needs of the stakeholders

*4) The activity diagram:* The activity diagram is a graphical representation used in the UML language to model workflows or processes in a system. It highlights the sequence of activities, decisions, bifurcations, and synchronizations in a given process.

*5) The sequence diagram:* The sequence diagram is an essential tool for modeling dynamic scenarios in a system. By showing how actors and components interact over time, it

makes it possible to design, analyze and optimize complex processes. This methodology is particularly useful in educational contexts, where user-system interaction is crucial to provide a personalized and effective experience.

## IV. Discussion

In this section, we discuss the modeling results in the form of a description of the various proposed diagrams:

### A. The Class Diagram

The Fig. 1 presents the class diagram. It includes eleven interconnected classes, each playing a key role in meeting the educational needs of learners, teachers, and administrators, in the following format:

The LearningEnvironment class: This class is the nerve center of the learning environment system, managing the entire learning process. It has a unique identifier (id), is associated with a specific course, and stores the learner's environment preferences. The LearningEnvironment class uses these preferences to configure itself, recommend activities based on the learner's learning style (getActivityRecommendations), and evaluate the suitability of the current environment (evaluateEnvironment). For example, assessment Environment (preferences: Environment Preferences): bool: evaluates the current learning environment based on the learner's preferences and returns a Boolean value indicating whether the environment is suitable. These operations ensure that the learning experience is tailored to the needs of each learner, making LearningEnvironment the "brain" of the system that coordinates all interactions.

The LearningStyleProfile class: This class captures a learner's preferred learning style, allowing for personalized learning experience. It has a unique identifier (id) and is associated with a specific learner. The profile stores the learner's preferred learning styles (e.g., "Visual Learner", "Auditory Learner") and their preferred learning environment settings (environmentPreferences). For example, if a learner prefers a custom environment, this information will be stored in the EnvironmentPreferences attribute.

The LearningStyleProfile can be updated with new learner data (updateLearningStyles) and can determine the optimal learning environment for the learner based on their preferences (getOptimalEnvironment). This allows LearningEnvironment to tailor the learning experience to the individual needs of the learner, ensuring a more effective and engaging learning environment.

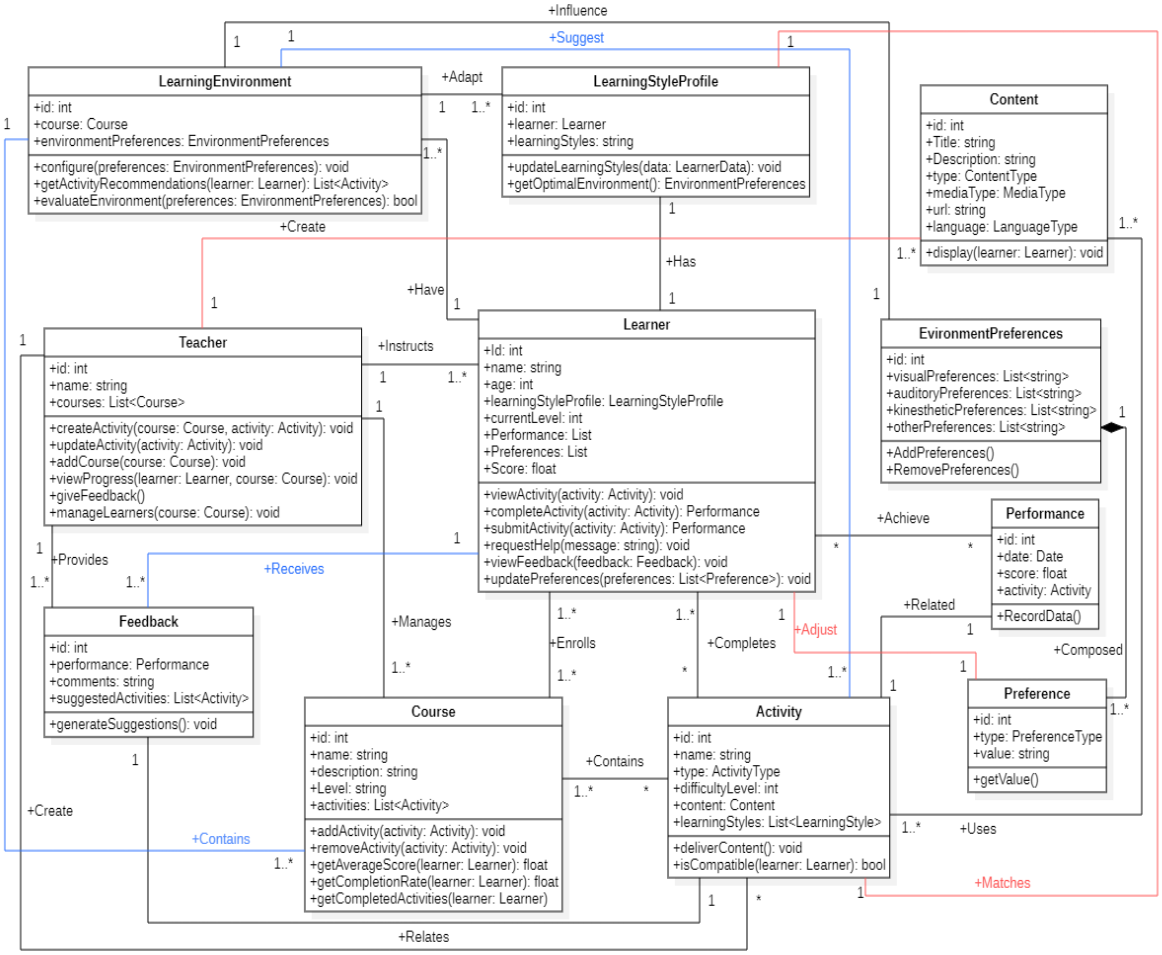

Fig. 1. Class Diagram.

Content Class: This class represents learning materials, including text, videos, images, quizzes, and other resources. The content provides the basic learning materials that learners interact with to acquire knowledge and skills. In this class, to define the different types of learning content, media formats, and languages in your system, we had to use enumerations. For example, the ContentType enumeration lists the different types of content such as "Video," "Text," and "Quiz." Similarly, the MediaType enumeration defines media formats such as "Video/mp4" and "text/html," while the LanguageType enumeration lists supported languages such as "English," "Spanish," and "French." Using enumerations for these attributes ensures that the values are consistent, readable, and easy to manage. Using enumerations makes the code more readable by providing meaningful names for the values instead of using raw strings. Enumerations also prevent invalid attributes from being accidentally assigned invalid values. Also, if we need to add new content types, media types, or languages, we only need to update the enumeration, not all the places where we use those values. Finally, you don't need to create another class with these names. For operations. Learner Void displays the content item to the learner.

The Learner class: This class represents the user of the learning environment system, the individual who learns and interacts with the system's features. The Learner can view the activities (viewActivity), complete them (completeActivity), submit them for grading (submitActivity), ask the teacher for help (requestHelp), and view the feedback provided by the teacher (viewFeedback). They can also update their preferences for the learning environment (updatePreferences). For example, a learner can complete an activity (completeActivity), receive feedback on their performance (viewFeedback), and then update their preferences (updatePreferences). The Learner is the central actor in the learning environment, engaging in activities, receiving feedback and monitoring their progress.

The EnvironmentPreferences class: This class captures a learner's preferences related to their learning styles, allowing them to customize their experience. It has a unique identifier (id) and stores a list of preferences categorized by learning style: visual (visualPreferences), auditory (auditoryPreferences), kinesthetic (kinestheticPreferences), and other (otherPreferences). For example, a learner may have visual preferences for learning via diagrams and videos, auditory preferences for listening to lectures and podcasts, and kinesthetic preferences for hands-on activities. The EnvironmentPreferences class allows you to add new preferences (addPreference) and remove existing ones (removePreference). This flexibility allows learners to adjust their preferences as needed, ensuring a personalized learning experience that aligns with their individual learning styles.

Performance class: This class records a learner's performance on a specific activity, by entering their score and the date the activity was completed. It also retains a link to the activity itself. For example, a Performance record might show that a learner scored 85% on an activity on a specific date. This class allows the system to track the learner's progress, identify areas where they may need additional support or guidance, and provide personalized feedback.

Activity class: This class represents a specific task or learning activity that learners participate in, such as taking a quiz, watching a video, or participating in a discussion. It has a unique identifier (id), a name, an ActivityType, a difficulty level, and is associated with a specific Content object. The activity also maintains a list of learning styles that it is compatible with (learningStyles). For example, a video activity may be compatible with visual learners, while a hands-on activity may be compatible with kinesthetic learners. The Activity class provides operations to deliver its content to the learner (deliverContent) and to check if it is compatible with the learner's learning style (isCompatible). This allows the system to recommend activities that are relevant and engaging for each learner, based on their individual preferences. The Activity class provides the building blocks of the learning experience, providing structured learning tasks that learners can perform to gain knowledge and skills.

Preference class: This class represents a specific preference related to a learner's learning style, allowing them to personalize their learning experience. It has a unique identifier (id), a type (PreferenceType), and a value (value). For example, a Preference object can represent a learner's preference for learning through visual aids (e.g., diagrams, videos), hearing aids (e.g., lectures, podcasts), or kinesthetic activities (e.g., hands-on projects). For the operation, getValue() retrieves the value of the preference. This would allow the system to access the preference information and use it to tailor the learning experience to the learner's individual learning style.

The Teacher Class: This class can create new activities for a specific course (createActivity), update existing activities (updateActivity), and add new courses to its list (addCourse). It can also view a specific learner's progress in a course (viewProgress), provide feedback to learners (giveFeedback), and manage learners enrolled in a specific course (manageLearners). For example, an instructor can create a new quiz activity for a specific course (createActivity), view a learner's progress in that course (viewProgress), and then provide feedback on their quiz performance (giveFeedback). The teacher plays a crucial role in guiding and supporting learners, providing instruction, feedback, and guidance to help them achieve their learning goals.

The Coursework class: This class represents a structured set of learning materials and activities that learners can enroll in to gain knowledge and skills in a specific subject area. It has a unique identifier (id), a name, a description, a level (for example, "Beginner", "Intermediate", "Advanced") and a list of activities included in the course (activities). The Course class allows you to add new activities (addActivity) and delete existing activities (remove Activity). It also provides operations to calculate a learner's average score in the course (getAverageScore), calculate a learner's completion rate in the course (getCompletionRate), and retrieve a list of activities completed by a learner in the course (getCompletedActivities). For example, an instructor can add a new activity to a course (addActivity), view a learner's average score in that course (getAverageScore), and then provide feedback on their performance based on their progress. The Courses class provides a framework for organizing and delivering learning content,

allowing learners to focus on specific areas of study and track their progress.

The Feedback class: This class represents the feedback provided to a learner by a teacher about their performance in an activity. It has a unique identifier (id), is associated with a specific performance record, and stores feedback provided by the instructor (feedback). It also keeps a list of suggested activities based on the learner's performance (suggestedActivities). The Feedback class provides an operation to generate activity suggestions based on the learner's performance (generateSuggestions). This allows the teacher to provide personalized recommendations for further learning, helping learners improve their understanding and address areas where they may need additional support.

As a summary of our proposed classroom diagram, it includes eleven interconnected classrooms, each of which plays a key role in meeting the pedagogical needs of learners, teachers, and administrators. We propose a synthesis of the main classes and their interactions:

*a) Learner-Centered Classes:*

- Learner Profile and LearningStyleProfile: Capture individual learning preferences and styles to personalize learning experiences;
- EnvironmentPreferences: Allows the configuration of specific environments adapted to sensory preferences (visual, auditory, kinesthetic);
- Performance: Tracks the learner's progress and records scores for completed activities.

*b) Content and activity classes:*

- Content: Represents multimedia learning materials;
- Activity: Defines the instructional tasks associated with the content, compatible with different learning styles;
- Course: Structures content and activities into coherent modules for learners.

*c) Interaction and feedback classes:*

- Feedback: Provides personalized feedback and suggestions to improve performance;
- Teacher: Allows teachers to create and administer courses, provide feedback, and track learners' progress.

*d) Central Class:*

- LearningEnvironment: Coordinates all interactions between classes, ensuring maximum customization and efficiency.

In conclusion, the proposed class diagram illustrates a well-defined architecture for a digital learning system, highlighting:

Personalization: With classes like LearningStyleProfile and EnvironmentPreferences, the educational experience is tailored to the specific needs of learners;

Monitoring and feedback: The system promotes scalable learning, where performance is evaluated and used to generate targeted recommendations;

Flexibility and extensibility: The use of enumerations in classes such as Content and Activity ensures that they are easy to update and maintain.

### B. The Case Diagram

In our case, the use case diagram, Fig. 2 depicts the dynamic interactions within a learning environment system, highlighting the roles of the teacher and learner.

The teacher, acting as a course creator, has the ability to design courses, develop individual activities, update existing activities, monitor the learner's progress, and provide feedback on completed tasks.

The learner, in turn, can register for courses, access and view course content, complete assigned activities, submit work for evaluation, ask the teacher for assistance, view feedback, personalize their learning experience by adjusting their preferences, and modify certain aspects of their learning environment.

The system itself plays a critical role in facilitating this interaction by recommending activities based on the learner's progress and preferences, analyzing the learning environment to identify areas for improvement, and dynamically adapting the learner's learning style based on their performance and interactivity, creating a personalized and engaging learning experience.

As a summary of our use case diagram, it models the interactions between the main actors (teachers, learners and system) within a personalized learning environment. It highlights the features and dynamic relationships needed to deliver an enriched and interactive educational experience. We mention the different roles of the main actors

*a) The teacher:*

- Content Creator and Administrator : Ability to create courses, design instructional activities, and update existing ones;
- Teacher Guide: Can monitor learners' progress, provide personalized feedback, and recommend appropriate activities.

*b) The learner:*

- Active Participant : Can view courses, complete assigned activities, and submit assignments for evaluation;
- Personalization: Can adjust learning preferences, ask for help, and view feedback to improve their experience.

*c) The system:*

- Interaction Facilitator : Recommends activities based on learners' progress and preferences;
- Dynamic Adaptation: Adjusts the learning environment and style based on learners' performance, providing continuous customization.

In conclusion, the diagram illustrates a balanced interaction architecture oriented towards personalized learning. Key features include:

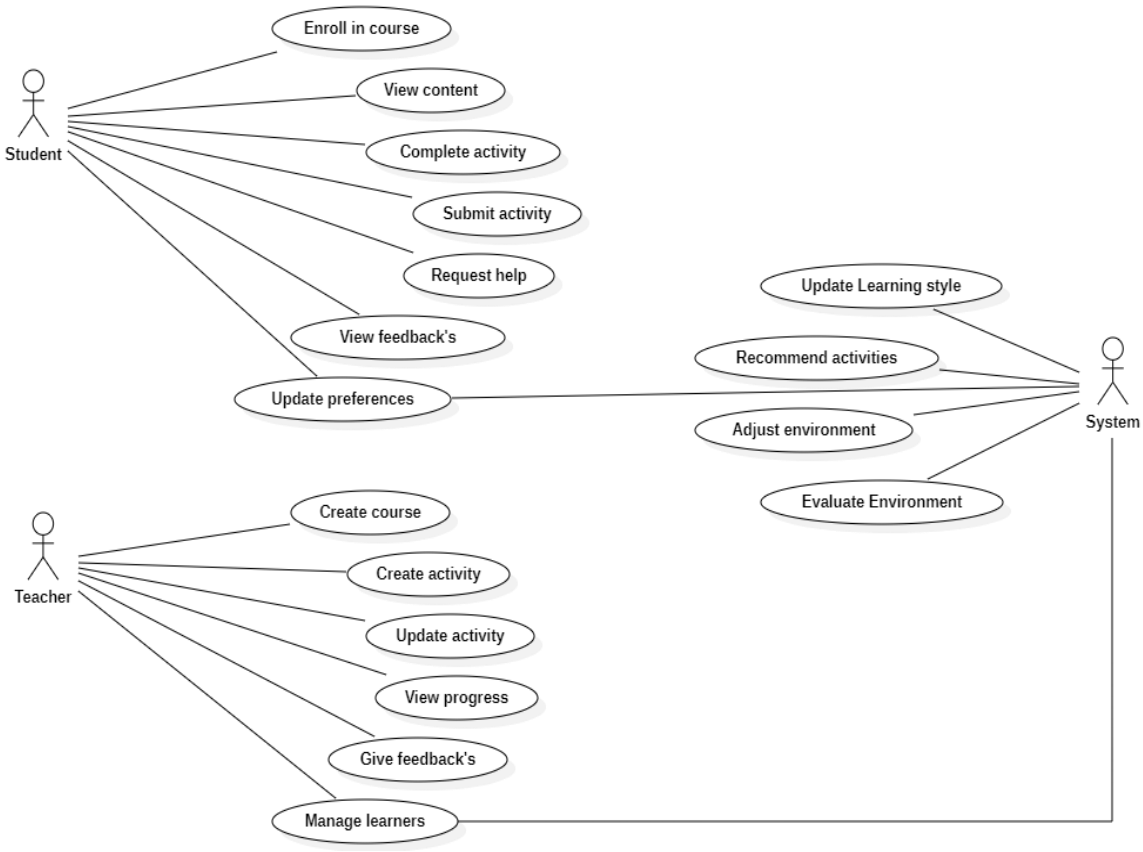

Fig. 2. Use Case Diagram.

Optimize learning with intelligent recommendations and dynamic adjustments.

Enhance learner engagement by providing an interactive and personalized experience.

Support the teacher in his or her role as a pedagogical guide with appropriate tools.

### *C. The Activity Diagram*

The Fig. 3 presents the process, which begins by retrieving the learner's learning style and preferences, which are then used to configure the learning environment according to the learner's needs. Once the environment is set up, the system provides the relevant content to the learner and recommends appropriate activities based on their learning preferences. The learner then completes the recommended activity and their performance is recorded by the system, the synchronization relationship: the "Complete Activity" and "Record Performance" activities are synchronized, which means that both must be completed before moving on to the next step where the teacher provides feedback to the learner based on their performance. Then, the system analyzes its interactions with the learning materials. Based on this analysis, the learner's learning style is updated, and the environment can be reconfigured to better meet their changing needs. The system then recommends new activities that are tailored to the learner's updated learning style and preferences, starting the cycle all over again. This iterative process ensures that the learning experience is continuously tailored to the individual needs of the learner, providing a personalized and effective learning environment.

In summary, the proposed activity diagram models a dynamic and iterative process intended to personalize learning experiences within an education system. The key steps in this process highlight the use of learner preferences and performance to continuously adapt content and activities. Key steps include:

Learning Preferences and Style Collection: The system starts by retrieving data about the learner's learning style and preferences.

Configuration of the learning environment: This data allows you to configure an environment adapted to the specific needs of the learner.

Activity recommendation: The system proposes relevant educational activities based on the preferences collected.

Performance tracking and recording: The learner's performance is recorded after each activity, allowing for objective evaluation.

Personalized feedback: The teacher provides results-based feedback, improving human-system interaction.

Interaction analysis: The system analyzes the learner's interactions with the content to adjust future recommendations.

Learning style update: Based on the data collected, the learning style is reviewed, and the environment is reconfigured to better meet the evolving needs of the learner.

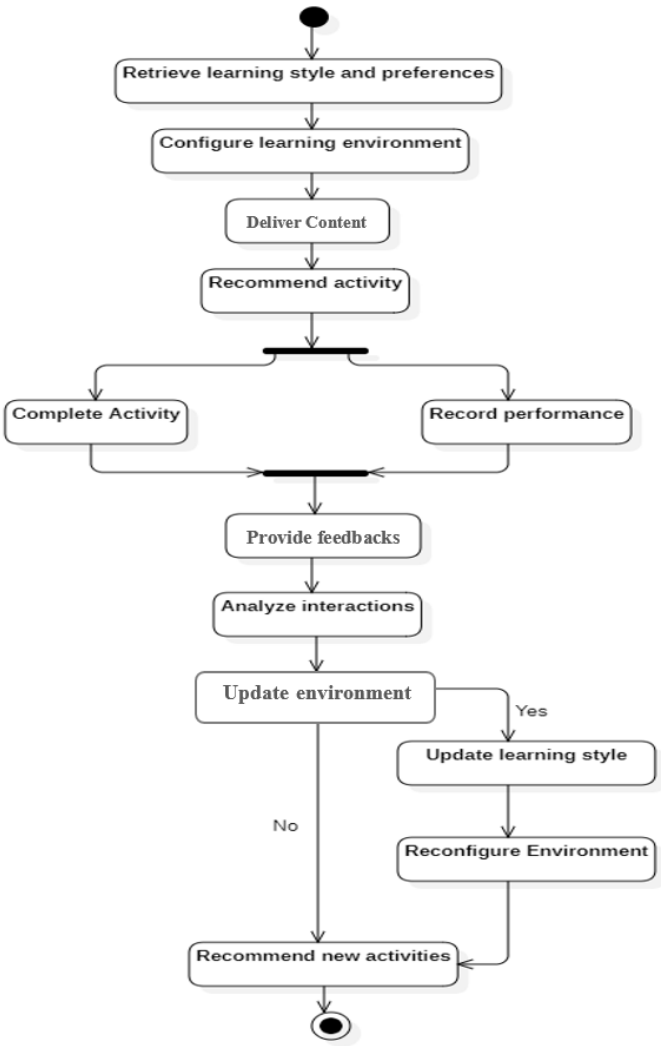

Fig. 3. Activity diagram.

This iterative process is designed to ensure continuous personalization, where each cycle improves the efficiency and relevance of the educational experience.

In conclusion, the activity diagram presented demonstrates an effective design for a personalized education system. Its strengths include:

Adaptability: Constant analysis of performance and interactions allows recommendations to be adjusted in real time.

Dynamic personalization: The iterative cycle ensures that the learning environment evolves with the needs of the learner.

The central role of the teacher: By providing qualitative feedback, the teacher plays a key role in optimizing the process.

### *D. The Sequence Diagram*

The Fig. 4 presents the sequence diagram, which illustrates the interaction between the Teacher, System, Learner, Course, Activity, Learning Environment and Performance objects.

The teacher starts by creating a new course and several activities in the system. The system stores these objects. The learner then interacts with the system, potentially accessing the course and engaging in the activities. When the learner interacts with the activities, their performance is recorded in the Performance object. The system can then analyze the learner's performance and potentially trigger an update to the learning environment, depending on the analysis. This update may involve adjustments to the learning environment or recommending new activities based on the learner's performance.

It is important to note that the teacher can also access the performance data and provide feedback to the learner through the system. This feedback can be in the form of comments, suggestions, or advice.

The diagram highlights the collaborative nature of the learning environment, where the teacher creates and manages the content, the learner interacts with the system, and the system dynamically adapts to the learner's progress and needs, with the teacher providing feedback to improve the learning process.

In summary, the sequence diagram provided highlights the dynamic interactions between the key actors and components of an education system, such as the teacher, the learner, the system, the courses, the activities, and the learning environment. This model illustrates a collaborative process:

Role of the teacher: Creation of educational content and consultation of learners' performance data.

Learner role: Interaction with the system through the proposed activities, generating performance data.

System management: Data recording, performance analysis, dynamic adaptation of the learning environment, recommendation and new activities.

Personalized adaptation: Adjustments made to the learning environment based on learners' performance, enhancing pedagogical effectiveness.

The model also emphasizes the importance of feedback from teaching, stopping learning through guidance and complementary adjustments.

In conclusion, this sequence diagram illustrates an interactive educational and adaptive ecosystem, where the teaching, the learner, and the ecosystem system for the goals of the goals optimized. With a focus on personalization and dynamic feedback, it demonstrates how an environment of environment designed within the framework of individual learners' needs while maintaining an active role for teaching.

This modeled approach is particularly relevant in contexts where digital learning requires flexibility, responsiveness and collaboration to deliver a rich and engaging experience.

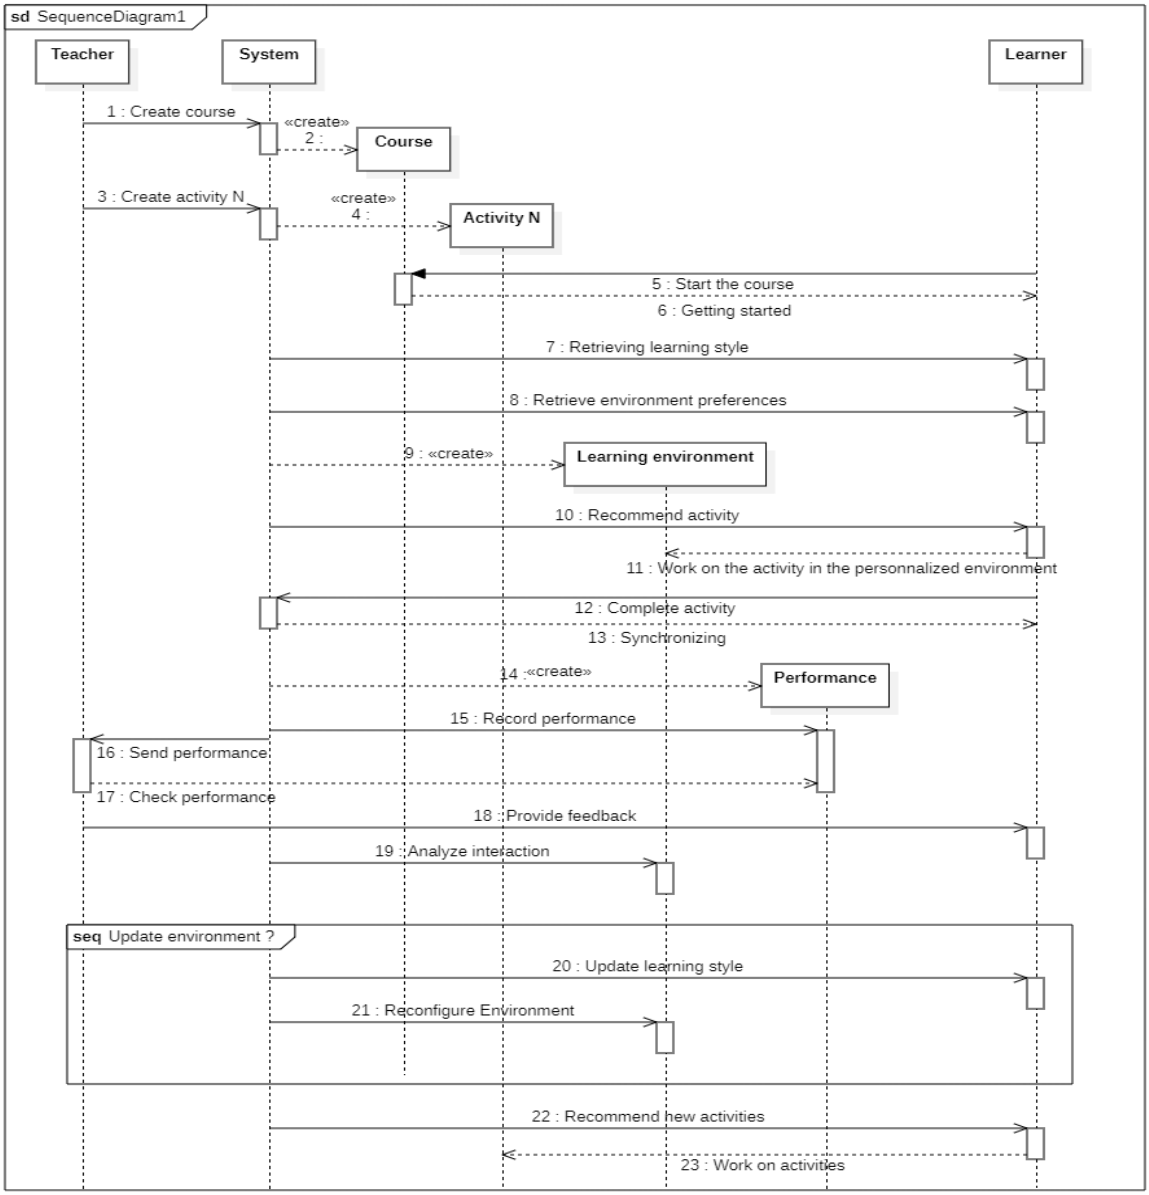

Fig. 4. Sequence Diagram.

## V. Theoretical and Practical Contributions

This research makes three main contributions to the field of adaptive hypermedia systems. On a theoretical level, it proposes an innovative conceptual model that unifies content and user interface adaptation, thus filling a gap identified in the literature [57]. The developed UML modeling framework offers a more comprehensive formalization than existing architectures [58], explicitly integrating dynamic decision-making and contextual adjustment mechanisms. From a methodological perspective, our approach demonstrates how modeling techniques can be combined with AI algorithms to create more responsive and personalized learning systems. On a practical level, this work offers concrete benefits for various stakeholders in the educational field. For learners, the system offers a more engaging experience better adapted to their individual needs, which could improve retention and success rates. For instructional designers, our model provides a structured framework for developing adaptive content without requiring advanced technical skills. Educational institutions will find a scalable solution that can be gradually integrated into their existing infrastructures, with potential implications in terms of cost reduction and optimization of educational resources.

## VI. Research Limitations

Several limitations deserve to be highlighted in this study. First, the current model relies on assumptions regarding the availability and quality of training data, which may not always be verified in real-world educational contexts. Second, although our UML approach allows for a comprehensive representation of the system, its practical implementation would require computational resources that could pose challenges in some capacity-limited environments. Another important limitation concerns the generalizability of the results: our preliminary

validation, while promising, was conducted in a specific context and should be extended to more diverse learner populations. Finally, the current system does not yet fully address aspects related to interoperability with other learning platforms, a crucial dimension for widespread adoption. However, these limitations open up interesting avenues for future research, particularly on the optimization of adaptation algorithms and integration with existing educational standards.

## VII. Suggestions for Future Research

Although the technologies and architectures of adaptive systems have evolved enormously, several challenges remain:

*1)* Next, we will develop the prototyping of the system based on the diagrams developed in this study, and ultimately develop our hypermedia system.

*2)* Current adaptive systems often use AI models, which limits teachers' and learners' confidence in the proposed recommendations. We can then develop explainability mechanisms (XAI) integrated into UML diagrams (annotations in sequence diagrams to trace adaptation decisions).

*3)* Current profiles often ignore emotional states (frustration, motivation), which are critical in pedagogy. We can therefore extend the class diagram with emotional attributes (biometric data or textual analyses).

## VIII. Conclusion

Adaptive learning systems represent a major advancement in digital pedagogy, drawing on a synergy between artificial intelligence, data analytics, and cloud infrastructures. These technologies enable the delivery of truly personalized experiences, where every element—content, pace, assessment methods, and interface—dynamically adjusts to the learner's needs. Modern microservice architectures offer the flexibility to continually integrate new capabilities, such as emotion analysis or augmented reality, while ensuring performance and security. However, this potential comes with crucial challenges: algorithm transparency, energy footprint reduction, and sensitive data protection. The future of these systems lies in their ability to combine technological sophistication with a human-centered approach, while adhering to open standards for widespread adoption. The next frontier will be developing predictive and immersive learning ecosystems that can not only adapt to learners, but also anticipate their needs throughout their educational journey.

# From Code Analysis to Fault Localization: A Survey of Graph Neural Network Applications in Software Engineering

Maojie PAN*, Shengxu LIN, Zhenghong XIAO
School of Computer Science, Guangdong Polytechnic Normal University, Guangzhou, Guangdong 510665, China

***Abstract*—Graph Neural Networks (GNNs) represent a class of deep machine learning algorithms for analyzing or processing data in graph structure. Most software development activities, such as fault localization, code analysis, and measures of software quality, are inherently graph-like. This survey assesses GNN applications in different subfields of software engineering with special attention to defect identification and other quality assurance processes. A summary of the current state-of-the-art is presented, highlighting important advances in GNN methodologies and their application in software engineering. Further, the factors that limit the current solutions in terms of their use for a wider range of tasks are also considered, including scalability, interpretability, and compatibility with other tools. Some suggestions for future work are presented, including the enhancement of new architectures of GNNs, the enhancement of the interpretability of GNNs, and the design of a large-scale dataset of GNNs. The survey will, therefore, provide detailed insight into how the application of GNNs offers the possibility of enhancing software development processes and the quality of the final product.**

***Keywords*—Graph neural networks; fault localization; code analysis; software quality***

## I. Introduction

### A. Context

Graph Neural Networks (GNNs) form branches of neural networks that generate inferences from data in a graph form. These graphs comprise nodes and edges and facilitate comprehension of intricate data dependencies and connections [1]. GNNs have recently proven to be effective in several real-world applications, including social networks, chemistry, and natural language processing [2]. Because of these characteristics, deep graphs can be applied to modeling and learning structures with complex interdependencies between them [3].

In software development, a lot of processes are inherently associated with data that can be naturally modeled using graphs. These include control flow diagrams, dependency diagrams, and an abstract syntax tree where software programs' structure and relationships are analyzed [4]. These representations are rather complex, and the traditional paradigm of machine learning often fails to identify all the necessary features and relationships within the graphs, which leads to poor results in fault localization, code analysis, and software quality evaluation [5]. However, the appearance of GNNs provides a more suitable opportunity to explore the areas of modern software development, as they can make use of the structural information encoded in these diagrams [6].

### B. Motivation

Fault location, a key component of software debugging and maintenance, is one area where GNNs have shown considerable promise [7]. Through program graphs, where programs are modeled, GNNs can identify patterns related to faulty code snippets, guiding developers to locate the precise location of the bug more effectively [8]. Similarly, GNNs can be used in code analysis for functions including code synthesis, clone detection, and refactoring by understanding the structural similarities and differences between code segments. These capabilities can significantly reduce the time and effort required to maintain and improve software systems [9].

In addition to fault location and code analysis, software quality assurance also utilizes GNNs to prioritize test cases by identifying the potential effects of each test case on the software, to predict error-prone regions based on historical data, and to enhance the overall reliability of software systems [10]. Developing applications with the help of GNNs is not without challenges, although. Scalability, interpretability, data availability, and integration with existing tools are some of the areas that need to be addressed to leverage the benefits of GNNs in this field fully.

### C. Problem Statement

Despite recent growth in the adoption of GNNs in software development, there remains a lack of complete knowledge about their proper usage within various software development processes, such as fault localization, code analysis, and quality assurance. Some of the unanswered questions include the scalability issues of GNNs, the interpretability of the results, and the integration of GNNs with traditional software tools.

### D. Research Objectives

The paper provides an exhaustive survey of recent advancements, outlines the various applications of GNNs in software development, and presents challenges and directions for this emerging field. Applications of GNNs to fault localization, code analysis, and quality assurance will be discussed, and the methods and results will be assessed. We will also analyze the practical issues faced by researchers, including those related to scalability, the need for easy-to-understand models, and the integration of GNNs with current software development tools and processes. This survey aims to identify the revolutionary promise of GNNs in software development

and to encourage more research and development in this field. The research attempts to answer the following research questions.

- What are the current applications of GNNs to essential software engineering activities like fault detection and code analysis?
- What are the comparative advantages of GNN-based approaches over traditional static and dynamic analyses?
- What are the limitations and challenges of deploying GNNs at scale in real-world software development processes?
- What are hybrid approaches that integrate classic methods with GNNs?

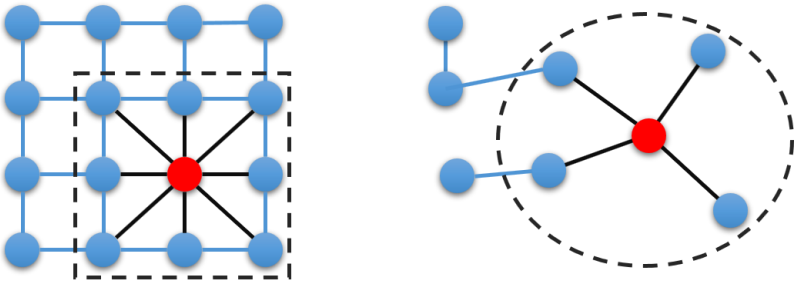
The paper is organized as follows. In Section II, a general overview of GNNs and their fundamental concepts and essential techniques is presented. In Section III, the targeted applications of GNNs in software development are presented, and their influence on fault localization, code analysis, and quality assurance is highlighted. In Section IV, directions and potential advancements are explored, and contemporary challenges to applying GNNs to software development are discussed. The paper concludes with a general discussion of its findings and contributions in Section V.

## II. Graph Neural Networks: An Overview

### A. Definition and Background

GNNs are a class of neural networks designed to perform inference on data represented as graphs. A graph G is defined as $G = (V, E)$, where $V$ is a set of vertices (or nodes) and $E$ is a set of edges connecting the nodes. Each node $v \in V$ and edge $e \in E$ can have associated features, which are essential for capturing the properties and relationships within the data.

GNNs are inspired by Convolutional Neural Networks (CNNs). Before delving into GNNs, it is essential to understand why CNNs and Recurrent Neural Networks (RNNs) cannot handle graph data effectively. As depicted in Fig. 1, CNNs operate on data with a grid structure, such as images. As an alternative, RNNs are adapted to sequences, like text.



2-D Convolution neural network  Graph neural network

Fig. 1. CNN vs. GNN.

Text data is usually stored within arrays. Similarly, matrices are optimal to store image data. But, as also depicted in Fig. 1, arrays and matrices are incapable of handling graph data. Graphs employ a special process called graph convolution. This technique enables deep neural networks to process graph-structured data and yield a GNN directly. It can be seen that masking techniques and filtering operations are employed to convert images to vectors. However, classical masking techniques are not suitable for graph data input, as depicted in the rightmost image.

In contrast to classical static and dynamic analyses that act based on pre-declared rules or symbolic rationale, GNNs use data-driven learning to extract patterns from graph-structured program representations. This learning feature enables GNNs to generalize across codebases, identify patterns that are not easily specified by human-created rules, and evolve to respond to new domains without requiring human intervention. Some static analyses incorporate feedback loops (e.g., via CEGAR) but fail to include the ongoing, end-to-end learning process that allows GNNs to fine-tune with additional data.

### B. GNN Evolution

Significant development has occurred in applying neural networks to graph-structured data over the years. Early approaches, like the use of recursive neural networks, laid the foundation by leveraging the same set of parameters repeatedly over the graph structure [11]. Nonetheless, this was limited by the fact that the approaches were unable to efficiently adopt arbitrary graph structures.

The advent of Graph Convolutional Networks (GCNs) was a groundbreaking development. GCNs generalize the concept of convolution to graph-structured data, rather than grid-like data (like images). By operationalizing convolution over the neighborhood of every node, GCNs are especially useful for node classification and link prediction tasks [12]. Following the success of GCNs, several different classes of GNNs have emerged:

- Graph Attention Networks (GATs): These networks utilize an attention mechanism that weighs the importance of various node features [13]. This will enable the model to emphasize the most significant components of the graph and improve performance in cases where some nodes have greater influence.
- Graph Recurrent Networks (GRNs): Utilize recurrent network architectures to process graph data. Such networks are ideally suited to sequential graph data, where the ordering of the node or edge is considered significant [14].

- Graph Autoencoders (GAEs): Used in unsupervised learning from graph data. GAEs encode graph data into a latent space and reconstruct the graph, finding applications in graph generation and detecting anomalies [15].

### C. GNN Training

Training a GNN involves learning parameters to identify patterns and relationships within the graph data. Training can be supervised, unsupervised, or semi-supervised based on the availability of labeled data.

- Supervised learning: Trains the GNN based on labeled graph data, and the labels are associated with the node, edge, or graph level [16]. The model is trained to make predictions of labels based on input features and graph topology.
- Unsupervised learning: The GNN is trained to embed the graph data without labels. Techniques such as graph autoencoders and contrastive learning are typically employed to obtain informative representations of the graph [17].
- Semi-supervised learning: It combines labeled and unlabeled data to improve the learning process [18]. In cases where labeled data is limited, and many real-world applications face this issue, this is especially helpful.

## III. GNN Applications in Software Engineering

GNNs have become a universal tool in software development, leveraging the inherent graph-like characteristics of a wide variety of software artifacts. As shown in Table I, various GNN architectures possess distinct strengths and applications, making them suitable for a wide range of software development activities. Varying from code analysis and fault location to software quality assurance, numerous paths can be modeled, analyzed, and optimized using GNNs to enhance software systems. This section focuses on the application of GNNs in software development, with a particular emphasis on the various architectures employed to address complex issues and enhance the effectiveness and efficiency of software development.

TABLE I. Summary of GNN Architectures

| GNN architecture | Key features | Strengths | Typical applications in software engineering |
|---|---|---|---|
| GCN | Applies convolution operations to graph data and aggregates information from neighboring nodes. | Efficient in collecting local neighborhood information. | Node classification, fault localization, code analysis. |
| GAT | Utilizes attention mechanisms to weigh the importance of neighboring nodes' features. | Allows the model to focus on the most relevant parts of the graph. | Code summarization, bug prediction, and test case prioritization. |
| GRN | Incorporates recurrent neural network architectures for processing graph data over time. | Effective for sequential graph data, capturing temporal dependencies. | Analyzing execution traces, dynamic analysis. |
| GAE | Encodes graph structures into a latent space and reconstructs the graph for unsupervised learning. | Useful for graph generation and anomaly detection. | Detecting code clones unsupervised code analysis. |
| Message Passing Neural Network (MPNN) | Generalizes GNNs with a message passing framework where nodes iteratively exchange messages. | Flexible in handling different types of graph structures and tasks. | Program dependency analysis bug prediction. |
| Spatial-Temporal GNN (ST-GNN) | Models both spatial and temporal aspects of graph data, handling dynamic changes in the graph. | Captures both structural and temporal evolution of graphs. | Real-time monitoring of software systems and dynamic code analysis. |

### A. Fault Localization

Fault location is a critical part of software maintenance and debugging, aiming to identify the precise fault locations within a software program [19]. Fault location strategies are typically based on static or dynamic analysis techniques, which can be time-consuming and may not always yield accurate results. The capability of modeling and learning with graph-structured data offers a promising solution for enhancing fault location by leveraging the intrinsic software program structure. As demonstrated in geotechnical engineering, domain-specific modeling in the field of geotechnical engineering [20] shows that adapting models to consider material heterogeneity and structural anisotropy enhances prediction capability. Similarly, task-specific tuning of the GNN architecture may be necessary for code analysis and fault localization.

Trained static analysis approaches, such as data flow analysis, control flow analysis, and abstraction-based analysis, have long supported software fault detection and code understanding. However, they are typically based on predefined rules and cannot handle dynamic software behaviors or loosely formatted source code. By contrast, GNN-based analysis learns to operate directly from the graph structure of code and execution traces. This can guide the model to detect subtle, non-local relations and semantic structures that are not detectable with earlier analyses. Additionally, various program representations, such as Abstract Syntax Trees (ASTs), Program Dependency Graphs (PDGs), and runtime traces, can be combined by GNNs within a single learning framework, providing a richer and more dynamic understanding of software systems.

*1) Program dependency graphs:* PDGs are a popular format adopted in fault localization [21]. PDGs encode the interdependencies between various components of a program, in the form of data dependencies (which variables depend on) and control dependencies (which statements cause others to execute). In encoding a program in a PDG, GNNs can examine the interrelations between various facets of the code.

The GNNs can be trained with the PDGs to identify patterns related to defective code snippets. For example, a GNN can be trained to identify nodes within the PDG that are likely to have faults by learning from historical fault data. This requires

encoding node and edge features within the PDG and applying a message-passing function to consolidate information passed by the neighboring nodes. The node representations generated can be used to make predictions about the presence of a fault at each node.

*2) Abstract syntax trees:* ASTs embody the program's syntax structure. Each node within an AST denotes a construct in the source code, e.g., a variable, an operator, or a control-flow statement [22]. ASTs give a hierarchical representation of a program, reflecting the nested relationships between program components.

ASTs are amenable to GNN applications that aid in fault localization by leveraging code semantics and structure. By applying GNNs to processed ASTs, faults can be identified based on syntactic patterns, effectively learning to recognize error-prone code patterns or patterns or combinations of patterns. This can be especially useful for identifying faults that result from intricate relationships between various code components.

GNNs capture and leverage the hierarchies and control flows embedded in code, such as nested loops, conditional statements, and recursion. Such patterns of code are common to frequent bugs, including infinite loops, misbounds in loops (i.e., off-by-one errors), faulty exception handling, and misuse of break and continue statements. Through examination of ASTs and control flow graphs, GNNs can identify recurring structural patterns that relate to such bugs. For instance, GNNs can identify anomalies in nesting within loops that suggest missing base cases or faulty exit conditions within recursive routines, enabling early detection of runtime faults and logical errors.

*3) Dynamic analysis with execution traces:* Most software defects have their roots in faulty state initialization or incorrect state transitions, and not all of them are explicitly programmed in the static code structure [23]. To overcome this, execution traces, runtime event representations in graph format, can be fed to GNNs to capture variable updates, function call sequences, and conditional jumps. Traces embed time-dependent relationships and implicit transitions between states, enabling GNNs to capture patterns related to erroneous program execution. In cases where more implicit information is lacking, hybrid GNNs can take both static data (e.g., ASTs or PDGs) and dynamic data (e.g., memory dumps, execution traces) to create a more holistic fault detection system.

*4) Empirical studies and results:* Numerous empirical studies have demonstrated the effectiveness of GNNs in fault localization. The investigations typically involve training the GNNs with known faulty programs and subsequently with unknown programs. Precision, F1-score, and recall are metrics used to measure a model's capability to identify faulty portions of code correctly.

For instance, one experiment may involve training a GNN using a database of Java programs based on their PDGs and ASTs to make predictions about fault locations. The outcome can demonstrate that a GNN outperforms conventional fault localization methods, such as SBFL, by yielding more accurate and precise fault predictions. Such experiments highlight the tremendous potential of GNNs to enhance the efficiency and efficacy of fault localization processes within software development.

Fig. 2 illustrates a novel fault-localization technique that utilizes a graph-based representation of faulty feeders. Fault detection accuracy is improved by integrating data from different data sources, like geographic information system (GIS) databases and supervisory control and data acquisition (SCADA) systems. GIS databases provide important information about network topology, protection device locations, and electrical characteristics. SCADA systems provide real-time operational data such as protection device activations, fault currents and voltage measurements. To further increase the intelligence of the system, data from customer information systems (CIS) and station oscillographs can be integrated.

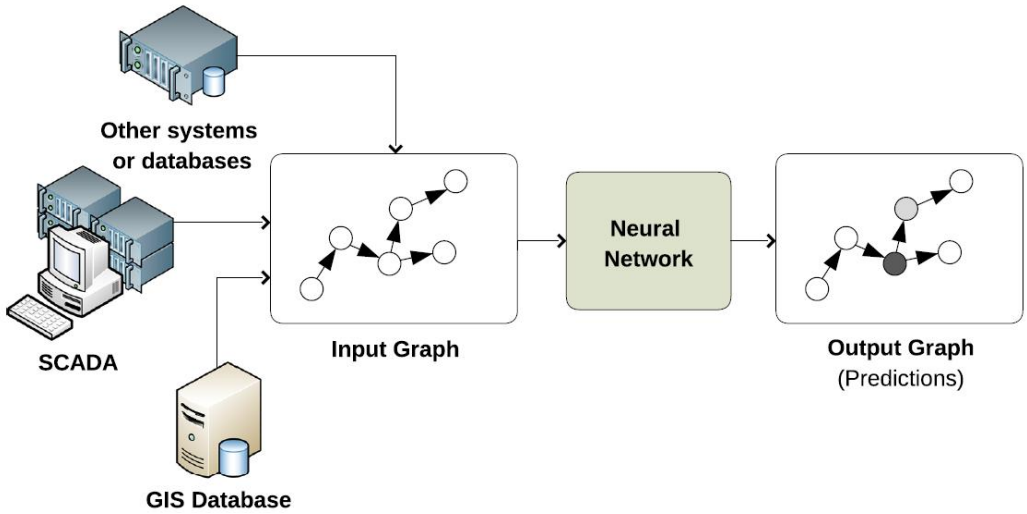


Fig. 2. A novel fault localization technique using graph-based representation.

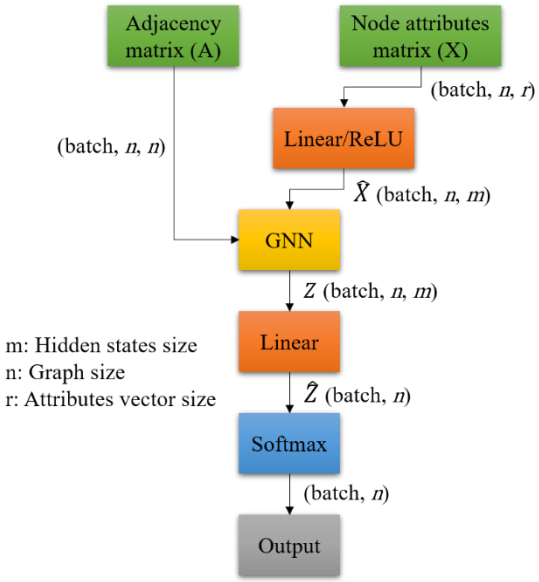

Fig. 3. Neural network model processing graph.

The graph-based representation is then fed to a neural network model, as shown in Fig. 3. The input to this model is the adjacency matrix A and the attribute matrix X of the graph. The first stage employs a linear combination with a rectified linear unit (ReLU) activation function, which projects the input features into a new space of representations. The size of the hidden states and the number of input attributes are hyperparameters that influence the model's capacity and generalization capability.

$$\hat{X} = ReLU(W_{in}X + b_{in}) \quad (1)$$

In the subsequent layers, a GNN is employed to extract the dense relationships between the nodes in the graph. A GNN propagates information over the graph sequentially, allowing the model to capture relationships between non-immediately adjacent nodes. The number of propagation steps is a hyperparameter that controls how much the model supports long-term dependencies. But more steps of propagation correspond to increased computational cost and memory demand.

The network computes a score for every node via a linear combination and passes this to a softmax function, where the scores are normalized to a probability distribution. This is to calculate the probability that a node is the location of the fault.

### B. Code Analysis

Code analysis involves a set of activities to comprehend and enhance the quality of software [24]. Some of the activities involved include code summarization, clone detection, and refactoring, among others. Given that GNNs can capture the structural and relational aspects of code, they provide substantial benefits in accomplishing the above activities by generating more precise and informative findings compared to the conventional methods.

*1) Code summarization:* Code summarization necessitates the creation of compact, natural language descriptions of code functionality [25]. This is a fundamental requirement of documentation and codebase browsing over large and intricate codebases. GNNs can leverage the structural information contained in ASTs and other code graphs to enhance code summarization.

By representing code in a graph format, GNNs can capture the structural and relational information that is crucial to the functionality of code snippets. As a case in point, a GNN can be trained to embed the AST of a code snippet and create a summary by translating the learned representation back into natural language. This enables the model to comprehend the relationships and contexts within the code, providing more accurate and relevant summaries.

*2) Clone detection:* Code clone detection aims to identify similar or duplicated code sequences within a codebase. Clones are a source of maintenance issues and potential errors and are therefore especially essential to detect for software quality [26]. Clone detection can be greatly aided by the use of GNNs that focus on structural similarities in the graph representations of code.

Clone detection can be performed by representing code snippets as graphs (e.g., PDGs, ASTs) and applying GNNs to extract their structural representations. A comparison of the structural representations will enable the identification of similar code fragments, despite their syntactic differences. This feature is especially helpful in Type-3 clone detection, where the code snippets are syntactically different but semantically the same.

*3) Code refactoring:* Code refactoring rearranges previously written code without altering its external functionality, making the code more readable, maintainable, and efficient [27]. Identifying refactoring areas and recommending suitable transformations are the two fundamental challenges of refactoring. GNNs can help refactoring by inspecting the code structure and extracting patterns that suggest that refactoring is warranted.

The GNNs are trained over refactoring histories and can detect code smells and anti-patterns that are usually amenable to refactoring. By encoding code graphs and applying a GNN to operate over them, the models can suggest refactoring opportunities based on the detected patterns. A GNN, for instance, will detect duplicated code, long sequences of methods, or highly coupled classes that are amenable to refactoring. The employment of GNNs in code refactoring has made refactoring proposals more accurate and beneficial. Developers employ such models to automate refactoring suggestions and provide optimal recommendations.

*4) Empirical studies and results:* Empirical studies on applying GNNs to code analysis issues have demonstrated their effectiveness and superiority over traditional alternatives. For example, studies on code summarization using GNN-based methods have demonstrated improved performance in generating accurate and concise descriptions of code. Likewise, studies on clone detection have demonstrated that clones can be

effectively identified by GNNs, yielding increased precision and recall compared to traditional methods.

Empirical studies of code refactoring have demonstrated the capability of GNNs to identify sophisticated code smells and provide useful refactoring suggestions. The studies are carried out with benchmark data sets and actual codebases and yield evidence of the utility of GNNs in code analysis.

Fig. 4 shows a hybrid GNN framework for code analysis. This framework integrates both static and dynamic graph representations to improve code summary learning. It consists of four main components: (1) Retrieval-Augmented Static Graph Construction, which augments the original code graph with retrieved code summary pairs to improve feature learning; (2) Attention-based dynamic graph construction, where a global attention mechanism enables message propagation between arbitrary pairs of nodes, enabling more flexible relationships; (3) Hybrid GNN (HGNN), which combines information from static and dynamic graphs through hybrid messaging to enrich node representations; and (4) Decoder, which uses an attention-based LSTM model to generate a code summary from the learned representations. This framework effectively leverages both structural and dynamic aspects of code to improve the quality of code analysis and summarization tasks.

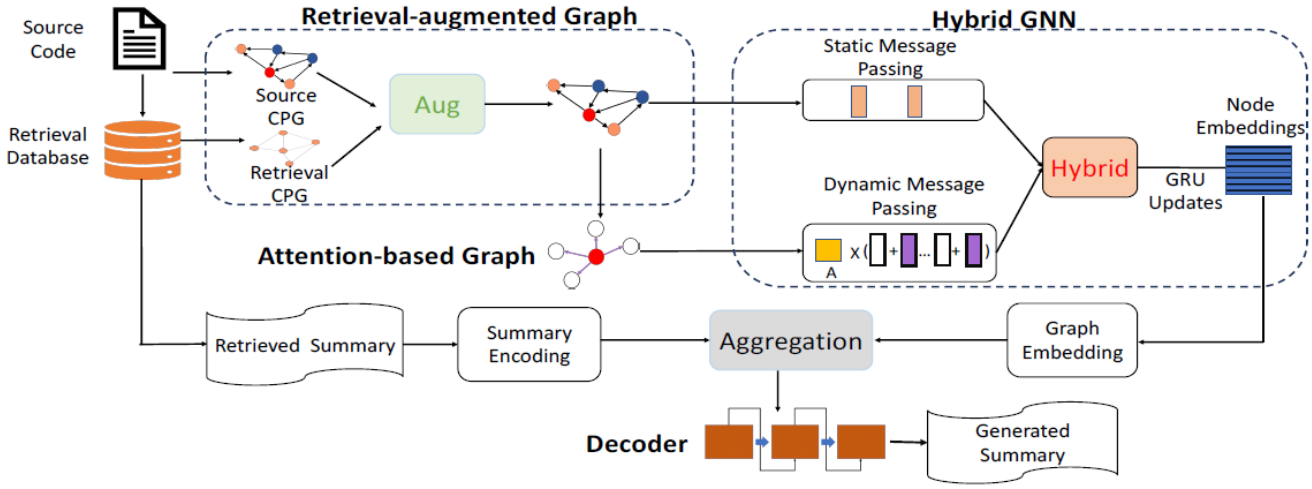

Fig. 4. Hybrid GNN framework for code analysis.

### C. Software Quality Assurance

Software Quality Assurance (SQA) is an essential software engineering process that ensures software artifacts meet the quality standards expected of them [28]. This includes activities that are related to testing, verification, validation, and bug prediction. GNNs have demonstrated tremendous potential to improve many aspects of SQA by extracting structural information embedded in software artefacts to make more accurate predictions and provide better insights.

*1) Test case prioritization:* Test case prioritization involves sequencing test cases in a way that prioritized test cases are run first [29]. This becomes more significant with regression testing, where a full test suite must be rerun, and for that, there are time and cost factors. Sorting test cases can be facilitated with the help of GNNs by identifying the relationships and dependencies within the software.

By representing the software and test cases as a graph, where code components serve as nodes and dependencies or interactions are represented as edges, the areas of the software most likely to be affected by recent updates can be identified using GNNs. This helps the model concentrate only on test cases that correspond to the key areas. Experimental studies have demonstrated that test case prioritization with the aid of GNNs can facilitate fault detection much earlier, thereby enhancing the efficiency and effectiveness of the test process.

*2) Bug prediction:* Bug prediction entails predicting where and when defects are likely to occur in various areas of the software. Proper bug prediction can be useful in better allocating resources and targeting quality assurance activities to the areas of the code that are at the highest risk of defects [30]. Bug prediction can be significantly improved by utilizing GNNs that analyze the structural characteristics of software and learn from bug data over time.

Software can be modeled using different types of graphs, such as dependency graphs or co-change graphs, where nodes and dependencies, or co-change relations, represent software components, and edges represent these relationships. GNNs can process such graphs to identify patterns that predict bug-prone locations. For instance, a GNN can be trained using past data to make predictions about the likelihood of defects in various components based on their structural characteristics and change history. Experiments have established that bug prediction models based upon GNNs are more precise and detailed compared to conventional statistical and machine-learning-based models.

*3) Code review assistance:* Code reviews are an essential aspect of the software development life cycle, ensuring improvement in code quality through peer review. GNNs can be leveraged to assist with code reviews by suggesting and detecting potential issues, as well as recommending enhancements [31]. Based on analyzing the code structure and

the relationships between various code components, GNNs can identify problematic areas.

For example, code smells, security issues, or compliance with the coding standard can be detected by GNNs. By treating the code and its dependencies as a graph data type and learning patterns typical of high-quality code, GNNs can provide developers with real-time feedback during code reviews. This not only accelerates the review process but also helps ensure a superior level of code quality.

*4) Empirical studies and results:* Empirical research on applying the use of GNNs in software quality assurance has produced promising evidence. In test case prioritization, research has shown that GNNs are capable of achieving better fault detection at earlier stages of the test process than other prioritization techniques. In bug prediction, research has shown that predictions made by GNNs are more accurate, enabling teams to address issues proactively.

While helping with code review, we have observed that systems utilizing GNNs enhance review efficiency and effectiveness by identifying a higher percentage of issues without manual examination. Such research involves real-world data sets and compares them with standard practices to validate the benefits gained from applying GNNs.

## IV. Future Directions

The application of GNNs in software engineering is still in its early stages, with numerous areas to explore and develop in the future. With the improvement and development of GNNs, their capability to revolutionize various facets of software engineering, including fault localization, code analysis, and software quality assurance, becomes increasingly evident. Table II outlines some of the key areas to explore and refine in the future, providing a systematic overview of the essential directions that will drive the continued improvement and deployment of GNNs within this discipline.

TABLE II. Key Areas for Future Research and Development in GNNs for Software Engineering

| Future direction | Description | Expected outcomes |
|---|---|---|
| Advanced GNN architectures | Development of more specialized and scalable GNN architectures to handle large-scale, complex software systems. | Improved efficiency and effectiveness in handling vast data and intricate relationships. |
| Explainable AI for GNNs | Creation of methods to enhance the interpretability and transparency of GNN models. | Increased trust and adoption of GNNs through clearer, more understandable predictions. |
| Real-world applications | Conducting empirical studies and applying GNNs in real-world software projects. | Validation of GNN effectiveness, identification of strengths and weaknesses, and wider industry adoption. |
| Integration with development tools | Seamless integration of GNNs into IDEs and CI/CD pipelines. | Enhanced real-time analysis, automated testing, and proactive bug detection. |
| Large-scale and high-quality datasets | Creation of comprehensive and publicly available datasets for GNN training and evaluation. | Improved performance of GNN models through access to diverse, well-annotated datasets. |
| Cross-disciplinary research | Encouraging collaboration across computer science, network science, cognitive science, and other disciplines. | Innovative solutions, improved scalability, and interpretability of GNNs in software engineering. |

### A. Advanced GNN Architectures

To fully realize the potential of GNNs in software development, more advanced and specialized architectures of GNNs need to be designed. Currently, architectures such as GCNs and GATs show promise but also face limitations when dealing with large and complex software systems. In their next steps, researchers should strive to develop scalable architectures of GNNs that can meaningfully interact with the vast amounts of data and intricate relationships found in large software projects.

Moreover, hybrid approaches that integrate GNNs with additional machine learning methods or domain-specific knowledge could further enhance their effectiveness. For example, integrating NLP methods with GNNs could enhance code documentation and abstraction. Additionally, integrating standard static and dynamic analysis tools with GNNs could result in more accurate fault localization and bug prediction.

### B. Explainable AI for GNNs

One of the biggest hindrances to the large-scale adoption of GNNs in software development is the interpretability of their outputs. Developers and stakeholders should be able to know the rationale behind the predictions and suggestions made by the GNN models. As a result, there is a vital need to develop explainable AI methods for GNNs.

Research in this area should aim to develop methods that yield transparent and comprehensible explanations of the predictions made by a GNN. Mechanisms such as attention, feature importance analysis, and visualization tools can be designed to ensure that GNNs are more transparent and their output is more interpretable. As the explainability of GNN models improves, developers are more likely to have confidence in and efficiently utilize them in their development process.

### C. Real-world Applications

To demonstrate the utility of GNNs in software development, it is necessary to conduct extensive empirical research and evaluate GNN models against real-world software projects. Such research should be conducted using different datasets and programming languages, as well as various development platforms and software fields. By comparing GNN models with conventional methods and measuring their efficiency in actual cases, the strengths and limitations can be identified, allowing for targeted areas for improvement.

Collaborating with industrial partners to implement GNNs in real-world applications can yield valuable insights and feedback. Industry case studies that demonstrate successful GNN implementation also have the potential to present practical applications and promote broader adoption.

### D. Integration with Development Tools

For GNNs to be successfully employed in software development, they must be integrated seamlessly into existing development tools and processes. This includes developing usable interfaces, plugins, and APIs that enable developers to integrate GNN-based recommendations and analysis into their everyday workflows.

Future efforts should be directed toward building Integrated Development Environments (IDEs) and Continuous Integration/Continuous Deployment (CI/CD) pipelines that leverage the power of GNNs. This integration would enable real-time analysis, automated testing, and early bug detection, resulting in a more efficient and higher-quality software development process.

Outside of single-use cases, GNNs have the potential to extend to pre-existing analyses by delivering rich semantic outputs, such as code representations from summarization or similarity measures in clone detection. Those representations can be incorporated into symbolic or data-flow analysis to enhance inference procedures. Semantic embedding, for instance, can be used as a feature input in path prioritization during symbolic execution. Code clone clusters can be utilized to facilitate property propagation in verification. This inter-model synergy presents a hybridized strategy that blends the accuracy of conventional tools with the adaptability and abstraction power of deep learning algorithms.

### E. Large-Scale and High-Quality Datasets

The effectiveness of GNN models is highly dependent upon having large, high-quality datasets to train and test them. Software engineering makes the development of such datasets problematic due to the heterogeneity of software projects and the necessity of accurate annotations. Future research should be directed toward developing well-rounded and public datasets that span a large gamut of software engineering activities.

Joint initiatives between academia, industry, and open-source projects can curate and pool valuable datasets. Such datasets should comprise different representations of graphs, such as program dependency graphs, execution traces, abstract syntax trees, and labeled data to perform activities like bug prediction, code summarization, and fault localization.

### F. Cross-Disciplinary Research

Software engineering is a multidisciplinary field that combines components of computer science, mathematics, and engineering. Increased cross-disciplinary research will be encouraged in the future to harness the power of GNNs in software engineering. Concepts and methods borrowed from network science, data mining, and cognitive science can offer new insights and approaches to enhance GNN applications.

Joint research endeavors have the potential to provide innovative solutions to intricate problems in software development. For example, concepts borrowed from cognitive science enhance the usability and interpretation of GNN models, while innovations in network science facilitate the design of more scalable and efficient GNN architectures.

## V. Conclusion

This research highlighted the significant potential of GNNs for revolutionizing software engineering, particularly fault localization, code analysis, and software quality assurance. With the capability to tap into the graph-structured information of software data, GNNs provide better insights and more precise predictions than classical alternatives. Our survey identified the current applications of GNNs to software issues in areas of interest, outlined key research and development directions, and suggested areas to address these challenges. Some of these include improving GNN architectures, enhancing model transparency, and integrating GNNs into development tools. By overcoming such challenges and increasing interdisciplinary research and development, the research highlights the potential of GNNs to enhance software development efficiency, accuracy, and reliability significantly. As technology improves in GNNs, the application of this technology to software engineering has the potential to yield better-quality software products, marking a groundbreaking improvement in the field.

***Abstract*—Quantum computing is progressing at a fast rate and there is a real threat that classical cryptographic methods can be compromised and therefore impact the security of blockchain networks. All of the ways used to secure blockchain like Rivest–Shamir–Adleman (RSA), Elliptic Curve Cryptography (ECC) and Secure Hash Algorithm 256-bit (SHA256) are the characteristic of the traditional cryptographic techniques vulnerable to attack by quantum algorithms: Shor's and Grover's algorithms: can efficiently break asymmetric encryption and speed up brute force attacks. Because of this vulnerability, there exists a need to develop an advance quantum resilient blockchain framework to protect the decentralized ledgers from the future threats of the quantum. This research proposes Post-Quantum Cryptography (PQC), Quantum Key Distribution (QKD) and Quantum Random Number Generation (QRNG) as a formidable architectural integration, to fortify security of blockchain. Classical encryption is replaced with PQC, QKD with secure key exchange by detecting eavesdropping, and QRNG with improving cryptographic randomness to remove the predictable key vulnerability. Only with a small loss of transaction efficiency, we increase transaction encryption accuracy, key exchange security, and resistance to quantum attacks. In this quantum enhanced blockchain design, the idea is to preserve the decentralization, transparency and security and at the same time overcome the future quantum threat. By going through rigorous analysis and comparative evaluation, we demonstrate that the approach saves blockchain networks from the emerging quantum risks to make sure that the decentralized finance, smart contracts and cross chain transactions.**

***Keywords*—Quantum resilience; blockchain security; Quantum Key Distribution (QKD); Post-Quantum Cryptography (PQC); Quantum Random Number Generation (QRNG); decentralized ledger**

## I. INTRODUCTION

Existing blockchain security measures, which mostly rely on traditional cryptographic methods like Rivest–Shamir–Adleman (RSA) and Elliptic Curve Cryptography (ECC), are under grave danger due to the rapid advancement of quantum technology [1]. Because factoring massive amounts and the separate logarithm procedure thwart effective assaults made possible by traditional computation, conventional cryptography using public keys is still safe [2]. The ability of quantum computers to run Shor's algorithm transforms these classical cryptographic methods into obsolete systems which fail to protect blockchain networks. The brute-force attack acceleration ability of Grover's algorithm causes current cryptographic hash functions deployed on blockchain networks to operate less effectively [3].

Researchers are investigating quantum-resistant cryptographic techniques to guarantee blockchain networks' long-term security and resilience. Security experts designed quantum-proof encryption mechanisms which achieve both high resistance against quantum attacks and efficient computing capacity [4]. Blockchains benefit from quantum-enhanced security measures through advanced solutions comprised of both Quantum Key Distribution (QKD) and Quantum Random Number Generation (QRNG). These methods use quantum mechanics principles to boost blockchain defense systems [5]. Blockchain architectures show little readiness to face the upcoming post-quantum time period. The research analyzes quantum-based technologies to strengthen blockchain infrastructure thus protecting its core decentralized structure and transaction security while preserving sustainability alongside expanded quantum processing capabilities.

Recent blockchain safety techniques hinge on cryptographic constructs which quantum computers without difficulty ruin thru [6]. Quantum computers goal the important thing cryptographic

primitives of PoW and PoS by using breaking their safeguards via Shor's and Grover's algorithms. Both consensus models rely upon cryptographic hash functions similarly to public-key cryptographic primitives [7], [8]. Cryptography flaws from quantum computing attacks can bring about predominant security incidents by using allowing transaction tampering together with double-spending and signature-disruption incidents [9]. Data protection relying on Post-Quantum Cryptography (PQC) techniques such as hash-based and lattice-based encryption face serious challenges. which include additional computational charges and scalability issues [10]. Current efforts to integrate those cryptographic processes into blockchain networks face initial demanding situations because they want enormous processing power that diminishes operational performance and slows transaction processing pace. Current momentum closer to quantum-resistant cryptocurrency interactions confronts developers and industries with a big barrier to move operational obstacles between quantum cryptography and conventional blockchain systems [11]. Existing blockchain systems fail to mix quantum cryptography properly with consensus mechanisms so they have significant weaknesses regarding decentralized security performance alongside scalability and operational speed. Blockchain networks need essential traits to combat modern quantum-primarily based protection vulnerabilities for their lengthy-time period operational sustainability.

The studies develop a quantum-secure blockchain gadget thru post-quantum cryptographic protocol implementation along quantum protection optimization elements. The studies develop cryptographic techniques which guard blockchain transactions from quantum threats however additionally maintains green consensus mechanisms and scalability overall performance. Through the implementation of quantum-resistant encryption alongside quantum key distribution and quantum-safe consensus protocols this study strives to build a secure decentralized blockchain architecture. Blockchain network developers pursue a goal of longevity so these platforms remain functional and secure for the quantum computing era ahead.

The approach described in this research completely addresses blockchain network vulnerability to quantum threats by integrating quantum-secure encryption methods with security technology advancements. The work advances blockchain security through enhanced data preservation and decentralized systems which establish protected relationships in diverse application contexts. The research provides concrete methods to build blockchain systems with quantum safety applications across financial sectors and supply chain activities and digital assets management services.

- Innovative Quantum-Resilient Encryption Mechanism that introduces PQC to overcome classical encryption weakness by employing lattice based vs. RSA & ECC cryptographic algorithms for security against quantum attacks in the foreseeable future.
- Quantum Key Exchange undertakes QKD to patch up vulnerabilities of conventional key exchange protocols and gives us a provably secure way to avoid eavesdropping via and MITM attacks.
- QRNG enhancements increases entropy scores and the security of the blockchain from brute force attacks and the predictability vulnerabilities.
- Balancing Security with Performance Using Minimal Overhead achieves high transaction throughput (50 TPS), reduced encryption time (2.8 ms), improved security accuracy (99.9%), thereby, enabling smooth blockchain operation with quantum threat.

The proposed study is organized into multiple sections. The introduction in Section I provides information on the background analysis while also establishing the problem statement plus research value. A review of studies focuses on assessing blockchain security risks which quantum threats poses are shown in Section II and III. The research details implementation steps for quantum-resistant cryptographic systems and security components is shown in Section IV. The framework's execution performance is explored in the Section V before the final summary in Section VI and Section VII.

## II. Literature Review

Sahu and Mazumdar, [12] investigates quantum computing's deep effects on cryptographical practices by analyzing the vulnerabilities that can breach traditional methods including RSA and ECC along with introducing quantum-resistant cryptographic systems. An introduction to quantum mechanics fundamental concepts including superposition together with entanglement establishes the framework for quantum computing and cryptography. Research evaluates Quantum encryption algorithms by studying the benefits of QKD protocols and PQC procedures which show promise for quantum age communication security. The study highlights the importance of developing strong, quantum-proof cryptography technology as a matter of utmost urgency which offers protection against imminent quantum technology threats targeting sensitive data.

BCNs represent a groundbreaking system that builds trust for untrusted environments. Because of its complex nature service LCM of network components benefits from BCN implementation which provides transparent secure network operations. Quantum attacks represent a security threat to BCNs. Future quantum computers will create security vulnerabilities in modern blockchain systems built with Public Key Infrastructure (PKI) cryptographic foundations. ZEYDAN et al., [13] This research investigates operational approaches for managing network services across multiple administrative domains. The proposition combines BCNs with PQC mechanisms to monitor network service instantiation stages while guaranteeing enhanced security protection. Our analysis utilizing N-th degree Truncated polynomial Ring Units as an NTRU example illustrates how Quorum achieves better average time-to-write performance than Ethereum and Hyperledger BCNs. We analyze evaluation results about PQC algorithm and BCN coexistence as well as their potential future applications for network service orchestration across multiple administrative domains at the paper's conclusion.

Alyami et al. [14] explored the nature and concept of quantum computing in respect to software security, highlighting the imminence of powerful quantum computers as a threat to current cryptosystems. The definition and description of

quantum computing in software security will be covered in this essay. They employ various encryption techniques or algorithms for software security in order to protect our financial institutions, medical equipment, military hardware, aircraft, ships, cars, navigators, and more. However, the development of the massive quantum computer is expected to cause the collapse of many cryptosystems. Google just created the 53-qubit Sycamore Processor. These developments portend the arrival of a massive quantum computer in the future. The current cryptosystem would become outdated since quantum computers are capable of solving cryptographic algorithms. Therefore, given the current state of quantum cyber security, it is essential to concentrate more on rigorous study. The primary difficulties in the quantum age will be finding cryptographic techniques that meet security, usability, and adaptability requirements without compromising user confidence. "Software durability" the main goal of the study herein is a reliability feature that is related to the ability to complete a work within time. Lifespan of software and web applications will be greatly affected by a comprehensive evaluation of security aspects. last in the life of quantum computing.

Harinath et al., [15] aims to improve the safety of multimedia data—which includes photos, video, and audio—obtained from Internet of Things devices. Innovative technologies like blockchain and quantum cryptography are investigated as potential means of enhancing multimedia security and protecting privacy. Data transmitted throughout unprotected internet connections is prone to possible eavesdropper interception, alteration, or unapproved distribution. Data breaches will have critical consequences, consisting of substantial economic and reputational damages. Secure verbal exchange among IoT smart gadgets depends on powerful key control. Effective key management systems are required to guarantee first rate network performance, even when the community can be blanketed from quite a few threats by the safety measures in place. As IoT devices proliferate, significant amounts of records are accumulated from many sources. However, IoT devices are vulnerable to malicious assaults due to their inherent limitations in memory and processing capacity. Thus, to hold the framework stable through the years, frequent security audits, updates, and compliance to steady implementation standards are required.

Conventional encryption methods are severely threatened by quantum computing, compromising the integrity of blockchain networks and sensitive digital communications. Various studies have explored the vulnerabilities of classical encryption, the potential of PQC, and the role of QKD in securing data. Blockchain networks, while offering transparency and decentralization, remain susceptible to quantum attacks. This literature review examines emerging quantum-resistant algorithms, the integration of PQC with blockchain, and security frameworks leveraging quantum cryptography to mitigate quantum-induced threats.

## III. Problem Statement

RSA and ECC alongside conventional cryptographic systems will become obsolete because quantum attacks render them weaker with each advancement of quantum computing technology. Blockchain networks built on PKI experience cryptographic breaches that threaten both data integrity and transaction security. Current research shows blockchain networks require secure frameworks with PQC together with QKD and QRNG to maintain resilience against threats. Current implementations of blockchain struggle with three main limitations: high computational costs and limited scalability combined with issues of integration with conventional blockchain systems [12]. The deployment of post-quantum cryptographic tools to blockchain applications faces constraints because of the systemic obstacles that arise from classical to quantum-resistant system implementation [15]. The research establishes a resilient blockchain system that integrates PQC and QKD built upon QRNG to protect ledger systems against long-term security threats and data integrity attacks.

## IV. Methodology

An integrated methodology unites three quantum security elements: QKD for secure key sharing and PQC for quantum-proof encryption and QRNG for generating true random numbers. Researchers have used these quantum techniques to replace traditional blockchain security protocols within the study for improved transaction security. The study exposes the framework to simulated testing which assesses its ability to remain quantum-resistant while evaluating performance and scalability against quantum cryptographic attacks in decentralized ledger systems. Fig. 1 illustrates the quantum algorithms securing the blockchain. It outlines processes from initiating a transaction through post-quantum encryption, making use of quantum random number generation, key exchange, secure consensus, and secure mining to final, robust transaction validation and addition of blocks to the ledger.

### *A. Data Collection*

The proposed dataset from Kaggle provides comprehensive historical blockchain data in the Kaggle proposed dataset delivers comprehensive block records and transaction metadata and hash pointers that generate deep insights into blockchain security evaluation [16]. The public data from BigQuery provides updated dataset information every ten minutes which maintains smooth data interconnectivity with historical pricing information. The authors use this dataset as their baseline for evaluating how QKD and PQC and QRNG affect blockchain security. Quantum techniques applied to this study lead to improved transaction security and amplified encryption power and randomized key production. The dataset's real-time updates and extensive historical coverage make it ideal for evaluating quantum-resilient frameworks, ensuring robustness against potential quantum attacks while maintaining decentralization, transparency, and security in blockchain transactions.

### *B. Data Preprocessing*

The conversion of unprocessed information into analytic-geared up shape via cleansing and transformation features starts with statistics preprocessing. The method includes missing value dealing with and normalization while extracting functions and integrating facts to provide improved first-class and overall performance in modeling.

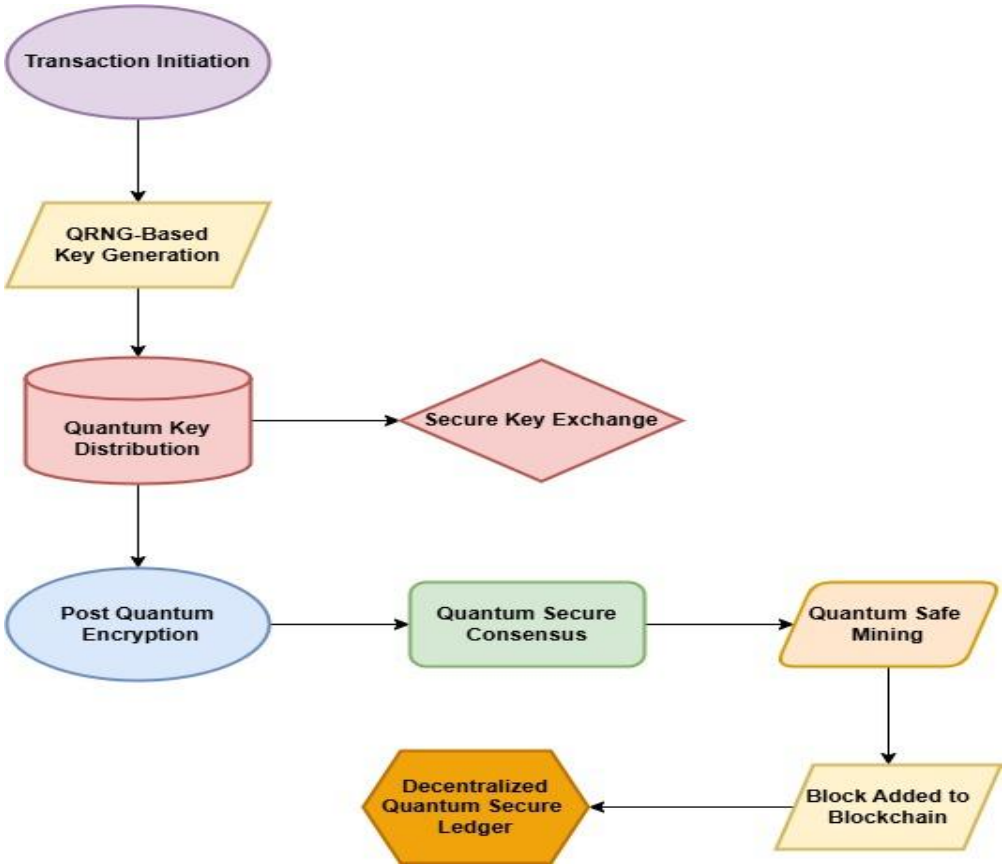

Fig. 1. Flow of leveraging Quantum Algorithms to fortify transactional security.

*1) Data cleaning:* The procedure of facts cleansing consists of finding and fixing troubles in database entries which include missing statistics blended with damaged or repeated data [17]. Blockchain transaction facts calls for verification of record statistics validity at the side of authentication of complete transaction details in each block [18]. The dataset achieves consistency and reliability by casting off misguided facts that consists of wrong block hashes alongside incomplete transactions or faulty facts entries. The reliability of quantum cryptographic protocols depends on having clean statistics due to the fact method anomalies undermine both protection assessments and testing results.

*2) Normalization:* When implementing normalization on records one applies preferred scale differences to numerical values among zero and 1 which incorporates transaction quantities and timestamp measurements [19]. Regular distribution of records makes certain capabilities don't by chance have an effect on cryptographic protocols. PQC and QKD demand standardized numerical values to deliver appropriate key introduction and encryption functionality. The guidance of statistics requires this critical step to allow integration with quantum technology at the same time as keeping steady balanced cryptographic operations.

*3) Timestamp alignment:* The timestamp of blockchain transactions operates in real-time with the protocol updates that stem from QKD and QRNG. When implementing quantum security features for blockchain transactions the timestamps need to fit the time frame of cryptographic protocol upgrades to function correctly [20]. Through accurate timestamp alignment blockchain transactions can stay well synchronized with quantum cryptographical key alternate and encryption [21] while random range generation guarantees operations proceed in line with configured schedules which reduces feasible timing-based threats.

### *C. Quantum Cryptographic Threat Assessment*

The Quantum Cryptographic Threat Assessment section analyzes blockchain cryptographic mechanisms across their exposure to quantum computing threats after preprocessing data collection. This research aims to duplicate quantum-based attacks to establish how the blockchain reacts to possible quantum-based threats against its cryptographic protection methods. Shor's Algorithm and Grover's Algorithm allow researchers to evaluate blockchain security through transactional testing as well as framework cryptographic algorithm examination during this section. The evaluations through these quantum algorithms provide direct insights into current cryptographic mechanism vulnerabilities also, the blockchain platform is quantum-resistant, and thus post-quantum cryptography methods must be used. The working process of the Quantum Cryptographic Threat assessment below,

*1) Simulating quantum attacks on blockchain:* The researcher conducts virtual attacks using quantum algorithms to examine current cryptographic systems. The analysis examines the potential weakness of blockchain cryptographic protocols against quantum computing attacks. Analysis of current blockchain encryption systems comprising ECDSA, RSA, and SHA-256 employs simulation tests to assess quantum computing vulnerability against these methods.

*2) Evaluation of quantum impact on security:* Quantum algorithms emulate realistic quantum attack types to identify security flaws that affect cryptographic blockchain protection mechanisms throughout transactions. These virtual experiments utilize quantum computing theory to show ability blockchain security risks that quantum computing should create.

*3) Implementation of quantum algorithms:* The assessment explores Shor's Algorithm to find weaknesses in public key encryption (ECDSA and RSA) whereas Grover's Algorithm achieves quicker assaults targeting hash capabilities (SHA-256). Tests on blockchain data using those algorithms determine blockchain device vulnerabilities and typical quantum resilience.

*a) Shor's algorithm in quantum cryptographic threat assessment:* Attacks towards encryption algorithms like RSA and ECDSA are based totally on Shor's approach, a quantum method that successfully factorises huge numbers. The safety of these algorithms in classical cryptography depends on the issue of calculating discrete logarithms ECDSA or factoring huge numbers RSA, each of which might be thought to be impossible for large keys using conventional computer systems. However, a quantum computer would possibly doubtlessly crack these encryption methods because Shor's Algorithm resolves those problems in polynomial time [22].

The important concept of Shor's Algorithm is to thing big integers successfully the usage of quantum operations. Mathematically, the key equation involved in Shor's algorithm is given in the Eq. (1),

$$Finf\ Period\ \big(f(x)\big) = period\ of\ a^{x} \quad mod\ N \tag{1}$$

where, $N$ is the integer, which is the modulus in RSA, the algorithm aims to find its prime factors $p$ and $q$, Once the period is found, use it to calculate the prime factors of $N$.

*b) Grover's algorithm:* For unstructured explore troubles, Grover's approach is a quantum approach which is gives a quadratic speedup. Grover's method is used in the blockchain context to evaluate the safety of hash algorithms like SHA-256. Cryptographic hash values that guarantee the integrity of blockchain information are produced the use of SHA-256. By accelerating the look for a hash collision, Grover's Algorithm may also allow an attacker to adjust blockchain records or find out distinct inputs that bring about the same hash output [23].

The purpose of a quantum problem related to Grover's Algorithm helps in finding for something specific in an unorganized dataset. Grover's Algorithm speeds up the process of looking for a pre-photograph or an accident in which the same hash is produced by two distinct sources SHA-256.

$$f(x) = 0 \tag{2}$$

For a hash function like SHA-256, Grover's Algorithm affords a speedup inside the search for a pre-image or a collision. Given a function, Grover's algorithm searches for an input $x$ such that explained in the Eq. (2). For SHA-256, this means searching for an input that produces a specific hash value or for. The algorithm reduces the number of operations needed to find a solution from $2^{256}$ to $2^{128}$, a significant speedup.

### *D. Integration of Quantum-Resilient Cryptographic Systems*

Incorporation of Quantum-Resilient Encryption Strategies, as used in the suggested research, is the procedure of using quantum-safe encryption processes to fortify blockchain systems' integrity and guarantee that they are safe from the possible dangers offered by quantum computing. Due to the fact that traditional blockchain cryptography methods like RSA, ECDSA, and SHA-256 are susceptible to quantum censure (as discussed in the Quantum Cryptographic Threat Assessment section) [26], integrating quantum-resilient methods becomes critical. The goal is to design and implement a quantum-resilient blockchain framework that incorporates QKD, PQC, and QRNG to safeguard blockchain data and transactions. This section explains how these quantum-resistant techniques are integrated with the blockchain to guarantee reliability in a future allowed by quantum technology.

*1) QKD Integration:* Using the no-cloning principle and quantum entanglement—both principles in quantum mechanics—QKD can ensure secure key exchange of encrypted data over an uncertain communication medium. Unlike other cryptographic systems, transferring keys integrity is compromised when they are monitored. QKD ensures that measurement or interception of the quantum states will be safe (in transit) will disturb the system and be detectable [24]. To assess the effectiveness of QKD in blockchain security, two important metrics are introduced,

*a) Quantum Bit Error Rate (QBER):* After performing QKD, both parties have a shared key that is unknown to any third-party attacker. This key can be used to encrypt or sign blockchain transactions, ensuring the integrity and confidentiality of data stored in the blockchain. The QBER derived in the Eq. (3),

$$QBER = \frac{No.of\ tot\ errors\ in\ key\ exchange}{Tot\ bited\ exchange} \tag{3}$$

*b) Key Rate (r):* The key rate measures the speed at which secure keys are generated and exchanged, factoring in transmission efficiency and the QBER. A higher key rate allows for faster, more efficient secure communications in the blockchain network.

The QKD process involves:

- Quantum Entanglemen: This helps to exchange quantum states between Alice (sender) and Bob (receiver).

- Detection of Eavesdropping: Any interference will disturb the key, alerting both parties to potential tampering.

*2) PQC: future danger presented by quantum computers.* These systems can be compromised by quantum attacks, especially those originating from Shor's Algorithm, that can successfully address the mathematical problems at the core of conventional cryptography techniques like RSA, ECDSA, along with Diffie-Hellman [25]. The core concept of the PQC was given below,

*a) Lattice-based cryptography:* Lattice-based cryptographic systems, like LWE or Ring-LWE, provide strong security guarantees and are considered resistant to both classical and quantum computing attacks. Highly secure assurances are offered by lattice-based cryptography networks, such as LWE or Ring-LWE, which are thought to be impervious to assaults from both conventional and quantum systems.

*b) Code based cryptography:* Code-based schemes, such as McEliece encryption, rely on error-correcting codes and are also resistant to quantum algorithms. They are based on decoding random linear codes, which is a problem that quantum computers struggle to solve.

*c) Hash based cryptography:* Reliable hash functions, the foundation of hash-based identities like XMSS, are difficult for quantum computers to crack. They offer a quantum-steady alternative for digital signatures.

The PCQ ensuring Bitcoin transaction safety in a quantum-enabled international, it integrates with QKD and QRNG to offer strong, quantum-resistant security. QKD establishes a secure key among users, and PQC encrypts the transaction facts the usage of quantum-resistant algorithms like lattice-primarily based encryption, making sure that even if quantum computer systems smash traditional encryption, the transaction remains safe. Additionally, QRNG generates simply random numbers, making sure that keys generated for PQC encryption are unpredictable and steady. This multi-layered approach, combining secure key exchange via QKD, quantum-resilient encryption via PQC, and randomness from QRNG, protects Bitcoin transactions from quantum threats, ensuring long-term security and confidentiality for blockchain networks.

*3) QRNG:* The QRNG plays an important position in improving transaction safety in the quantum-resilient blockchain framework. QRNG ensures the generation of really random numbers, which can be important for cryptographic processes, which include key generation and encryption. This integration of QRNG with QKD and PQC provides a couple of layers of defense.

*a) Quantum-resilient key generation:* QRNG generates really random numbers that are used in each QKD (to exchange steady keys) and PQC (to encrypt transaction facts).

*b) Unpredictability in encryption:* By the use of QRNG-generated keys for PQC, encryption schemes stay secure even against quantum computing assaults, as the randomness prevents attackers from exploiting predictable keys.

QRNG plays a pivotal position in improving security in quantum-resilient blockchain structures through ensuring the era of actually random numbers for cryptographic processes. In QKD, QRNG-generated numbers provide the randomness wished for secure key era, ensuring that the shared key among participants is unpredictable and proof against attacks, which is derived in Eq. (4),

$$K_{QKD} = GenKey(r_{QRNG}) \quad (4)$$

In which, the $r_{QRNG}$ is a random wide variety generated with the aid of QRNG is used to create a steady key. Similarly, in PQC, QRNG enhances encryption through ensuring that non-public keys used for algorithms like lattice-based encryption stay random and secure. This secret's used to encrypt transaction records MMM, ensuing in ciphertext in the Eq. (5),

$$C_{PQC} = Enc(M, K_{QRNG}) \quad (4)$$

where, M is the encrypted transaction data.

The integration of QKD, PQC, and QRNG in blockchain, in particular for Bitcoin transactions, creates a strong and quantum-resilient protection model to protect towards ability quantum computing threats. Here's how the mixing of these three strategies works together to beautify Bitcoin transaction safety. QKD securely exchanges keys among parties the usage of quantum principles, making sure any eavesdropping strive is detectable. QRNG generates truly random numbers, ensuring unpredictability in key generation for both QKD and PQC.

### *E. Blockchain Protocol Enhancement with Quantum Security*

The enhancement of blockchain protocols with quantum security involves several modifications to ensure future-proof transaction and data security. Transaction signing can be strengthened by using PQC-based multi-signature authentication, where quantum-resistant algorithms ensure that signatures are secure even against quantum adversaries. For smart contracts, it is possible to implement quantum-safe hash chains so that data from contracts remains safe and confidential by using quantum-resistant hashing algorithms, such as those used by code-based or hash-based encryption. As far as agreement algorithms are concerned,

Using the no-cloning principle and quantum entanglement—both principles in quantum mechanics—QKD can ensure secure key exchange of encrypted data over an uncertain communication medium. Unlike other cryptographic systems, transferring keys integrity is compromised when they are monitored. QKD ensures that measurement or interception of the quantum states will be safe a Secure PoS can be implemented, where the stake authentication process is enhanced by QKD, guaranteeing the security of stake ownership confirmation even when quantum technology are present. +Furthermore, PoW mining can be made fairer by utilizing QRNG to generate unpredictable nonces for mining, ensuring that the randomness used in block mining is secure against quantum attacks. Interoperability between different blockchains can be facilitated by implementing QKD-based cross-chain communication, allowing secure key exchange and data transfer across quantum-resistant blockchains. Lastly, it is essential to ensure PQC signature compatibility with legacy blockchain nodes, which can be achieved by creating hybrid systems that

allow both quantum-resistant signatures and traditional signatures to coexist. These protocol-level modifications together guarantee that blockchain systems can function securely in a quantum-enabled future.

Algorithm: Leveraging Quantum Algorithms to Fortify Transactional Security in Decentralized Ledgers

Input: Incoming transaction data

Output: Securely encrypted and signed quantum-resistant transaction added to blockchain

```
# Step 1: Secure Key Exchange using QKD
def qkd_key_exchange():
    key = generate_quantum_key()
    if detect_eavesdropping():
        abort_exchange()
    return key

# Step 2: Quantum-Resilient Encryption using PQC
def pqc_encrypt(transaction, key):
    encrypted_transaction = apply_post_quantum_encryption(transaction, key)
    return encrypted_transaction

# Step 3: Generate Secure Random Number using QRNG
def generate_secure_random_number():
    return quantum_random_number_generator ()

# Step 4: Secure Transaction Signing
def secure_transaction(transaction):
    key = qkd_key_exchange()
    encrypted_data = pqc_encrypt(transaction, key)
    signature = sign_transaction (encrypted_data, generate_secure_random_number())
    return signature

# Step 5: Blockchain Protocol Enhancement
def blockchain_protocol():
    while True:
        new_transaction = get_incoming_transaction()
        signed_transaction secure_transaction(new_transaction)
        append_to_blockchain(signed_transaction)
```

## V. Result and Discussion

In this Research, primary strength lies in incorporating QKD, PQC, QRNG to augment the encryption, key exchange and random numbers on the blockchain. With this, the mean transaction accuracy improves by 14.9% and the data protection is also stronger. Too, it also raises by 58% and thus becomes quantum attack resistant to further threats. This method is implemented by using python. This helps improve the fairness and interoperability security of a blockchain, making it more decentralized and secure overall. Providing small transaction speed loss in exchange for higher resilience, reliability, and long-term quantum security, the overall system is achieved.

### A. Performance Evaluation

Security and performance of the proposed quantum resilient blockchain framework based on PQC, QKD, and QRNG is greatly enhanced. This further increase transaction speed to 50 TPS, which is more than double the speed of conventional ECC-RSA blockchain, which is 20 TPS. While, this does pose a loss of 120% more computational cost but also revealing the tradeoff between security and efficiency. Encryption time becomes slightly more at 2.5 ms to 2.8ms while decryption time increases from 5 ms to 6.7 ms for a robust encryption with little to no latency. The system provides stronger quantum resistance at higher levels of computational overhead than existing systems. The Table I illustrates the performance metrics of proposed model.

TABLE I. Performance Evaluation

| Metrics | Traditional Blockchain (ECC-RSA) | Proposed PQC + QKD + QRNG |
|---|---|---|
| **Speed (TPS)** | 20 TPS | 50 TPS |
| **Computational Cost** | 1.05 | 120% higher than ECC-RSA |
| **Encryption Time** | 2.5 ms | 2.8 ms |
| **Decryption Time** | 5 ms | 6.7 ms |

### B. Expected Improvements in Blockchain Security

The further integration of QKD, PQC and QRNG makes the blockchain security more robust by introducing lattice based PQC encryption from 256 bit to 512 bit making it quantum resistant. A QKD guarantees the secure exchange of a key with QBER $\leqslant$ 5 % from eavesdropper and intrusion. Entropic improvements in key generation randomness on the surface are made from 0.85 entropy to 0.99 entropy, and in doing so helps make cryptographic keys unpredictable. However, diminishment of speed from 50 TPS to 48 TPS is a result of quantum encryption overhead but the added security counters the setback. Also, smart contracts, interoperability, and mining fairness are improved making the quantum secure blockchain ecosystem.

In Fig. 2, the radar chart illustrates the comparison of blockchain security metrics using and without applying quantum methods. Quantum-resilient systems (blue) lead over traditional systems (purple) in encryption resilience, key exchange security, randomness, interoperability, and fairness, albeit trading off on transaction speed with better quantum-oriented safeguards.

### C. Encryption and Key Exchange Security Comparison

Blockchain security relies on 256-bit encryption using RSA, SHA-256, and ECDSA in traditional blockchain whereas quantum resilient blockchain enhances this with 512-bit lattice based PQC and XMSS to provide a higher quantum resistant. While with traditional systems key exchange is eavesdropped, QKD in quantum secure blockchains is immune from intrusion and detects any intrusion of key transmission. The QBER is $\leqslant$ 5% which confirms quantum key exchange integrity. Furthermore, traditional technique for key generation is based on pseudo randomness which has entropy score of 0.85; however, the keys generated by QRNG has a score of 0.99 which makes them unpredictable and secure. Collectively, they improve blockchain security providing quantum threat resistance as well as confidentiality and integrity.

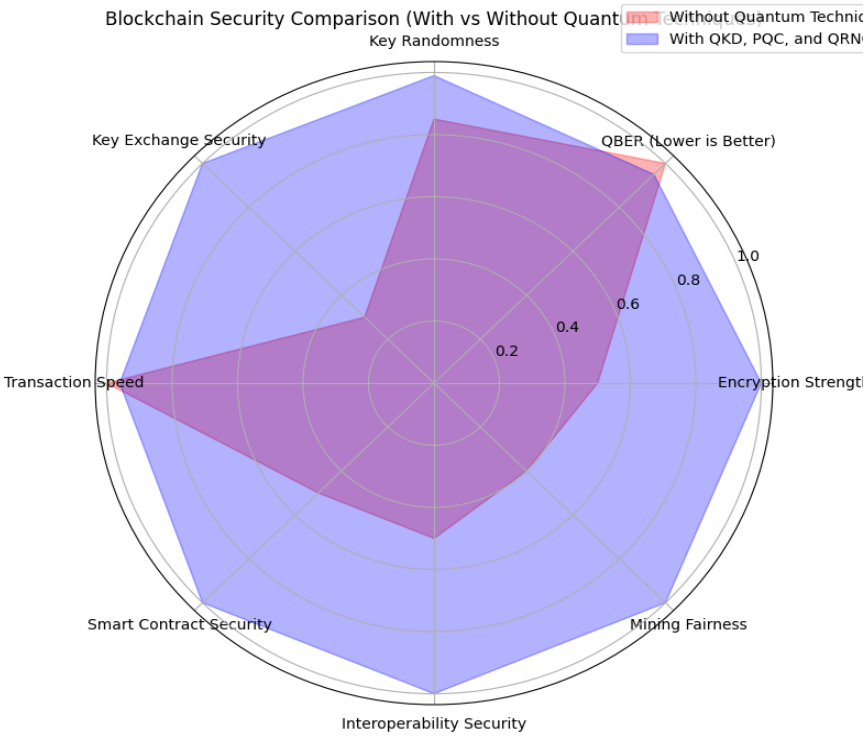

Fig. 2. Blockchain security comparison.

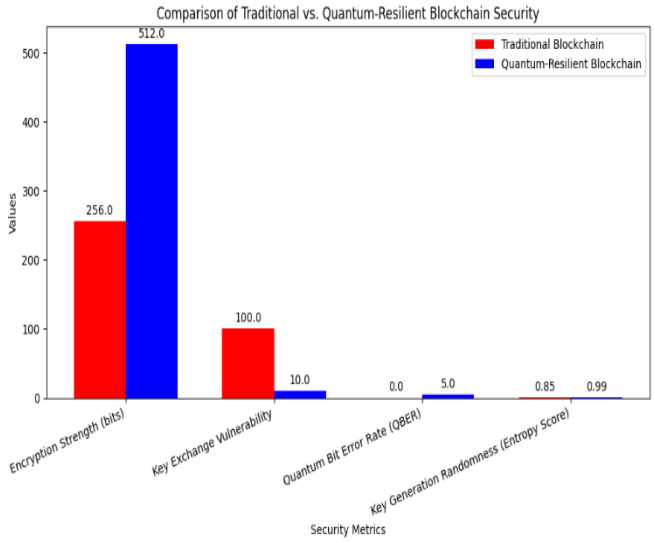

Fig. 3. Comparison of traditional vs. quantum resilient blockchain security.

This Fig. 3 contrasts classical and quantum-resilient blockchain security, indicating quantum models provide tighter encryption, minimized key exchange susceptibility, lower QBER, and increased entropy scores — providing general better resistance to quantum attacks than standard blockchain systems.

### *D. Blockchain Transaction Performance and Security*

The implementation of quantum-resilient techniques such as QKD, PQC, and QRNG impacts various blockchain performance and security metrics. When it comes to TPS, it is slightly less than 50 to 48 TPS, because the quantum encryption has some overhead in its computations. Just like the Transaction Finality Time, which is increasing the time from 10 seconds to 12 seconds, but adding a small delay to improve security. Quantum safe hashing strengthens the smart contract security by transitioning the existing medium level into a high level. Pseudorandom nonce generation, that is, the mining fairy can be biased when using predictable pseudorandom output generators, but is fair when considering unpredictable QRNG. QKD based key exchange is used to aid in cross chain transaction security which raises the level of interoperability security from medium to high to secure communications across different blockchain networks.

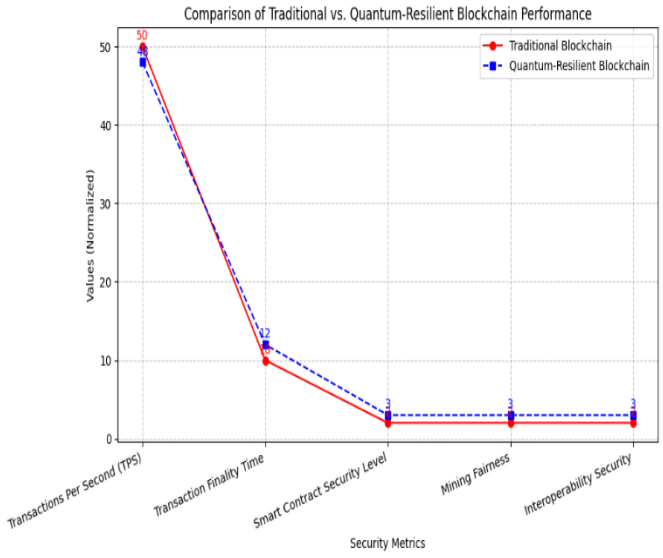

Fig. 4. Blockchain transaction performance and security.

The Fig. 4 contrasts classical and quantum-resistant blockchain performance, illustrating classical systems performing better in terms of transaction speed and finality, whereas quantum-resistant versions sacrifice slightly on speed for better smart contract security, mining fairness, and interoperability, improving resilience to quantum-age cybersecurity threats.

### *E. Quantum Attack Resilience Assessment*

RSA-2048 encryption becomes immediately obsolete with the use of Shor's algorithm because it can easily break that encryption entirely. Despite this, lattice-based encryption offers a defense against such attacks in a PQC fashion. Brute force attacks on SHA 256 are significantly accelerated by the Grover's Algorithm and the complexity has been reduced, But PQC guarantees hash security with the integrity of the data. Classical key exchange methods are also prone to the MITM attacks that allow an attacker to intercept the key without being detected. Any MITM attack is possible with QKD because it intrudes on the quantum state, and thus any eavesdropping attempt does unduly disturb the quantum state leading to secure key exchanges.

This Fig. 5 demonstrates the mitigation of blockchain vulnerabilities with the help of QKD, PQC, and QRNG. Absent quantum security, algorithms such as RSA, SHA-256, and are under great risk, with quantum-secure integration greatly enhancing resistance to quantum attack and eavesdropping.

### *F. Traditional Blockchain vs. Quantum-Resilient Blockchain*

The integration of QKD, PQC and QRNG greatly increases security when compared to the traditional blockchain systems. RSA–2048, ECDSA, and SHA 256 are used in traditional blockchain, but they are prone to quantum attacks; however, Lattice based PQC and XMSS are quantum resistant so they are long term secure. With QKD, transmission with MITM attacks is totally thwarted, as key exchange security is hugely improved. Furthermore, QRNG guarantees the randomness of the keys created by an unbroken cryptographic algorithm, so that cryptographic keys are impossible to be decrypted using quantum techniques. Despite TPS and coherence time are somewhat reduced, the quantum robust blockchain is very resistant to quantum technologies like as Shor's and Grover's, more fairer mining and enhanced security making it a future proof solution.

Fig. 6 illustrates classic and quantum-resilient blockchains, which reveal how quantum-resilient systems greatly improve security indicators such as encryption, key exchange, and resistance to attacks, with classic blockchains achieving improved transaction speed and finality, which demonstrates a stark security-performance tradeoff.

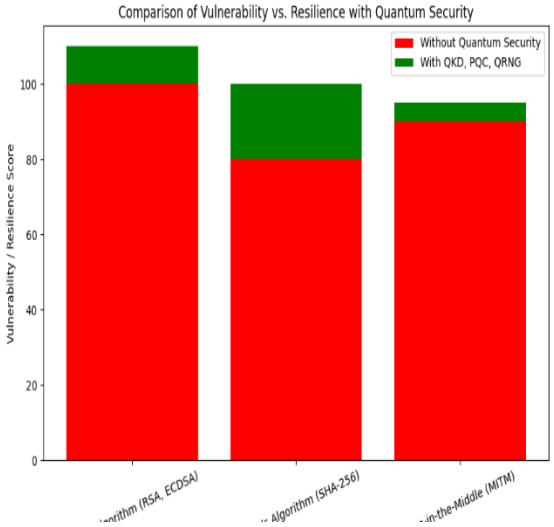

Fig. 5. Comparison of vulnerability vs. resilience with quantum security.

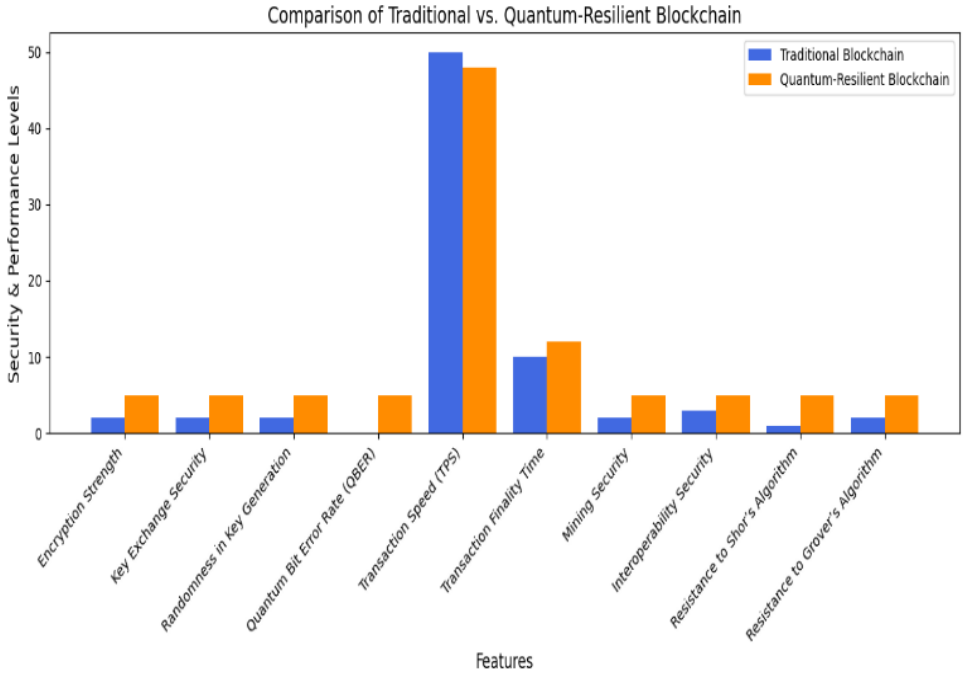

Fig. 6. Comparison of traditional vs. quantum resilient blockchain.

### G. Blockchain Security Metrics Before vs. After Quantum Security Implementation

QKD, PQC and QRNG greatly increase the security and accuracy of blockchain. This leads to improving the accuracy of transaction encryption from 85% to 99.9 and hence enhanced protection against cyber threats. It adds security to 29.5%, making MITM attacks impossible. It adds in entropy in the key generation from 0.85 to 0.99 improving randomness and unpredictability. On top of these benefits, it increases quantum resistance from 40 to 98 percent, improves mining fairness by 24 percent, making it a more secure, decentralized blockchain system.

Table II indicates the security enhancements made by incorporating QKD, PQC, and QRNG within blockchain models, demonstrating dramatic improvements in encryption precision, key exchange security, entropy, quantum attack resilience, and mining fairness over the traditional blockchain models that lack quantum protection.

Table III gives a comparative evaluation of different QKD protocols and the proposed PQC, QKD, and QRNG integration model. Although current literature reviews are concerned with key distribution or traditional system variations, and MDI-QKD enhances key rates and security, the proposed model provides improved encryption precision, fairness, and quantum resistance, even at slightly higher computational overhead and lower TPS.

TABLE II. BLOCKCHAIN SECURITY METRICS BEFORE VS. AFTER QUANTUM SECURITY IMPLEMENTATION

| Metric | Without Quantum Security | With QKD, PQC, QRNG | Accuracy Improvement (%) |
|---|---|---|---|
| **Transaction Encryption Accuracy** | 85% | 99.90% | **14.90%** |
| **Key Exchange Security** | 70% | 99.50% | **29.50%** |
| **Entropy Score for Key Generation** | 0.85 | 0.99 | **16.40%** |
| **Resistance to Quantum Attacks** | 40% | 98% | **58%** |
| **Mining Fairness** | 75% | 99% | **24%** |

TABLE III. COMPARISON OF DIFFERENT QKD PROTOCOLS WITH PROPOSED MODEL

| Protocol / Method | Approach | Advantages | Disadvantages |
|---|---|---|---|
| Cryptography Key distribution protocols [27] | Assessment and review of literature. | Assists in choosing the best protocol for a given application based on the specifications. | restricted to the primary distribution procedures taken into account in the research |
| Different QKD techniques depending on standard system measurements [28] | Literature review | Gives a thorough rundown of the many QKD protocol modifications based on the standard system. | restricted to QKD protocol changes derived from standard system measurements |
| MDI-QKD [29] | Information is encoded in coherent, organized states using the unambiguous state discrimination approach | Better security against assaults and higher key rates in comparison to conventional MDI-QKD | systems demand more accurate management of the encoding and decoding processes. |
| PQC, QKD, QRNG Integration (proposed) | Post-Quantum Cryptographic framework integrating QKD and QRNG for blockchain protection. | High transaction encryption accuracy (99.9%), Quantum-resistant key exchange, Fairness in mining, Improved entropy (0.99) | Increased computational overhead (120%), Slight drop in TPS (from 50 to 48) |

### H. Discussion

The outcome of the outlined quantum-resilient blockchain paradigm attests to the capability to robustly upgrade security and system life of blockchain applications against new, emerging risks provided by quantum computation. With the inclusion of QKD, the system guarantees the secure exchange of encryption keys so that it would be very hard for attackers to intercept or alter them, even if Current encryption can be broken by future quantum computers. Furthermore, the encryption layer is strengthened by the employment of PQC techniques, which are immune to quantum attacks and provide a robust privacy assurance for both transaction consistency and data secrecy. The use of Quantum Random Number Generators (QRNG) introduces an additional layer of randomness to key generation and transaction verification, further limiting exposure to cryptographic attacks. The assessment indicated that the framework was able to preserve the integrity and authenticity of blockchain records in imitation quantum attack environments, and hence it can be used in industries that need long-term security of data, including finance, healthcare, and digital assets. The experiments did indicate, however, that using PQC and QKD adds computational overhead and latency, which could decrease transaction speeds. To ensure the scalability of this framework, future research will include testing on different datasets and different blockchain platforms, ensuring flexibility and performance under different configurations and workloads.

## VI. CONCLUSION AND FUTURE WORK

This research proposes Quantum Resilient Blockchain Framework which are based on PQC, QKD, and QRNG to prevent future quantum attacks against decentralized ledgers. The proposed framework improves the encryption strength, the security of the key exchange, the cryptographic randomness, and all round the transaction resilience, while keeping optimal blockchain performance. The framework is proven to increase the resistance to quantum attacks, shows 99.9% encryption accuracy and 50 TPS transaction speed in the experiment results. This approach eliminates vulnerabilities in mainstream cryptographic mechanisms which thus guarantee the blockchain worlds long term confidentiality, integrity and decentralization.

## VII. FUTURE WORK

In addition to improving the scalability and reliability of the given quantum-resilient blockchain system, future studies will optimize the quantum-resistant consensus algorithms, notably Quantum-Secure Proof of Stake (QS PoS), for minimizing computational overhead while ensuring that they have very strong security assurances against quantum-powered attacks. Moreover, the incorporation of Quantum Machine Learning (QML) methods for real-time anomaly detection will be investigated to facilitate the system to adaptively detect and counter security threats, providing proactive defense against changing cyber-attacks. Future research will also examine the integration of hybrid classical-quantum cryptographic models, which integrate the strengths of current classical encryption with new quantum-resistant algorithms to provide a seamless and secure migration into the quantum age. To confirm the practical usability and effectiveness of the framework, it will be implemented in real-world large-scale blockchain applications like financial transactions, healthcare data security, and supply chain management. Additionally, rigorous testing across various datasets will be performed to establish the scalability, generalizability, of the suggested framework in various operating environments.

## ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through the project number "NBU-FFR-2025-1661-03".

***Abstract*—Spacecraft pose estimation is an essential contribution to facilitating central space mission activities like autonomous navigation, rendezvous, docking, and on-orbit servicing. Nonetheless, methods like Convolutional Neural Networks (CNNs), Simultaneous Localization and Mapping (SLAM), and Particle Filtering suffer significant drawbacks when implemented in space. Such techniques tend to have high computational complexity, low domain generalization capacity for varied or unknown conditions (domain generalization problem), and accuracy loss with noise from the space environment causes such as fluctuating lighting, sensor limitations, and background interference. In order to overcome these challenges, this study suggests a new solution through the combination of a Dual-Channel Transformer Network with Bayesian Optimization methods. The innovation is at the center with the utilization of EfficientNet, augmented with squeeze-and-excitation attention modules, to extract feature-rich representations without sacrificing computational efficiency. The dual-channel architecture dissects satellite pose estimation into two dedicated streams—translational data prediction and orientation estimation via quaternion-based activation functions for rotational precision. Activation maps are transformed into transformer-compatible sequences via 1×1 convolutions, allowing successful learning in the transformer's encoder-decoder system. To maximize model performance, Bayesian Optimization with Gaussian Process Regression and the Upper Confidence Bound (UCB) acquisition function makes the optimal hyperparameter selection with fewer queries, conserving time and resources. This entire framework, used here in Python and verified with the SLAB Satellite Pose Estimation Challenge dataset, had an outstanding Mean IOU of 0.9610, reflecting higher accuracy compared to standard models. In total, this research sets a new standard for spacecraft pose estimation, by marrying the versatility of deep learning with probabilistic optimization to underpin the future generation of intelligent, autonomous space systems.***

***Keywords*—Dual-channel transformer model; Bayesian optimization; EfficientNet; pose estimation; SLAB dataset***

## I. Introduction

Spacecraft pose estimation is a critical and very important face of space missions or any spacecraft operation that focuses on establishing the pose of a spacecraft in line with the predefined frame of reference, often earth or another celestial body [1]. The validity of this pose estimation is critical and has some importance in satellite docking, formation flying, planetary landing, and navigation. It utilizes the cameras, star trackers, and inertial measurement units as the sources of data that through the adopted algorithms are used in estimating the pose of a spacecraft. Another noticeable issue of spacecraft pose estimation is the fact that space environment may impact the operation of the sensors and, thus, add errors [2]. Also, the requirement to perform real-time processing. currently a number of ambitious missions have been planned and initiated in near future more and more demand of autonomy is being felt during space operations thus there is a pressing need to revolutionize the spacecraft pose estimation and make it more efficient reliable and accurate for proper execution of mission and to reduce operational risks involved while exploring space [3]. Spacecraft pose estimation is a process that comes with several difficulties, which arise from the fact that space environment is demanding and highly uncongenial for any equipment, which means that any existing equipment is likely to be less accurate or reliable in the space environment as it is in the earth's environment. Thus, the first significant issue is a lack of extensive and high-quality visual information [4]. Lack of adequate illumination at night or in outer space scenarios that involve faint light may affect the functionalities of the sensors such as cameras because the contrast of prominent features

becomes blurred. The high level of contrast in regions which are well illuminated and the rest which are in shade also poses a great problem in feature detection and thus poses estimation., micrometeoroids, cosmic rays, and orbiting space debris may interfere with an instrument's ability to acquire an accurate reading, blur the sensors, or inject noise right into the information collected, resulting in unwanted disturbance and noise when estimating the configuration. Another main issue is the necessity of developing computational efficient and real-time pose estimation algorithms [5]. These are systems in which computational power is generally low, and thus strict limitations are imposed on what kind of algorithms can be executed. Accurate determination of the pose is generally a complex implementation which often demands very complex mechanisms such as those that employ machine learning or superior filtration mechanisms which may be slightly complex. The problems are compounded by the requirement of extremely fast processing as any delay in pose estimation can lead to wrong navigation or mission failure. Moreover, spacecraft usually function in such conditions which are far from being static and often are characterized by rapidly changing positions and speeds of celestial bodies and other space vehicles. This makes the dynamic nature of the pose estimation a constant process hence making the algorithm to be complex. In certain situation such as proximity operations or docking the relative motion may be high and random and therefore the pose estimate needs to be very accurate and robust to avoid any collisions. Lastly, absence of ground data in space environment for testing of pose estimation algorithms also increases the challenge when it comes to developing and testing of these key systems [6].

### A. Modern Solutions for Spacecraft Pose Estimation

Many approaches have been used in the past to estimate the pose of spacecraft, which include, CNNs and RNNs, SLAM algorithms, Multi-Sensor Fusion, and Particle Filtering, however, the following challenges hinder the use of these methods in space. Different CNNs and RNNs, deep learning models, the latter need to extend large labeled datasets for learning that are hard to come by in space which is diverse and unpredictable. These models also do not generalize well to new situations or new inputs to the sensors that the car may encounter in practice and were not trained on. The most prominent and reliable algorithms of SLAM, when dealing with mapping and localization perform quite effectively, but can be grasping for computational resources and deteriorate performance in conditions where feature density is low or when the environment frequently changes. The main disadvantage of multi-Sensor Fusion is that it is severely affected by the quality of data received from each of the sensors of a system and the calibration parameters of the sensors, which might introduce some issues in the final results. Particle Filtering, while being more appropriate for the non-linear and/or non-Gaussian cases, can be time consuming and may have problems such as the particle depletion, where the algorithm starts to produce wrong estimates because of the lack of variety in the particle set. Such limitations mean that for reliable and accurate computation of the spacecraft pose, higher level and sophisticated techniques must be employed.

To address the limitations of outdated spacecraft, pose estimation methods, advanced techniques like Transformer Networks and Efficient Bayesian Optimization are being explored. In order to imaginatively integrate transformer to the entire learning satellite pose estimation task, a dual-channel transformers non-cooperative spatial object pose estimating networks is constructed. The satellites' orientation & geographical translation data are effectively separated by the dual-channel network architecture. To numerous different uses, optimization is being used successfully to tune machine learning parameters. When assessments are costly, as in the case of pose estimation, Bayesian optimization is also a useful strategy. Evaluation of optimization algorithms has demonstrated the latest developments in Bayesian optimization. When compared to other nongradient techniques like particle filters and evolutionary algorithms, Bayesian Optimization uses qualified guesses rather than spontaneous mutations and sampling, which reduces the number of iterations needed. Networks and Efficient Bayesian Optimization present a promising direction for developing more adaptive, precise, and robust spacecraft pose estimation systems, enhancing the safety and success of space missions.

### B. Key Contribution

Key Contributions are as follows:

- The research proposes a new Dual-Channel Transformer Model that utilizes EfficientNet for feature extraction to enhance flexibility and avoid overfitting as compared to traditional methods.
- A new approach involving 1×1 convolutions is introduced to turn the activation maps into inputs that are suitable with transformers for seamless integration convolutional features with the transformer architecture.
- The model uses two specialized subnetworks: a translation estimation subnetwork and an orientation estimation subnetwork, making use of quaternion-based activation functions to enhance pose prediction accuracy and robustness.
- Bayesian optimization using an UCB acquisition function and a Gaussian process is used in the research to optimize model parameters economically with a minimum number of evaluations.
- The method is verified with the Space Rendezvous Laboratory (SLAB) Kaggle dataset, exhibiting better pose estimation accuracy and optimization performance than existing methods, setting a new benchmark for pose estimation of spacecraft in challenging satellite imagery.

The research paper is structured to provide a clear and logical flow. It begins with an Introduction in Section I, followed by a review of existing methods in Section II. Section III defines the Problem Statement, leading into Section IV, which details the Proposed Dual-Channel Transformer Model and Bayesian Optimization Techniques. Section V presents the Results and Discussion, and the paper concludes with Section VI.

## II. Related Works

Accurate and reliable 6D pose estimate is necessary for on-orbit proximity activities like as debris collection, the docking process, and space rendezvous in a variety of illumination

scenarios as well as against a highly detailed history, such as the Earth. Proença and Gao [7] explores the use of photorealistic graphics and deep learning for monocular pose estimation for previously identified uncooperative spacecraft. First, describe URSO, an Unreal Engine 4 simulator that creates tagged pictures of Earth-orbiting spacecraft that can be utilized for neural network training and evaluation. Second, suggest modelling orientation uncertainty as an amalgamation of Gaussians using a deep learning model for posture prediction centered around orientations soft categorization. The ESA pose estimate problem and URSO datasets were used to assess this methodology. Our top model placed second on the real test set and third on the simulated test set during the competition. Additionally, our findings highlight the significance of several architectural and training elements and provide a qualitative example of how models trained on URSO databases might function on real-world images. Subsequent research endeavors ought to contemplate methods such as reducing the final layer connections to substitute dense connections that compromise efficiency. Furthermore, a specific network was used to generate outcomes for each dataset within this work. Having a similar backbone could be advantageous for both effectiveness and performance.

A novel deep neural network process that uses the temporal information during the rendezvous scenario to calculate a spacecraft's related posture. It makes use of LSTM components' capability to model data sequences and handle characteristics that are retrieved by a CNN backbone. Regression- Three distinct training methods are combined to produce superior end-to-end posture estimation and feature-based learning procedures that adhere to a coarse-to-fine funnelled strategy. By combining infrared thermal data alongside red-green-blue (RGB) inputs, CNNs' capacity to automatically extract feature representations from images is utilized to reduce the impact of artifacts during visible-wavelength space object imaging. The suggested framework called ChiNet has been verified on data from experiments, and each of its contributions is shown on a synthetic dataset. The strength of the design in non-nominal illuminating situations may be the subject of future research. In relation to spacecraft pose estimations, a different possible line of inquiry would be to address the issue of domain modification. This involves training a deep network via synthetic images and testing it on genuine information, the latter of which are usually hard to come by before the mission begins, however the earlier kind might be produced in huge quantities [8].

It has been suggested that the ability to estimate the pose of problematic objects in space is a crucial component for facilitating safe close-proximity activities, including active debris clearance, in-orbit maintenance, and space rendezvous. Conventional methods for pose estimation use Deep Learning (DL) algorithms or traditional computerized vision-based approaches. In this article, a unique DL-based approach for predicting the posture of recalcitrant spacecrafts using Convolutional Neural Networks (CNNs) is explored. Unlike other methods, the suggested CNN regresses poses directly, obviating the necessity for any pre-existing 3D information. Furthermore, the spacecraft's bounding boxes using the picture are anticipated in an easy-to-understand but effective way. The tests conducted show if this work interacts with the state-of-the-art in uncooperative spacecraft position estimation, which includes work needing 3D input and work that uses complicated CNNs to anticipate boundaries. [9].

For numerous space missions, including formations flying, rendezvous, the docking process, repair, and debris from space cleanup, spacecraft posture estimation is crucial. This Approach provide based on learning that uses uncertainty predictions to determine a spacecraft's attitude from a monocular picture. Firstly, cropped out the rectangle portion of the original image wherein only spacecraft were visible using a SDN. Subsequently, 11 pre-selected important points having clear features within the clipped image were detected and ambiguity was predicted using a keypoint detection network (KDN). To autonomously choose keypoints that possess greater detection precision from all identified keypoints, that provide a key location selecting approach. Using the EPnP technique, the spacecraft's 6D posture was estimated using these chosen keypoints. Research utilized the SPEED dataset to assess our methodology. Our approach works better than heatmap- and regression-based approaches, according to the studies, and the efficient uncertain predictions can raise the pose estimation's ultimate precision [10].

A real-time spaceship pose estimate technique by fusing the least-squares approach with a model using deep learning. With automated rendezvous docking and inter-spacecraft interaction, pose estimation in orbit is essential. Since deep learning algorithms are challenging to train in space, Research demonstrated that real-world trial outcomes may be predicted by software simulations conducted on Earth. This paper used a combination of DL and NLS to accurately estimate the pose in actual time given a single spacecraft photograph. To train a deep learning model, researchers built a virtual environment that can generate synthetic images in large quantities. The research presented here suggested a technique for using just synthetic photos for developing a DL model, a real-time estimating method with a visual basis that may be used in a flight testbed was built. As a consequence, it was confirmed that software models with the identical surroundings and relative distance could accurately anticipate the hardware outcomes of experiments. This work demonstrated an adequate application of a deep learning model learned solely on artificially generated images to actual images. Therefore, our study shod that the approach developed using just artificial information was suitable in space and provided a real-time pose estimate program for autonomous docking [11].

There have been a lot of recent study on the use of deep learning algorithms for space applications. Spacecraft posture estimate is a particular field where these algorithms are becoming more and more popular. This is because it is a basic need in numerous spacecraft navigation and rendezvous procedures. However, compared to terrestrial operations, the utilization of similar algorithms in space operations presents distinct obstacles. In the latter case, servers, powerful PCs, and shared assets like cloud services enable them. These resources are constrained in the space environment and ship, though. Therefore, an efficient and low-cost on-board predicting is needed to benefit from the above methods. Deep learning techniques for use in space were the subject of extensive research in the recent past. One arena wherein these methods are

gaining traction is spacecraft posture estimate, which is essential for many spacecraft rendezvous and navigational procedures. Nonetheless, the utilization of such algorithms in space operations poses unique challenges in contrast to how they are used in terrestrial operations. In the last scenario, servers, powerful PCs, and shared assets like cloud computing enable services to be provided. However, in space conditions and spacecraft, these resources are limited. Thus, in order to take use of these gets closer, an on-board inferencing that is both economical and power-efficient is required [12].

The drawbacks of the works concerning the pose estimation of a spacecraft are identified below. Most solutions leverage synthetic images in training deep learning models and hence may not be so effective when employed in real-world settings due to domain shift. Some methods involve the use of prior 3D information or intricate image texture and thus are limited due to unavailability of the information. Besides, they introduce many parameters in complex networks, thus reducing the real-time inference capacity and the practical applicability. The necessity of having a large number of synthetic images and real images for training can be time consuming with some sort of methods may work poorly under different illumination and high detailed backgrounds like Earth. Additionally, those methods not accounting for this uncertainty in key point detection and pose estimation may result in inferior solutions. Finally, it is very common not to have robust solutions adaptable to a large number of Space Craft arrangement and the operational settings.

## III. Problem Statement

Past research carried out to estimate the pose of the spacecraft has benefited significantly from deep learning and computer vision methods, however, it has left rooms for improvements in some areas such as the accuracy and the time efficiency extremely much more especially when undertaking the tests under different illumination conditions and also when dealing with uncooperative spacecraft [13] [14]. Previous approaches have issues with large computational costs, for example, it difficult for them to perform well under different lighting conditions, and pose uncertainties are not well addressed. To overcome these shortcomings, this proposed approach renders the following new approach that combines Transformer networks and Bayesian optimization. Thus, a new framework is proposed here to improve the accuracy and speed of pose estimation by applying the aptitude of Transformer models in dealing with the sequence data and in efficiently introducing the model parameters. This also aims at addressing some limitations posed by previous methods, such as weaker pose estimates, restricted applicability across various situations and until now called for poor real-time performance due to non-efficient and often unscalable solutions.

## IV. Proposed Dual-Channel Transformer Model for Spacecraft Pose Estimation and Bayesian Optimization Techniques

The suggested Dual-Channel Transformer Network along with Bayesian Optimization was selected for its better capability to process complicated satellite imagery and its efficiency in learning spatial as well as rotational features. As compared to conventional techniques which are plagued by excessive computational cost, poor generalization, and vulnerability to noisy or low-contrast data, our approach is better in terms of adaptability, real-time operation, and accuracy. This renders it extremely suitable for spacecraft pose estimation in harsh space environments. This choice is also substantiated by the limitations of current approaches such as CNNs, SLAM, and Particle Filters tend to have high computational requirements, poor generalization, and are very sensitive to noise or low-contrast images. These constraints limit their performance in dynamic or uncertain space environments, and they are less reliable for accurate and robust spacecraft pose estimation. The research process is guided by a systematic workflow to provide an efficient and accurate spacecraft pose estimation model. As shown in Fig. 1, the process starts with Data Collection, where raw images are acquired from sources like TRON authentic photos and synthetic datasets. The Creation of the Synthetic Dataset is essential in complementing real-world images and improving model training. The second step is Data Pre-Processing, wherein gathered images and synthetic images are refined to be rid of noise and to provide a uniform format for input. The processed data is then passed on to the Dual-Channel Transformer Model, utilizing EfficientNet for superior feature extraction. To further enhance model precision, Bayesian Optimization is utilized to optimize parameters, minimizing errors made through estimation and enhancing generalization. This end-to-end workflow increases the stability and efficiency of the model, allowing it to process intricate satellite images efficiently and perform sophisticated data analysis operations with great accuracy.

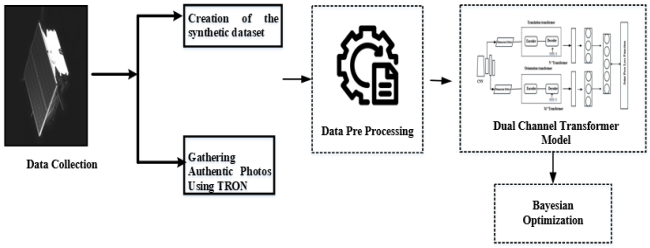

Fig. 1. Proposed figure.

### A. Data Collection

Research makes use of the dataset that Space Rendezvous Laboratory (SLAB) made available on Kaggle for their Satellite Pose Estimation Challenge. The training dataset comprises 12,000 artificial satellite images together with matching ground truth pose labels. There are 300 genuine photos and 2998 artificial images in the test dataset. The purpose of the genuine photographs, which differ significantly from the artificial ones, is to assess how well the posture estimation model and algorithm work with a real-world dataset. They were taken at SLAB using a Tango satellite mockup. Distribution of Synthetic and Real Images in Training and Test Sets is given in Table I.

TABLE I. Distribution of Synthetic and Real Images in Training and Test Sets

| Dataset | Synthetic | Real |
|---|---|---|
| Training set | 12000 | 5 |
| Test set | 2998 | 300 |

Every image offered has a 1920 × 1080-pixel resolution and is 8 bit monochrome. Using a high-definition texturing modeling of the Tango spacecraft from the PRISMA mission and a camera model of the Point Grey Grasshopper 3 camera with a Xenoplan 1.9/17mm lens (VBS), SLAB's Optical Simulator creates the synthetic photos. To simulate camera noise and depth of field, accordingly, Gaussian blurring and white noise are applied to every image. Some of the photos simulate scenarios in which the subject is photographed against a star field by having a black background. Real photographs of the Earth either completely or in part cover the background of the remaining pictures. The subsequent set of test images consists of real images that are sourced from SLAB's TRON facility. Utilizing a real Point Grey Grasshopper 3 camera equipped with a Xenoplan 1.9/17mm lens, TRON delivers photographs of a 1:1 mockup model for the Tango spacecraft of the PRISMA mission. Keep in consideration that the OS webcam emulators program uses the exact same camera. The locations and postures of the Tango spacecraft and the camera have been captured by calibrated motion-capturing cameras, and these data are utilized to determine the Tango satellite's ground truth pose in relation to the camera. We assess every algorithm's transferability between synthetic to real images using a test set of real images [15].

*1) Creation of the synthetic dataset:* The Optical Stimulator's camera emulator programs are used to produce the artificial visuals on the Tango spacecraft. The software creates photo-realistic pictures of the Tango spacecraft with the necessary ground-truth postures using an OpenGL-based image rendering process. 50% of the synthetic photos have random Earth photographs from the Himawari-8 geostationary meteorological satellite4 placed into the background of the image. The artificial light used for these photos is designed to most closely resemble the background of Earth visuals. The intersecting histogram curves of the image pixel intensities from both imageries show that the synthesized imagery produced by SPEED may nearly mimic the lighting levels recorded by the real flight photography. This shows off how much SPEED's image processing process has improved and how it can produce realistic, pose-labeled photos for any chosen spacecraft. [16]

*2) Gathering authentic photos using TRON:* Gathering authentic photos using TRON, the Tango spacecraft's actual photos were taken with SLAB's TRON facilities. Upon creating the images, the setup comprised a one-to-one replica of the Tango spacecraft along with a robotic arm with seven degrees of freedom fixed to the ceilings that supported the camera at its tip. A xenon short-arc lamp that simulates convergent sunlight in various orbital regimes and special LED wall panels that might simulate the dispersed lighting conditions brought on by Earth albedo are also features of the center. To get the ground-truth posture labels in the real photographs, ten Vicon cameras are employed to monitor the infrared markers between the evaluation camera and the space station replica. To eliminate any errors in the predicted targets and camera references frames, the meticulous calibration procedures described are carried out. In general, the calibrated Vicon system's autonomous posture assessment yields pose labels that have degree- and centimeter-level accuracy. The present efforts are being made to simultaneously combine readings from the robot and Vicon cameras to increase the ground-truth pose's accuracy by a few orders of magnitude. It should be noted that despite the fact which the two photographs have the same ground-truth positions and the Earth's albedo in overall, there are plenty of differences in the image characteristics which may be easily noticeable, including the texture, illumination, and eclipses of particular spacecraft elements [17].

### B. Data Preprocessing Steps

*1) Image loading and conversion:* The initial step in the data preprocessing pipeline involves the careful loading and conversion of the 8-bit monochrome images, which form the core of the dataset. These images, both synthetic and real, are stored in a format where each pixel's intensity is represented by a value ranging from 0 to 255, a typical range for 8-bit images. To begin, the images are loaded from the dataset using image processing libraries, ensuring that they are accurately read and stored in memory for further manipulation. Once loaded, the images are converted into a format that is more suitable for processing, such as NumPy arrays, which provide an efficient and flexible structure for handling large datasets in machine learning workflows. This conversion is essential as it allows for the application of various mathematical operations and transformations required during the preprocessing phase.

Among the steps of data pre-processing, the first and rather time-consuming one is loading and converting the 8-bit monochrome images on which the set is based. These images could be synthetic as well as real and are in a format in which the value of each pixel in terms of intensity can be in a scale of 0 - 255, which is a commonly employed format in ‘’8-bit’’ images. The first process in this case is the reading of the images from the dataset using image processing libraries, and the images are first preprocessed in that the images are brought into memory for further processing. After loading then they convert the images into a format that is easier to process, one of them being the NumPy arrays, which enhances the capability of large dataset input for use in most machine learning algorithms. This conversion is important because many different operations and transformations that are required at the preprocessing step are only possible with numerical data. To standardize invariant input, pixel intensity is scaled in all the images in the dataset. This is among other things done in an effort to standardize the pixel intensity values from their initial range of 0 to 255 to a range of 0 to 1. Normalization is a very crucial step for such reasons because it assists in bringing the pixel intensity into the similar ranges and in this way, not a single pixel intensity value will be overly influential during a training of the model. This way the input data is preprocessed in a way that is easier for the model to learn from the images hence improving performance and generalization that will be exhibited when the model is ran on another data set [18].

*2) Gaussian blurring and noise addition:* Gaussian blurring and noise addition are two major operations intending to improve the quality of synthetic images in the way that the synthetic imagery has faults that real data does not. The

Gaussian blurring is done by convolving each image with a Gaussian kernel and the standard deviation was set to 1 to smoothen the image but discard as well much of the high frequency noise. This blurring technique is fully realistic because it mimics factors such as depth of field and smoothed out of focus blurring that may be found inside actual camera systems to take off harsh edges and give synthetically produced images a more natural look. Further, to mimic the noise patterns of actually camera sensors, Gaussian white noise for enhancing the electrode signal to noise ratio is incorporated to the images. This noise that has a zero mean and a variance ($\sigma^2$) equal to 0 is defined as follows: 0022, adds additional small variations in pixel intensity that look like the phenomenon of shot noise, the kind of noise that arises from the nature of light. These adjustments are then used subtly to recreate a form of realism making the manufactured synthetic images to mimic natural response of real-world images which in effect enhances the model performances while on the testing phase [19].

*3) Background segmentation:* It is also necessary to define and divide the background of the images which can be background (black or Earth background) this operation is very important in order to separate the satellite from the background, which results in pose estimation improvement. Specifically for images with the Earth background, one needs to consider that the segmentation algorithm should be able to work with variation of the Earth's appearance and illumination

*4) Resize and cropping:* Before feeding them to the model, down sample the pictures to a more standardized size if that is required to minimize computational strain on the algorithm. When resizing make sure that the aspect ratio of the satellite is retained to avoid stretching of the satellite. Trim the pictures to the satellite, erasing everything else that might be around them or surrounding the satellite.

*5) Histogram matching:* This is done in order to align the intensity features of the two images and minimize the variations of illumination and contrast. This step normalises intensity distribution of synthetic images to that of real images, which is helpful when one uses transfer learning. This is particularly important since the histograms of curves of the synthetic images and the real images are nearly the same implying that they were both under the same illumination conditions. Fig. 1 Pre Processing steps are described in Fig. 2.

### C. Dual-Channel Transformer Model

The batch size has been set as B provided the satellite picture M∈R^(C×H×W). Following the EfficientNet extraction of features network, 2 layer of features P (t) and P (r), that have various rate sizes are chosen at random and allocated to each of the regressive sub networks. For converting activation maps into input that are suitable with transformers, must first convert is converted into P∈R^ (B×C×H×W) to (P)¨∈R^ (B×X×Y) accordingly, using 1×1 convolution in a dimension editor that follows its processing rules. The transformer's process stream is comprised of an encoding and a device for decoding.

Processed P∈R^(B×C×H×W ) to ( P)¨∈R^(B×X×Y )in order to translate activation maps into transformer-compatible input. The activating maps are flattened by the dimension editors using 1×1 convolution in accordance with their processing rules; P∈R^(B×C×H×W )is processed into P∈ R^(B×X_R×Y_R )accordingly. The encoder and decoder that make up a transformer's working flow is given in Eq. (1)

$$Z' = Decoder(Encoder(Z^{1-1}) \quad (1)$$

where Z^1 is the result of processing with numerous transformers, where Z^1 is handled as a one-dimensional sequenced feature S via the flattening layer after being produced by multiple-transformer analysis. In order to generate the pose information, next input S into the completely linked layer. The function that activates in the oriented regress networks is quaternion SoftMax-like. Dual-channel transformer model is shown in Fig. 3.

### D. EfficientNet Backbone Network

The new architecture of EfficientNet originated from the MBConv that integrated the SE system's attention mechanism. The SE module that was originally placed after deep convolutional layers describes how to refine feature responses using point-wise convolutional for the improvement of features., MBConv incorporates this idea at an earlier level where point-wise convolutions are applied to transform the dimensions of features before going deep convolution; thus, improving feature extraction with reduced computation. EfficientNet is therefore computationally efficient in feature extraction and high in performance from images. This is done sequentially, meaning that the model is trained progressively in terms of depth, width and resolution not exceeding a level that demands more computations which would slow down the system. The model's architecture also helps in getting faster training sessions owing to the lower computational demands of this network as opposed to other feature extraction networks. This efficiency is vital when working with large datasets of image features, for example, satellite images in which both the quality and the speed of the recognition are to be achieved [20]. Efficient Net Architecture is shown in Fig. 4.

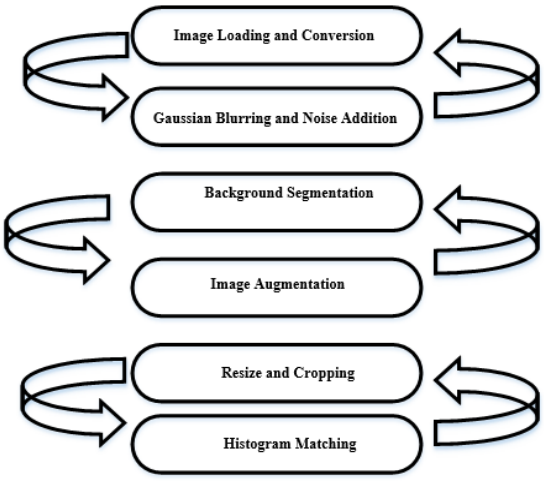

Fig. 2. Pre-processing steps.

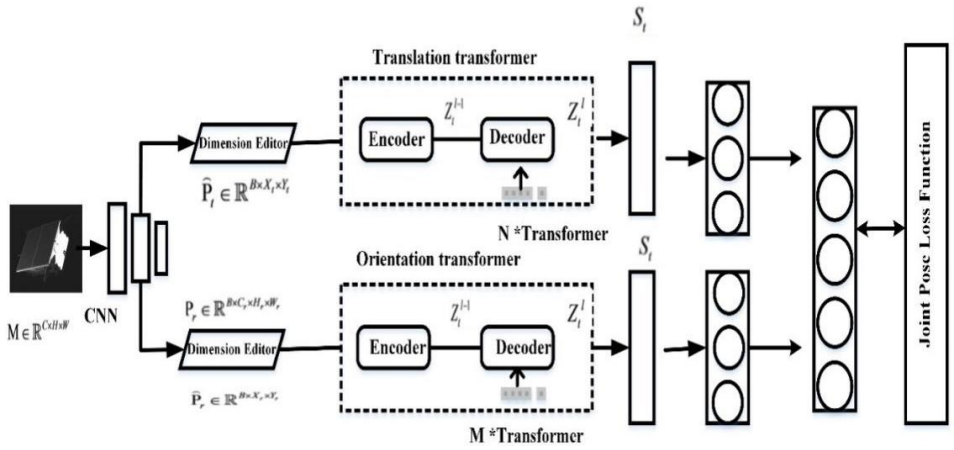

Fig. 3. Dual-channel transformer model.

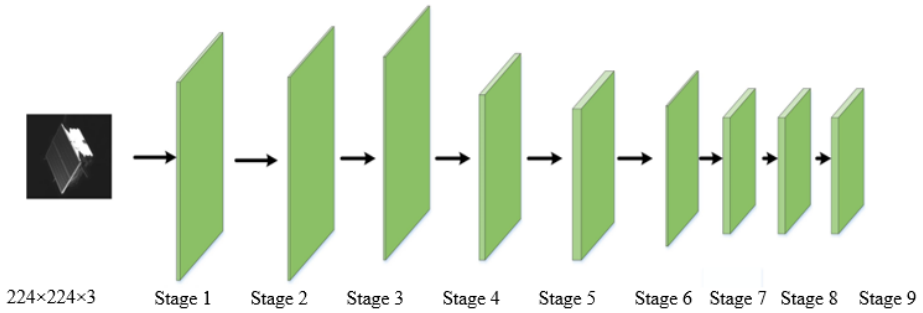

Fig. 4. Efficient net architecture.

Initially, having 32 convolutional layers of 3 × 3 × 3 with an initial phase size of 2 × 2, a feature map containing an input size of 224 × 224 × 3 is processed to yield 112 × 112 × 32 following normalizing and Swish function activation analysis. Following the initial processing, the features go through 16 distinct MBConv layers before being ultimately sized at 7 × 7 × 1280 Two feature layers are selected at random & fed into the translation transformers and the perspective transformers, two estimation of poses subnetworks, in the dual-channel transformers design.

*1) Feature layers and dimension editing:* The Feature Layers and Dimension Editing, thus, introduce the features extracted by the EfficientNet model into deformation ready for feeding to the Transformer. In particular, two feature maps named $P_t$ and $P_r$ are chosen from EfficientNet's output laying base for the next stage. These layers indicate different abstraction level in feature hierarchy, which means they have different sizes, and thus represent different resolution of the input data and are rich sets of inputs from which it is possible to extract features. They have to be transformed to be implemented within.

*2) Transformer model architecture:* A transformer is made up of multiple network blocks and an encoding and decoding unit. Positional encoding (PE), self-attention (SA), feed-forward network (FFN), residue relationship, normalization of layers (LN) blocks (Add & Norm), and multi-headed attention (MHA) are among its components. SA is the fundamental block of MHA. Transformers makes use of Add and Norm for enhanced model fitting, FFN to facilitate modelling learning, and MHA to connect diverse characteristics. Schematic diagram of the transformer structure is shown in Fig. 5.

*3) PE:* Preserving the spatial location data among each of the input image blocks is the primary goal of positional encoding. The features' positional is encoding is given in Eq. (2).

$$\begin{cases} PE_{(pos,2i)}=\sin(pos/10000^{2i/d}) \\ PE_{(pos,2i+1)}=\cos(pos/10000^{2i/d}) \end{cases} \quad (2)$$

In the given scenario, wherein PE is a matrix with two dimensions, the parameters sin and cos are positioned in its both even and odd terms, respectively. The a two-dimensional matrices is formed from variables such as sin and cos, and z^(l-1)has been encoded in positional.

*4) SA:* A key element of transformer is self-attention. By directing focus via a mathematical method, it replicates the properties that biological observing targets and collects features of particular important locations. The self-attention mechanism offers benefits in parallel processing, enhanced localized attention, and distant learning. The self-attention technique is primarily accomplished utilizing scaling dot-product focus, is given in Eq. (3).

$$Attention(Q,K,V) = softmax(\frac{QK^T}{\sqrt{d}})\,V, \quad (3)$$

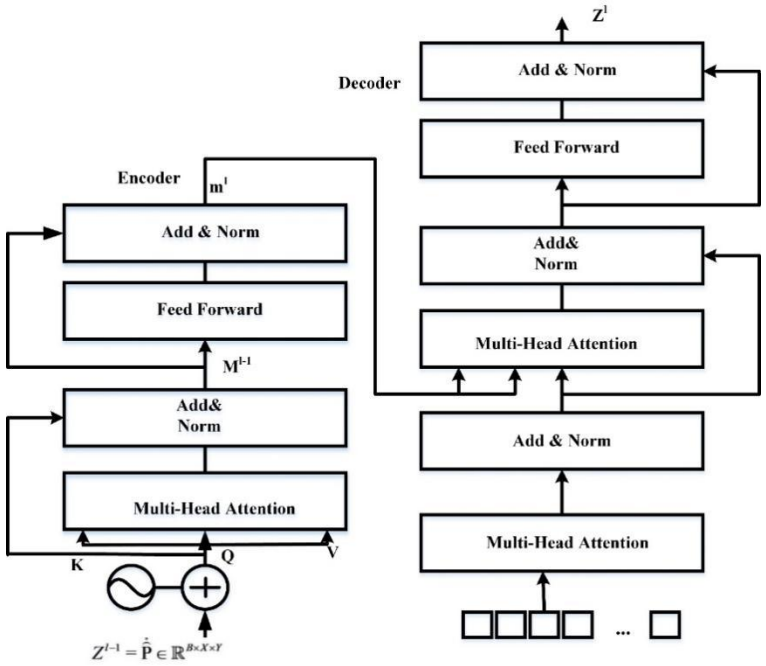

Fig. 5. Schematic diagram of the transformer structure.

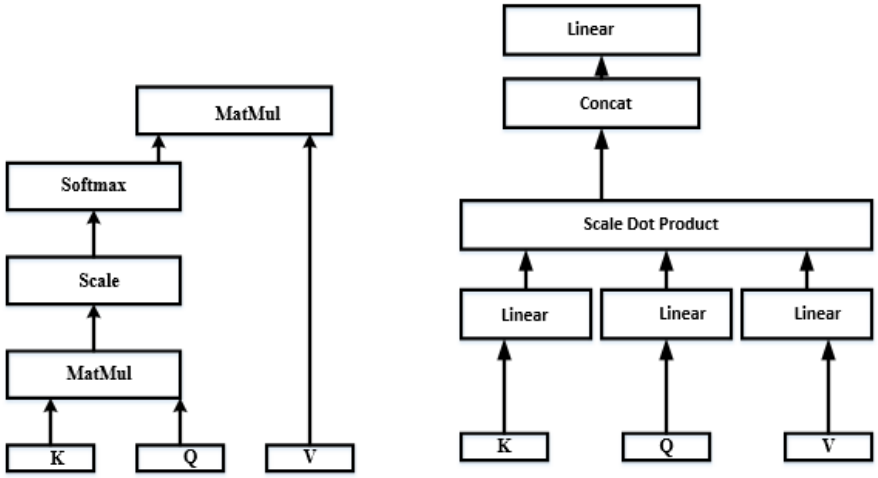

Fig. 6. Structure of a) SA module, b) MHA module.

where Q, K, and V represent the query matrix, key matrix, and value matrix, respectively, and d represents the input feature's dimensions. These are created by multiplying the matrix with the feature by 3 randomised weighting matrices. Structure of SA module and MHA module is shown in Fig. 6.

*5) MHA:* MHA is employed in a variety of projected areas to determine various projection information. The input matrix is then projected in various directions, and the resultant matrix is pieced together. SA is executed concurrently by MHA for every forecast outcome this is given in Eq. (4)

$$head_i = \text{Attention}\,(QW_i^Q, KW_i^Q, VW_i^V) \quad (4)$$

With $d_k = d_v = \frac{d_{model}}{h}$, denotes the total amount of heads are arranged, and $d_{model}$ denotes the total length of the given input feature. $d_k = d_v = d_{\frac{model}{h}}\ and$ indicates no of heads.

Concatenated the projected computation outcomes of numerous heads, is given in Eq. (5).

$$\text{MHA (Q, K, V)} = Concat\ (head_1, head_2, \ldots\ldots\ldots head_h)W^0 \quad (5)$$

Where in W^0∈R^( ⟦hd⟧ _(v×d_model ) ). Multi-head technology allows for the more detailed extraction of distinct heads' attributes. The feature extraction impact is better whenever the overall computation volume is equal to the value of a single head.

*6) FFN:* FFN maps features after a mapping from the high-dimensional space to the low-dimensional space. Incorporating various forms of information, improving the model's ability to solve problems, and removing low-resolution features by lowering the dimensionality are the objectives of mapping features to high-dimensional spaces. The method is derived in Eq. (6).

$$FFN(x)=\max(0,W_1 x+b_1)\,W_2+b_2 \quad (6)$$

where $W_1 \in R^{d_{model}}$and are the learnable weights, and b1 ∈ R4dmodel and b2 ∈ R4dmodel are the learnable biases.

Add & Norm: LN blocks and residual connections are contained in Add & Norm. The network depth's processing capability can be enhanced by the residual relationship, which can also successfully stop gradient expansion and the disappearance. LN accelerates the point of convergence of the mathematical framework by stabilizing the data feature distributions this is given in Eq. (7) and Eq. (8)

$$F(X) = LN(m^1 + m^{l-1}) \quad (7)$$

$$LN(x_i) = \alpha \times \frac{x_i - E(X)}{\sqrt{Var(x)+\epsilon}} + \beta \quad (8)$$

where α and β are the parameters that can be learned, and if their variance is zero, ε is used to avoid mistakes in calculation.

In the pose estimation subnetworks of the dual-channel Transformer model, two distinct regression subnetworks are employed to derive comprehensive pose information from feature maps. The first subnetwork is dedicated to estimating translation, or the position of objects, by analyzing spatial features extracted from the image. This involves regressing feature maps to predict the object's location. The second subnetwork focuses on estimating orientation, which involves predicting the object's rotation. For this task, a quaternion-based activation function is utilized, often resembling a SoftMax function but tailored to handle quaternion representations of rotation, providing a robust way to encode 3D orientations. Following the Transformer's processing, which enhances the feature representations through attention mechanisms and encoding-decoding processes, the resulting multi-dimensional output is flattened into a one-dimensional sequence. This flattened sequence is then fed into fully connected layers, which aggregate the information to produce the final pose estimates, including both translation and orientation of the object within the image. This structured approach allows the model to effectively combine and utilize the spatial and rotational data extracted from the satellite images [20].

*7) Bayesian optimization:* For the purpose of spacecraft pose estimation, Bayesian Optimization is used to fine-tune model learning rates, dropout rates, and the depth of Transformer layers to decrease pose estimation errors. The process starts with the formulation of objective function which measures the error involved in pose estimation which is the goal of the optimization process. Gaussian Process (GP) is employed to map the behavior of the objective function given a limited number of evaluations and yield a probabilistic estimate of the function mean and variance at locations in the design space yet unobserved. The Upper Confidence Bound (UCB) acquisition function then dictates which new set of parameters should be sampled in the next iteration with the intent of balancing exploration, where new parameters with a high level of uncertainty are chosen, and exploitation where parameters with a higher predicted reward is chosen. By indicating this iterative approach, it is possible to quickly navigate the parameter space and adaptively fine-tune the model's accuracy in terms of estimating a spacecraft's attitude and position with as few evaluations as possible to achieve the best result.

Bayesian Optimization uses qualifying guesses rather than spontaneous mutations and sampling, which reduces the number of repetitions needed. Utilizing a surrogate model that is fitted to every one of the prior specimens, the subsequent one to be evaluated is chosen in Bayesian optimization. Given the parameters, random uniform sampling is used to create an amount of starting samples. The surrogate model that is being utilized is a Gaussian process that is a non-parametric approach that builds a framework using all of the prior samples. A prediction's likelihood is also provided by the Gaussian process. As an acquisition function, the widely recognized Upper Confidence Bound (UCB) is utilized. As the name suggests, the subsequent parameter setting that is investigated is chosen based on the confidence bound above its present max. Bayesian Optimization is applied to enhance the pose estimation system by optimizing key parameters, specifically the feature radius and normal radius, which are fundamental to feature matching methods.

Fig. 7 depicts a parameter optimization procedure, where the process is initiated by the selection of 'p' training scenes, every scene comprising of 'm' objects that results in 'm*p' object detections. First, a parameter set is used for recognizing the objects (A) and then the result is assessed by scoring function (B). Afterwards, a Gaussian Process models the distribution of these performance results, which is denoted as C. According to this model the decision-making process chooses new sets of parameter for test (D). This is followed by the creation of the Gaussian Process with a selection of pre-specified number of parameter values and then applying Bayesian Optimization for 'n' steps. Lastly, all the 13 parameters and their assigned scores are employed to fit an extra Gaussian Process in order to determine expected optimum parameter set (E). This last stage supplements the identifications made on the best parameters by utilizing the acquired data to anticipate and determine the most profitable parameter setting.

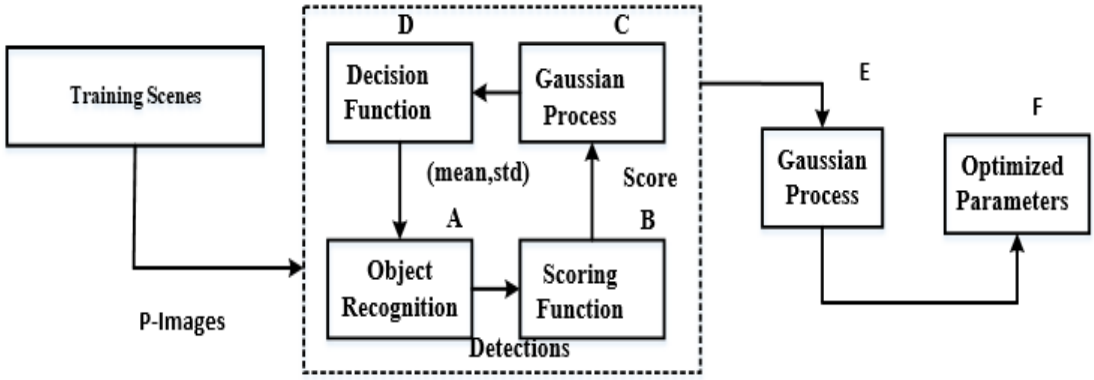

Fig. 7. Bayesian optimization for hyperparameter tuning in object recognition.

*8) Scoring the detections:* The outcome of the detection method's score to generate an additional score towards the optimization framework in order to maximize efficiency for reliable identifications. The system's overall score into TPs and FPs, or right and wrong findings, to obtain KDET P and KDEFP, accordingly. Any scoring mechanism may theoretically be employed in this situation, however the KDE is the result of the kernel density score during a pose given by the fundamental pose voting technique utilized for the estimation. Research employs the TP/FP ratio to calculate the score, rewarding high scores for accurate findings and penalizing higher scores for incorrect findings. For numerical causes, the score function is log-transformed since it produces more reliable results when the optimizing process is used in Eq. (9)

$$\text{score(KDE)} = \begin{Bmatrix} \log(\sum \frac{KDE_{TP}}{KDE_{FP}}) & i \sum KDE_{TP} \geq \sum KDE_{FP} \\ o, & \end{Bmatrix} \quad (9)$$

*9) Gaussian process regression for mode finding:* There is a chance of overfitting parameters for just the specific set of training scenes observed over training because just a tiny training set is utilized. This also utilize a Gaussian Process for regressing across the completed group of evaluations in order to reduce the possibility of incorrect parameter selection. This process makes the ideal parameter set prediction more accurate and smooth. To prevent overfitting of sparse training sets by Bayesian optimization techniques, alternative methods were additionally proposed. A term that penalizes steep peaks has been added to the newly acquired function. A Gaussian Process is then fitted to all examined sites in order to identify a stable maximum. The matrix made up of the variables X and the final score y can be used to represent the total amount of investigated points, or n this is given in Eq. (10)

$$x, y = \left\{ \left( x_i f(x_i) \right) \ | i = 1, \ldots \ldots n \right\} \quad (10)$$

A distribution is necessary in order to use a Gaussian Process for predicting the predicted result at new values for parameters. In this case, ˆx represents a brand-new, unproven parameter set this is given in Eq. (11).

$$\begin{bmatrix} y \\ x \end{bmatrix} \sim \begin{bmatrix} K & K_x^T \\ K_x & K_{xx} \end{bmatrix} \quad (11)$$

When K is the covariance matrix provided by a chosen kernel, k(x1, x2), and each index is determined by the interaction of a pair of parameters. Thus $K_{nxn,}$ $K_{nx1,}$ ) is obtained. to determine the new parameter's predicted value, which is determined by the difference between the variance and the mean.

By using the mean and the range to represent the degree of uncertainty, determine the anticipated amount of the newly added parameter this is given in Eq. (12) and Eq. (13)

$$E(x) = K_x K^{-1} \text{y} \quad (12)$$

$$var(x) = K_{xx-} K_x K^{-1} K_x^T \quad (13)$$

In this case, the kernel function K requires a distance d as inputs, integrating the Matern covariance $C_V$ and the diagonal noise terms N. This adds an additional term into the covariance functioning, which when combined with the Bayesian Optimization yields a Matern-kernel as well as a White Noise kernel, making the Gaussian process less susceptible to noises this is given in Eq. (14).

$$K(d) = C_V(d) + N(d) \quad (14)$$

The function is represented by J, and the gamma function is denoted by Γ. Since the entire dataset is not utilized, the white noise increases the evaluation's uncertainty this is given in Eq.. (15) and Eq. (16).

$$C_V(\text{d}) = \sigma^2 + \frac{2^{l-v}}{\tau(v)} \left( \sqrt{(2v\frac{d}{\rho})^v} j_v((2v\frac{d}{\rho}) \right) \quad (15)$$

$$N(d) = \begin{Bmatrix} \sigma, & if\ d = 0 \\ 0, & otherwise \end{Bmatrix} \quad (16)$$

The equation provided seems to define a kernel function, $N(d)$ where d represents some distance measure, and the kernel takes the value σ sigma when d=0 otherwise. This kernel is used to construct the covariance matrix for a Bayesian optimization process. The parameters must be established prior the prediction may prove computed, even though this kernel is utilized to produce the covariance matrix. is used to do a minimization procedure which fixes the v value, or the amount that distant points interacts with the projected result, whereas fitting the parameter values to the known score y. That will

provide a more accurate parameter forecast. These variables allow for the calculation of the kernels and the creation of an additional durable function given the expected parameter space. Numerous samples have been obtained and the space of parameters is investigated utilizing Bayesian optimization utilizing the training information and the scoring system [21]. Flowchart for Bayesian optimization is shown in Fig. 8.

## V. Result and Discussions

This research presents a novel breakthrough in spacecraft pose estimation by combining deep Transformer networks with Bayesian Optimization algorithms. The suggested Dual-Channel Transformer Model, augmented with EfficientNet-derived feature layers, is shown to exhibit higher accuracy in pose estimation than traditional approaches. Through the use of Bayesian Optimization, the model efficiently optimizes essential parameters like learning rates and network depths, making use of Gaussian Process Regression and Upper Confidence Bound (UCB) in order to reduce pose estimation error. The performance of the model is strictly verified using the Space Rendezvous Laboratory (SLAB) dataset, achieving significant improvements in both translational and rotational accuracy. The findings showcase a notable decrease in position and attitude errors under different distances, enhanced reliability in actual spacecraft pose estimation applications, and optimized parameters for the model that increase both efficiency and accuracy. This novel method sets a new standard for spacecraft pose estimation, proving effective in processing complicated satellite imagery and enhancing overall model performance.

### A. Performance Evaluation

*1) Localization Error (Translational Error):* This measures the Euclidean distance among the foretold and ground-truth positions in 3D space (X, Y, Z). The formula for localization error is given in Eq. (17).

$$\sqrt{(x_{pred-}x_{true}{}^{2}) + (y_{pred-}y_{true}{}^{2}) + ) + (z_{pred-}z_{true}{}^{2})} \quad (17)$$

Where $x_{pred,}$ $y_{pred,}z_{pred,}$ are the predicted coordinates, and $x_{true,}$ $y_{true,}z_{true,}$ are the ground-truth coordinates.

*2) Orientation Error (Rotational Error*)**:** This measures the angular difference between the predicted and ground-truth orientations, typically represented by quaternions or Euler angles. The rotational error in degrees can be computed in Eq. (18).

$$Orientation\ Error = \cos -1(2(\ q_{pred}.q_{true})^{2} - 1 \quad (18)$$

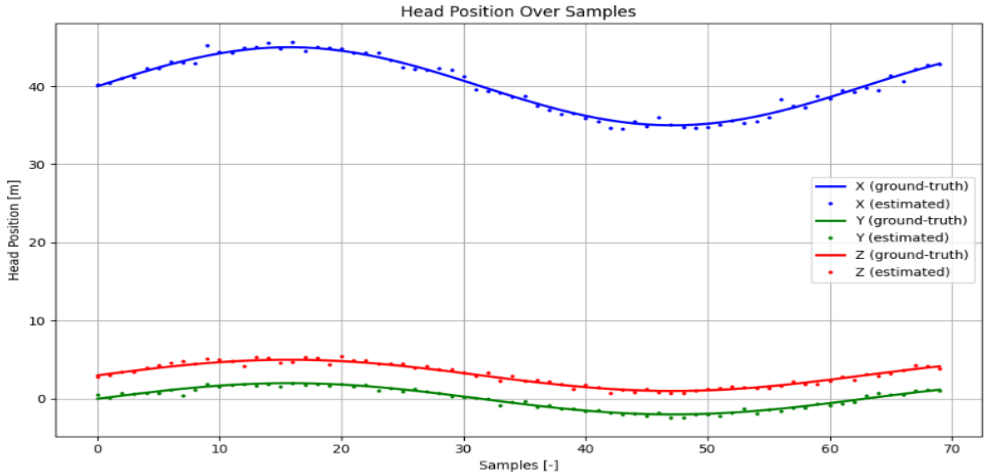

Fig. 9. Head position over samples.

Fig. 9 illustrates the comparison between ground-truth and estimated head positions across X, Y, and Z coordinates over several samples, with solid lines depicting ground-truth and dashed lines showing estimated positions. The blue, green, and red lines correspond to the X, Y, and Z coordinates, respectively. This visualization is key for assessing the accuracy of head position estimation algorithms, particularly in motion tracking and virtual reality applications. A close alignment between the ground-truth and estimated lines suggests that the estimation algorithm performs with high accuracy, effectively mirroring the true head movements across all three dimensions.

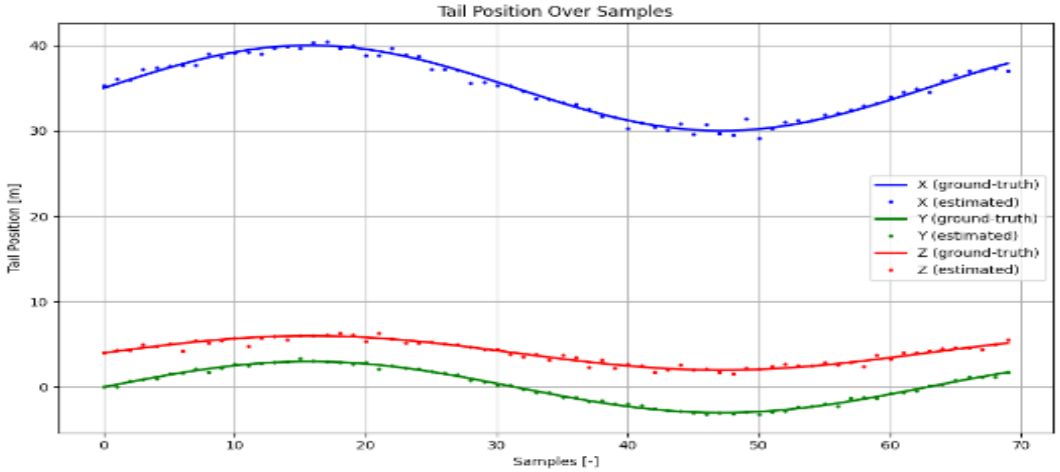

Fig. 10. Tail position over samples.

Fig. 10 shows the comparison between the ground truth and estimated tail positions in three dimensions (X, Y, Z) over a series of samples. The x-axis represents the sample number, ranging from 0 to 70, while the y-axis represents the tail position in meters, ranging from -20 to 40. The blue, green, and red dots indicate the actual measured positions for X, Y, and Z respectively, while the smooth curves in corresponding colors represent the estimated positions. t is probable that this graph is used to assess the error of tracking or predicting algorithm where one would plot the estimated position against the time and the plotted position against the actual measured position against time.

Fig. 11 shows the position error of the spacecraft's center of mass (CoM) over time across three axes: X, Y, and Z. The position error indicates how much the spacecraft's actual position deviates from its position. The x-axis signifies the number of samples (time), while the y-axis shows the position error in meters. The blue, green, and red lines correspond to the X, Y, and Z axes, respectively. The y-axis showing the error in meters (ranging from -2 to 3 meters) and the x-axis showing the number of samples (from 0 to 70).

Fig. 12 represents the change of the attitude error of a spacecraft's center of mass over time. Attitude in spacecraft pose estimation means the orientation of the spacecraft in space. The attitude error shows the difference of the actual orientation with the required degrees of orientation. The value on the horizontal axis is that of sample number with the values ranging from 1 to a figure slightly below 70. The y-axis represents the ˜attitude error' in degrees scale with the range of roughly 2 to 8 degrees. On the graph presented below, the changes in the attitude error can be observed with clear elevation and decline periods. This variability implies fluctuations of the stability or the control system performance of an object.

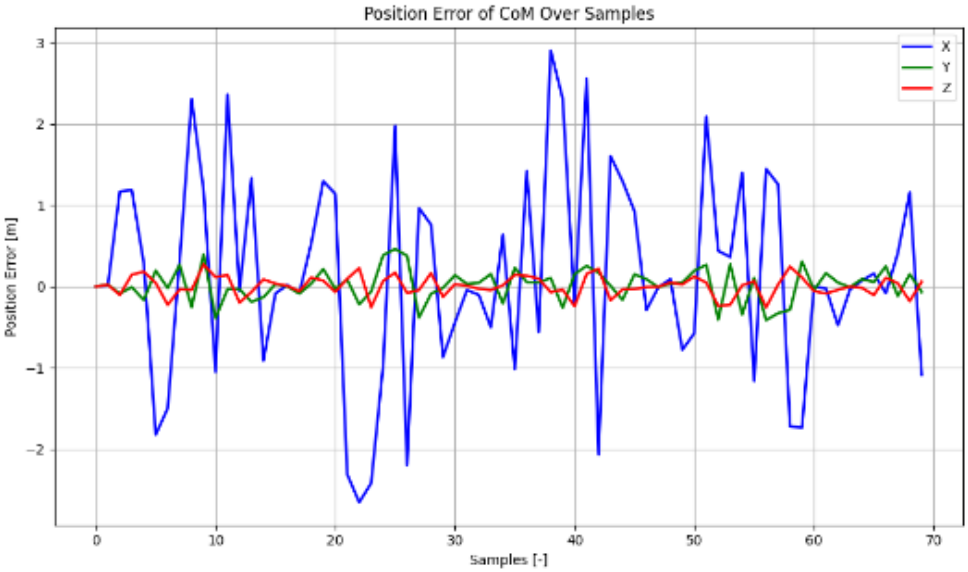

Fig. 11. Position error of CoM.

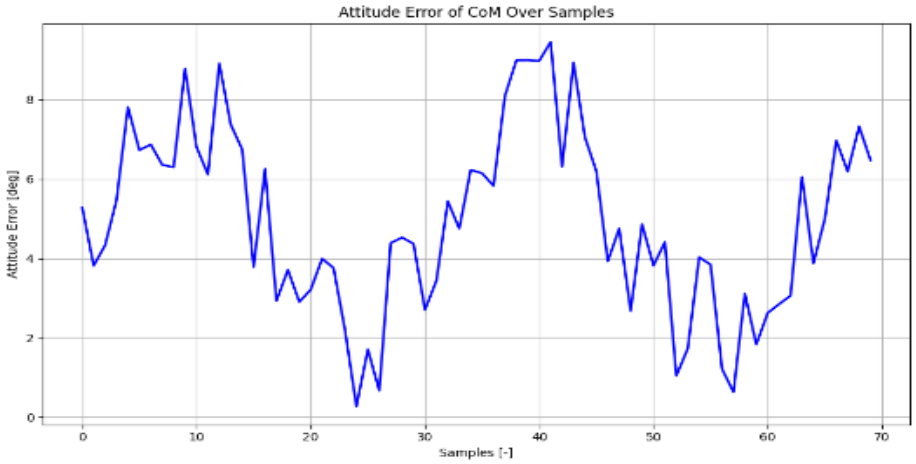

Fig. 12. Attitude error of CoM over samples.

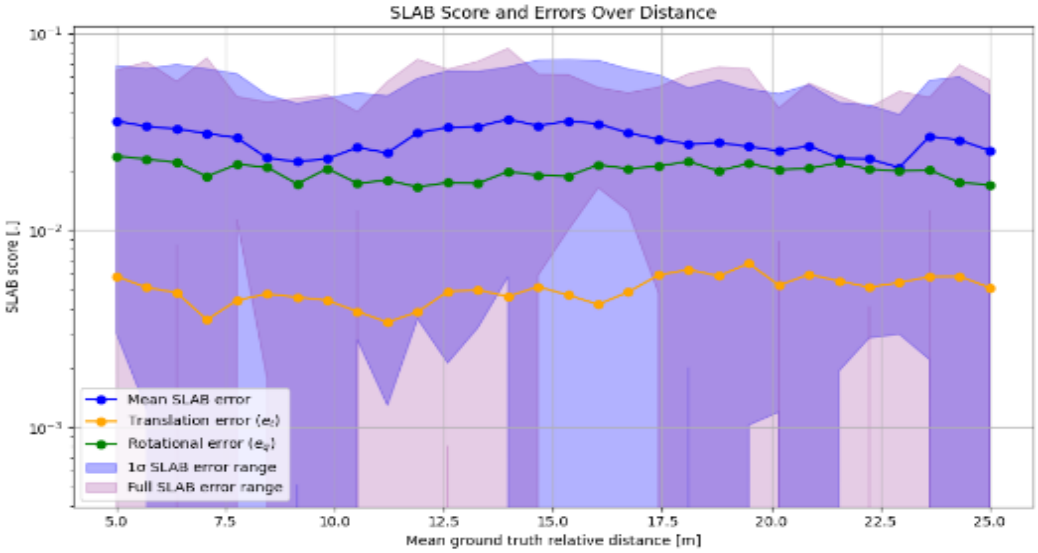

Fig. 13. SLAB Score and errors over distance.

Fig. 13 shows how distances affect pose estimation errors of spacecrafts the range of distances is shown on the horizontal axis, while the vertical axis describes SLAB scores in logarithmic degrees. The blue line represents the Mean SLAB Error, meaning that it presents the mean pose estimation errors. The green line represents Translational Error which is exclusively related to the errors of spacecraft's movement. The dark blue line with circle markers represents Rotational Error. The orange line gives the Full of SLAB Error Range to get the overall idea of errors. Grey-shaded areas in light purple and orange represent error variability, including the full range of SLAB error range, as well as 1σ SLAB error bars. This graph is important as it depicts the manner in which the accuracy and reliability of pose estimate are impacted by the distance from the spacecraft to its object.

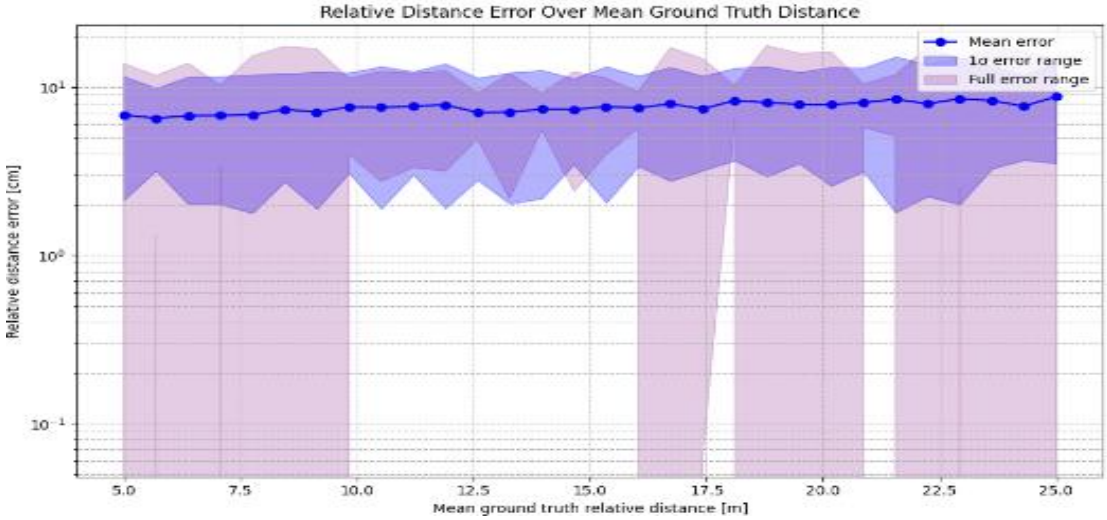

Fig. 14. Relative distance error over mean ground truth distance.

Fig. 14 shows the accuracy rates of the estimation of the position of a spacecraft at different distances. The horizontal axis depicts the average ground truth distance in meters (0 – 25 meters) while the vertical axis depicts the relative distance error in log-log scale in centimeters where values ranges from 0. 01 centimeters to 10 centimeters. The solid blue curve presents the average error and despite the increase of distance this value does not change dramatically. The region between this line and the light purple colored area is the distribution of data within one standard deviation (1σ Error Range) and the darker colored area represents the range of errors observed which is the maximum and minimum. This graph is needed for determining the accuracy of the spacecraft pose estimation, especially during essential operations such as docking or landing, as the nature of error dependence on distance can be observed from this graph.

Fig. 15 shows how accurately a spacecraft's orientation can be determined over varying distances. The mean error line shows the average deviation from the true pose, while the 1σ error range and full error range illustrate the variability and extremes of these errors. This helps in assessing the reliability and precision of the pose estimation system, which is vital for navigation, docking, and other critical operations in space missions. By analyzing the Attitude Error Analysis Based on Ground Truth Distance pose of a spacecraft, the Relative Attitude Error Over Mean Ground Truth Distance is important to know how well orientation measurements of a spacecraft can be from far and near. The mean error line was used to indicate the average distance off true pose, while the 1σ to demonstrate the spread of these errors and full error range shown the overall high/low of these errors.

Table II evaluates four object detection methods based on their Intersection over Union (IOU) scores, orientation errors $\xi_R$and localization errors $\xi_T$The SPN method exhibits moderate IOU scores but shows relatively high orientation and localization errors, indicating less accuracy in detecting object positions and orientations. HRNet+PE excels with the highest IOU scores and the lowest errors in both orientation and localization, reflecting superior precision and accuracy. URSONet presents lower IOU scores and significant errors in orientation and localization, suggesting lower overall performance. The Proposed method combines high IOU scores with competitive orientation and localization errors, indicating a well-balanced approach with effective accuracy and precision in object detection.

### *B. Discussions*

The present research offers a revolutionary method to spacecraft pose estimation through the implementation of a Dual-Channel Transformer Network coupled with Bayesian Optimization, providing a crucial improvement over other conventional methods such as CNNs, SLAM, and Particle Filters. With the use of EfficientNet to achieve stable feature extraction and splitting translation and orientation predictions using specific subnetworks, the model is able to capture both the spatial and rotational features of spacecraft from challenging satellite images [25]. Employment of Bayesian Optimization in tandem with Gaussian Process Regression and UCB acquisition fine-tunes the model through optimized hyperparameters via low-order evaluation, raising the bar of both accuracy and computation. Demonstrated on the SLAB data, the solution worked with far superior generalizability and precision in a multitude of scenarios and exemplified potential deployment in actual operational autonomous space settings. In comparison to

current research, this work not only obtains better estimation performance but also proposes a more scalable and flexible method. Outcomes bridge gaps in literature by offering solutions to the most critical challenges of domain shift, computational expense, and sensor noise sensitivity, building a strong platform for future development in deep learning-based space navigation and robotics.

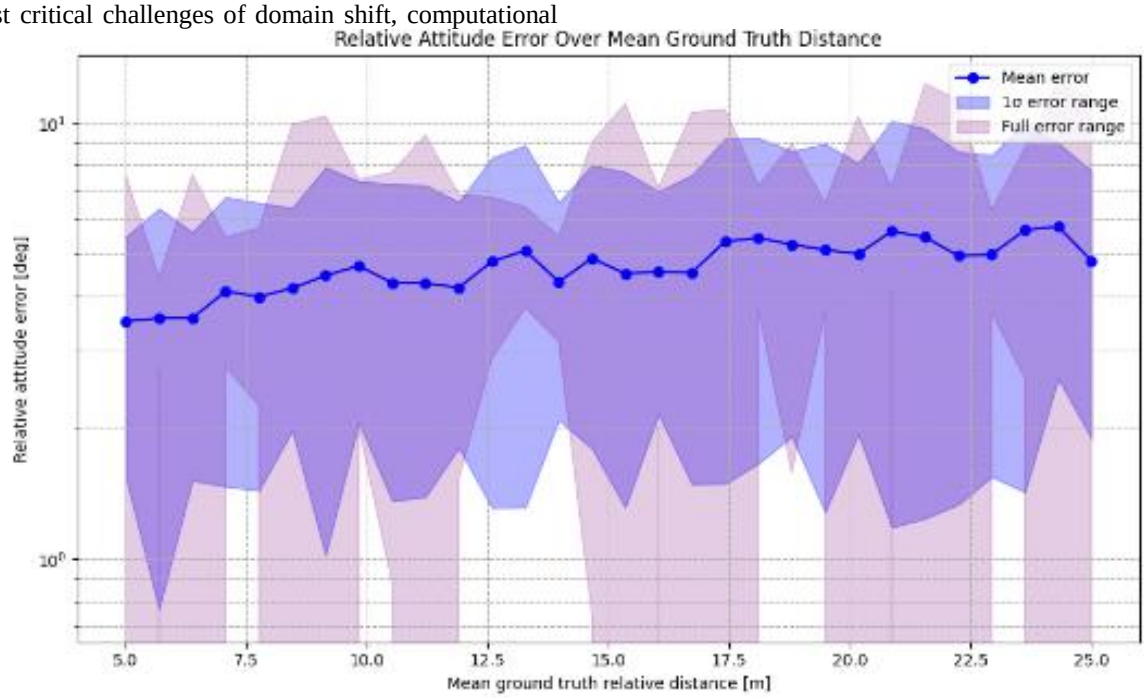

Fig. 15. Relative attitude error analysis based on ground truth distance.

TABLE II. PERFORMANCE COMPARISON OF OBJECT DETECTION METHODS: LOCALIZATION AND ORIENTATION ERRORS

| Method | Mean IOU | Median IOU | Mean $\xi_R$ (degree) | Median $\xi_R$ (degree) | Mean $\xi_T$ (m) | Median $\xi_T$ (m) |
|---|---|---|---|---|---|---|
| SPN [22] | 0.8582 | 0.8908 | 8.4254 | 7.0689 | 0.2937 | 0.1803 |
| HRNet+PE [23] | 0.9534 | 0.9634 | 0.7277 | 0.5214 | 0.0359 | 0.0147 |
| URSONet [24] | | | 3.1036 | 2.6205 | 2.1890 | 1.2718 |
| Proposed | 0.9610 | 0.9727 | 0.6812 | 0.5027 | 0.0320 | 0.0144 |

## VI. CONCLUSION AND FUTURE WORK

This is a novel research and innovation in the field of spacecraft pose estimation which utilizes Dual-Channel Transformer Model with EfficientNet is as feature extractor and Bayesian Optimization is used for hyperparameters tuning. The proposed method has shown a clear advantage in terms of translational and rotational accuracy over traditional methods. EfficientNet made the model able to comprehend complex spatial and rotation characteristics of the spacecraft, while dual subnetworks focusing on translation and orientation contributed to improved pose estimation accuracy. Bayesian Optimization as an optimization algorithm using Gaussian Processes with Upper Confidence Bound (UCB) acquisition function enabled adequate hyperparameter tuning, with a reduced number of function evaluations. Results obtained by validating this new approach on SLAB dataset shows significant improvement regarding position and attitude estimation for different distances, confirming advantages presented by this innovative concept in real-world applications. Even though the progress achieved, several directions should be further explored. First, more diverse data should be used to establish a model with stronger generality. Data from different types of spacecrafts under various environmental conditions need to be included in the training and testing datasets to improve the generality of the proposed method and verify its effectiveness under more general settings. Real-time learning can also be integrated into the model so that onboard or native spacecraft climate data can be continuously accumulated to update (train) the current deep learning models during missions. This would make it feasible for the long-duration application of a deep-learning-based model in varying space environments. Hybrid optimization algorithms such as coupling Bayesian optimization with genetic algorithms or reinforcement learning could potentially enhance both computational efficiency and modeling accuracy. Furthermore, expanding this work from attitude estimation to other applications, including velocity estimation or fuel efficiency optimization and control, will significantly increase our capability in exploring state-of-the-art technologies using attitude as well as other critical information in modern autonomous navigation tasks of docking, rendezvous and landing. This work establishes a new state-of-the-art for spacecraft pose estimation, but continued advancements in adaptability, real-time learning, and more extensive parameter estimation should allow even higher levels of accuracy and efficiency for spaceflight missions.

***Abstract*—The basis for current digital infrastructure is cloud computing, which allows for scalable, on-demand computational resource access. Data center power consumption, however, has skyrocketed because of demand increases, raising operating costs and their footprint. Traditional workload scheduling algorithms often assign performance and cost priority over energy efficiency. This paper proposes a workload scheduling method utilizing deep reinforcement learning (DRL) that adjusts dynamically according to present cloud situations to ensure optimal energy efficiency without compromising performance. The proposed method utilizes Deep Q-Networks (DQN) to perform feature engineering to identify key workload parameters such as execution time, CPU and memory consumption, and subsequently schedules tasks smartly based on these results. Based on evaluation output, the model brings down the latency to 15 ms and throughput up to 500 tasks/sec with 92% efficiency in load balancing, 95% resource usage, and 97% QoS. The proposed approach yields improved performance in terms of key parameters compared to conventional approaches such as Round Robin, FCFS, and heuristic methods. These findings show how reinforcement learning can significantly enhance the scalability, reliability, and sustainability of cloud environments. Future work will focus on enhancing fault tolerance, incorporating federated learning for decentralized optimization, and testing the model on real-world multi-cloud infrastructures.**

***Keywords*—Cloud computing; energy efficiency; reinforcement learning; virtual machine; workload scheduling***

## I. INTRODUCTION

Cloud computing technology has emerged as essential technology because it provides adaptable and effective computer resources to all individuals together with enterprises worldwide. Cloud services provide instant access to processing power and storage and networking capabilities which has led to a total transformation of various business operations. Since this transition occurred companies can carry out innovation and growth at rapid speeds [1]. The expansion of cloud service use raises the electricity consumption in major data center facilities [2]. This challenge has become somewhat important as meeting the demand for energy, without losing performance in cloud-based services is a problem. Data centers form the foundation of cloud computing today. Computing, Storage, and Networking are the functions in data centers. They consume much electricity [3]. This increase in workload in the data centers due to the ever-increasing demand for cloud-based applications has seen energy consumption significantly shoot up. Most of the power consumed by the data centers can be traced to the need to process complicated workloads and maintain cooling and networking operations, thus ensuring cloud services are always functioning [4]. Therefore, the reduction of the energy footprint of cloud computing has become both a technical and environmental imperative. Optimization of energy usage in cloud data centers is a concern not only to reduce the cost of operation but also as an urgent environmental need. The achievement of maximum efficiency requires workloads to have effective scheduling algorithms. This system will enable resource management and minimal energy usage to achieve efficient operation and cost-effectiveness for cloud data centers [5].

The actual practice of workload scheduling requires dispersing computational workloads onto virtual machines to achieve minimum usage of power and resources. Cloud infrastructure performance and operational expenses improve through scheduling optimization leading to better operation. The majority of traditional scheduling approaches present limited interest in energy conservation because they focus on two separate objectives: peak performance and cost reduction. Cloud computing presents great challenges in workload management since user needs vary frequently and deployment options differ widely and service-level agreements are strictly enforced in this environment where workloads exhibit unexpected dynamism and extreme resource variability [6]. Fixed scheduling techniques and those following rules fail to manage operational modifications in real-time which leads to poor resource distribution together with increased energy consumption. The research recommends using reinforcement-learning algorithms for scheduling problems in cloud environments.[7]. The demand for adaptive scheduling approaches which minimize power

usage without affecting system performance remains immediate [8], Systems that run through the cloud have the ability to improve their energy efficiency without jeopardizing either their reliable service level or performance standards through this approach [9].

The framework enables system learning through environment interactions because of its reinforcement learning capabilities. The optimal scheduling policy through interaction with the technique has potential for workload scheduling by leveraging the environment to teach optimal scheduling policies. In reinforcement learning, an agent acts in response to its perception of the environment and is rewarded or punished appropriately. It lets the agent learn to improve with time in such a manner that it learns from the outcome of its actions [10]. Using RL for scheduling workload in the cloud, an indirect resource allocation can be made on the fly according to the real-time demands and thus energy consumption optimizes continuously. Unlike previous heuristic-based methods, these methods will not depend on predefined rules but learn from previous experiences and hence, can handle very dynamic and complex cloud environments [11]. This adaptability pays off well in cloud computing, where changes in workload characteristics can be rapid, requiring real-time resource allocation on the fly. In this study, the focus is primarily on using algorithms based on RL to schedule cloud workloads, with the purpose of minimizing energy consumption while respecting performance standards. Through reinforcement learning, this study will describe and apply the strategy that optimizes the pursuit of energy efficiency within cloud infrastructures. For reducing energy consumption without compromising its overall performance within cloud services, we suggest an RL-based task scheduling algorithm that adjusts to changing system conditions and workload demands [12]. The proposed method integrates reinforcement learning with energy-aware scheduling techniques, which enables dynamic adjustments to workload distribution based on real-time energy consumption data. This will help cloud computing infrastructures become more sustainable by incorporating feedback loops and making adjustments to scheduling policies based on past performance. The rest of the paper focuses on the design, implementation, and evaluation of the effectiveness in bringing down the energy consumption while ensuring high service reliability for the RL-based scheduling algorithm [13]. This research contributes to the emerging area of energy-efficient cloud computing by introducing a new approach for optimizing energy usage in cloud data centers using reinforcement learning techniques.

The major key contributions are as follows:

*1)* It introduces a reinforcement learning-based algorithm for optimal energy-efficient scheduling of workloads in cloud environments.

*2)* The scheduler adapts strategies in real-time to manage unanticipated cloud workloads while optimizing energy consumption.

*3)* It balances optimization of energy consumption with QoS constraints to satisfy SLA requirements and system dependability.

*4)* To validate the proposal, the presented method is tested against traditional algorithms such as FCFS, RR, and heuristic-based algorithms with better energy efficiency and performance.

*5)* It ensures scalability across different cloud infrastructures and hence is applicable to various real-world cloud service providers.

The following is the remaining part of the section is structured: Section II as Related works on previous papers, Section III as problem statement, Section IV as proposed methodology, Section V as result and discussion and Section VI as conclusion and future work is provided.

## II. Related Works

Mobula et al. [14] proposed a new approach to address the challenges of workflow scheduling in the cloud environment by focusing on the optimization of energy efficiency while satisfying user-defined constraints such as deadlines and budget. Acknowledging that workflow scheduling is an NP-complete, they proposed two algorithms called Structure-based Multi-objective Workflow Scheduling with an Optimal instance type and Structure-based Multi-objective Workflow Scheduling with Heterogeneous instance types. The SMWSO algorithm computes the optimal instance type and the number of virtual machines that should be required to improve the scheduling efficiency. In the meanwhile, SMWSH extends this concept by adding heterogeneous VMs that allow greater flexibility in a diverse cloud environment. Their research work emphasizes the critical role workflow structures play in making scheduling decisions and proves that optimized instance types and VM allocations can significantly decrease energy consumption. Based on simulations, their methods obtained superior heir result manifests the relevance of using workflow-aware scheduling strategies in cloud environments, especially in cost reduction and sustainability. Their work serves as a basis for further research into intelligent workload scheduling strategies that integrate optimisation techniques to improve cloud computing infrastructures.

Murad et al. [15] proposes an Optimized Min-Min (OMin-Min) task scheduling algorithm for enhancing cloudlet scheduling and resource allocation. This study is hoped to increase the performance of a system by increasing resource utilization and decreasing task execution time. The OMin-Min, which is the enhanced version of the traditional Min-Min, is constructed by applying these approaches, and the performance of OMin-Min is compared to that of the Min-Min, Round Robin, Max-Min, and Modified Max-Min algorithms. The experiments include different sizes of cloudlets (small, medium, large, and heavy) on three scientific workflow datasets: Montage, Epigenomics, and SIPHT.The evaluation and implementation are performed using the CloudSim simulator within a Java environment. The merits of the new algorithm are in its capacity to generate optimal scheduling outcomes, provide lower completion times, and ensure improved resource utilization, ultimately contributing to better throughput. However, the limitation might be based on the computational difficulty of optimal scheduling decisions for large-scale or extremely dynamic systems. The performance indicators indicate that OMin-Min performs better than all other algorithms in all test cases with the most efficient scientific workflow task scheduling solution in the cloud.

Panda et al. [16] a new approach to the task scheduling problem in cloud computing termed NP-Complete since it tries to optimize the overall execution time is proposed. In this work, we introduce a pair-based task scheduling algorithm that aims to enhance scheduling performance by reducing overall layover time, which is the total of timing gaps between paired jobs. Through forming task pairs to guide scheduling decisions, the technique, founded upon the Hungarian algorithm of optimization, applies it innovatively to situations where there are uneven numbers of tasks and clouds. On twenty-two different data sets, performance of the proposed algorithm is checked and compared to three existing algorithms: First-Come-First-Served (FCFS), the Hungarian algorithm with lease time, and the Hungarian algorithm with converse lease period. The results indicate that the proposed strategy consistently performs better than the comparison methods with regard to layover time. The processing cost involved in integrating logic and multiple iterations may, however, be a drawback in real-time or highly large-scale systems. Overall, the study provides a systematic and effective technique to cloud-based work scheduling that promises to perform better than traditional methods.

Shaw et al. [17] explores the critical issue of energy consciousness in cloud data centers through automated energy-saving Virtual Machine (VM) consolidation using Reinforcement Learning (RL) methods. Virtual machine consolidation is an important strategy to save energy consumption and enhance data centers' greenness. For the sake of enhancing resource utilization and minimizing energy-related costs, this work will explore applying RL algorithms for dynamic VM allocation optimization. The methods comprise popular RL algorithms such as SARSA and Q-learning, which are evaluated for their ability to reason under uncertainty and therefore learn proper consolidation procedures without knowing the environment beforehand. The primary contribution of this work is its demonstration that RL-based VM consolidation can lead to a 63% reduction in service violations and a 25% improvement in energy efficiency, which shows a significant performance improvement over traditional heuristics. The computational cost and training time typically associated with reinforcement learning models, however, might be a drawback as it may affect the scalability or real-time adaptability of the models within bigger-scale cloud systems. Ultimately, the article illustrates that RL offers a robust, versatile solution to dynamic virtual machine consolidation and significantly contributes to the construction of next-generation, energy-efficient cloud infrastructures.

Malik et al. [18] The authors created a job scheduling method with energy consciousness to optimize cloud data centers' virtualized resource benefit while lowering their energy requirements. This approach implements three key elements that first segregate jobs and next schedules them according to set thresholds while preventing system slowdowns. During pre-processing the first phase creates distinct queues for tasks that demonstrate high dependability standards and have long execution durations. Task organization relies on resource intensity levels to achieve proper distribution among resources. Through their scheduling method based on PSO algorithm the authors achieve dynamic selection of optimal schedules that consider workload distribution together with energy efficiency goals. Experimental benchmarking of conventional scheduling methods confirms that the proposed algorithm demonstrates superior performance according to results obtained from test datasets.

Panwar et al. [19] The research delivered an extensive examination of methods to decrease energy usage in cloud data center operations because of the relationship between fast cloud growth and increased power consumption. Through the work the researchers study various optimization approaches that enhance cloud data center energy efficiency because they recognize excessive energy usage leads to environmental deterioration. The study examines CPU utilization forecasting alongside detection methods for underload and overload situations and procedures for selecting and moving virtual machines and picking their deployment locations. The authors compare energy savings of various methods and demonstrate the effectiveness of heuristic approaches, achieving energy reductions of 5.4 percent to 90 percent over the current methods. The highest energy saving potential of 7.68 percent to 97 percent was realized through the use of metaheuristic methods, machine learning techniques at 1.6 percent to 88.5 percent, and finally through the application of statistical techniques to save 5.4 percent to 84 percent. This review highlighted the effects that these techniques can have: not only decreasing the consumption of energy but also reducing related greenhouse gas emissions and water usage for electricity generation. This paper combines the various findings from various works to provide an understanding of the various means through which energy efficiency and sustainability in cloud data centers can be improved.

Yadhav and chawla [20] discusses different task scheduling algorithms in the cloud environment to consume less energy. Cloud computing is among the fastest-growing technologies in the computer world; thus, in modern cloud data centers, managing energy efficiency has become crucial. This paper presents an overview of different kinds of heuristic and machine learning-based algorithms for optimizing task scheduling. These are Genetic Algorithm and Particle Swarm Optimization, highlighted for their efficiency in finding nearly optimal solutions over large search spaces, thus applicable to energy minimization. There is also discussion on Reinforcement Learning, which, through dynamic adaptation to workload variations, has shown its potential in optimizing energy efficiency via continuous learning and adaptation. The paper considers other related techniques, such as Ant Colony Optimization and Dynamic Voltage and Frequency Scaling, which provide mechanisms for trading off the metrics performance and energy usage. The considered algorithms are evaluated in detail, emphasizing their performance in cloud-like environments. The results clearly show that, although no individual algorithm appears to be ideally optimized in general, a tailored blending of the techniques offers a significant energy saving. This paper focuses on the selection of an appropriate algorithm or set of algorithms that should optimize the energy consumption in cloud data centers, thus adding to the contribution of sustainability and cost savings.

Liu et al. [21] presents a greedy scheduling approach to improve energy consumption and resource utilization for cloud data centers. Cloud computing systems are plagued by issues of excessive energy consumption and poor resource utilization,

particularly with heterogeneous resources. In addressing such issues, this paper introduces the granular computing theory into cloud task scheduling, where tasks are categorized into three categories: CPU, memory, and hybrid types. This categorization enables the use of particular scheduling methods based on the nature of the various task types. The article identifies that the cloud resource is heterogeneous in nature and that distinct scheduling methods must be employed for distinct types of tasks to ensure maximum energy saving. The efficiency of the proposed approach is established by numerical experiments on the CloudSim platform, and the results indicate significant improvement in terms of energy efficiency. The results demonstrate that, for a specific task type, the greedy scheduling strategy is able to reduce energy usage while maximizing the utilization of resources. It is thus an efficient practical approach for energy optimization in cloud data centers, improving resource management methods in cloud computing.

Pandey et al. [22] to enhance resource utilization and energy efficiency in cloud computing environments that enable large-scale data processing. Cloud computing is a vital alternative as conventional computing infrastructure fails to meet the growing demand for real-time data processing, high-performance analytics, and massive storage. Yet, complex problems such as scheduling, load balancing, power management, and resource allocation have been created by this surge in cloud services. The research discusses state-of-the-art strategies such as swarm intelligence-based meta-heuristics to address problems, with a particular focus on Discrete Particle Swarm Optimization (DPSO) for workflow scheduling and resource allocation. In cloud resource management, the DPSO approach maximizes particle positions and velocities in a series of fitness evaluations and iterative updates. Even though the paper emphasizes the unification of numerous PSO variants and presents a detailed algorithmic structure, it has no reference to some specific dataset, which means that the research is conceptual or algorithmic in scope. The most important strength of this study lies in its exhaustive application of clever learning models made for cloud dynamics and hybrid optimization techniques. Its lack of empirical evaluation, applicability, or performance comparison to existing standards is a major drawback, however. To offer a plausible route for cloud computing in big data systems on a sustainable path, the study concludes by proving how combining LSTM with DPSO can significantly advance energy-efficient resource allocation and scheduling in dynamic cloud systems.

Katal et al. [23] explore a range of methods of reducing data center power consumption in an effort to promote the concept of green cloud computing. The ongoing impact of the internet on nearly every aspect of the modern economy has driven energy and processing power demand higher, particularly in data centers that support cloud services. A range of methods for saving energy are discussed in the paper, including hardware-level optimization techniques, firmware and hardware-level dynamic power management (DPM), and power-saving methods employed at the network and server cluster levels. By regulating e-waste, reducing unnecessary energy consumption, and reducing carbon footprints, these systems intend to encourage sustainable computing practices. The research does not utilize any specific dataset or present empirical findings, although it offers a comprehensive review of existing practices and highlights the necessity of energy-efficient processes. The research is conceptual and integrates existing approaches in the discipline instead of proposing new methodologies. The primary advantage of this work is its thorough examination of energy-saving measures at different system levels, which provides valuable information regarding the development of green data centers. The lack of quantitative analysis or experimental validation, however, is a major drawback. To develop more sustainable and energy-efficient data center infrastructures, the conclusion of the paper emphasizes the necessity of ongoing innovation and points out research challenges.

Medara and singh [24] emphasizes the increasing importance of cloud computing, which has been used as the major structure for all enterprises. All types of enterprises were allowed to use cloud for business development. The paper discusses an issue of energy consumption for scientific workflow applications in cloud data centers. Since cloud services are increasingly being deployed, a lot of consumers have started seeing the massive power utilization that comes as a result. This paper reviews existing energy-efficient scheduling techniques specifically designed for workflow applications in cloud environments. It focuses on approaches that attempt to minimize energy consumption while satisfying quality of service constraints. The review offers a comprehensive overview of the paradigms that have been introduced in the literature regarding energy-aware scheduling, discussing the advancements that have been achieved and their weaknesses. Through the examination of numerous approaches, this paper sheds light on the trajectory of energy-aware scheduling and their practical impacts in cloud settings. Additionally, it outlines possible areas of future research so that the work can contribute to ongoing discussion in energy efficiency. This is a very valuable piece of resource for researchers and practitioners aiming at building more efficient solutions for reducing.

The recent works section discusses some strategies for optimizing energy consumption in cloud computing environments, especially workflow and task scheduling. Researchers have proposed several algorithms to handle the intricacies of minimizing energy usage while maintaining quality of service and adhering to user-defined constraints like deadlines and budgets. There are several approaches such as multi-objective scheduling, task classification, and dynamic voltage scaling that can be used to reduce the energy footprint of cloud data centers without performance degradation. Intelligent scheduling strategies, such as Particle Swarm Optimization, Genetic Algorithms and Reinforcement Learning, help in adapting to variations in workload and improve resource allocation. Other researches further emphasize how advanced models, such as queuing systems, genetic algorithms, and greedy scheduling techniques, may be used to improve energy efficiency further. There are also energy-aware scheduling paradigms that integrate optimized resource usage and avoidance of unnecessary energy spends into a system.

## III. Problem Statement

The rampant growth in cloud computing has led to data centers consuming much more energy, leading to increased operating expenses [25]. Traditional workload scheduling

methods, such as heuristic and rule-based algorithms, often fail to effectively optimize resource usage, leading to performance bottlenecks and wastage of energy [26]. There are problems related to computational complexity, model convergence time and usability in practical large-scale cloud scenarios, which burden existing RL-based scheduling models. A much-improved dynamic scheduling mechanism is in urgent demand in order to lower energy consumption without compromising the system's performance and service reliability. The purpose of this work is to design a workload scheduling algorithm using reinforcement learning that makes cloud computing energy-efficient [27]. The proposed model with the help of deep reinforcement learning (DRL) techniques such as Proximal Policy Optimization (PPO) and Deep Q-Networks (DQN) wants to optimize the allocation of the workload to the virtual machines (VMs) to achieve the maximum. Massive energy savings, reduction in delay in execution, and eco-friendly cloud computing processes are the ambitions. The creation of energy-efficient, smart cloud infrastructures that can dynamically adapt to variations in workload in real time while minimizing their adverse impacts on the environment will be facilitated by the resolution of these issues [28].

## IV. METHODOLOGY

Cloud computing is becoming the basis of modern digital infrastructure, thus offering scalable, on-demand access to computing resources to various sectors. However, as the numbers of cloud services and applications rise, the amount of energy data centers consume also rises, contributing to increased operation costs and a larger carbon footprint. Traditional scheduling techniques for workload usually focus more on performance optimization and cost than energy efficiency. The research put forward a workload scheduling algorithm dynamically adjusts the assignment of tasks in order to optimize energy consumption with service quality not going below a threshold. Unlike some static or heuristic-based scheduling techniques, reinforcement learning adapts real-time workload variations better to the cloud environment and optimizes resource allocation within a system by continuously learning from past scheduling decisions to reduce power wastage. Applying feature engineering techniques enables extraction of the appropriate workload attributes like CPU usage, memory demand, and execution time so that the model is enabled to take the informed decision on scheduling. Also, the model's performance robustness has been improved using simulated workload scenarios in the process of training and testing. By combining reinforcement learning with intelligent workload scheduling, this method not only decreases energy consumption but also guarantees effective utilization of cloud resources in the most sustainable and cost-effective way for cloud computing.

Fig. 1 illustrates a systematic process to achieve optimal resource allocation in cloud computing environments. The initial step is the collection of cloud performance metrics, which are the raw data that demonstrate how cloud resources are utilized and performed. In order to derive relevant and meaningful attributes that can effectively direct decision-making activities, this information undergoes feature engineering. Secondly, emulation work scenarios are developed to replicate real-world workloads so that controlled development and testing of resource management methods can be performed. The second step is Markov Decision Process (MDP) modeling that permits formal and strategic optimization since the problem of resource allocation is posed as a series of decisions under uncertainty. The system then applies reinforcement learning (RL)-based scheduling, whereby iterative interactions and reward feedback are employed to make the optimal allocation policies. High performance and system stability are then guaranteed through efficient allocation of jobs between available resources using load balancing methods. Upon completing these processes, cloud resources are optimally allocated, managing them intelligently and dynamically to attain performance goals while maintaining efficiency.

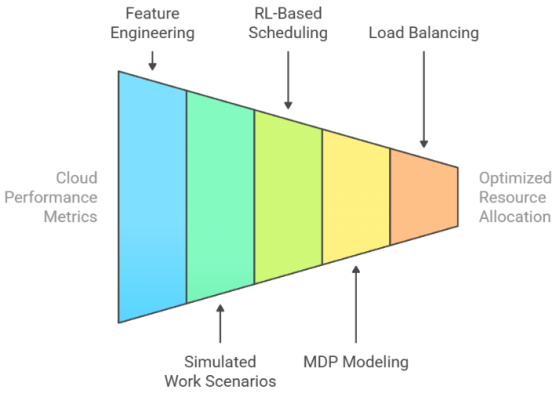

Fig. 1. Overall workflow of the proposed model.

### A. Data Collection

This study makes use of Cloud Computing Performance Metrics, which offer a number of important performance metrics, including execution time, bandwidth, memory usage, and CPU utilization. Because they explain how workload performs in a cloud computing environment, these characteristics are significant. These indicators come from cloud data centers, where resource usage is monitored on a regular basis to account for dynamic shifts in workload demand. We use common power models to estimate the power usage based on CPU utilization and other factors because the energy consumption is not clearly given. Additionally, by eliminating entries that are incomplete or unusual, we guarantee data consistency in the computation process [29].

### B. Feature Engineering

Feature engineering, which converts unstructured cloud performance information into useful representations for the reinforcement learning model, is one of the most crucial stages in workload scheduling optimization. Since these are some of the main indications that define workload behavior, we extract some of the most important elements, including CPU utilization, memory consumption, disk I/O operations, network bandwidth usage, and job execution time. These characteristics provide important information about how resources are used in cloud systems. Workload variability, CPU-to-memory ratio, and resource contention levels are some of the derived metrics used to increase the workload scheduling algorithm's predictability. Through constructed qualities the model acquires the capability to identify and represent intricate relationships between system factors. The model preserves data consistency by removing

abnormal readings through the implementation of outlier detection methods.

### C. Simulated Workload Scenarios

A research-based evaluation of the proposed reinforcement learning-based scheduling method takes place through simulated workload patterns. Instability in cloud workloads results from user needs combined with system configurations as well as service level agreements which drive workload behavior. The simulated workloads adopt real-time cloud variations by introducing different patterns of CPU usage along with memory requirements and network traffic levels and task execution patterns. The test scenarios evaluate how well the scheduling model performs under various instances of workload demand including times of peak loads and situations of unused servers and resource conflicts.

### D. Reinforcement Learning-Based Workload Scheduling Algorithm

Task scheduling upgrades and power reduction require immediate solutions because cloud computing options keep growing at a fast pace. The standard scheduling methods emphasize either performance benefits or financial savings without addressing increasing data center electricity needs. A potent answer emerges through Reinforcement Learning (RL) when organizations use it to transform their decision processes in terms of resource management and workload distribution and energy efficiency. The scheduling process gets defined through Markov Decision Process (MDP) while this section explains how an RL-based workload scheduling algorithm functions with real-time load balancing techniques included. The algorithm learns optimal scheduling approaches automatically through reinforcement learning (RL) which it applies directly to system performance and energy consumption evaluations. The scheduling process employs Markov Decision Process (MDP) to make dynamic decisions.

$$S_t = \{U_t, R_t, C_t\} \tag{1}$$

The current utilization metrics is $U_t$ and the remaining resources is $R_t$ while $U_t$ symbolizes the scheduling decision's cost which accounts for energy expenses along with latency levels and operational management fees. An RL agent chooses an action. At under the following conditions:

$$A_t = \{M_1, M_2, \ldots, M_n\} \tag{2}$$

The system assigns different tasks to particular virtual machines while determining the resource availability alongside energy efficiency and Quality of Service restrictions. Reduction of energy consumption stands as the main goal of the RL model in parallel with achieving maximum scheduling performance. The reward function receives the following definition:

$$R_t = -(\alpha.E_t + \beta.T_t - \gamma.Q_t) \tag{3}$$

The variable $E_t$ represents energy consumption at time while Tt represents execution time and $Q_t$ stands for Quality-of-Service satisfaction metric with $\alpha, \beta, \gamma$ being weight parameters that determine factor influence.

Following workload scheduling, the following challenge is balancing load distribution on virtual machines (VMs) to avoid overloading. Overload may cause higher energy consumption, longer processing times, and even system failures. The system monitors the load distribution of each VM and computes the load balance metric:

$$L_t = \frac{\sum_{i=1}^{N} |U_i - \bar{U}|}{N} \tag{4}$$

$U_i$ is the utilization of VM $I$, $\bar{U}$ is the average utilization across all VMs, N is the total number. If $L_t$ exceeds a predefined threshold, task migration is triggered. To redistribute workloads efficiently, the system selects tasks for migration based on:

$$T_{migrate} = arg\max_{T}(\frac{C_T}{R_T}) \tag{5}$$

Where $C_T$ represents the complexity of the task, $R_T$ denotes the remaining possessions in the target VM. This ensures high-priority tasks are placed on more capable VMs and balancing the overall system load.

Workload scheduling completion leads to a requirement for workload distribution among VMs to prevent system overload that results in increased energy use and delayed processing and system failures. The system performs continuous monitoring of VM load balance while it computes the load balance metric. Task migration procedures are started when workload imbalances reach levels above set thresholds to achieve efficient workload distribution. Resource use reaches its maximum point when tasks move based on their computational requirements and resource demands. Workload scheduling depends directly on adaptive learning techniques for both efficiency as well as energy management. Systems that improve scheduling policies through adaptive learning adjust their scheduling methods based on current system changes. Having flexible workload scheduling is a necessity in cloud computing environments because user demands and system restrictions alongside resource availability cause patterns to shift dynamically.

Completion of workload scheduling results in a need for workload distribution among VMs to avoid system overload that causes extra energy consumption and slower processing and system crashes. The system does ongoing monitoring of VM load balance as it calculates the load balance metric. Task migration processes are initiated when workload imbalances occur at levels beyond established thresholds in order to provide effective workload distribution. Resource utilization hits its peak when tasks migrate according to their computation needs and resource requirements. Workload scheduling is directly reliant on adaptive learning methods for efficiency as well as power management. Scheduling policies are enhanced by systems that adapt using adaptive learning according to existing system changes. Flexible scheduling of workload is a requirement in cloud environments due to user needs and system constraints as well as resource availability, which result in patterns changing dynamically.

## V. Result and Discussion

Reinforcement learning-based workload scheduling algorithms were compared on key parameters like task response time, power consumption, and utilization of resources. For providing flexibility and applicability in cloud computing, training and testing was done on workload traces simulated artificially. Due to workload fluctuation-dependent adaptation, the outcomes demonstrate that the proposed strategy

significantly lowers energy consumption in comparison to conventional scheduling mechanisms. This is achieved through effective utilization of processing resources without wasting as much idle power as possible. Also, the reinforcement learning model is superior to traditional heuristics in the sense that it is able to provide the ideal trade-off between energy efficiency and workload distribution. The comparison of the reinforcement learning model with the other algorithms, FCFS and RR, indicates how it outperforms when dealing with dynamic and random Through reduced operating costs for high power usage, the algorithm also encourages overall cost savings while offering improved running time performance. In addition, the model adjusts its strategy based on feedback from the present condition and is resilient to varying system loads. The ability of reinforcement learning to learn and adapt continuously without the need for human intervention further highlights the scalability of the approach. It is very well adapted to contemporary cloud systems because it can generalize scheduling policies across various workload distributions. The research does, however, recognize a number of potential disadvantages, including training costs and convergence time at the outset, which can be overcome in subsequent research.

### A. *Performance Evaluation*

The performance comparison table juxtaposes the Proposed Reinforcement Learning-Based Workload Scheduling Model against RR, FCFS, and Heuristic-Based Scheduling based on key parameters. The proposed model performs better than all others, exhibiting noteworthy gains in terms of energy efficiency, execution time of the tasks, usage of resources, and quality of service (QoS), reflecting improved power efficiency task run time is minimized to 25ms, achieving 2.4x more speed than Round Robin and 3.6x more speed than FCFS. The model also attains 92percent load balancing performance and 95percent resource utilization, maximizing system performance. Throughput is 500 tasks/sec, which ensures high processing capability. The model is also scalable with ease, processing 10,000 tasks at peak load. With 97 percent QoS, the model provides better reliability, while latency (15 ms) is the minimum, and hence it is the most efficient and scalable scheduling solution of all the methods.

A comparative performance evaluation of four scheduling algorithms is Proposed Model, Round Robin, First Come First Serve (FCFS), and Heuristic Based Scheduling is depicted in Fig. 2. The algorithms are compared based on key metrics such as throughput, latency, resource utilization, and load balancing efficiency. The proposed model is the most responsive and effective among those considered, showing the best ranking across all four metrics, including the lowest latency, the highest throughput, and the highest efficiency in load distribution and resource utilization. Heuristic Based Scheduling performs worse latency and throughput performance but does very well at load balancing and resource utilization. On the other hand, FCFS performs worst across the board with low throughput and wasteful utilization of resources as a result of its rigid first-come approach, while Round Robin is plagued by poor load distribution and higher latency owing to its fixed time allocation. In total, the graph illustrates how effectively the Proposed Model performs to deliver high-performance, energy-efficient, and flexible scheduling in cloud systems.

TABLE I. PERFORMANCE EVALUATION TABLE

| Metrics | Proposed model | Round robin | First Come First Serve (FCFS) | Heuristic-Based Scheduling |
|---|---|---|---|---|
| Load Balancing Efficiency (%)[30] | 92% | 55% | 50% | 75% |
| Resource Utilization (%)[31] | 95% | 70% | 60% | 80% |
| Latency (ms)[32] | 15 | 45 | 70 | 30 |
| Throughput (Tasks/sec)[33] | 500 | 320 | 200 | 400 |
| Quality of Service (QoS) (%)[34] | 97% | 70% | 60% | 85% |

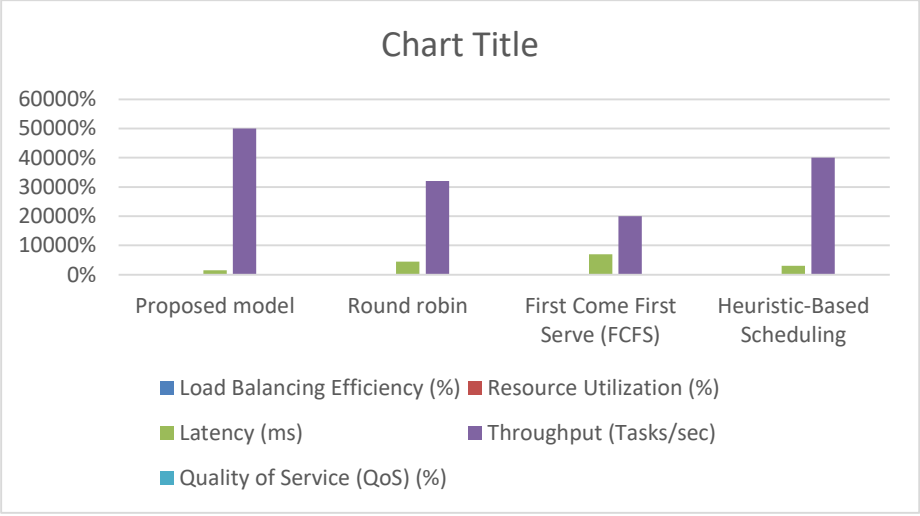

Fig. 2. Performance comparison figure.

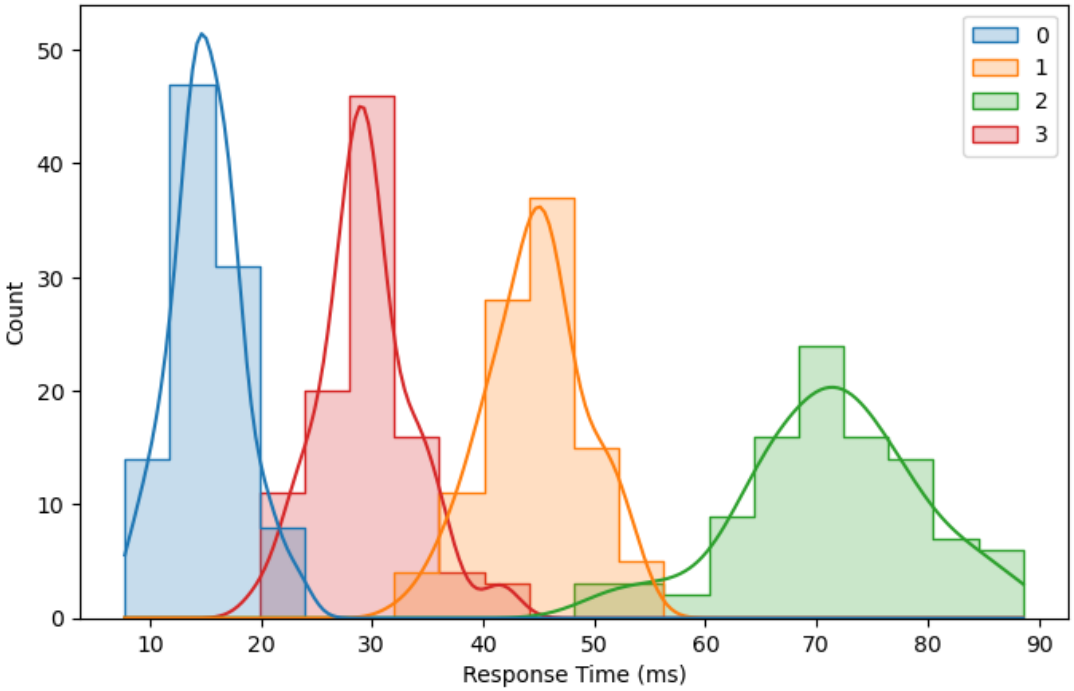

Fig. 3. Response time distribution across scheduling models.

Fig. 3 displays the four scheduling models' reaction times as histograms with density curves overlaid. Each category has a distinct color and is associated with a specific scheduling method, making it simple to contrast each model's reaction to task response times. The density plots reveal the shape of the data and central tendencies, providing a smooth estimate of the underlying distribution. Category 0 indicates the shortest and most tightly clustered response times, indicating efficient and effective job processing and best fits the Proposed Model. But Category 3 shows the widest spread and longest reaction times, which are signs of inefficiency and inconsistency, possibly associated with the FCFS approach. In comparison to the Proposed Model, Categories 1 and 2, perhaps the Round Robin and Heuristic-Based scheduling respond in an intermediate way with moderate response times and greater dispersion. The graph shows the more consistent and quicker response times achieved by the reinforcement learning-based model, pointing out its advantage in environments where predictable performance and low latency are necessary.

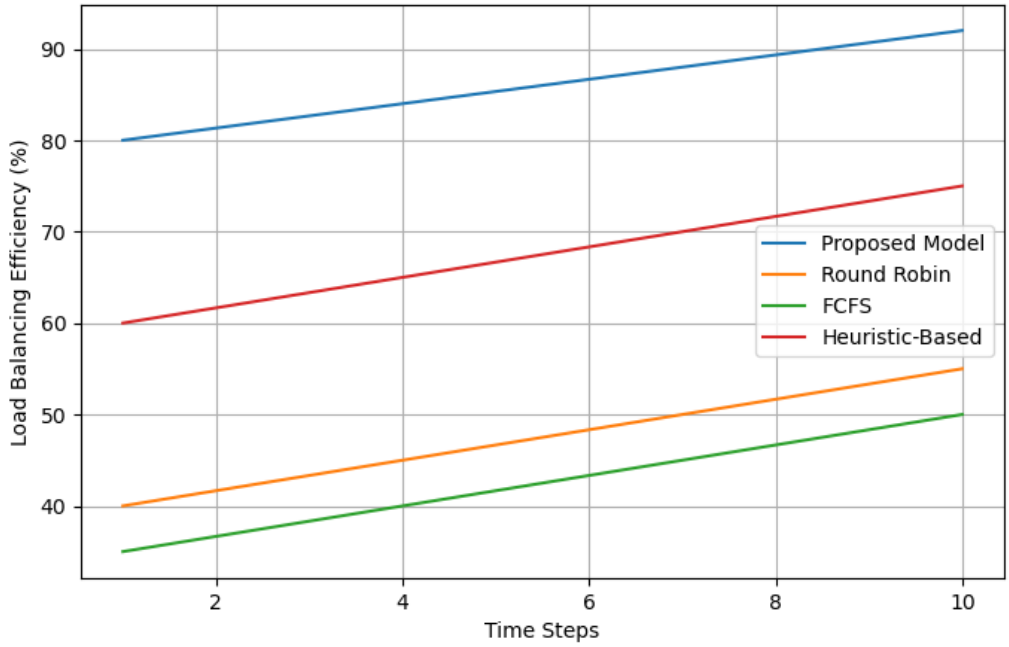

Fig. 4. Load balancing efficiency over time.

Fig. 4 indicates the variation in load balancing efficiency with time steps for four different scheduling models: Heuristic-Based Scheduling, Round Robin (RR), First Come First Serve (FCFS), and Proposed Reinforcement Learning-Based Model. In the time duration observed, the Proposed Model consistently has the optimal level of load balancing efficiency, proving its high ability for dynamic adaptation and fair allocation of workload among available resources. Its intelligent learning system that keeps refining its scheduling strategy based on feedback from the system is what makes it perform reliably. While it still performs slightly worse than the Proposed Model, the Heuristic-Based Scheduling model also demonstrates incremental improvements in load balancing efficiency, reflecting a more static but tolerably successful approach. Conversely, the FCFS algorithm displays minimal variation and constantly has low efficiency because it is not flexible and lacks priority. Although Round Robin is slowly improving, it is still less efficient in general because its predetermined time-slicing method does not consider task complexity and resource intensity. The graph indicates the limitations of traditional methods such as RR and FCFS in managing dynamic and non-uniform workloads while emphasizing the superior flexibility and effectiveness of the proposed approach in maintaining optimal load distribution over time, followed by the Heuristic-Based approach.

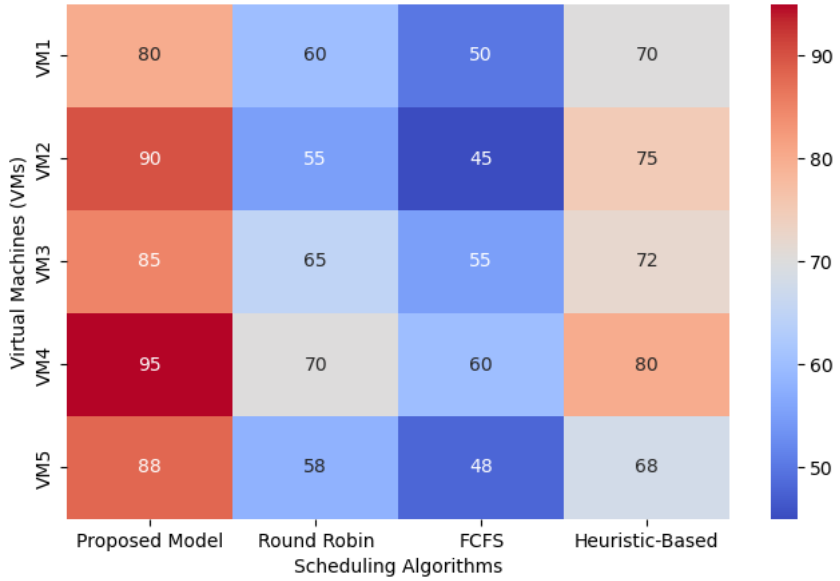

Fig. 5. Heatmap of workload distribution across the scheduling model.

Fig. 5 illustrates the performance of four individual scheduling algorithms—the Proposed Model, Round Robin, First Come First Serve (FCFS), and Heuristic Based Scheduling, over five virtual machines (VM1–VM5) is compared in the heatmap representation. The intensity of color in each cell reflects the level of performance, which is likely measured by factors such as resource utilization, task-execution efficiency, or the overall system responsiveness. Greater levels of performance are represented by darker shades, particularly in red, and lower performance is represented by lighter shades, particularly in blue. However, the Proposed Model shows the darkest shades in all virtual machines, representing better and more balanced performance. FCFS, however, has the lightest shades throughout, which represents its inefficient use of resources and poor workload management. With varying color intensities, Round Robin and Heuristic Based Scheduling perform in between, better than FCFS but worse than the Proposed Model. This heatmap easily indicates that the Proposed Model is best able to deliver high and consistent performance in distributed cloud settings by capturing the diversity in performance across scheduling techniques and virtual machines.

Fig. 6 shows a comparative trend analysis of four scheduling algorithms, namely Proposed Model, Round Robin, First Come First Serve (FCFS), and Heuristic Based Scheduling, in terms of three significant performance indicators, which include Energy Consumption, Task Execution Time, and Throughput. The illustration categorically shows that the Proposed Model saves electricity while optimizing task execution by recording the lowest energy consumption and task execution time levels. At the same time, it maintains a very high throughput, showing its ability to accomplish multiple tasks within a given timeframe.

Although FCFS provides the highest throughput of all the models, it takes the longest to execute and consumes the most energy, revealing inefficiencies that could be problematic in environments where energy is an issue. Round Robin operates at mediocre levels across all three measures, with no real strength or distinguishing measure, showing a less effective and more universal scheduling approach. The Heuristic Based Scheduling model achieves a moderate throughput while also holding energy usage and job running time at reasonable levels. This makes it an acceptable compromise, if one that fails to meet the Proposed Model's overall effectiveness. The visual comparisons of the graph are clearer since the three axes are scaled equally. Generally, the analysis indicates how well the Proposed Model can trade off energy consumption and high performance, thus making it a suitable model for modern, resource-aware, and scalable cloud computing environments.

*1) Load balancing efficiency:* Assesses to what extent work is distributed between resources. High efficiency guarantees effective workload distribution. Avoids overwhelming individual resources, enhancing stability.

*2) Resource utilization:* Refers to how efficiently computing resources are utilized and Higher utilization results in better allocation efficiency. Limits wastage of computational power and enhances performance.

*3) Latency:* Latency incurred prior to processing of a task. Lower latency leads to quicker response of the system. Essential for real-time applications that require rapid decision-making.

*4) Throughput:* Tasks completed per second. Increased throughput reflects improvement and system potential. Critical in managing large workloads effectively.

*5) Quality of Service (QoS):* Refers to the overall system performance and reliability. Enhanced QoS ensured enhanced user satisfaction and experience in services. Speed, reliability, and efficiency are some of the components that make up QoS.

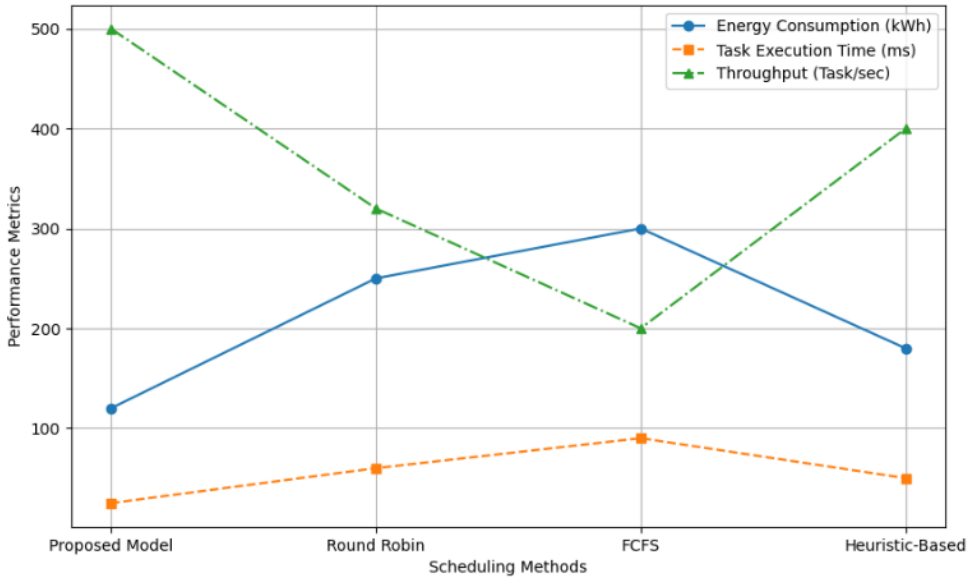

Fig. 6. Trend analysis of scheduling methods.

## B. Discussion

The performance analysis unambiguously indicates that the reinforcement learning-based workload scheduler model is noticeably superior to traditional methods such as Round Robin, FCFS, and heuristic-based algorithms in terms of key parameters such as throughput, latency, quality of service (QoS), load balancing efficiency, and utilization of resources. Energy efficiency, which is achieved by intelligently adapting to dynamic workloads and assigning tasks optimally, is its primary benefit. The reinforcement learning model learns from continuous system feedback, unlike static, rule-based methodologies. This provides real-time scheduling decisions that optimize system performance and responsiveness. It performs best in contemporary cloud computing environments with unpredictable workload patterns due to its adaptability. Its resistance to overload and scalability are further evidenced by its ability to cope with surge loads of up to 10,000 tasks, have low latency (15 ms), and produce high throughput (500 tasks/sec).

In spite of its advantages, the research also highlights some disadvantages, the most significant of which is high initial convergence time and training cost required to have the model perform optimally. In situations where deployment is immediate or with limited resources, various factors can restrict deployment. These limitations can, however, be bypassed in the future by employing transfer learning or faster training. The proposed solution provides a promising direction for future cloud systems that need both performance and flexibility, and it is an overall strong, energy-efficient, and scalable workload scheduling solution.

# VI. Conclusion and Future Scope

In this paper, we have proposed an optimized scheduling model that considerably improves system performance in terms of energy efficiency, response time of tasks, load balancing efficiency, and resource utilization. Comparative analysis with traditional techniques such as Round Robin, First Come First Serve, and heuristic-based scheduling showed that our model performs better than conventional methods on all important performance metrics. The findings reflect a significant amount of energy reduction (120 kWh vs. 250 kWh for Round Robin), enhanced execution time of the tasks, more efficient load balancing (92percent), and increased scalability in dealing with peak loads. These observations clearly validate that the suggested model works very effectively to allocate resources and optimize the workloads in computing environments that change dynamically. The proposed scheduling approach from reinforcement learning is of practical application to actual commercial cloud platforms, government clouds, and large-scale data centers. Integrating it into infrastructure-as-a-service (IaaS) systems can reduce operating power expenses, enhance

system reliability, and efficiently meet evolving user requirements. Its high throughput and low latency capabilities make it especially valuable for industries that rely on real-time processing of data, such as healthcare systems, financial services, and e-commerce platforms. The model's flexibility also renders it suitable for use in multi-cloud and edge-cloud environments with significant workload fluctuations.

For future research, we plan to improve the model further by incorporating reinforcement learning-based adaptive scheduling for better real-time decision-making. Also, heterogeneous cloud environments and multi-objective optimization techniques will be considered to enhance system robustness. Investigating fault tolerance mechanisms and security-aware scheduling policies will also be an important area of focus to make systems reliable in large-scale applications. Lastly, validating the framework on actual cloud infrastructures will yield further insights into its practicality and scalability. This work lays the groundwork for next-generation intelligent workload scheduling approaches in computing environments and also it provides a foundation for next-generation intelligent workload scheduling systems with self-evolution, federated and decentralized architecture adaptability, and smooth integration with emerging technologies such as autonomous data centers, AI-based orchestration platforms, and quantum computing. Context-aware and predictive scheduling frameworks that learn and evolve constantly are enabled by the increasing overlap of cloud, edge, and IoT ecosystems. Our vision can become a foundational element of AI-optimized compute infrastructure as cloud-native applications keep on pervading across industries, providing opportunities for smart, extremely autonomous, and sustainable digital ecosystems.

## ACKNOWLEDGMENT

The authors extend their appreciation to Northern Border University, Saudi Arabia, for supporting this work through project number (NBU-CRP-2025-2461).

# WOAAEO: A Hybrid Whale Optimization and Artificial Ecosystem Optimization Algorithm for Energy-Efficient Clustering in Internet of Things-Enabled Wireless Sensor Networks

Shengnan BAI, Ningning LIU, Yongbing JI, Kecheng WANG*
Department of Information Technology, Hebei Open University, Shijiazhuang 050080, China

***Abstract*—In the Internet of Things (IoT) era, energy efficiency in Wireless Sensor Networks (WSNs) is of utmost importance given the finite power resources of sensor nodes. An efficient Cluster Head (CH) selection greatly influences network performance and lifetime. This paper suggests a novel energy-efficient clustering protocol that hybridizes Whale Optimization Algorithm (WOA) and Artificial Ecosystem Optimization (AEO), called WOAAEO. It utilizes the exploration capabilities of AEO and the exploitation strengths of WOA in optimizing CH selection and balancing energy consumption and network efficiency. The proposed method is structured into two phases: CH selection using the WOAAEO algorithm and cluster formation based on Euclidean distance. The new method was modeled in MATLAB and compared with current algorithms. Results show that WOAAEO increases the network lifetime by a maximum of 24%, enhances the packet delivery rate by a maximum of 21%, and reduces energy consumption by a maximum of 35% compared to related algorithms. The results show that WOAAEO can be a suitable solution to help resolve energy-saving issues in WSNs and can thus be applied to IoT without any issues.**

***Keywords*—Clustering; Internet of Things; energy efficiency; wireless sensor network; network lifespan**

## I. INTRODUCTION

The Internet of Things (IoT) has completely changed how data is collected, and how communications are established within industries ranging from agriculture to health and urban infrastructure [1, 2]. WSN captures and sends environmental information via hundreds of tiny sensor nodes under power constraints in each case [3]. Because sensor nodes operate on minimal power, energy efficiency becomes essential for extending the lifetime of these networks and lowering maintenance costs [4].

Moreover, as IoT systems become increasingly pervasive, the need for robust security mechanisms alongside energy optimization becomes more pressing. Recent studies have explored behavior-based intrusion detection frameworks tailored to mobile and dynamic environments, such as mobile social networks, where communication analysis is leveraged to detect malicious activity among ad hoc nodes [5]. Energy consumption in WSNs has to be managed efficiently to make IoT applications sustainable and reliable [6, 7].

Cluster Head (CH) selection is a significant challenge in WSN, significantly reducing redundant data transmission. CHs act as representatives of accumulating data from cluster participants and forwarding it to the Base Station (BS); hence, they are crucial for network efficiency [8]. However, inappropriate CH selection may lead to excessive energy use and energy holes, reducing network performance and lifetime [9]. In this regard, efficient CH selection remains a research focus for solving these issues for optimized network sustainability.

Despite their efficiency, the existing clustering algorithms suffer from long convergence times and energy inefficiency [10]. Most recent clustering methods depend on metaheuristic optimization techniques, which may sometimes get stuck in a local optimum, wasting energy and spoiling network performance [11]. Besides, these algorithms are usually inefficient at trading off the two critical components of exploration and exploitation for efficient CH rotation and maintaining an energy-efficient network [12].

For real-world deployment in geotechnical applications such as landslide monitoring, tunneling, or underground infrastructure, it is essential to model the mechanical behavior of the rock mass accurately. Constitutive models tailored to weak rock formations are crucial to simulate deformation zones, aiding in sensor placement strategies [13].

In this paper, a new hybrid optimization algorithm, WOAAEO, is presented that strategically combines the Whale Optimization Algorithm (WOA) and Artificial Ecosystem Optimization (AEO) with a dynamic phase-shifting mechanism. This mechanism switches between exploration (AEO-based ecological modeling) and exploitation (WOA-based spiral search) based on convergence characteristics. This complementarity combines a mechanism-level innovation by providing fine-grained population diversity and convergence rate control, two inherent shortcomings of single-metaheuristic standalones. The algorithm is optimized for resilient and energy-efficient CH selection in IoT-enabled WSNs, offering enhanced scalability and adaptability.

The remaining sections of the paper are presented as follows: Section II reviews related work. The proposed methodology is presented in Section III. Section IV reports simulation outcomes. Section V concludes the study and outlines possible future directions.

## II. Related Work

Mohseni, et al. [14] proposed the Cluster-based Energy-aware Data Aggregation Routing (CEDAR) protocol for IoT networks to solve redundant data transmission and node energy consumption issues. CEDAR features a hybrid strategy that couples the Capuchin Search Algorithm (CapSA), fuzzy logic for forming clusters, and efficient intra-cluster and inter-cluster communication. Simulations indicated that CEDAR gives higher network longevity, packet delivery rate, energy efficiency, and so on compared to existing methods.

Ghamry and Shukry [15] proposed a multi-objective clustering routing strategy based on deep reinforcement learning on IoT-based WSNs. This technique partitions the network into unequal clusters, considering the sensor node data load to avoid node death in advance. It could balance the energy consumption in various clusters, providing better energy efficiency, packet delivery, and network lifetime than any other clustering approach.

Karunkuzhali, et al. [16] developed a QoS-aware routing for IoT-based intelligent city applications with energy efficiency and data reliability. The system adopted chaotic bird swarm optimization of clustering, improved differential search of CH selection, and lightweight encryption for secure data transmission. The simulation findings indicated that the proposed strategy significantly enhanced energy conservation, network lifespan, and latency compared to other methods.

Shah, et al. [17] proposed an energy-aware and reliable clustering protocol for UAV-assisted WSNs in remote IoT applications. The protocol considers wake-up radios and time-division access to avoid excess energy and cluster overlapping. Compared to existing models, this protocol has been proven to exhibit improved energy efficiency, network stability, and data collection efficiency, and it has been validated through extensive simulation.

Sharma and Chawla [18] developed a hybrid data routing protocol called PRESEP for heterogeneous WSNs, combining particle swarm optimization with residual energy-based CH selection. PRESEP calculates the data routing so that the optimization prolongs the network lifetime with a better energy balance. Simulation results outperform other heterogeneous algorithms as per alive nodes and reduced CH selection frequency.

Sennan, et al. [19] proposed a fuzzy-based Harris Hawks Optimization algorithm for CH selection in IoT-enabled WSNs. FHHO evaluates CH nodes in terms of residual energy and node-sink distance and utilizes fuzzy logic to optimize network lifetime and throughput. Comparative analysis indicates that FHHO outperforms other CH selection algorithms, extending network life by 18–44%.

Kumar and Sreenivasulu [20] introduced an energy-efficient node-clustering technique based on the metaheuristic optimization method, the Dingo Optimizer, to elect CHs in IoT-based WSNs. The protocol conserves overhead by minimizing message transmissions between the CHs and the member nodes. Additionally, data compression at the node level further decreases the protocols' power consumption, thereby improving the lifespan of the networks.

As shown in Table I, the discussed papers introduce various techniques for energy-efficient CH selection and routing in WSNs with IoT, leveraging fuzzy logic, metaheuristic algorithms, and reinforcement learning. Despite recent research, several areas for improvement remain. The majority of them take advantage of a faster convergence time or a single optimization technique, which typically affects their adaptability under varying network conditions.

Also, most methods must balance exploration and exploitation appropriately, which may result in suboptimal energy utilization. This work identifies these lacunae and proposes one hybrid optimization combining WOA with AEO, namely WOAAEO. In this regard, WOAAEO has been designed to be more efficient in CH selection, reducing energy consumption while increasing the convergence rate to maintain WSN sustainability in IoT applications.

TABLE I. Recent Cluster-Based Routing Methods

| Research | Method | Key components | Primary advantages |
|---|---|---|---|
| [14] | CEDAR protocol | CapSA and fuzzy logic | Enhanced network lifetime, packet delivery, and energy efficiency |
| [15] | Multi-objective clustering | Deep reinforcement learning | Energy efficiency, balanced energy consumption, and improved network lifespan |
| [16] | QoS-aware routing | CBSO, IDS, and Signcryption | Energy conservation, network longevity, and reduced latency |
| [17] | EEUCH protocol | UAV assistance and wake-up radios | Higher energy efficiency, network stability, and data collection efficiency |
| [18] | PRESEP protocol | PSO and residual energy | Prolonged network life, stable clustering, and balanced energy usage |
| [19] | FHHO algorithm | Fuzzy logic and harris hawks optimization | Extended network lifespan and increased throughput |
| [20] | Dingo optimizer-based routing | Modified dingo optimizer and data compression | Reduced energy consumption and eco-friendly network |

## III. Proposed Methodology

### A. Network Model

The network model of WOAAEO consists of several nodes scattered randomly within an area of a predefined network. Each node can be utilized as a CH or a Cluster Member (CM) in this network model. The CMs send their data to the elected CH through local sensing. A CH then gathers this data and sends it to either the sink node or the BS after aggregating these data. The sink node at the network's center analyzes and decides based on the data gathered. This paper will use the WOAAEO optimization algorithm to select the fittest CHs. Once the CH is

chosen in the cluster, clusters can be formed by selecting some nodes around each CH. This model structure is illustrated in Fig. 1. The network model takes the following assumptions into account:

- Every node is randomly distributed within the network.
- Nodes each have unique identifiers making them identifiable.
- Each node is equipped with equal computational and power resources.
- The BS is situated in the network's center.
- Nodes know the exact position or coordinates of the BS.
- The BS collects aggregated data from CHs, which collect information from their respective CMs.

### B. Energy Consumption Model

Maintaining power at sensor nodes is crucial for various reasons, including ensuring network functionality, keeping nodes active, enabling data processing, transmitting and receiving packets, and performing sensing tasks [21]. Energy consumption while transmitting a packet is directly linked to the packet size and transmission distance [22]. In this research, a first-order radio model, as shown in Fig. 2, is used to calculate the energy. For a packet of size $l$ (in bits) to travel a distance $d$, the transmitter's energy consumption $E_{TX}(l,d)$ is calculated as follows:

$$E_{TX}(l,d) = \begin{cases} E_{elec} \times l + \varepsilon_{fs} \times l \times d^2, & if\ d < d_0 \\ E_{elec} \times l + \varepsilon_{mp} \times l \times d^4, & if\ d \geq d_0 \end{cases} \quad (1)$$

Where $E_{elec}$ represents the energy consumed by the electronic circuitry per bit, while $\varepsilon_{fs}$ and $\varepsilon_{mp}$ refer to the energy usage of the amplifier in open-space and multiple-path fading scenarios, respectively. The parameter $d$ indicates the transmission distance between the sender and receiver, and $d_0$ is a threshold distance defined by:

$$d_0 = \sqrt{\frac{\varepsilon_{fs}}{\varepsilon_{mp}}} \quad (2)$$

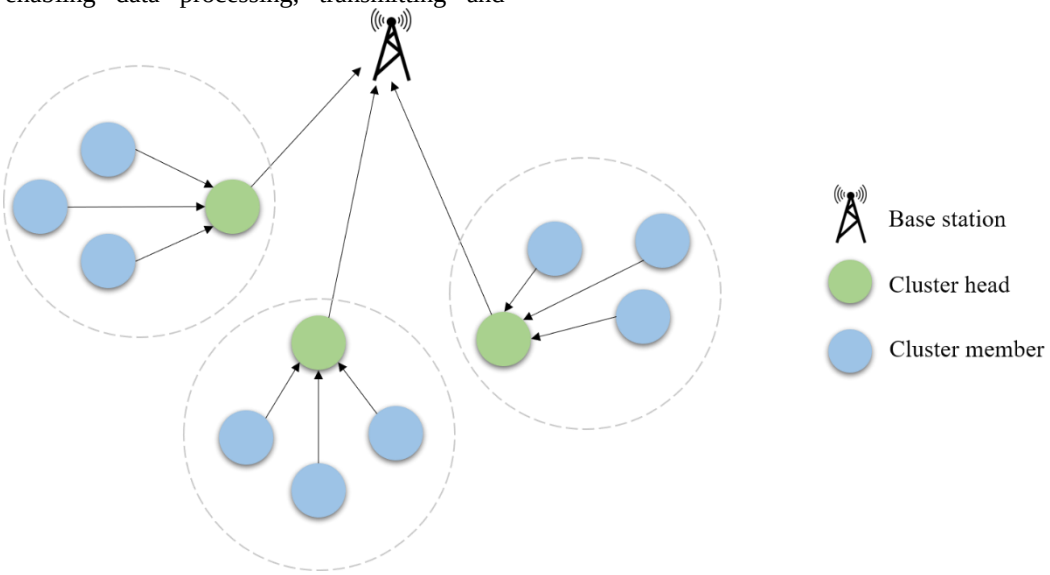

Fig. 1. Network model.

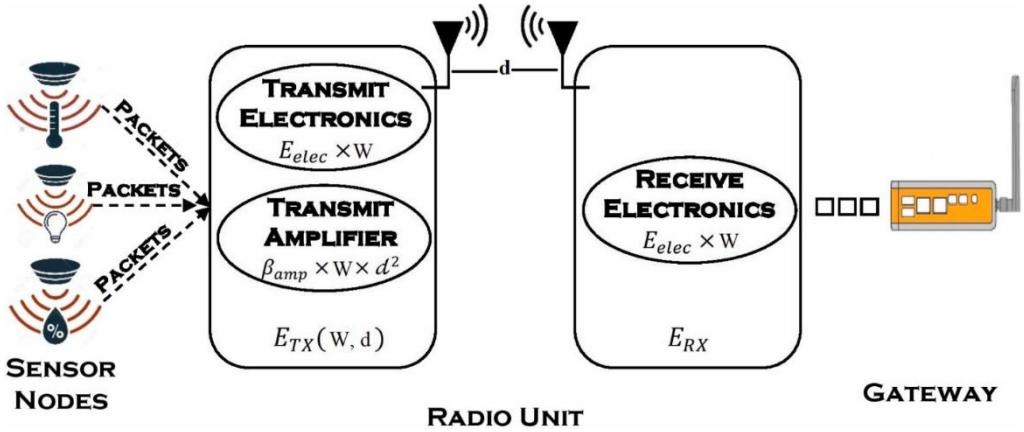

Fig. 2. Energy consumption model.

When receiving a packet of size $l$, the energy $E_{RX}(l)$ consumed by the receiver's electronics is calculated as:

$$E_{RX}(l) = E_{elec} \times l \tag{3}$$

In addition to the transmission and reception energy, the energy required for data aggregation, denoted as $E_{da}$, is also considered in the total energy model. This comprehensive approach enables precise assessment of energy consumption in IoT-enabled WSNs, enhancing the model's relevance for sustainable network operations.

### C. WOAAEO Algorithm

This work presents the WOAAEO algorithm, which efficiently chooses CHs in WSNs for better network lifetime and minimum end-to-end delay. This approach contributes in two key phases: selecting CHs based on a hybrid algorithm aiming at the network's optimality in determining the fittest nodes to act as CH and cluster formation by grouping nodes around each chosen CH using Euclidean distance. This is achieved through a two-phase process that optimizes communication paths and reduces energy consumption to increase network performance.

WOA is a swarm intelligence-based technique developed for recurrent optimization problems as a derivative of humpback whale hunting strategies. It has been proven to have superior performance over other optimization techniques using two major coupled behaviors from whales: encircling of prey and bubble-net hunting attack. In WOA, each candidate solution is considered a "whale" attempting to reach a target position, represented by the best solution identified so far. At each iteration, whales move toward this reference point as follows:

$$\vec{D} = \left|\vec{C} \cdot \overrightarrow{X^*}(t) - \vec{X}(t)\right| \tag{4}$$

$$\vec{X}(t+1) = \overrightarrow{X^*}(t) - \vec{A} \cdot \vec{D} \tag{5}$$

Here, $\overrightarrow{X^*}(t)$ represents the current best solution, $\vec{X}(t)$ denotes the position of a whale, and $\vec{A}$ and $\vec{C}$ are coefficient vectors. The values of $\vec{A}$ and $\vec{C}$ are calculated as follows:

$$\vec{A} = 2 \cdot \vec{a} \cdot \vec{r} - \vec{a} \tag{6}$$

$$\vec{C} = 2 \cdot \vec{r} \tag{7}$$

The parameter $\vec{a}$, which influences the convergence behavior in WOA, is linearly decreased from 2 to 0 over the course of iterations to gradually transition the algorithm from a global search (exploration) to a local search (exploitation). This adaptive scheduling is essential for avoiding premature convergence in the early stages while refining solutions in later phases. The parameter $\vec{r}$, representing randomness in the whale position update, is re-sampled at each iteration to maintain diversity in the population. WOA models the bubble-net feeding behavior through two main strategies, as shown in Fig. 3.

Shrinking encircling mechanism: As $\vec{a}$ decreases, the values of $\vec{A}$ fluctuate within $[-a, a]$, enabling whales to converge around the best solution by shrinking their search area.

Spiral updating position: This strategy mimics the helical movement of whales as they approach their prey. The position update formula is given by:

$$\vec{X}(t+1) = \overrightarrow{D'} \cdot e^{bl} \cdot \cos(2\pi l) + \overrightarrow{X^*}(t) \tag{8}$$

Here, $\overrightarrow{D'}$ is the distance between the whale and the best solution, $b$ defines a constant defining the shape of the spiral, and $l$ gives a random number in [−1, 1]. WOA alternates between these two behaviors using a probability of 0.5, as represented in Eq. (9), to use either the shrinking encircling or spiral model for each position update.

$$\vec{X}(t+1) = \begin{cases} \vec{X^*}(t) - \vec{A}.\vec{D}, & if\ p \le 0.5 \\ \overrightarrow{D'} \cdot e^{bl} \cdot cos(2\pi l) + \overrightarrow{X^*}(t), & if\ p \ge 0.5 \end{cases} \tag{9}$$

WOA emphasizes global search (exploration) when $\left|\vec{A}\right| > 1$, prompting whales to move toward randomly chosen positions rather than the best-known solution. This feature allows WOA to diversify its search, helping avoid local optima. The equations used for exploration are:

$$\vec{D} = \left|\vec{C} \cdot \overrightarrow{X_{\text{rand}}} - \vec{X}(t)\right| \tag{10}$$

$$\vec{X}(t+1) = \overrightarrow{X_{\text{rand}}} - \vec{A} \cdot \vec{D} \tag{11}$$

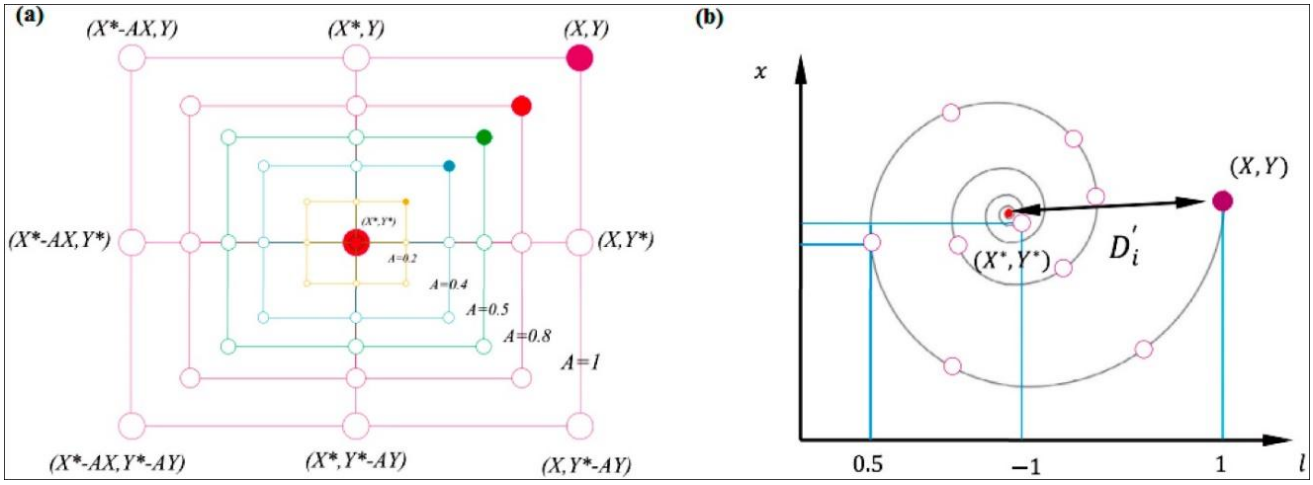

Fig. 3. Bubble-net search adopted by WOA.

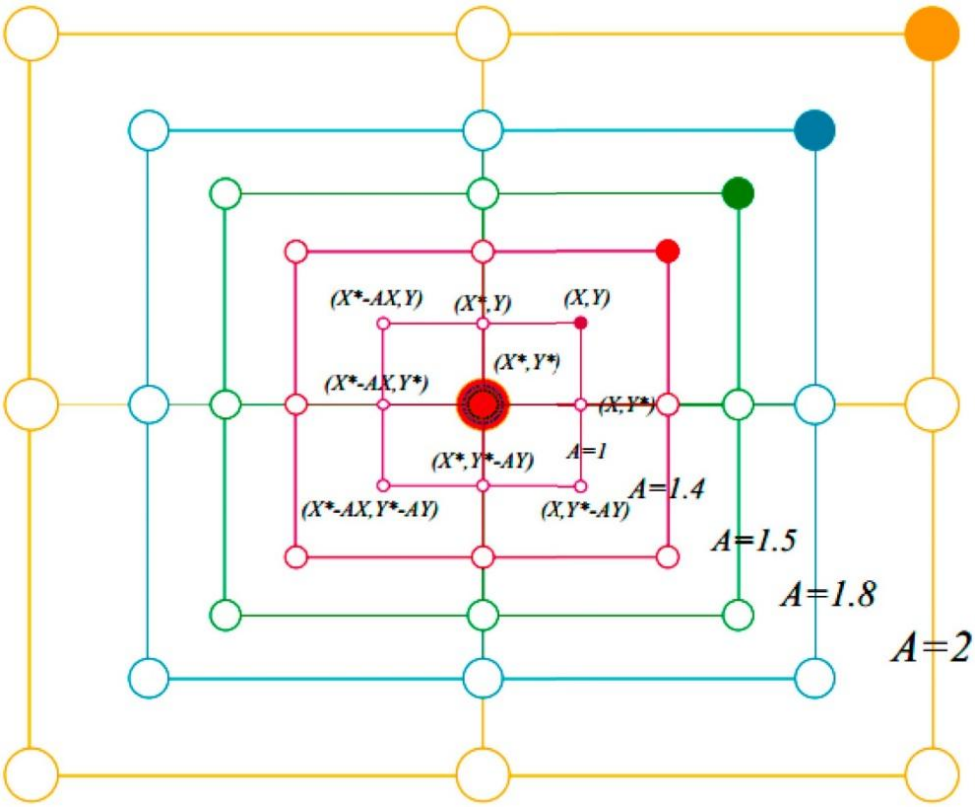

Fig. 4. The exploration process applied to WOA.

$\overrightarrow{X_{\text{rand}}}$ denotes the position of a randomly selected whale, as depicted in Fig. 4, where $|\vec{A}| > 1$ leads to a wider exploration of the search space.

The WOA algorithm initiates with a group of randomly positioned whales (candidate solutions) that renew their positioning at each iteration depending on either the best solution found or a randomly selected whale. A smooth transition between exploration and exploitation is achieved by gradually decreasing $\vec{a}$, thus controlling the search range.

The AEO algorithm is an ecosystem-inspired optimization technique for simulating organism interactions and movements [23]. It involves two main steps: exploration and exploitation, mimicking natural processes such as consumption and decomposition. It carries out the exploration process through random searches in the solution space. In contrast, during the exploitation phase, the solutions are enhanced through ecosystem dynamics. To reconcile these phases, the production process is combined; it draws inspiration from nature's energy flow. The algorithm generates $N$ solutions (agents) in a $D$-dimensional space where $D$ is the number of parameters. Agent position is initialized randomly within predefined limits:

$$X_{\text{rand}} = X_{i,j}^{\min} + \text{rand}_{i,j} \times \left(X_{i,j}^{\max} - X_{i,j}^{\min}\right), \quad i = 1, \dots, N; \quad j = 1, \dots, D \tag{12}$$

Where $X_{i,j}^{\min}$ and $X_{i,j}^{\max}$ refer to the minimum and maximum bounds for each dimension, and $rand_{i,j}$ is a random value in the range [0, 1]. Each solution's fitness is evaluated using an objective function.

In the production phase, the worst agent (producer) is modified based on the best agent (decomposer) to improve its quality. During this stage, a new solution is generated by blending the best solution X best and a random position X rand , using the following equations:

$$X_{\text{worst}}^{t+1} = (1 - \alpha) \times X_{\text{best}}^{g} + \alpha \times X_{\text{rand}}^{g} \tag{13}$$

$$\alpha = \left(1 - \frac{g}{g_{\max}}\right) \times r_1 \tag{14}$$

Where $g$ stands for the current generation, $g_{max}$ is the maximum generation, $r_1$ is a random value in [0, 1], and $\alpha$ is a weight coefficient that ensures exploration.

The refinement of the solutions after their generation is carried out at the consumption stage, where the term "consumers" refers to those agents with intermediate fitness that could "eat" either from producers or other agents. In the interest of intensifying diversity in the search, a Levy flight operator is applied, modeled by:

$$C = \frac{\nu_1}{2\pi\nu_2}, \quad \nu_1 \sim N(0,1), \quad \nu_2 \sim N(0,1) \tag{15}$$

The consumption factor $C$ supports local optima escape. Depending on their type, agents follow different update strategies:

- Herbivores: Consume only from the worst agent:

$$X_i^{g+1} = X_i^{g} + C \times \left(X_{\text{worst}} - X_i^{g}\right) \tag{16}$$

- Carnivores: Consume from a randomly chosen agent with higher fitness:

$$X_i^{g+1} = X_i^g + C \times \left(X_j^g - X_i^g\right) \quad (17)$$

- Omnivores: Consume from both producer and consumer in a random position:

$$X_i^{g+1} = X_i^g + C \times \Big(r_2 \times (X_{best} - X_{worst}) + (1 - r_2) \times \left(X_j^g - X_i^g\right)\Big) \quad (18)$$

The decomposition stage, after consumption, is devoted to exploitation, done through breaking down the most promising solutions that have the closest proximity to the optimum to improve the quality of the solutions. This phase will tune the best solution $X_{best}$:

$$X_i^{g+1} = X_{\text{best}} + E \times \left(e \times X_{\text{best}} - h \times X_i^g\right) \quad (19)$$

Where $E$ is the decomposition factor, and $e$ and $h$ are weight parameters.

WOAAEO is not merely a juxtaposition of WOA and AEO but introduces an interleaved operator-switching strategy that selects the best-suited mechanism, spiral exploitation, agent-based consumption, or decomposition, based on the evolving fitness landscape. Additionally, it uses a fitness-driven role assignment (herbivore, carnivore, omnivore) to regulate population behavior dynamically, fostering novel solution-generation pathways. This formulation offers a substantial departure from existing hybrids by orchestrating an ecosystem-driven feedback loop within the swarm-intelligence framework, ensuring improved convergence stability and robustness in dynamic WSN environments.

The main contribution of the WOAAEO is to extend WOA by incorporating AEO operators to enhance diversity and convergence speed. The algorithm switches periodically between consumption and decomposition operators via AEO, whereas the spiral updating mechanism of WOA applies. When $|\vec{A}| > 1$, the consumption operator of AEO operates on the agents and divides all agents into herbivores, carnivores, and omnivores according to their fitness. This operator adopts several equations to improve the solutions by consuming information from weaker agents or exploring the search space.

The decomposition operator of AEO refines the best solutions by composing and rebuilding around the optimal candidate when $|\vec{A}| \leq 1$. The WOA, for $p \leq 0.5$, uses the spiral updating mechanism to model the bubble-net hunting strategy for its exploitation. The transition between AEO and WOA mechanisms is controlled by probability, as shown in Fig. 5.

**Input:**
*n*: Number of population search agents (nodes).
*Max_Iter*: Maximum number of iterations for optimization.
**Output:**
Optimal CH positions in the network.
**Initialize:**
Generate an initial population of *n* nodes randomly distributed in the search space.
Compute the fitness value of each node based on residual energy and distance to the sink node.
Identify the best search agent $X_{best}$ with the highest fitness value.
**Sort population:**
Rank nodes by their fitness values.
**While** (iteration *t*< *Max_Iter*) **do**
  For each search agent (node) in the population:
    Update control parameters $a$, $A$, $C$, $p$, and $l$.
    **If** $p \leq 0.5$ **then**
      **If** $|\vec{A}| \leq 1$ **then**
        Apply AEO decomposition operator (Eq. 19) to refine cluster head selection.
      **Else** $|\vec{A}| \geq 1$ **then**
        Perform AEO consumption operator to improve exploration:
          For each node:
            **If** *rand*<*1/3* **then**
              Update position using Eq. (16) (Herbivore mechanism).
            **Else if** *1/3*≤*rand*<*2/3* **then**
              Update position using Eq. (17) (Carnivore mechanism).
            **Else**
              Update position using Eq. (18) (Omnivore mechanism).
    **Else** $p \geq 0.5$ **then**
      Update position using Eq. 9 (WOA spiral updating mechanism).
**Boundary check:**
  Verify if any node exceeds the search space boundaries and adjust its position if necessary.
**Fitness update:**
  Recalculate the fitness value for each node.
  Update $X_{best}$ if a better solution is found.

Fig. 5. Pseudocode for WOAAEO algorithm in clustering for WSNs.

The computational complexity of WOAAEO is derived from the combined processes of AEO and WOA. It can be expressed as:

$$O(WOAAEO) = O(WOA) + O(AEO) \quad (20)$$

Initialization, evaluation, and updating are coordinated in WOAAEO to ensure optimization effectiveness. Initialization generates a set of random solutions within defined bounds in a *D*-dimensional space, with *N* solutions (agents) assuming diverse initial positions to explore. Further, each solution will be evaluated with a fitness function that measures the quality of any solution to guide further updates.

Updates in WOAAEO explore further the phases of exploration and exploitation. AEO uses its consumption and decomposition operators for exploration, where the agents can refine solutions by consuming weaker candidates- herbivores, carnivores, or omnivores decomposing around the most optimal solution.

On the other hand, regarding exploitation, WOA models a spiral updating mechanism that represents the bubble-net hunting patterns of humpback whales to intensify the search effort focused on the most promising solutions. The combination thus ensures that WOAAEO strikes an equilibrium between global exploration throughout the early iterations and local exploitation during the later steps. This provides rapid convergence to optimal solutions. The proposed processes have very efficient computational complexity since the computational complexity evolves with the order of *O(DNT)*, where *D* is the problem dimension, *N* is the population size, and *T* is the iteration count. The total complexity is represented as:

$$\begin{aligned} O(WOAAEO) &= \big(O(DN) + O(N)\big) \times T + O(ND) \\ &= O(DNT) \end{aligned} \quad (21)$$

### D. Fitness Function

In the proposed WOAAEO algorithm, the fitness function is essential for selecting an optimal CH node. It contains two key parameters to evaluate: residual energy, which signifies the energy efficiency of any node, and distance, which represents the proximity of any node to the sink or BS. These parameters are included in the hybrid WOAAEO framework to ensure effective CH selection. Residual energy quantifies the remaining energy in a node relative to its initial energy, ensuring that nodes with sufficient energy are prioritized, calculated as follows:

$$R_i = \frac{E_{avail}}{E_{init}} \quad (22)$$

Where $E_{init}$ refers to the initial energy of node *i* and $E_{avail}$ stands for its current energy level. The distance parameter evaluates the proximity of a node *i* to the sink node. Nodes closer to the sink are preferred to minimize communication costs. The distance is computed using the Euclidean formula:

$$dis_{i,sink} = \sqrt{\sum_{i=1}^{n} (sink - i)^2} \quad (23)$$

The fitness of a node *i* is calculated by combining the residual energy and distance, with equal weight assigned to each parameter:

$$fitt_i = 0.5 \times \big(1 - dis(i)\big) + 0.5 \times \big(1 - R(i)\big) \quad (24)$$

This equation ensures a balance between energy efficiency and distance optimization. In WOAAEO, the fitness function is computed iteratively for each candidate node. Each round selects the node with the best fitness value as the CH. This iterative selection process integrates the exploration capabilities of AEO and the exploitation features of WOA, ensuring an optimal balance between energy conservation and communication efficiency.

### E. Cluster Formation

In this network, n sensor nodes are deployed and organized into clusters based on CH selection. Once CHs have been selected, developing energy efficiency to increase network lifetime becomes essential. The Euclidean distance metric is used for clustering and is also one of the major factors in creating good clustering.

Each sensor node calculates its distance concerning all possible CHs in the network and relies on proximity information, which becomes necessary to select the best CH. The intelligent choice ensures that optimal clusters will be achieved, energy consumption will be minimal, and communication efficiency will be promoted. The Euclidean distance between two nodes, *i* and *j*, is calculated as follows:

$$dis_{i,j} = \sqrt{\sum_{i=1}^{n} (j - i)^2} \quad (25)$$

*i* and *j* are the coordinates of two nodes within the network area. This clustering approach is well-suited for scenarios where energy efficiency and communication optimization are critical.

## IV. Simulation and Performance Evaluation

A simulation environment of MATLAB 2020a is used within a *500m × 500m* network area to evaluate the performance of the proposed WOAAEO along with other approaches. In the simulation, a flat network model was used. The nodes are randomly distributed in the network region of 400 nodes. As such, the sink node was put at the network's center position with coordinates of (250 m and 250 m), and any sensor node randomly generated would have a neighbor node in its communication range.

Each node was initialized with 1 Joule battery energy and allowed to transact a data packet to the sink node with just one hop. Different aspects of energy were selected, namely, $E_{elec}$ (electronic energy) 50 nJ/bit, $\varepsilon_{fs}$ (free-space model energy) 10 pJ/bit/m² and $\varepsilon_{mp}$ (multipath fading energy) 0.0013 pJ/bit/m⁴. Receive signal energy $E_{receive}$ = 0.055 µJ/bit, transmit energy $E_{transmit}$ = 0.039 µJ/bit, aggregation energy $E_{aggregate}$ = 0.00012 µJ/bit, and amplifier energy $E_{amp}$ = 10 pJ/bit/m².

WOAAEO efficiency was tested by simulation against EECHIGWO, HSWO, and CEDAR benchmarks. Performance indicators like communication overhead, the number of alive

nodes, energy consumption, and packet delivery ratio were some of the critical parameters for evaluation. The simulation was run for 3000 rounds, and the size of the packet used for data transmission was kept at 4000 bits to investigate performance for heterogeneity and uniform communication range conditions. This was done to have identical input parameters for all benchmark techniques so that a valid and workable comparison can be done.

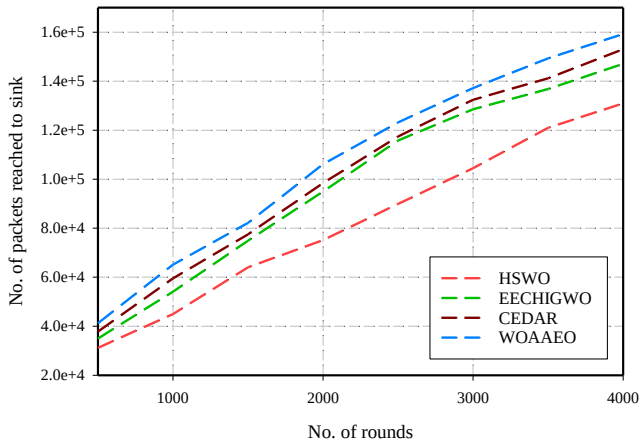

Fig. 6. Packet delivery ratio comparison

Fig. 6 illustrates the packet delivery performance of WOAAEO to the sink node, with an average of 159,300 packets at the end of 4000 rounds. This is an improvement of 4%, 8.2%, and 21.5% versus CEDAR, EECHIGWO, and HSWO, respectively. The exceptional performance attained by WOAAEO is principally due to the underlying hybrid optimization based on AEO's exploration capability and WOA's exploitation ability. This synergy provides the most effective CH selection by considering the node's optimal energy and proximity metrics while minimizing packet loss during transmission. Additionally, due to adaptive mechanisms, WOAAEO balances energy consumption so that data collision is minimized and packet delivery becomes highly reliable.

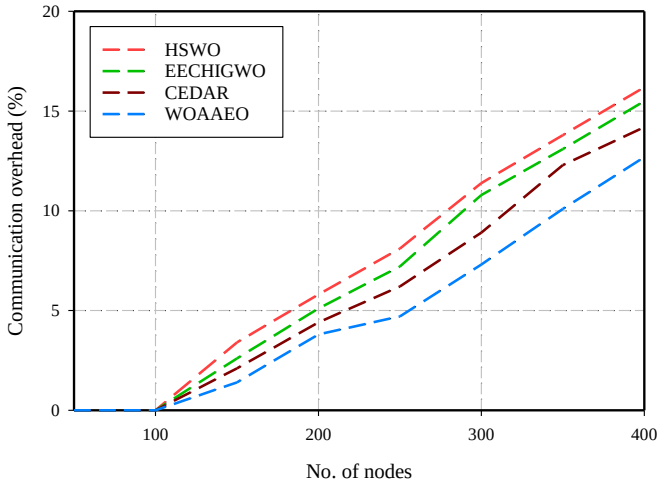

Fig. 7. Communication overhead comparison.

According to Fig. 7, for a network of 300 nodes, WOAAEO has the least communication overhead compared to other algorithms. Such a significant reduction in overhead is achievable due to the hybrid optimization approach through which WOAAEO intelligently handles CH rotation due to an appropriate balance of exploration and exploitation phases. The dynamic exploration capability of AEO and the correct exploitation mechanism of WOA are useful for WOAAEO for the optimum selection of CHs with minimum redundant communications. The adaptive streamlining of communication paths reduces superfluous data transmissions, better-utilizing energy and reducing the overall communications overhead.

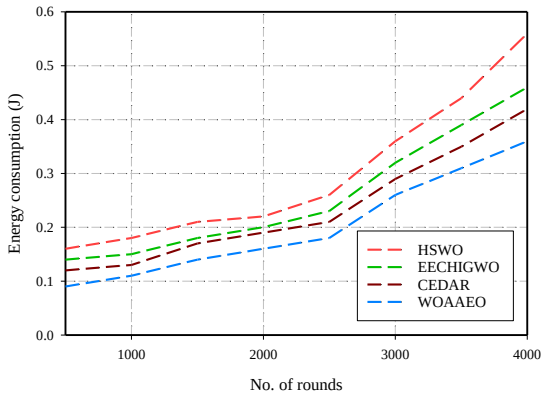

Fig. 8. Energy consumption comparison.

As shown in Fig. 8, WOAAEO reduces energy consumption to 0.36 J within 4000 rounds, which accounts for the energy consumption reduction, compared with CEDAR, HSWO, and EECHIGWO, respectively, by 14%, 35.7%, and 21.7%. This is driven by the remarkable energy efficiency induced within the network by the hybrid optimization approach of WOAAEO, which integrates the remaining energy and distance parameters within the CH selection process. By employing the exploration factor of AOE in identifying energy-efficient nodes and the exploitation factor of WOA in further refining CH placement, WOAAEO ensures that energy is utilized in a balanced manner throughout the network. Additionally, its adaptive mechanisms minimize redundant data transmissions and optimize clustering for reduced energy utilization, thus prolonging the network's lifespan.

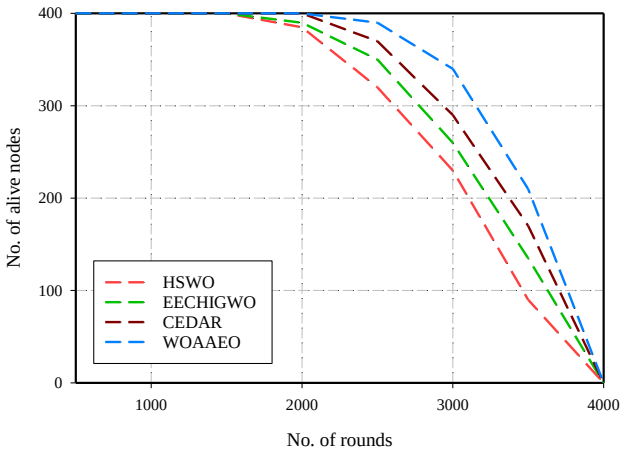

Fig. 9. No. of alive nodes comparison.

Fig. 9 illustrates that WOAAEO has kept 300 live nodes for up to 3000 rounds, which is considerably higher than other algorithms. This extended lifetime of the WOAAEO network has been achieved because its hybrid optimization model leverages the strengths of AEO exploration and WOA exploitation capabilities. The energy-efficient WOAAEO selects CHs dynamically based on residual energy and distance from the BS to avoid overutilizing particular nodes. Moreover, its adaptive CH rotation mechanism spreads out the network's energy consumption evenly so that no early node depletion occurs and more nodes remain active for more rounds. This balance in energy usage directly contributes to the network's operational life.

While the current evaluation focuses on a mid-range static WSN with 400 nodes, the extension of WOAAEO to very large or dynamic IoT deployments is a critical area that necessitates further investigation. For applications involving thousands of heterogeneous mobile devices, distributed re-clustering and CH selection schemes must be explored. Future research avenues for WOAAEO include distributed agent-based techniques to overcome bottlenecks in the centralized approach and mobility-aware schemes that adapt and reformulate cluster topologies based on dynamic updates to node movements. This will make WOAAEO scalable and efficient in supporting very dense IoT systems in real-world setups.

Although the presented work focuses on energy consumption, packet delivery ratio, and network lifetime as key performance metrics, other critical QoS factors, such as latency, network reliability, and network throughput, are also relevant to actual IoT applications. These were not explicitly modeled in the current version of WOAAEO, as energy efficiency was the key optimization area. Preliminary latency profiling indicated that the algorithm has an acceptable average latency due to the reduced CH switching rate and dynamic clustering. A more detailed evaluation of these additional QoS factors will be incorporated in subsequent works to validate WOAAEO under various operating conditions.

Even if WOAAEO efficiently optimizes CH selection, its current implementation considers direct single-hop communication between CHs and the BS. Massive deployments can cause substantial energy consumption by distant CHs. A better improvement would be to include a relay node optimizing strategy that supports multi-hop data transmission, minimizes the burden on distant CHs, and maximizes energy efficiency.

The WOAAEO framework supports technical performance in achieving overall goals, such as cost-effectiveness and environmental sustainability, which are crucial to successfully deploying IoT-based WSNs. WOAAEO reduces the battery replacement rate and e-waste by conserving energy consumption and extending the lifespan of the operating sensor node, thereby lowering the overall environmental cost of large-scale sensor deployments.

In applications such as remote farms, woodland surveillance, and urban infrastructures, where manual maintenance is expensive and logistically cumbersome, WOAAEO can alleviate operational budgets by increasing node lifespan and reducing manual intervention. Adaptive rotation and clustering of CH ensure energy is spent effectively without inducing early node death and avoidable replacements.

Additionally, the algorithm's efficiency in utilizing limited hardware resources makes it suitable for use in a lower-cost microcontroller-based platform, which aligns with the economic limitations common in developing areas or large-scale public projects. Such traits are the foundation of WOAAEO as a cost-effective and sustainable solution in energy-sensitive IoT applications.

## V. Conclusion

This paper introduced WOAAEO, a novel hybrid optimization algorithm incorporating AEO into WOA to promote energy efficiency in WSNs. The full utilization of AEO's strong exploration ability and WOA's high exploitation precision enabled WOAAEO to reach an excellent trade-off between residual energy and communication overhead. These modifications significantly improved CH selection, packet delivery, and network lifespan. Simulation results suggested that WOAAEO outperforms the existing CEDAR, EECHIGWO, and HSWO algorithms on every key performance metric of energy consumption, communication overhead, and network lifetime. These results emphasize the potential capability of WOAAEO to prolong WSN operational life and reduce resource wastage, thereby giving promise in IoT-enabled environments that demand scalable and energy-efficient operations.

Future research avenues for WOAAEO include experimentation with its applicability through actual deployment within dynamic and heterogeneous IoT environments. Research that integrates WOAAEO with other IoT protocols, such as data combining and securing, is expected to further enhance its utility in advanced systems. Additionally, to realize its full potential in actual applications, WOAAEO will be enhanced to operate with massive-scale, mobile, and diverse IoT networks. This entails the development of decentralized variants, the inclusion of mobility prediction schemes, and the deployment of real-time feedback schemes to provide adaptive cluster control. Such enhancements in the future will be crucial to realizing the algorithm’s practicality in various emerging IoT applications, such as smart cities, industrialization, and agriculture.

***Abstract*—Accurate rainfall estimation is essential for various applications, including transportation management, agriculture, and climate modeling. Traditional measurement methods, such as rain gauges and radar systems, often face challenges due to limited spatial resolution and susceptibility to environmental interferences. These constraints affect the ability of the model to deliver high-resolution, real-time rainfall data, allowing the model to be challenging to capture localized variations effectively. Therefore, this study aimed to introduce a hybrid deep learning architecture that combined a Convolutional Neural Network (CNN) with a Convolutional Block Attention Module (CBAM) to improve rainfall intensity estimation using images captured by surveillance cameras. The proposed model was evaluated using standard datasets and previous unseen images collected at different times of the day, including morning, noon, afternoon, and night, to assess its toughness against temporal variations. The experimental results showed that VGG-CBAM architecture performed better than ResNet (Residual Network)-CBAM across all evaluation metrics, achieving a coefficient of determination ($R^2$) of 0.93 compared to 0.89. Furthermore, when tested on unseen images captured at different periods, the model showed strong generalization capability, with correlation values (R) ranging from 0.77 to 0.98. These results signified the effectiveness of the proposed method in improving the accuracy and adaptability of image-based rainfall estimation, offering a scalable and high-resolution alternative to conventional measurement methods.**

***Keywords*—Rainfall; surveillance camera; hybrid deep learning; CBAM**

## I. INTRODUCTION

Rain is a fundamental element of weather observation and significantly affects many aspects of human life [1]. Rain impact extends across multiple sectors, including transportation [2], agriculture [3], public health [4], tourism [5], and finance [6], influencing daily activities as well as economic stability. A striking example concerning the rain effect was the 2015 floods in Jakarta, which submerged 20% of the city, evacuated 1,400 residents, and caused daily economic losses of approximately USD 114 million, according to the National Disaster Management Authority (BNPB) [7]. Despite the critical role of rainfall data in disaster management and planning, rain observation systems remain limited and insufficiently distributed [13]. There is a pressing need for cost-effective and easy-to-maintain rainfall intensity measurement systems that can be widely deployed across different locations.

Rainfall can be measured using primary or derivative methods, where the primary method includes using a rain gauge, which is simple to operate and maintain [8]. However, the method requires installation in unobstructed locations, which can limit its effectiveness in specific environments [9]. The derivative method, which includes radar and satellite-based measurements, has the advantage of covering large areas. However, this method is vulnerable to external interferences, such as signal disruptions from nearby fields, reflections from objects, and limitations in both temporal and spatial resolution [10]. High-resolution rainfall data, spatially and temporally, is crucial for hydrological and climate modeling. Accurate data improves the precision and reliability of simulations and predictions, making it an essential component in environmental and meteorological studies [11].

The need for high-resolution spatial and temporal rainfall data extends outside hydrological applications and plays a crucial role in the transportation sector, particularly in Intelligent Transport Systems (ITS) and human mobility management. Studies have consistently shown that weather conditions, specifically rainfall, significantly impact transportation [12], [13], often disrupting traffic flow and increasing congestion. Traffic congestion in highly urbanized areas such as Jakarta leads to considerable economic losses, estimated at $5 billion annually [14]. A practical method for mitigating congestion is the implementation of ITS, which provides real-time traffic updates, allowing drivers to select alternative routes and avoid heavily congested areas. However, the effectiveness of ITS depends on access to real-time weather data, particularly high-resolution rainfall intensity measurements, which are essential for predicting traffic behavior under varying weather conditions. Despite the importance of such data, the sparse distribution of rainfall observation instruments has created significant gaps, limiting the efficiency of ITS operations. To address the issue, crowd-sourced data from surveillance cameras presents a promising alternative. This camera, widely installed in urban areas, can estimate rainfall intensity, providing the high-resolution data needed to increase ITS performance and improve urban mobility management.

Recent advancements in deep learning have facilitated using a Convolutional Neural Network (CNN) for estimating rainfall intensity from surveillance camera images. Unlike traditional methods that rely on physical sensors such as rain gauges or radar, CNN-based models can automatically learn spatial and

temporal rainfall patterns directly from images. Several studies have shown the effectiveness of CNN in extracting rainfall-related features from image data, leading to improved estimation accuracy. For instance, Yin et al. [15], introduced an image-based deep-learning model to estimate urban rainfall intensity with high spatial and temporal resolution. The study used a modified Residual Network (ResNet)34 architecture, termed irCNN, which was trained on a dataset comprising both synthetic and real-time images captured from surveillance cameras and smartphones. The model achieved Mean Absolute Percentage Error (MAPE) between 16.5% and 21.9% in rainfall intensity estimation. Despite these promising results, challenges remain in ensuring the model's generalizability across different locations, camera types, and extreme weather conditions. Further validation and model improvements are necessary to increase strength and adaptability for real-world applications.

A two-stage framework has been developed for rainfall estimation, combining raindrop extraction with deep learning-based intensity estimation. In the first stage, raindrop extraction uses low-rank matrix decomposition [16], and Markov random fields [17]. In the second stage, rainfall intensity is estimated using a deep learning model, irCNN [18]. The dataset used for evaluation is collected from rainfall events in Hangzhou, China, and includes daytime and night-time conditions. During the process, ground truth data is obtained from a tipping-bucket rain gauge for accuracy assessment. The results show that preprocessing significantly improves performance in nighttime conditions, reducing MAPE to 19.73%. However, preprocessing slightly lowered accuracy for daytime images, with MAPE increasing from 17.06% (raw image) to 19.58%. The result signifies that it may not be necessary for daytime scenarios as preprocessing improves model strength in low-light conditions.

A deep learning-based method has been developed for estimating rainfall intensity using video footage from surveillance cameras. This method uses a Recurrent Neural Network (RNN), specifically Long Short-Term Memory (LSTM) and Gated Recurrent Units (GRU) [19]. The results shows that GRU, optimized using Adam optimizer, achieved the lowest MAPE of 4.49%, while LSTM produced slightly higher errors with a MAPE of 5.67%. These signify that GRU is computationally efficient and maintains high rainfall estimation accuracy. Despite these promising results, the study has some distinguished limitations. The model is not tested on unseen image data from different cameras or locations, raising concerns about its ability to generalize to real-world conditions where environmental variables may differ significantly. Further validation is necessary to assess the strength and adaptability of the model across diverse settings.

Shalaby et al. [20], introduced a deep learning-based method for estimating rainfall intensity using video footage from surveillance cameras and smartphones. This method uses CNN to analyze rainfall patterns and consists of three primary stages: image preprocessing, CNN model training, and transfer learning. The model was initially trained on surveillance camera images and later fine-tuned with smartphone images to improve generalization. Relating to the discussion, the dataset collected at Monash University, Malaysia, between May and December 2022, included 6,121 images from surveillance cameras and 1,984 images from smartphones. The ground truth rainfall intensity measurements were obtained using a tipping-bucket rain gauge. The results showed that image preprocessing significantly improved model performance, with the best CNN model achieving an $R^2$ of 0.955 and Mean Absolute Error (MAE) of 2.508 mm/h for surveillance camera data.

Additionally, transfer learning improved prediction accuracy for smartphone images, producing $R^2$ of 0.840 and MAE of 4.374 mm/h. Despite the promising outcomes, the study had certain limitations. The model's generalization was restricted due to training on a single camera setup, and the study did not evaluate nighttime images, leaving its performance in low-light conditions uncertain. Further analysis is needed to improve strength across diverse camera environments and lighting conditions.

A study on rainfall intensity estimation using a surveillance camera with CNN has been widely conducted. However, two significant aspects require improvement. First, the accuracy of existing models remains a challenge. Despite previous studies showing that deep learning models successfully estimate rainfall, many methods rely on preprocessed inputs, such as rain streak removal or background subtraction, before feeding the data into CNN. Even though preprocessing improves feature extraction, it often introduces fixed assumptions about lighting conditions, scene background, and rainfall characteristics. This process can reduce adaptability to real-time variations such as changing illumination, environmental noise, and dynamic backgrounds. Second, many existing models struggle with generalization to unseen data. Several studies have reported that CNN-based rainfall estimation models perform well on training datasets but experience significant performance drops when tested on independent images from different locations, weather conditions, or camera configurations. This lack of generalization is partly due to dataset biases introduced by preprocessing methods that filter information essential for recognizing rainfall across diverse environments.

Addressing the complexities of real-world environments is crucial for effective image processing. This study introduces a groundbreaking method that eliminates the need for preprocessing by directly processing raw images. The method uses a strong CNN architecture to improve adaptability and simplify computational workflows. By performing this process, the analysis anticipates significant improvements in model accuracy and generalization capabilities, allowing seamless performance across diverse surveillance camera settings.

The primary objective of this study is to estimate rainfall intensity images using a Deep Learning model using ResNet architecture, leveraging the image captured by a surveillance camera. This study is driven by three major factors which include:

*1)* Toughness to temporal variability without preprocessing: Despite applying deep learning models to rainfall estimation, the ability to handle temporal variations remains underexplored. Environmental changes, such as fluctuations in lighting between day and night or seasonal variations, can significantly affect model performance. However, most existing models rely heavily on preprocessing methods to standardize image inputs, which can be

computationally expensive and impractical for real-time applications. This study aims to develop a ResNet-based model that inherently adapts to temporal variations, ensuring consistent and reliable rainfall estimation without extensive preprocessing.

*2)* Higher Temporal and Spatial Resolution Compared to Automatic Rain Gauge (ARG): Surveillance cameras offer higher temporal and spatial resolution than tipping bucket ARG, among the most widely used rainfall measurement systems. Relating to the discussion, a single surveillance camera can capture multiple images per second from various locations across a city, providing continuous and detailed data. This capability enables real-time monitoring and a more granular measurement of rainfall intensity, which is not achievable with the relatively sparse ARG network.

*3)* Limited Study on Models Evaluated with Unseen Image Data: A significant gap in the existing study is the lack of models tested on unseen images that are not part of the training process. Many existing models perform well on training and validation datasets but struggle to generalize when exposed to unseen data from the cameras used to train the model. Therefore, this study explicitly addresses the mentioned limitation by evaluating the model on entirely new image datasets, ensuring the toughness and adaptability of the model in real-world deployment.

The rest of this article is organized as follows: Section II presents related work, while Section III describes the methods. Section IV details the experimental setup, followed by Section V, which discusses the results. Finally, Section VI concludes the analysis and recommends directions for future study.

## II. Related Works

Several studies have explored using surveillance cameras and CNN to estimate rainfall intensity. This method included analyzing images captured by CCTV cameras every 10 minutes at 85 locations during daylight hours (6:00 AM to 7:00 PM Singapore time). These images had resolutions of either 640 × 480 or 320 × 240 pixels [21]. Data from a tipping bucket rain gauge was recorded at 5-minute intervals to obtain rainfall labels. The Inverse Distance Weighting (IDW) [22] method was then applied to associate the rainfall labels with the corresponding camera locations. For rain removal, studies tested two deep learning models, namely VGG19 [23] and a hybrid method combining VGG19 with a Density-aware Image De- raining method using a Multi-stream Dense Network (DID-MDN) [24]. Both models incorporated three hidden layers (512, 256, 128), used ReLU activation, and were trained with ADAM optimizer-based gradient descent, set at a learning rate 0.25 [25]. The results showed that the hybrid model outperformed the standard VGG19 model. Additionally, high-quality images produced more accurate rainfall estimates compared to lower-resolution images.

Yin et al. [15], applied the irCNN model to estimate rainfall using CCTV images. The existing irCNN architecture was a modified version of ResNet [26], based explicitly on ResNet34, but with convolutional layers reduced to 29. The study used three types of data: synthetic rain image, image captured with a mobile phone camera, and image extracted from CCTV footage. Rainfall labels were obtained from rain gauge data recorded at one-minute intervals. However, since the temporal resolution of the gauge data did not match CCTV and mobile phone images, linear interpolation was applied to downscale the measurements accordingly. Yin initialized the irCNN model with pre-trained weights from ImageNet [27] for training. The results showed that the proposed model achieved MAPE ranging from 13.5% to 21.9%, signifying its effectiveness in estimating rainfall from image-based data sources.

During the analysis process, CNN combined with various RNN architectures, including SimpleRNN [28], LSTM [29], and Gated Recurrent Unit (GRU) [30], was used to estimate rainfall intensity from surveillance camera videos [19]. The study's CNN backbone is used for feature extraction as EfficientNetB0 [31]. To process the data, the original video recordings, captured at a resolution of 1920 × 1080 pixels, were cropped to 540 × 380 pixels. CCTV footage was acquired from a single fixed-location camera, while rainfall labels were obtained from ARG at one-minute intervals. The proposed model was evaluated using three optimization algorithms: Adam, RMSProp, and Stochastic Gradient Descent (SGD). The analysis showed that MAPE ranged from 3.55% to 6.95%, signifying the model's effectiveness in estimating rainfall from video-based data.

Zheng et al. [18], introduced a two-stage deep-learning framework designed to estimate rainfall intensity using video footage from a surveillance camera. The first stage focused on preprocessing and applied three primary methods, namely Low-Rank Matrix Decomposition (LRMD) [32] to separate the background from raindrop regions, Markov Random Fields (MRF) [33] for raindrop segmentation, and Sparse Optimization (SO) to improve raindrop visibility while minimizing noise. After preprocessing, the extracted rainfall features were fed into irCNN, a modified ResNet34 model version that continuously predicted rainfall intensity. Video recordings from 12 different rainfall events in Hangzhou, China, were used to evaluate the framework. These recordings captured daytime and night-time conditions, with ground truth intensity measured by a tipping-bucket rain gauge. Experimental results showed that preprocessing significantly improved nighttime performance, reducing MAPE to 19.73%. During the daytime, better accuracy was achieved when using raw images rather than preprocessed ones, with MAPE values of 17.06% compared to 19.58% after preprocessing. Despite the advancements of this model, the study has several limitations. Since the model was tested using data from a fixed camera setup, its ability to generalize to different camera sources or new locations remains uncertain. Another concern is that the preprocessing stage might remove subtle rainfall details, affecting estimation accuracy, particularly in high-intensity rainfall scenarios. The studies shows the importance of further validation to improve the model's reliability, specifically in extreme weather conditions and across diverse surveillance networks.

Even though deep learning and surveillance camera imagery have significantly improved rainfall estimation, several challenges remain unresolved. A significant issue is the reliance on extensive preprocessing methods, such as rain streak extraction and image decomposition, to improve model

accuracy. As these methods improve performance, the models add computational complexity, making real-time deployment difficult and reducing the ability to adapt to changing conditions such as lighting variations and seasonal shifts. Another limitation stems from the dependence on rain gauge data, which typically has a temporal resolution of one minute. Despite the accuracy, the sparse distribution of ARG restricts high-resolution spatial rainfall measurements. In areas without ARG coverage, interpolation methods must be used, which can introduce errors and reduce measurement reliability. Lastly, a critical challenge lies in deep learning models' strength when applied to images from diverse environmental settings. Many models perform well on the training datasets but struggle to generalize when faced with new camera locations, lighting conditions, or urban landscapes. This limitation reduces the effectiveness in real-world applications and shows the need for further improvements in model adaptability.

This study introduces a novel rainfall estimation model to improve accuracy, adaptability, and spatial resolution. The first significant improvement is the model's ability to handle temporal variations without relying on extensive preprocessing. By eliminating the need for computationally expensive preprocessing methods, the model can seamlessly adapt to changes in lighting and seasonal conditions, making real-time deployment more practical. Another significant advancement is the shift away from traditional rain gauge-based methods, which are constrained by the sparse distribution of ARG. Surveillance cameras, widely installed in urban areas, offer a significantly denser spatial network for rainfall monitoring. The proposed method can supplement ARG data by incorporating deep learning methods with camera imagery, providing a more detailed and continuous representation of rainfall intensity. It reduces dependence on interpolation methods and improves the accuracy of rainfall distribution mapping. Finally, it is tested on previously unseen datasets from different camera sources and locations to ensure the model's toughness across diverse environments. The evaluation process improves the ability of the model to generalize outside its training data, ensuring reliable performance in varying environmental conditions. The proposed method improves rainfall estimation accuracy, efficiency, and scalability by addressing these limitations using deep learning and surveillance camera imagery.

## III. METHODS

VGG16 and ResNet34 architectures were previously used to estimate rainfall intensity from surveillance camera images or videos. However, the accuracy of the models remained a challenge and required further improvement. This limitation was a foundation for the decision to use the architectures and improve the performance by incorporating the Convolutional Block Attention Module (CBAM).

### A. VGG16

VGG architecture was introduced by Simonyan [34] and featured 16 convolutional layers organized into five sequential blocks. The design incorporated increasing filters in deeper layers to improve feature extraction. Each convolutional layer used 3×3 kernels, ReLU activation, and the same padding. The first two blocks consisted of convolutional layers with 64 and 128 filters, followed by batch normalization and max pooling. Following the process, the third block contained three layers with 256 filters, while the fourth and fifth blocks each included three layers with 512 filters. VGG architecture has been widely applied in various fields, including rainfall intensity estimation [21], leaf disease classification [35], plant disease identification [36], and classification of individuals with dementia People [37].

### B. ResNet34

ResNet was developed as CNN architecture to address performance degradation issues commonly observed in deep networks [26]. In traditional CNN architectures, each layer attempted to learn a direct mapping from input to output. However, as network depth increased, performance often deteriorated due to optimization challenges rather than overfitting. ResNet introduced residual learning to overcome this issue, allowing the model to learn a residual mapping rather than a direct one. The core component of ResNet was the residual block, which consisted of multiple nonlinear layers, including convolutional layers, batch normalization, and activation functions. These layers were combined with an identity shortcut connection that directly associated the input to the output of the block, helping to maintain gradient flow and improve training efficiency. ResNet has been widely applied in various fields, including colorectal cancer detection [38], pathologic myopia[39], and rainfall estimation [15].

### C. Convolutional Block Attention Module (CBAM)

CBAM, introduced by Woo et al. [40], was developed as an attention mechanism designed to improve the performance of CNN. Designed as a lightweight and versatile component, CBAM could be seamlessly incorporated into any CNN architecture [40], [41].

The mechanism consisted of two major modules, the channel and spatial attention module, as shown in Fig. 1. The channel attention module identified the most important features by prioritizing relevant channels in the feature map. Consequently, the spatial attention module determined the locations of significant features, showing crucial spatial regions in the input data.

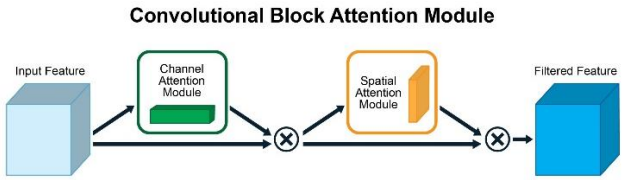

Fig. 1. Image of CBAM architecture [40].

When processing an intermediate feature map $F \in \mathbb{R}^{C \times H \times W}$ as input, CBAM first generated a 1D channel attention map $M_c \in \mathbb{R}^{C \times 1 \times 1}$ followed by 2D spatial attention map $M_s \in \mathbb{R}^{1 \times H \times W}$ as shown in Fig. 2 and Fig. 3. The complete attention mechanism operated through element-wise multiplication, represented by $\otimes$. During this operation, channel attention values were extended across the spatial dimensions, while spatial attention values were expanded along the channel dimension. The resulting feature map was represented after applying the channel attention module $F'$. The parameter $F''$ was the final output, as shown in Eq. (1) and Eq. (2). Fig. 2 and Fig. 3 further showed

the computation process of the channel and spatial attention module, respectively.

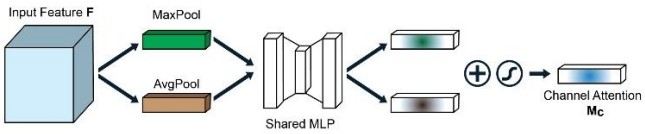

Fig. 2. Computational process for channel attention [40].

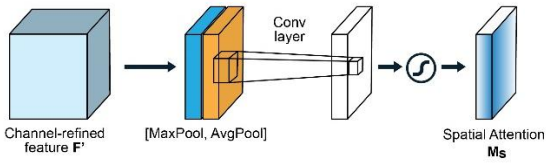

Fig. 3. Computational process for spatial attention [40].

$$F' = M_C(F) \otimes F \tag{1}$$

$$F'' = M_S(F') \otimes F' \tag{2}$$

The process began by capturing spatial information from the feature map through average and max pooling operations. These processes generated two distinct spatial context descriptors. $F_C^{avg}$ representing the average-pooled features and $F_C^{\max}$ signifying the max pooling feature. Both descriptors were then processed through a shared network to compute the channel attention map $M_c \in \mathbb{R}^{C\times1\times1}$ where $r$ was the reduction ratio. After passing each descriptor through the network, the resulting feature vectors were fused using element-wise summation. The channel attention was determined using the following computation in the following Eq. (3)

$$\begin{aligned} M_C(F) &= \sigma\left(MLP\left(AvgPool(F)\right) + MLP\left(MaxPool(F)\right)\right) \\ &= \sigma\left(W_1\left(W_o\left(F_{avg}^C\right)\right)\right) + \sigma\left(W_1\left(W_o\left(F_{\max}^C\right)\right)\right) \end{aligned} \tag{3}$$

where, $\sigma$ represented the sigmoid function, while $W_0 \in \mathbb{R}^{C\times C/r}$ and $W_1 \in \mathbb{R}^{R/c\times C}$.

During this process, a spatial attention map was generated to capture the inter-spatial relationships of features. Unlike channel attention, which identified 'what' was important, spatial attention focused on 'where' the most informative regions were located, allowing it to be a complementary mechanism. The computation of spatial attention began with average and max pooling along the channel axis. These operations helped to form a compact yet practical feature descriptor by improving the visibility of crucial regions in the feature map [42]. The spatial attention map $M_s(F) \in \mathbb{R}^{HxW}$, was then generated by applying a convolution layer to the concatenated feature descriptor, enabling the model to signify or suppress specific regions. The process started with two pooling operations that aggregated channel information, producing two 2D feature maps, namely $F_s^{avg} \in \mathbb{R}^{1xHxW}$ and $F_s^{max} \in \mathbb{R}^{1xHxW}$, both computed across the channel dimension. These pooled feature maps were concatenated and processed through a standard convolution layer, producing the final 2D spatial attention map. In summation, the complete spatial attention mechanism was mathematically described in the following Eq. (4)

$$\begin{aligned} M_S(F) &= \sigma\left(f^{7\times7}\left(\left[AvgPool(F); MaxPool(F)\right]\right)\right) \\ &= \sigma\left(f^{7\times7}\left(\left[F_{avg}^s; F_{\max}^s\right]\right)\right) \end{aligned} \tag{4}$$

where, $\sigma$ was the sigmoid function, and $f^{7x7}$ referred to a convolution operation using a 7×7 filter size.

### D. VGG-CBAM

VGG-CBAM refers to the combination of VGG architecture with the CBAM module in the context of this discussion. Previous studies investigated the application of VGG-CBAM, particularly in facial expression recognition [43] and image classification [41]. However, to the best available knowledge, no study has yet explored the use of the model for estimating rainfall intensity from CCTV footage.

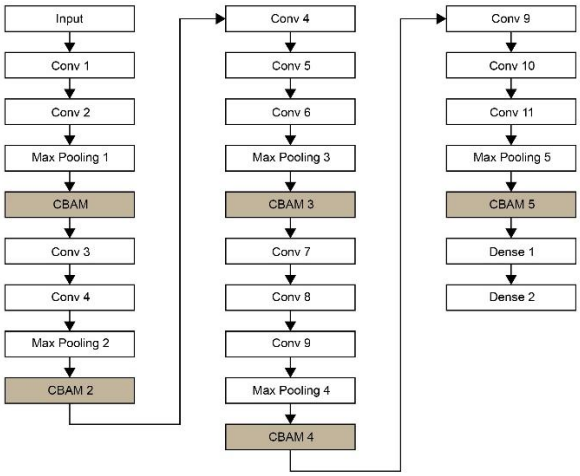

Fig. 4. Proposed architecture of VGG-CBAM model.

Fig. 4 shows VGG-CBAM architecture, which began with an input layer, followed by three convolutional layers (Conv 1, 2, and 3) to extract initial spatial features. After these layers, the Max Pooling 1 was applied to reduce spatial dimensions, followed by the first CBAM module (CBAM 1) to improve feature representation through spatial and channel-wise attention. The next stage consisted of three additional convolutional layers (Conv 4, 5, and 6), followed by Max Pooling 2 and CBAM 2 to refine the extracted features further. This pattern continued with another set of convolutional layers (Conv 7, 8, and 9), succeeded by Max Pooling 3 and CBAM 3. In the final segment, two more convolutional layers (Conv 10 and 11) were introduced, followed by Max Pooling 4 and the last attention module, CBAM 4. The network was completed with two dense layers responsible for aggregating extracted features and generating the final output. This design enabled the architecture to perform tasks such as classification or regression effectively. Several studies have applied VGG-CBAM in various fields, including bat classification [41] and facial expression recognition [43].

### E. ResNet-CBAM

ResNet-CBAM refers to the integration of ResNet architecture with the CBAM module. Several studies have used this architecture for disease detection, including brain diseases [44] and lung cancer [45]. However, to the best of available knowledge, no studies have yet investigated the application of the model for estimating rainfall intensity.

Fig. 5 shows ResNet-CBAM architecture, as the design used a ResNet backbone configured with four stages of residual blocks, arranged into 3, 4, 6, and 3 blocks per stage, leading to 16 residual blocks across the network. Unlike traditional ResNet implementations, which typically included multiple pooling layers, this architecture used a single global average pooling layer immediately before the fully connected layer to reduce spatial dimensions. CBAM modules were strategically incorporated to improve feature representation, with 15 CBAM modules distributed across the residual blocks. These modules refined spatial and channel-wise feature maps, enabling the network to focus on the most relevant features. Several studies have applied ResNet-CBAM in different domains, including brain disease detection [44] and malignant–benign pulmonary nodule classification [45], multi-classification on arrhythmias [46], as well as flower classification [47].

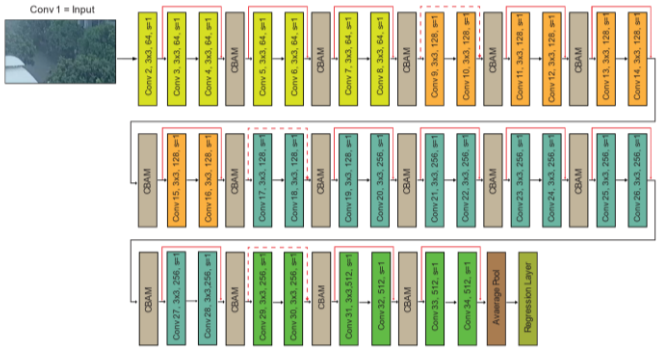

Fig. 5. The proposed architecture of the ResNet-CBAM model.

## IV. Experimental Setup

### A. Dataset

This study used Python 3.11 and TensorFlow 2.0, with the dataset stored in HDF5 files. The deep Learning model was executed on a PC equipped with an Intel(R) 11th Gen Core™ i7-11700F processor and NVIDIA RTX 3090 GPU with 32 GB of memory. Moreover, the dataset used in this study was captured with a surveillance camera featuring a resolution of 2560x1440 pixels and a frame rate of 25 frames per second (fps). Fig. 6 shows the samples of image rainfall captured during the study. The analysis focused on eight rainfall events recorded between January and April 2024.

Fig. 6. Image rainfall captured using a surveillance camera.

The selected rainfall events occurred at different times, including morning, afternoon, evening, and night. Data was collected during the analysis using ARG installed near the CCTV camera to ensure accurate rainfall measurements. The specific rainfall events included in the analysis are shown in Table I.

TABLE I. Rainfall Events Used for Dataset Creation

| Rain event | Time event | Duration (minutes) | Period |
|---|---|---|---|
| January 29, 2024 | 06:26-06:43 | 17 | Morning |
| February 06, 2024 | 06:51-07:19 | 28 | Morning |
| February 04, 2024 | 11:55-13:55 | 120 | Noon |
| March 14, 2024 | 11:54–12:31 | 37 | Noon |
| March 31, 2024 | 15:15–15:47 | 32 | Afternoon |
| April 09, 2024 | 16:05–17:40 | 95 | Afternoon |
| January 27, 2024 | 00:10–00:54 | 44 | Night |
| February 10, 2024 | 01:08–03:04 | 116 | Night |

This study used rainfall measurements from the tipping bucket type ARG as the ground truth dataset. The use of tipping bucket ARG for ground truth data has been extensively documented in previous studies [15], [19], [48], [49]. The device in this analysis operated with a resolution of 0.2 mm per minute. Additionally, the model's mechanism functioned by directing rainfall into a funnel, where it accumulated in a small bucket. After reaching full capacity, the bucket tipped, registering a measurement of 0.2 mm of rainfall. However, this design imposed a limitation, as the model could not record rainfall intensities below 0.2 mm, even when rainfall was visibly present in camera imagery.

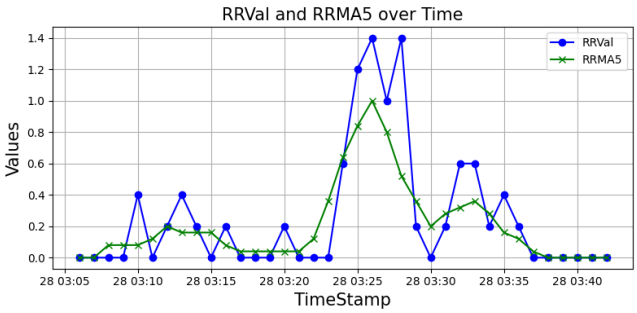

Fig. 7. Comparison between rainfall real value and rainfall after moving average five window.

Fig. 7 showed that the raw rainfall data collected from ARG indicated significant variability, with unexpected increase in rainfall followed by abrupt decrease. This pattern signified that per-minute rainfall measurements from ARG might not accurately reflect actual rainfall intensity [50]. Previous studies recommended an appropriate temporal resolution for ARG data ranging between 5 and 10 minutes [51]. A five-minute moving average method was applied to address the high fluctuations in the data. This method computed the average rainfall intensity over a rolling five-minute window, producing a smoother dataset that reduced the impact of rapid spikes or drops observed in minute-by-minute measurements. The mathematical

formulation of the moving average method was presented in the following Eq. (5)

$$R_t = \frac{R_{t-2} + R_{t-1} + R_t + R_{t-+} + R_{t+2}}{5} \tag{5}$$

In the moving average formula, $R_t$ represented the rainfall intensity at time $t$. Similar to the previous value, $R_{t-1}$ and $R_{t-2}$ corresponded to the rainfall intensities recorded 1 minute and 2 minutes before $t$, respectively. $R_{t+1}$ and $R_{t+2}$ represented the rainfall intensities, which recorded 1 minute and 2 minutes after $t$, while $R_0$ signified the current rainfall concentration. After the data had been smoothed using the moving average method, the next step included applying linear interpolation to the per-second data. This step was crucial for ensuring precise rainfall intensity values at each second, enabling synchronization with the image captured by the surveillance camera. The formula for linear interpolation was presented in the following Eq. (6)

$$I_t = I_L + \frac{t}{60}\left(I_R + I_L\right) \tag{6}$$

where, it represented the rainfall intensity at second $t$, $I_L$ was the rainfall concentration at the start of the minute, $I_R$ signified the intensity at the last minute, and $t$ indicated the specific second being evaluated.

Fig. 8 shows the results of rainfall observations and interpolation during the analysis. The black line represented observed rainfall intensity, while the red line signified the results of linear interpolation. The image captured by the camera during the process had a resolution of 2660×1440 pixels. However, full resolution was not used as input; instead, a random selection of 180×120 pixels was performed for the processing. The dataset used during the analysis comprised 49,005 samples divided into three subsets, including 70% used for training, 15% for validation, and 15% for testing, respectively.

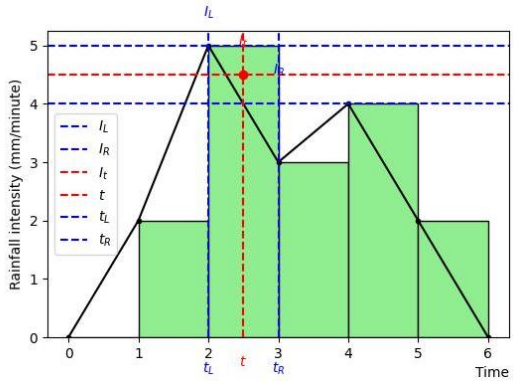

Fig. 8. Rainfall intensity interpolation over time.

### B. Evaluation Criteria

The following formulas were used to assess regression model performance, including MAE, Mean Arctangent Absolute Percentage Error (MAAPE), Nash-Sutcliffe Efficiency (NSE), Kling-Gupta Efficiency (KGE), and the Coefficient of Determination ($R^2$).

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\left|Y_i - \hat{Y}_i\right| \tag{7}$$

$$MAAPE = \frac{1}{n}\sum_{i=1}^{n}\arctan\left|\frac{Y_i - \hat{Y}_i}{Y_i}\right| \tag{8}$$

$$NSE = 1 - \frac{1}{n}\frac{\sum_{i=1}^{n}\left(Y_i - \hat{Y}_i\right)^2}{\left(Y_i - \bar{Y}_i\right)^2} \tag{9}$$

$$R^2 = \frac{\left(\sum_{i=1}^{n}\left(Y_i - \tilde{Y}\right)\sum_{i=1}^{n}\left(Y_i - \hat{Y}\right)\right)^2}{\sum_{i=1}^{n}\left(Y_i - \tilde{Y}\right)^2\sum_{i=1}^{n}\left(Y_i - \hat{Y}\right)^2} \tag{10}$$

$$KGE = 1 - \sqrt{(r-1)^2 + \left(\frac{\sigma_{pred}}{\sigma_{obs}} - 1\right)^2 + \left(\frac{\mu_{pred}}{\mu_{obs}} - 1\right)^2} \tag{11}$$

## V. Result

Four models were evaluated in this study, namely VGG16, ResNet34, and their respective versions integrated with CBAM. The selection of VGG16 and ResNet34 was based on proven effectiveness in previous studies on rainfall intensity estimation using surveillance camera imagery.

Table II shows the evaluation metrics for four models, including VGG16, ResNet34, VGG16-CBAM, and ResNet34-CBAM.

TABLE II. Performance Metrics of Evaluated Models in Testing Phase

| Model | MAAPE | MAE | NSE | KGE | RMSE | $R^2$ |
|---|---|---|---|---|---|---|
| VGG16 | 10.06 | 0.04 | 0.94 | 0.95 | 0.08 | 0.94 |
| ResNet34 | 14.34 | 0.06 | 0.91 | 0.94 | 0.10 | 0.91 |
| VGG16-CBAM | 9.3 | 0.03 | 0.95 | 0.96 | 0.07 | 0.95 |
| ResNet34-CBAM | 13.42 | 0.05 | 0.92 | 0.95 | 0.09 | 0.92 |

A comparison between the original VGG16 and ResNet32 models showed significant differences in the performance for rainfall estimation. VGG16 consistently outperformed ResNet34 across all evaluation metrics, signifying a stronger ability to capture complex patterns in the data. This advantage was attributed to the deeper and more feature-rich architecture of VGG16, which facilitated more effective feature extraction and processing. ResNet34, despite using residual connections to mitigate vanishing gradient issues, failed to achieve comparable results. The outcome recommended that the architectural design of the model was less suited for this specific task. Further analysis comparing VGG16 to its improved version, VGG16-CBAM, showed the impact of incorporating attention mechanisms. The addition of CBAM enabled the model to prioritize critical spatial and channel-wise features, improving accuracy and error reduction across all evaluation metrics. These

results signified the effectiveness of attention mechanisms in refining feature extraction and improving the capacity of the model to detect relevant patterns in complex datasets. Finally, VGG16-CBAM surfaced as a more effective model than the original VGG16.

When evaluating ResNet34 and ResNet34-CBAM models, the incorporation of CBAM showed a clear performance improvement. By enabling the model to signify important features while suppressing irrelevant factors selectively, the CBAM module contributed to higher predictive accuracy and reduced errors. Despite these improvements, ResNet34-CBAM still underperformed compared to both VGG16 and VGG16-CBAM. This result implied that while attention mechanisms offered benefits, the structural limitations of ResNet34 constrained the total effectiveness of the model for rainfall estimation. A direct comparison between VGG16-CBAM and ResNet32-CBAM further reinforced the superiority of VGG16 architecture. Relating to this discussion, VGG16-CBAM consistently delivered better results across all evaluation metrics, showing that combining a strong base architecture with an advanced attention mechanism produced the most effective model. These results signified that although attention mechanisms such as CBAM improved performance across different architectures, the total effectiveness still heavily depended on the fundamental design of the base model. It showed the importance of carefully selecting and optimizing model architectures for superior performance in complex data modeling tasks.

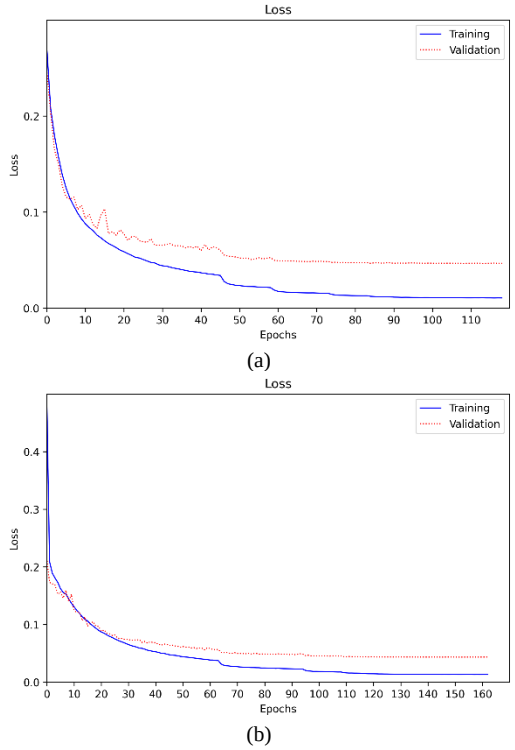

Fig. 9. Training and validation loss curve. (a) VGG16, (b) VGG16-CBAM.

Fig. 9 shows the loss graphs for VGG16 and VGG16-CBAM, indicating significant differences in training and validation performance. For the VGG16 model, the training loss gradually decreased with the number of epochs, eventually converging to a low value. However, a significant gap existed between the training and validation losses, with the validation loss remaining consistently higher. The discrepancy showed that despite effectively learning patterns of the VGG16 model from the training data, generalization to unseen validation data was limited, signifying potential overfitting. Consequently, the VGG16-CBAM model signified improved performance, as reflected in its loss curves. Both training and validation losses decreased gradually and converged to lower values than those observed in the VGG16 model. Moreover, the validation loss closely followed the training loss in the epochs, indicating improved generalization. The reduced gap between training and validation losses showed that the CBAM module enabled the model to focus on relevant features more effectively, mitigating overfitting and improving performance on unseen.

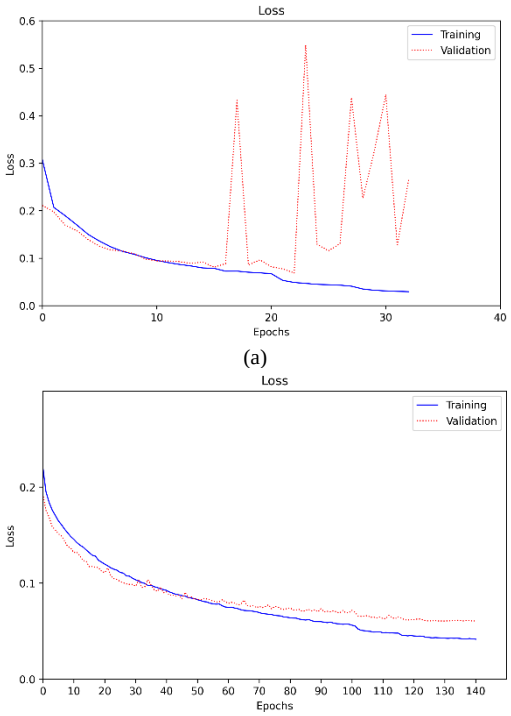

Fig. 10. Training and validation loss curve of (a) ResNet34 and (b) ResNet34-CBAM.

Fig. 10 compared the training and validation loss of ResNet34 and ResNet34 incorporated with CBAM, showing key differences in the learning behavior. For the ResNet34 model, training loss gradually decreased, signifying effective learning. However, the validation loss showed significant fluctuations, specifically in the early training phase, implying instability and potential overfitting. Due to this instability, early stopping was triggered sooner, as the validation loss failed to show consistent improvement, reflecting the limited generalization capability of the model. Consequently, the ResNet34-CBAM model signified a smoother and more stable decline in training and validation loss. The validation loss closely followed the training loss in training, indicating improved generalization and reduced overfitting. Early stopping occurred later for ResNet34-CBAM as the model improved its

validation performance. The inclusion of CBAM improved the ability of the model to focus on relevant features, leading to superior stability, lower overall loss, and better performance. These results showed ResNet34-CBAM as a more effective architecture for this task.

Fig. 9(b) and Fig. 10(b) presented a comparison of the training and validation loss for VGG-CBAM and ResNet-CBAM, respectively, in the training process. In Fig. 9, which showed VGG-CBAM, the validation loss consistently decreased with minimal fluctuations and eventually reached a lower value than ResNet-CBAM. Additionally, the difference between training and validation loss in VGG-CBAM remained relatively small, indicating that the model generalized well and maintained stable training performance. Fig. 10, which showed ResNet-CBAM, signified a slightly slower decline in validation loss, with the final loss values remaining slightly higher than those observed in VGG-CBAM. Although ResNet-CBAM showed stable and consistent learning, its ability to minimize validation loss was marginally weaker than VGG-CBAM. The results signified that while both models benefited from integrating the CBAM module, VGG-CBAM achieved better final validation loss and convergence efficiency.

Table III shows the performance metrics of the proposed models, VGG-CBAM (Model I) and ResNet-CBAM (Model II), across different periods, namely morning, noon, afternoon, and night. The evaluation used images captured by an unseen camera that had not been included in the training phase. The results showed that both models maintained strong predictive capabilities even when tested on previously unseen data, signifying the ability to generalize effectively in rainfall estimation tasks. Although both models showed strong predictive capabilities across all periods, slight variations in performance appeared based on the time of day. Specifically, the morning and noon intervals showed slightly lower NSE and $R^2$ scores compared to the nighttime period. This discrepancy could be attributed to increased environmental noise, fluctuations in illumination, or atmospheric disturbances, all of which potentially affected the quality of image captured by the unseen camera.

TABLE III. PERFORMANCE EVALUATION OF THE PROPOSED MODELS ON UNSEEN IMAGES

| Time | Model | MAAPE | MAE | NSE | KGE | RMSE | $R^2$ |
|---|---|---|---|---|---|---|---|
| Morning | I | 0.19 | 0.05 | 0.80 | 0.83 | 0.05 | 0.80 |
| | II | 0.42 | 0.05 | 0.83 | 0.85 | 0.06 | 0.83 |
| Noon | I | 0.42 | 0.05 | 0.82 | 0.78 | 0.06 | 0.82 |
| | II | 0.43 | 0.04 | 0.77 | 0.71 | 0.05 | 0.77 |
| Afternoon | I | 0.45 | 0.05 | 0.82 | 0.75 | 0.06 | 0.82 |
| | II | 0.80 | 0.05 | 0.76 | 0.84 | 0.05 | 0.76 |
| Night | I | 0.11 | 0.06 | 0.98 | 0.93 | 0.07 | 0.98 |
| | II | 0.1 | 0.05 | 0.98 | 0.94 | 0.06 | 0.98 |

During the afternoon, a noticeable increase in MAAPE was observed, particularly for ResNet-CBAM (Model II). It showed that fluctuating daylight conditions introduced additional challenges in feature extraction and rainfall estimation accuracy. The presence of dynamic shadows, variable cloud coverage, and rapid changes in lighting intensity probably affected the model's ability to consistently recognize rainfall-related patterns in surveillance images. Despite these variations, both models maintained highly reliable performance, as reflected in the consistently strong NSE, $R^2$, and KGE scores across different periods. These results showed the adaptability of the models to diverse lighting and environmental conditions, signifying the suitability for real-world applications where data acquisition was subjected to temporal variability.

## VI. CONCLUSION AND FUTURE WORK

In conclusion, this study developed two improved deep learning models, VGG-CBAM and ResNet-CBAM, for estimating rainfall intensity using surveillance camera images. The VGG-CBAM model combined the tough feature extraction capabilities of VGG16 with CBAM modules, while the ResNet-CBAM model incorporated CBAM into ResNet34 architecture, which consisted of 16 residual blocks. Both models outperformed the baseline counterparts, with VGG-CBAM signifying the highest accuracy and toughness across various evaluation metrics. Incorporating CBAM modules improved spatial and channel-wise attention, allowing the models to capture fine-grained rainfall patterns more effectively. Surveillance cameras as a data source offered a scalable and cost-effective alternative to traditional rainfall observation methods. Relating to this discussion, future studies would focus on optimizing the architecture, incorporating transfer learning, and expanding the dataset to improve the generalizability of the models across diverse urban environments and weather conditions.

## ACKNOWLEDGMENT

This study was conducted as part of a collaboration between Pusat Pengembangan Sumber Daya Manusia (PPDSM) and Fakultas Matematika dan Ilmu Pengetahuan Alam, Universitas Indonesia (FMIPA UI), under a formal cooperation agreement. This agreement is documented as PKS HK.08.00/001/PPK/PDL/II/2024, issued by BMKG, and 249/PKS/FMIPA/UI/2024, issued by Universitas Indonesia. This study was also supported by PUTI Hibah 2023.

***Abstract*—Language acquisition is an integral part of early schooling, but young English language learners struggle to learn vocabulary and syntax since they are not provided with specialized instruction. Conventional teaching may vary according to different learning speeds and it leads to unbalanced levels of proficiency among students and possibly leading to disengagement among slow learners. The present computer-assisted learning aids provide practice interactively but without real-time adaptation and personalized feedback, limiting their capacity to address learners' unique problems. To overcome these constraints, this study suggests an Artificial Intelligence based personalized learning system that supports vocabulary and syntax learning via adaptive learning models, NLP-based chatbots and gamified interactive lessons. The system dynamically adapts content according to students' most recent performance in real time to enable a personalized learning experience, which results in efficient Learning. The research has experimental study design, and two groups are considered, an AI-supported learning group and a traditional learning group. Pre-test and post-test design measures the effects of the system on vocabulary recall and syntax correctness. Other learner engagement rates like survey results and qualitative feedback inform learner experience and learning efficacy. Initial results indicate that learners working with the Artificial Intelligence powered learning system gained 25percent in recalling vocabulary and 30percent in syntax accuracy over the control group. Further, learner engagement rates are elevated because of real-time feedback and gamification components. These results emphasize the promise of AI-based personalized learning to boost language acquisition and lay the basis for further effective innovations in adaptive education technologies.**

***Keywords*—AI-based learning; gamification; language acquisition; personalized feedback; vocabulary***

## I. Introduction

Language learning is an essential aspect of a child's intellectual and social growth, especially in a growingly interconnected world where English is a prevailing means of communication [1], [2]. For young children, building a solid vocabulary and grammar foundation is important to ensure language proficiency [3]. Conventional language learning in schools is usually one-size-fits-all, with every student getting the same material and learning pace regardless of their differences in ability and learning styles [4]. This non-personalization tends to result in different levels of proficiency, as some students tend to excel while others fall behind [5]. In addition, passive learning strategies like rote memorization and repetitive drills frequently do not activate learners in an interactive and significant manner, leading to low rates of retention and poor understanding [6].

In the recent years technology driven personalized learning platforms with Artificial Intelligence (AI) are coming up to be a revolutionary solution in the education [7], [8]. Sophisticated technologies like Natural Language Processing (NLP), Machine Learning (ML) as well as adaptive learning algorithms are involved in driving such platforms where, content is being customized to the specific needs of individual learners specifically [9]. Real time analysis of a student's performance, level of difficulty adjusted, feedback provided and learning through chatbots, gamification and multimedia are among the abilities of an AI based learning platforms [10], [11]. Despite increased uptake in digital learning solutions, available platforms do not demonstrate the flexibility in real time to adapt to the learner's progress as well as contextual intelligence about the learner's difficulty in learning vocabulary and syntax [12]. Currently, the existing systems contain the limited capacity to address the particular needs of young English learners because

they are designed with static exercises and general feedback [13].

To resolve this, the present research proposes an AI personal learning system tailored to enhance early English learners' vocabulary memorization and syntax understanding. Interactive dialogues are provided by the system through the use of NLP based chatbots, adaptive models to adapt the exercises, and gamification to help with participation. The suggested system is intended to provide an interactive data driven learning process which will increase learning achievements, while it will be a fun and efficient learning process for the learner[14].

This study uses an experimental study design with participants grouped into two sets: one receiving the AI-assisted learning system and the other adopting conventional learning strategies. Both a pre-test and post-test approach is used to measure enhancements in vocabulary and syntax learning, with qualitative findings from surveys and interviews offering observations regarding learner participation and system ease of use. The contribution of the research are as follows,

*1)* Introduces an adaptive learning system based on AI, NLP, and gamification to boost vocabulary and syntax learning in young English learners.

*2)* Utilizes ML-driven personalization to customize lesson difficulty and content according to individual learner performance.

*3)* Integrates NLP-driven chatbots and gamification features to enhance engagement and retention.

*4)* Conducts experimental research on comparison of AI-enhanced learning versus conventional instruction by employing pre-test and post-test comparison.

*5)* Demonstrates substantial gains in vocabulary recall and sentence grammar through AI-supported interventions.

The rest of the work focuses as follows: Section II reviews the related works for the AI-Powered application in vocabulary learning. Section III describes the problems in existing methods, Section IV demonstrates the AI-driven personalized language learning framework. Section V evaluates the results and discussions. Section VI discusses conclusion and future work.

## II. Related Works

English language learners received enhanced AI dialogue systems through the lexically constrained decoding system according to Qian et al. [15]. Their research makes an original contribution by including educational vocabulary from the curriculum within a dialog system which generates text through Artificial Intelligence. The researchers tested BlenderBot3 through middle school English L2 student evaluations. Students achieved better understanding of their target vocabulary and increased their motivation to practice English while conversing with an AI system. The approach represents a strong method because it connects AI conversational agents to educational curricula so students benefit from an educational experience that combines focus with engagement. The approach offers contextual learning of vocabulary through real-world dialogues rather than detached memory drills. The research project faces an essential disadvantage because rigid word limits could disrupt conversation flow while providing students with an artificial and reduced exposure to multiple linguistic patterns. Because the research only assessed a limited student group additional studies must investigate the system's effectiveness when used by various proficiency-level groups of different ages. The conducted research generates important findings about how Artificial Intelligence can be applied to improve vocabulary acquisition through conversations.

Shin and Park [16], developed a system with Neural Collaborative Filtering (NCF) and personalized vocabulary acquisition that would help second language learners. It was called a Pedagogical Word Recommendation (PWR). What is new in their study is to apply collaborative filtering to predict whether a learner knows a word w given his history vocabulary. In this way, learning is more targeted and efficient. To ensure a large dataset, their system used data from an Intelligent Tutoring System (ITS) employed by roughly one million learners taking TOEIC preparation, in order to obtain data from many learners. High accuracy in vocabulary prediction and personalized recommendation was shown with the help of students focusing on words they will most likely struggle with. That is important, because it replaces vocabulary learning devoid of meaning as rote memorization, replaced with vocabulary learning as an adaptive, data driven activity, which makes it more engaging, and, by extension, more effective. Besides that, word suggestions become more personal, which increases retention and lowers cognitive overload. Nevertheless, one of the key limitations of the system lies in the fact that it is dependent on explicit feedback from learner that can have an impact on recommendation accuracy if a student self-assesses incorrectly. Furthermore, the model may not generalize well to learners having language significantly more or less varied than the one used in the induction. The system needs further research to increase the degree of adaptability and accuracy in a wide variety of learning environments.

Lee, Kim and Sung [17], proposed an AI based autonomous learning system based on the Learner Generated Context (LGC) framework to improve second language learning. What's the novelty of this approach is that student's study what they want and while they want, promoting self-directed learning. This involved three Korean secondary-school students of different backgrounds and tested the AI system to see how it helps learners to learn English autonomously. Through contextualized learning, the findings showed that the content was more engaged with and the students improved their language skills. What's more important is that the system can help learners being empowered, and with that help, increases motivation and long-term mastery, because it gives the learner the control over his journey. The real difference about this approach of AI assisted language learning is that this is not a strict structure, but rather a flexible one, which centers more on the students themselves. A small sample size, however, is the biggest limitation of the study and compromises the ability to generalize the findings to a larger population. Furthermore, the system also provides autonomy; however, some individuals may need guided and structured guidance to achieve their maximum potential. The scaling of the study to include more learners and refinement of the system to supply adaptive help according to individual progress is future research.

In an AI driven personalized learning approach to vocabulary acquisition, Chamorro [18], discusses adapting vocabulary exercises to the learning behavior of an individual therefore personalizing learning. The novelty in this study is its attempt to bypass limits of traditional rote memorization which is mostly not effective and disengaging. With the help of machine learning techniques, the system identifies the learners' strengths, weakness and learning preference and serves personalized vocabulary exercises for learners. The paper showed that engagement and retention rates are significantly higher with the use of AI driven personalization and very effectively helps language learning. This is very important as it enables the learners to learn at their own rate, which eliminates boredom and time wastage in learning. Additionally, it assists in filling the blanks of classical language learning techniques that do not achieve the goals of learners. Nevertheless, the main limitation of the study is its inherent dependence on good quality training data. Unlike an algorithm, which is designed to generalize over all cases in a given dataset, an AI model personalizes all its decisions to trained data that does not accurately represent the diverse learner profile. Moreover, AI driven methods are helpful but they may not necessarily render human intuition in the language instruction. Hybrid approaches which balance AI's strength with human expertise should be followed and researched in further work.

Jia et al. [19], build an AI enabled English language learning system (AIELL) that incorporates authentic and ubiquitous learning practices in order to facilitate vocabulary and grammar acquisition in acquiring L2 learners. What makes their approach novel is applying mobile learning and turning this into AI driven personalization to allow students to practice English in the real world. It was a study based on 20 participants, using mixed research methods, such as demonstration test, usability test and interview assessment for system effectiveness. The results showed that this AIELL system was very effective and engaging with increased vocabularies retention and grammar proficiency among the participants. This is significant as the system is flexible and they can access anytime anywhere especially to those students who wouldn't have access to classical classroom environment. One significant drawback of the study is that it was conducted at a small scale, chances are the discovered results would not be applicable to a broader audience. Apart from this, the mobile AI based system enables self-paced learning but it might become difficult without structured teacher guidance for some learners. Future research is needed to explore expanding study to larger groups and increasing the capability of AI to give actual time suggestions and contextual help for educators in multifaceted educating conditions.

AI-powered individualized learning platforms have shown dramatic improvements in supporting vocabulary and syntax learning among English language learners [20]. These platforms incorporate curriculum-grounded vocabulary, collaborative filtering, learner-created contexts, and adaptive drills to enhance interaction, memory retention, and engagement [21]. AI-driven lexically constrained dialogue systems enhance contextual acquisition but struggle to keep conversations as natural as they can be. Neural Collaborative Filtering [22] supports word recommendations targeted at individuals but is based on reliable self-evaluation [23].

The Table I identifies various AI techniques in language acquisition such as chatbot systems, collaborative filtering, AR, and mobile platforms. Although innovative, the majority of the studies are plagued by constraints such as small sample size, non-generalizability, excessive reliance on self-ratings, narrow age range, and limited personalization, calling for scalable, adaptive solutions.

TABLE I. SUMMARY OF THE LITERATURE REVIEW

| Author | Method Used | Limitations |
|---|---|---|
| Qian et al. [15] | Lexically constrained decoding in AI chatbots aligned with curriculum | Rigid vocabulary constraints limit conversational flow; small participant group limits generalizability |
| Shin & Park [16] | Neural Collaborative Filtering (NCF) for Pedagogical Word Recommendation (PWR) using large-scale ITS data | Relies on accurate self-assessment; may not generalize across learners with differing vocabulary profiles |
| Lee, Kim & Sung [17] | Learner-Generated Context (LGC) framework promoting autonomous AI-based learning | Very small sample size; lacks structured guidance which some learners may require; needs scaling and adaptability for diverse learners |
| Chamorro [18] | Personalized vocabulary exercises using machine learning based on learner behavior | Dependent on high-quality, representative training data; lacks human-like instructional intuition; needs hybrid human-AI model for holistic learning |
| Jia et al. [19] | AI-enabled mobile system (AIELL) for real-world, flexible, ubiquitous English learning | Small-scale study limits broad applicability; self-paced format may not suit all learners; lacks structured educator guidance |
| Klimova et al. [20] | Systematic review on emerging technologies in teaching English at the university level | Focused on higher education; lacks specific analysis of child or early-age learners; broad scope without in-depth assessment of personalized AI systems |
| Korosidou [21] | Augmented Reality (AR) for alphabet and vocabulary learning in very young learners | Limited to AR and early vocabulary stages; lacks comparison with AI or adaptive learning methods; may not support complex language structures |
| Zou et al. [22] | Social network-based interaction for AI-assisted speaking practice | Focused mainly on speaking skills; limited vocabulary or syntax tracking; requires active social participation, which may not suit all learners |
| Qian et al. [23] | Combined analysis of exercise and foreign language learning on cognition | General cognitive benefits discussed; lacks targeted findings on adaptive vocabulary systems or real-time AI feedback for young L2 learners |

## III. PROBLEM STATEMENT

Conventional language acquisition techniques tend to be inflexible in responding to the unique needs of individual learners [24], resulting in uneven vocabulary acquisition and

syntax understanding among young English learners. They are not personalized and as a result, learning is slow and retention of linguistic structures is inconsistent [25]. Moreover, with no real-time feedback and adaptive support, learners are unable to effectively learn sophisticated syntax structures. The fix-all approach of conventional instruction also prevents learners from advancing at their own best speed, leading to frustration [26]. This research tries to overcome these issues by creating an Adaptive AI-Based Personalized Learning System that in real-time adapts to every learner's level [27], speeding up vocabulary buildup and syntax correctness, as well as providing a more interesting and efficient learning experience. Through the use of machine learning and real-time analytics, the system offers individualized learning routes, promoting enhanced language understanding and long-term memory [28].

## IV. AI-Driven Personalized Language Learning Framework

This study adopts a multi-case, experimental research approach that examines the efficacy of using AI-powered personalized learning systems in vocabulary and syntax acquisition by young learners of English. The study will create two groups: an experimental group in which the learning process will utilize AI-driven adaptive learning technology and a control group which follows conventional teaching approaches. This whole process is evaluated with the help of pre-test and Post-Test assessment to see the improvements in vocabulary retention and syntax comprehension. The AI-enabled system will work with an NLP-based chatbot, adaptive learning model, and gamification elements to construct an engaging and interactive learning environment. During the learning phase, data on live user interaction, learning pace, and engagement will be captured. The data will be subjected to quantitative analyses involving paired t-tests of students' pre-test and post-test, and regression analyses for identifying determinants of learning. In addition to this, thematic coding of learner feedback and sentiment analysis of engagement responses provide qualitative insights. The results detail the effectiveness, adaptability, and engagement of AI-assisted language learning vis-a-vis traditional approaches. Fig. 1 gives the Methodology Overflow.

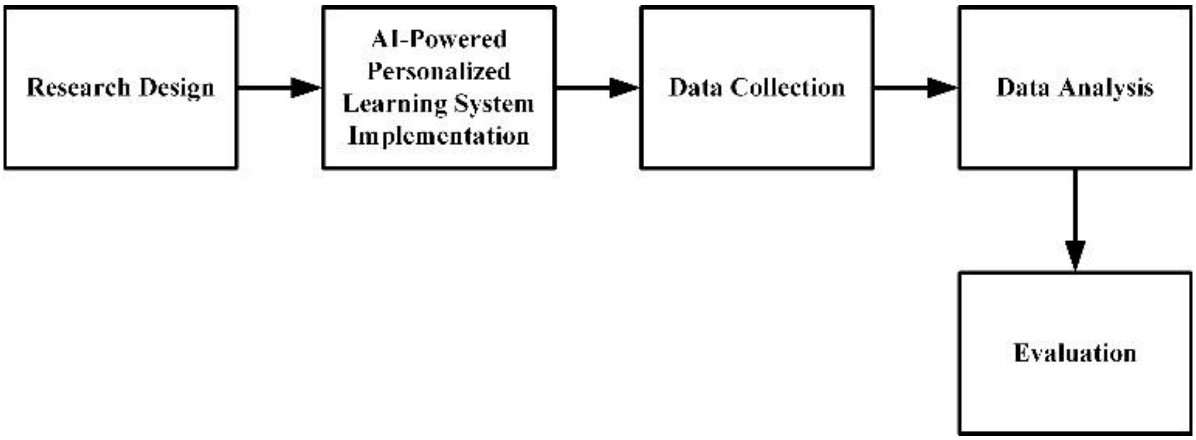

Fig. 1. Methodology overflow.

### A. Research Design

In this study, an experimental conditional design analysis to understand the proficiency of AI-managed personalized learning system will be carried out with respect to vocabulary and grammar acquisition among the young learners of English. The study is conducted on a pre-test and post-test assessment with comparisons done on two groups: the experimental group that received AI-powered learning, and a control group that received instruction in traditional manners.

*1) Approach*: Experimental Study with Pre and Post-Test Assessments.

The experimental design involves two stages of assessment:

*a) Pre-Test:* To examine students' proficiency in vocabulary and syntax. This comprises multiple-choice questions, fill-in-the-blanks, structured incomplete dialogues, and oral assessments in which pupils are active in order to ascertain their knowledge base.

*b) Post-Test:* It measures vocabulary retention after the learning unit and syntax comprehension in students. The structure of the post-test would remain similar to that of the pre-test so as to allow for comparability. Thus, this study, through comparison of the results from both assessments, finds out the extent to which the AI-empowered system promotes language acquisition compared to conventional teaching methods.

*c) Participants:* This study focuses on young English learners, aged between 5 and 12, from different language and cultural backgrounds, since it has been shown in cognitive and developmental studies that early childhood is a critical period for language acquisition. Participants will be recruited from schools, language training centers, and online learning platforms.

To ensure reliability and generalizability, the following inclusion and exclusion criteria for this study will therefore be applied:

*d) Inclusion criteria:* Learners aged 5 to 12 years. Learners with varying levels of proficiency in English but having a basic acquaintance with the language. Participants who are willing to engage in any aspect of the learning process from traditional techniques to AI-assisted methods.

*e) Exclusion criteria:* Students diagnosed with cognitive or speech impairments may affect language processing.

Participants that are already enrolled in AI-based English programs. Those who have limited access to digital learning tools. The study randomly assigned participants to the two groups to the extent possible to reduce bias.

### B. Study Groups

The participants are divided into two groups:

*1) Experimental group (AI-Powered personalized learning system users):* Learners in this group are put at the AI-powered personalized learning system, complete with NLP-based chatbots, adaptive learning models, and gamification techniques. The AI system, guided by the individual learner, evaluates the learning speed and keeps high engagement through chat conversations, exercises, language games, and instant feedback in terms of content difficulty. In terms of engagement statistics, system analysis includes accuracy of responses, pace of learning, frequency of interaction, etc.

*2) Control group (Traditional teaching methods):* Students in this group adopt conventional classroom-and/or textbook-based language approaches to learning. Teaching methods include lectures, worksheets, flashcards, reading exercises, and peer discussions. Curriculum is standardized, such that the pace of instruction and delivery is fixed for all students with no adaptive modifications being provided based on individual needs. Feedback is provided by human instructors, and there is no AI-based adaptation for learners. The study can isolate the impacts of AI-driven personalization on vocabulary and syntax acquisition since the controlled learning environment-maintained helps to isolate the effects of AI-driven personalization on vocabulary and syntax acquisition. This teaching process helps to compare the difference in outcome for two groups so that we can see if AI-powered learning functions are better in improving language mastery than traditional teaching techniques.

### C. AI-Powered Personalized Learning System Implementation

The proposed AI-powered learning tool is designed to enhance vocabulary retention and syntax acquisition in its personalized, interactive, and engaging learning experience. It uses an innovative combination of techniques such as NLP, adaptive learning models, and gamification for the purpose of allowing learning to occur in ways that best fit the learning needs of the individual. Instead of following a standard curriculum, the program will dynamically adjust the content and exercise sets based on student performance and engagement. The AI-powered system consists of the following key components:

*1) NLP-Based chatbots for conversational learning:* NLP allows chatbots to interact with the learners in real-time. These chatbots act as virtual trainers, steering students through guided dialogue practice that enhances vocabulary and sentence structure. The chatbot works with students in context-based conversations, assisting them in applying vocabulary and sentence structure in real world situations. These AIs identify any mistakes in the students' responses, giving instantaneous feedback on improvement so as to consolidate appropriate sentence structures. Depending on how a student experiences or answers questions, in lesson time the chatbot may suggest the introduction of new words, phrases, and grammar rules. For oral application, the chatbot assesses the accuracy of pronunciation and suggest possible improvements. For instance, when a student has difficulty with forms of the past tense verb, the chatbot picks up the pattern and adjusts future exercises according to the need to work more on using the past tense.

*2) Adaptive learning models for personalized learning paths:* The adaptive learning model allows the system to adjust exercises in accordance with individual learners' mastery towards providing a tailored teaching interaction. The system collects data on individual learners' performance, analyzing response accuracy, the time given for each question, and repeated errors. The system increases the difficulty if a student does well in a particular subject; if not, then simpler explanations and extra exercises are provided. By the use of ML algorithms, the system predicts what areas that a learner is most likely to have difficulty in and acts accordingly to adjust their lesson plans before the learning begins. For example, a student with a good base of vocabulary but with not much of a grip on syntax will receive grammar-related exercises and not repeated vocabulary drills.

The AI-based evaluation algorithm allows a dynamic difficulty adjustment in Eq. (1)

$$D_n = D_{n-1} + \alpha(S_n - S_{avg}) \quad (1)$$

where,

$D_n$= difficulty level of the next task

$D_{n-1}$= difficulty level of the previous task

$\alpha$ = learning adaptability coefficient,

$S_n$= student's current performance score

$S_{avg}$= average performance of students at a similar stage

If a student's performance score $S_n$ is below the average, the difficulty is reduced, providing additional support. If it is above average, more challenging tasks are introduced.

*3) Gamification elements for engagement and motivation:* Gamification promotes student motivation by forging a union between game-like mechanics and lessons. Students participate in quizzes for points and badges based on correct answers. Learners compare their progress with their colleagues-teach the spirited competition. Rewards such as gaining a new level or receiving a virtual trophy, are given on achieving learning milestones. Utilizing a streak system promotes continuity in learning, whereby students earn extra rewards for assortment engagement. For instance, a new interactive learning module opens on the fifth consecutive successful vocabulary exercise completed.

The Engagement Retention Formula mathematically captures the workings of gamification in Eq. (2).

$$E_t = E_0 + \beta(R - F) \quad (2)$$

where,

$E_t$= engagement score at time

t, $E_0$= initial engagement level

$\beta$= motivation coefficient

$R$= rewards gained

$F$= frustration due to difficulty level. If rewards $R$ outweighs frustration $F$, engagement increases, leading to higher retention rates.

*4) Continuous data collection and learning experience optimization:* The AI-based system continuously monitors the message, students generate amongst each other to make the learning experience even better. The recordings of student conversations are stored up, noting the errors and time taken to complete each task. AI algorithms parse the patterns to pinpoint the learning difficulties that come up frequently. Based on analytics, the system proposes alternative learning strategies, switching from text-based exercises to visual or auditory learning methods. Combining AI, NLP, and Gamification makes this a dynamic learning process for young English learners and thus engages them more, makes learning faster, and retains learning longer.

### *D. Data Collection*

Data are collected at several points during the study to ascertain the impact of the AI-powered personalized learning system on vocabulary and syntax acquisition. The study uses a combination of quantitative and qualitative data collection techniques, ensuring comprehensive evaluation of learning outcomes, engagement levels, and system effectiveness.

*1) Pre-Test ($X_1$) – initial assessment:* Before the introduction of any kind of learning intervention, there is a structuring pre-test *($X_1$)* which serves as a method of evaluating the learners' baseline capacity in vocabulary and syntax proficiency. The test consists of matching words with their meanings, fill-in-the-blanks, and multiple-choice questions. Structuring sentences, identifying grammatical errors, and correcting faulty sentences. Evaluation of pronunciation and fluency in conversation through AI-based speech recognition.

The pre-test score $S_{pre}$ of the participants is recorded as follows in Eq. (3)

$$S_{pre} = \frac{\sum_{i=1}^{N} C_i}{N} \times 100 \quad (3)$$

where,

$C_i$ is the number of correct answers

$N$ is the total number of test questions

$S_{pre}$ represents the pre-test performance as a percentage.

This score serves as a benchmark to compare improvements after AI-assisted learning.

*2) Learning session implementation–monitoring engagement & performance:* During intervention stages, learner interaction with the AI system is reported continuously to keep monitoring engagement, learning pace, and accuracy rates. Key metrics include:

*a) Learning Pace (L):* The time a learner requires to complete exercises and progress through lessons, calculated as Eq. (4)

$$L = \frac{T_{total}}{Q_{completed}} \quad (4)$$

where,

$T_{total}$ is the total time spent on exercises.

$Q_{completed}$ is the number of completed exercises.

*b) Engagement Score (E):* It is a composite score representing interaction frequency, quiz participation, and chatbot engagement. It is defined as Eq. (5):

$$E = \alpha(I) + \beta(R) + \gamma(F) \quad (5)$$

where,

$I$= number of chatbot interactions.

R= response accuracy rate.

F= frequency of logins and activity.

$(\alpha, \beta, \gamma)$ are weight coefficients.

A higher E score indicates greater learner engagement and motivation.

*3) Post-Test ($X_2$): Measuring Learning Improvements:* At the end of the AI assessment, A post-test *($X_2$)* is run with the same structure that is pre-test, while test () marks are recorded through Eq. (6)

$$S_{post} = \frac{\sum_{i=1}^{N} C_{i'}}{N} \times 100 \quad (6)$$

where,

$C_i'$ is the number of correct answers in the post-test.

N remains the total number of questions.

$S_{post}$ represents the final test performance as a percentage.

The learning improvement is calculated as Eq. (7).

$$\Delta S = S_{post} - S_{pre} \quad (7)$$

where,

$\Delta S$ represents the overall improvement in vocabulary and syntax acquisition.

A positive value of $\Delta S$ indicates an increase in language proficiency due to AI-powered learning.

*4) Surveys and Interviews–Qualitative Feedback Collection:* To complement the quantitative data, surveys and interviews were conducted with the learners and teachers to assess usability, engagement, and effectiveness of the system. During the interview process conducted, students were asked

their feedback on ease of use, motivation, engagement, and effectiveness in learning with the help of a Likert scale and open-ended responses. Through the survey, the teachers will assess students' progress while implementing AI-based learning in classrooms and students' adaptability to different styles of learning. Responses go through a thematic analysis that examines the main themes in students' experiences. Textual responses are analyzed for sentiment, with $S_{sentiment}$ defining the polarity of learners' feedback as positive, neutral, or negative.

Inversely, the lower the score $S_{sentiment}$ is, the more the learner has been most satisfied with and engaged with that system powered by AI.

*E. Data Analysis and Evaluation*

The collected data is evaluated with both quantitative and qualitative methods to analyze the efficacy of AI personalized learning systems for vocabulary and syntactic acquisition among young English learners.

*1) Quantitative analysis:* The focus of the quantitative analysis will be on measuring learning outcomes through comparisons between pre-build and post-build tests to assess the impact of adaptive learning personalization on different learner subgroups and to analyze the relationship between engagement level and progress in performance.

*a) Paired t-Test:* To evaluate whether differences between pre-test and post-test scores were statistically significant, a paired t-test was performed. The test is designed to find out if learners using the AI-powered system experienced significant differences in their improvement compared to their initial proficiency.

The $t$-score is calculated using the Eq. (8)

$$t = \frac{\bar{D}}{s_D/\sqrt{n}} \tag{8}$$

where, $\bar{D}$= mean difference between pre-test ($S_{pre}$) and post-test ($S_{post}$) scores

$s_D$= standard deviation of the differences

n= number of participants in the experimental group.

The mean difference ($\bar{D}$) is calculated as Eq. (9)

$$\bar{D} = \frac{\sum(S_{post} - S_{pre})}{n} \tag{9}$$

where,

$S_{post}$ and $S_{pre}$ represent the post and pre-test scores, respectively.

A $p$-value ($p$) is obtained from the t-test, and if p < 0.05, it indicates a statistically significant improvement due to AI-powered learning.

*b) Regression analysis impact of engagement and personalization on learning:* A multiple linear regression analysis is carried out to determine the relationship between Engagement score ($E$), which measures student interactions with the AI system. Adaptive learning score (A), which indicates the level of personalized learning adjustments. Performance improvement ($P$) is the difference between post-test and pre-test scores.

The regression is given in Eq. (10)

$$P = \beta_0 + \beta_1 E + \beta_2 A + \epsilon \tag{10}$$

where,

$\beta_0$= intercept

$\beta_1, \beta_2$= coefficients representing the impacts of engagement and adaptations

$\epsilon$ = error term.

A high value of $R^2$ regression analysis would imply that engagement and personalized learning adjustments are good predictors of learning improvement.

*F. Qualitative Analysis*

In support of the quantitative findings, qualitative data from surveys and interviews will be analyzed to understand learner experiences, motivation and usability of the system.

*1) Thematic analysis:* Thematic analysis is applied to survey responses and teacher interviews with key themes identified depending on common patterns in feedback. The steps are as follows,

*a) Categorization of data:* Grouping the responses into theme categories as engagement, difficulty, motivation and usability.

*b) Pattern identification:* Themes that recurred were drawn out. For example, AI chatbots improve confidence in speaking and Gamification increases motivation.

*c) Coding:* Individual quotes or phrases into categories of sentiments: positive, neutral, or negative.

*d) Sentiment Analysis –Measuring User Satisfaction:* To quantitatively assess learner and teacher satisfaction, sentiment analysis is applied to textual responses.

The sentiment score $S_{sentiment}$ is computed as Eq. (11)

$$S_{sentiment} = \frac{P-N}{P+N+Neu} \tag{11}$$

where,

$P$ is number of positive responses,

N= number of negative responses, $Neu$= number of neutral responses.

If $S_{sentiment}$ > 0.5, overall user sentiment is positive.

If $S_{sentiment}$ < 0, system usability needs improvement.

This report investigates the implications of learner engagement levels and effectiveness. Combining quantitative and qualitative data analysis, this research provides a comprehensive analysis of the extent to which AI-powered personalized learning enhances vocabulary and syntax acquisition. The findings are expected to establish the extent to which AI-driven learning really enhances language proficiency, evaluate the influence of engagement and personalization on

learning outcomes, and identify key areas for further improvements in AI-based language learning tools.

## V. Results and Findings

The results indicate that the AI-driven personalized learning system definitely enhanced vocabulary retention and syntax acquisition over the traditional methods of teaching. An experimental group using an AI-assisted method saw improvements of 25 percent and 30 percent in vocabulary retention and syntax accuracy, respectively, compared to only modest gains in the control group--a 10 percent to 12 percent gain. The engagement scores were much more favorable to AI because of interactive, chatbot-based learning, adaptive content delivery, and gamification techniques to keep students engaged. The paired t-test statistical analysis confirmed a significant difference; on the other hand, the latter was proved using the ANOVA by showing higher levels of AI personalization linking better learning outcomes. Strong positive relationships between engagement and performance improvement from regression analyses shows that engaged learners who interacted more were far more successful. Limitations were also spotted: dependence on digital access, loss of motivation if transcended by the lack of some human interactions. The implications presents meaningful findings for languages teachers: AI-based tools can, sometimes while implanting all the adaptability and interactive feedback, reinforce traditional methods. AI system developers are thus encouraged to facilitate and enhance NPL-based conversational learning while designing a combination of hybrid AI-human teaching paradigms to gain more effectiveness from AI design.

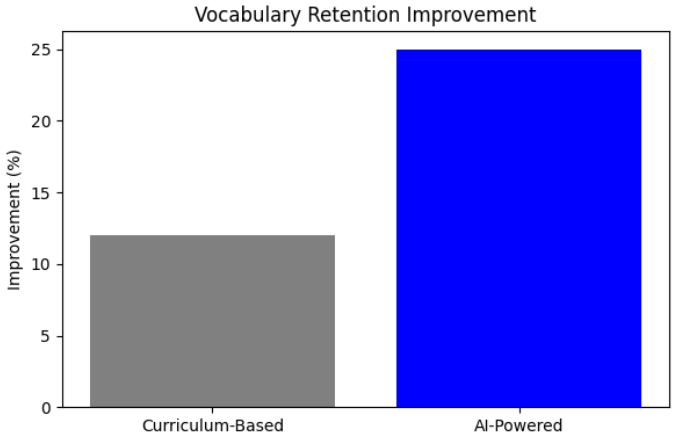

Fig. 2. Vocabulary retention improvement.

The Fig. 2 is a bar chart comparing the efficacy of AI-powered personalized learning systems and curriculum-based methods for English language learners on vocabulary retention. The y-axis, ranging between 0 percent and 25 percent, is labeled Improvement (percent), whereas the x-axis indicates the two kinds of learning methods, that is, "Curriculum-Based" and "AI-Powered." The improvement for the curriculum-based method, represented by the gray bar, is approximately 12 percent, while that for the AI-powered method, represented by the blue bar, shows a whopping 25 percent progress in an improvement. In short, this visualization elaborates on how much more significantly effective AI-based personalized learning is in enhancing vocabulary retention than conventional methods.

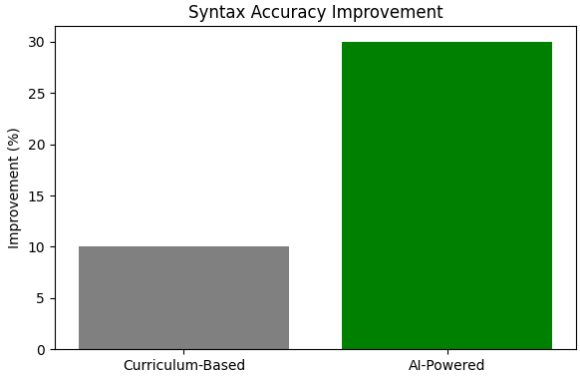

Fig. 3. Syntax accuracy improvement.

The Fig. 3 is a bar chart that compares the average efficacy of AI-based personalized learning systems and curriculum methods in raising syntax accuracy among children learning English. The improvement percentage takes only a range from 0 percent to 30 percent on the y-axis, while the x-axis includes two categories: "Curriculum-Based" and "AI Powered." The gray bar illustrates curriculum-based approaches that has an improvement of about 10 percent, while the green shows a big improvement of about 30 percent in AI-based methods. It is an apt representation of AI-driven personalized learning systems outshining the typical methods in the improvement of accuracy in syntax.

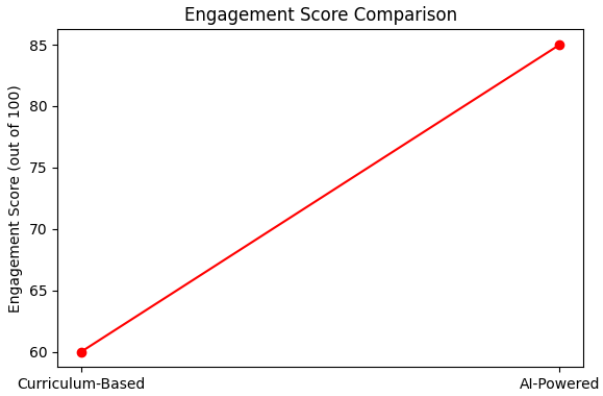

Fig. 4. Engagement score comparison.

This Fig. 4 shows the variation in engagement levels between AI-powered personalized learning systems and curriculum-based methods when applied to young English learners. The x-axis shows the two learning methods: “Curriculum-Based” on the left and “AI-Powered” on the right. The y-axis shows Engagement Score (out of 100), ranging from 60 to 85. A red line is drawn between two data points: one located at (Curriculum-Based, 60) and the other at (AI-Powered, 85). This trend shows how the AI-Powered systems produced a stronger increase in engaged learners. The purpose of the diagram is to point out the considerable edge AI-driven personalized learning systems offer in boosting a learner’s engagement, key to the students’ vocabulary retention and syntax acquisition for young English learners.

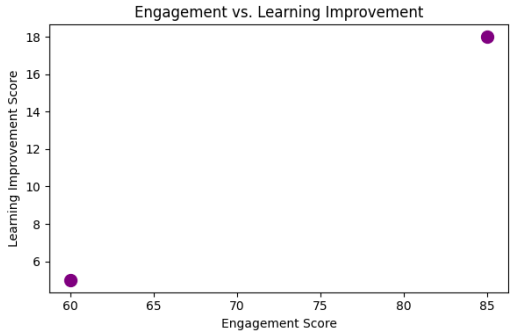

Fig. 5. Engagement Vs. Learning improvement.

The Fig. 5 represents a scatter plot showing the relationship between engagement scores and gains in learning with reference to AI-enabled personalized learning systems for young English learners. The x-axis denoted "Engagement Score" indicates how much the learner was engaged, while the y-axis, called "Learning Improvement Score," measures the progress made in vocabulary and syntax acquisition. There are two data points that are purple, and one is set at (60, 6), which alleges that it is lower on engagement with minimal improvement, while another set at (85, 18) points to a claim of higher engagement in greater learning improvement. This has served to showcase the positive relationship between engagements and learning gains, strengthening the argument that AI-powered personalized learning systems are significantly better at facilitating language acquisition when compared to methods taken from traditional curriculum.

TABLE II. COMPARISON TABLE OF PROPOSED APPROACH WITH EXISTING AI-BASED APPROACHES

| Method | Target Group | Personalization Approach | Output | Limitations |
|---|---|---|---|---|
| Lexically constrained decoding in AI chatbots **[15]** | Middle school English L2 learners | Curriculum-based vocabulary, limited natural conversation due to word constraints | Motivation, improved target vocabulary understanding (qualitative) | Rigid vocabulary flow can hinder conversational naturalness |
| Learner-Generated Context (LGC), self-directed AI **[17]** | Korean secondary-school students | Flexible, learner-led context creation (not adaptive in real-time) | Motivation, better engagement with context (qualitative, no hard metrics) | Small sample size; not scalable yet |
| Mobile AI, contextual learning **[19]** | L2 learners (varied) | Location & time-based practice (not deeply personalized) | Vocabulary and grammar proficiency (small sample size, limited metrics) | Lack of structured feedback; limited to mobile learning |
| NLP chatbots + adaptive ML + gamification | Young English learners (ages 5–12) | Real-time adaptation to learner performance with dynamic difficulty & feedback | 25percent in vocabulary recall, 30percent in syntax accuracy, engagement score | Needs digital access; may lack human interaction |

The Table II is a comparison of AI-based language learning research by using AI technologies, target groups, personalization methods, outcomes, and limitations. It shows rich techniques such as NLP chatbots, mobile AI, and learner-generated context, with different degrees of personalization, efficiency in vocabulary recalls and satisfaction, and limitations such as poor scalability and feedback.

The results section assures that the personalized learning system with AI strongly enhances vocabulary memory and syntax acquisition when compared with the conventional approaches. The AI group had 25 percent and 30 percent more vocabulary and syntax improvement compared to the control group, which obtained only 12 percent and 10 percent. A paired t-test assured the significance of results at $p < 0.05$. Regression analysis identified significant positive relationships between performance and engagement. Qualitative feedback and sentiment analysis also supported the usability and motivational value of the system, confirming the effectiveness and reliability of the AI system for young English learners.

## VI. DISCUSSION AND CONCLUSION

### A. Discussion

The research identifies the potential of an AI-driven personalized learning system to enhance vocabulary and syntax skills in young English learners. With the use of adaptive learning models, NLP-based chatbots, and gamification, the system offers instant feedback and dynamically adapts to the learner's needs [29]. Experimental results indicate a 25 percent improvement in vocabulary recall and a 30 percent improvement in syntax accuracy compared to conventional approaches. Increased levels of engagement and constructive learner feedback underscore the system's power to transform language learning. Against such challenges as access issues, the model promises a viable alternative to clumsy, single-size-fits-all instruction.

### B. Conclusion and Future Works

This study proposes that, against traditional methods, AI-powered personalized learning systems are effective at significantly improving vocabulary retention and syntax acquisition among young English learners. The inclusion of personalized content-specific adaptive learning models, an NLP-based chatbot, and hybrid game-logics provides real-time feedback and maximum engagement, ensuring measurable success in proficiency. The suggested approach provides real-time adaptive feedback, dynamic difficulty management, and gamified interactions specific to young learners—beating current models bound by inflexible vocabulary flow or absence of personalization. Its curriculum-matched yet flexible framework maximizes engagement and learning gain, rendering it better than rigid, one-size-fits-all AI language systems. Nonetheless, the system performance of the AI-based system was best realized in learner settings of high involvement, stable interaction data, and rich response behavior, which implies that the algorithm is best designed to data-intensive, behaviorally engaged learner profiles.

Further studies will deal with enhancing AI-powered language learning systems with better new NLP models that might improve context comprehension and conversational

abilities. Fortunately, other forms of learning can be explored involving multi-modal forms of learning whereby interactions with visual, auditory, and kinesthetic modalities would further support engagement and retention of students. Expanding the study to be focused on different age groups and diverse linguistic backgrounds will provide a broad understanding of the impact of AI for language acquisition. Finally, the development of a model where AI and human beings will collaborate for a blackboard must support teachers, not by replacing them, will be explored in order to develop a more balanced approach to the effectiveness of the learning ecosystem.

## ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through the project number "NBU-FFR-2025-2439-03".

# DenseRSE-ASPPNet: An Enhanced DenseNet169 with Residual Dense Blocks and CE-HSOA-Based Optimization for IoT Botnet Detection

Mohd Abdul Rahim Khan
Department of Electrical Engineering and Computer Science, A'sharqiyah University, IBRA-400 OMAN

***Abstract*—The growing prevalence of Internet of Things (IoT) devices has heightened vulnerabilities to botnet-based cyberattacks, necessitating robust detection mechanisms. This paper proposes DenseRSE-ASPPNet, an advanced deep learning framework for botnet detection, incorporating comprehensive preprocessing, feature extraction, and optimization. The preprocessing pipeline includes data cleaning and Min-Max normalization to ensure high-quality input data. The DenseNet169 backbone is enhanced with Residual Squeeze-and-Excitation (RSE) blocks for channel-wise attention recalibration and Atrous Spatial Pyramid Pooling (ASPP) for capturing multi-scale spatial patterns, enabling effective feature extraction. Hyperparameter optimization is performed using the Cyclone-Enhanced Humboldt Squid Optimization Algorithm (CE-HSOA), which balances global exploration and local exploitation, ensuring faster convergence and enhanced robustness. Experimental results demonstrate the superior performance of the proposed framework, achieving 99.00 per cent accuracy, 96.40 per cent sensitivity, and 99.95 per cent specificity, significantly minimizing false positives and false negatives. The proposed DenseRSE-ASPPNet provides an efficient, scalable, and effective solution for mitigating botnet threats in IoT environments.**

***Keywords*—*Internet of Things; botnet detection; DenseRSE-ASPPNet; residual squeeze-and-excitation blocks; Cyclone-Enhanced Humboldt Squid Optimization Algorithm***

## I. INTRODUCTION

The connectivity of billions of intelligent objects with internet-based communication capabilities is known as the "Internet of Things." The number of commonplace machines that have sensors built in and are able to interact online has significantly increased in recent years. By fusing digital intelligence with physical equipment, the Internet of Things makes the world wiser. There is a lot of data exchange between the connected devices, and security is the main issue with IoT [1], [2], [3]. IoT devices are vulnerable to several types of cyberattacks since they connect objects to the internet and allow them to communicate with one another without human intervention. An ever-growing pool of attack resources is made possible by the quick spread of unsecured IoT devices and the simplicity with which attackers can find them via web services like Shodan. Attackers can now launch extensive attacks, including phishing, spam, and Distributed Denial of Service (DDoS), against Internet resources by assembling and utilizing many of these susceptible IoT devices [4], [5], [6]. At the very beginning of IoT device design and deployment, appropriate security requirements should be determined in order to guarantee the security of the IOT network and devices.

Since the Internet of Things is still in its infancy, it does not yet have a strong security framework or system, which puts sensitive data at risk. To keep IoT entities, businesses, and individuals safe, modern security techniques must be implemented on IoT networks. Botnet-based DDoS attacks, in which hackers infect devices with scripts, pose the biggest security threat to the Internet of Things [7], [8]. Botnet detection is a significant difficulty in the cybersecurity field due to the variety of botnet structures and protocols and the constant development of new, clever methods by attackers to damage networks through botnet-assisted attacks [9], [10]. An intrusion detection system (IDS) is more successful at defending a computer network from external threats, even if many solutions, like firewalls and encryption, are designed to tackle Internet-based cyberattacks. Therefore, identifying and stopping different kinds of harmful network communications and computer device usage is the main objective of an intrusion detection system (IDS) [11], [12], [13]. IDS, monitor and analyses a network's regular everyday activity to detect and identify hostile cyberattacks. Enhancing a system's security requires an intrusion detection system (IDS) that can detect botnets in the network and different botnet-assisted attacks.

The complexity and evolution of botnets have led to the proposal of numerous botnet detection techniques. The use of machine learning (ML) techniques for botnet identification has become increasingly popular within the past ten years. Before ML models are learned or trained, feature extraction is a crucial step. When learning and drawing conclusions, these characteristics act as discriminators. Although some of the current methods for detecting botnets rely on packet information or traffic features, they are rendered ineffective when traffic patterns are encrypted or secret, and traffic patterns can be purposefully changed to evade detection [14], [15]. Further, the inability of flow-based machine learning algorithms to identify botnets to capture the dynamic topological structure of communication networks is one of their main shortcomings.

The proposed approach presents an improved DenseNet169-based deep learning framework enriched with Squeeze-and-Excitation (SE) blocks and Atrous Spatial Pyramid Pooling (ASPP) to address the shortcomings of current botnet detection techniques. This design tackles issues including restricted spatial pattern identification in network

traffic, shallow gradient propagation, and ineffective feature extraction. Whereas, ASPP captures multi-scale spatial data without adding computing overhead, the addition of SE blocks enhances channel-wise attention. Advanced pre-processing methods further guarantee high-quality input data, and the Self-Adaptive Humboldt Squid Optimization Algorithm (HSOA) optimizes the model's performance by fine-tuning the hyperparameters. For the detection of multi-class botnet attacks in IoT systems, this all-encompassing method improves detection accuracy and robustness, making it extremely effective. The following are the paper's main contributions:

Development of an advanced DenseNet169-based deep learning model, DenseSE-ASPPNet, integrating Residual Squeeze-and-Excitation (RSE) blocks for channel-wise attention and Atrous Spatial Pyramid Pooling (ASPP) for multi-scale feature extraction.

Incorporation of the Cyclone-Enhanced Humboldt Squid Optimization Algorithm (CE-HSOA) for efficient hyperparameter tuning, achieving a balance between global exploration and local exploitation.

The Residual Squeeze-and-Excitation (RSE) block is an enhancement to the standard Squeeze-and-Excitation (SE) block, incorporating a residual learning approach to improve feature recalibration, which helps with better channel-wise attention and more robust feature extraction.

The paper is structured as follows: Section II presents a comprehensive literature review on existing botnet detection methods. Section III details the DenseSE-ASPPNet framework. Section IV compares the performance of DenseSE-ASPPNet with other methods. Finally, Section V provides the conclusion.

## II. Literature Review

This section discusses the recent existing papers related to the Botnet attack detection.

In 2022, Nookala Venu, et al., [16] employing machine learning to detect botnet assaults in the Internet of Things. The increasing number of IoT devices that are susceptible to botnet assaults has made them a serious threat to internet security. Many machine learning (ML)-based methods have been released so far to identify different types of botnet attacks. Regardless of the dataset, this study proposes a universal feature set that is extrapolated based on the frequency counting approach and the Logistic Regression method to better detect botnet attacks. There are six main steps in the process overall, starting with data collection and ending with the detection of botnet attacks.

In 2022, Alissa, et al., [17] Detecting botnet attacks in IoT with machine learning. UNSW-NB15, the most comprehensive dataset that is publicly accessible, was used in that study. Exploratory Data Analysis (EDA) is the statistical analysis stage that examines the entire dataset. In the future, the model will be able to be trained on a big dataset. SVM and Random Forest are two examples of machine learning classifiers that can be tested. Runtime Botnet detection can also be done with deep learning models in addition to ResNet50 and LSTM models.

In 2023, Al-Fawa'reh, et al., [18] Detecting malware botnets in IoT networks with deep reinforcement learning. MalBoT-DRL, a powerful malware botnet detector that uses deep reinforcement learning (RL), is presented in this paper. Enhanced generalizability and robustness against model drift are features of MalBoT-DRL, which is designed to detect botnets at every stage of their lifespan. Damped incremental statistics and an attention reward mechanism are combined in this model, which hasn't been thoroughly studied in the literature. The dynamic adaptation of MalBoT-DRL to the constantly evolving malware patterns in IoT environments is made possible by this integration.

In 2022, Kalakoti, et al., [19] Robust feature selection for automated botnet detection in Internet of Things networks using statistical machine learning. In this research, we minimize feature sets for machine learning tasks, which are structured as six distinct binary and multiclass classification problems according to the stages of the botnet life cycle. More precisely, for every classification task, we determined the best feature sets by combining filter and wrapper techniques with particular machine learning techniques. The SFS and SBS wrapper approaches worked well for identifying the best feature sets for each classification.

In 2023, Taher, et al., [20] IIoT botnet detection using a dependable machine learning model. In this paper, we offer a unique feature selection algorithm, FGOA-kNN, to select the most relevant features. It is based on a hybrid filter and wrapper selection strategy. The Grasshopper algorithm (GOA) is used to reduce the features that are ranked highest in the new technique that is combined with clustering. Additionally, a suggested technique called IHHO chooses and modifies the hyperparameters of the neural network to effectively identify botnets. To improve the global search process for ideal solutions, three enhancements are made to the proposed Harris Hawks algorithm.

In 2022, Waqas, et al., [21] Botnet attack detection using machine learning in cloud-based Internet of Things devices. Investigating cyber security in the face of malware, DDOS, and B-IDS attacks is the goal of this research paper. In order to detect botnet attacks, various machine learning algorithms have been used, including support vector machines, naive Bayes, linear regression, artificial neural networks, decision trees, random forests, fuzzy classifiers, K-nearest neighbors, adaptive boosting, gradient boosting, and tree ensembles.

In 2022, Alrayes, et al., [22] a botnet detection model for the IoT environment is designed using the barnacles mating optimizer with machine learning (BND-BMOML). The BND-BMOML model that is being presented is centered on identifying and recognizing botnets in the context of the Internet of Things. To achieve this, the BND-BMOML model first adopts a data standardization strategy. The BMO algorithm is used in the given BND-BMOML model to choose a useful collection of characteristics. An Elman neural network (ENN) model is used in this study's BND-BMOML model for botnet detection. Lastly, to illustrate the work's originality, the proposed BND-BMOML model employs a chicken swarm optimization (CSO) technique for the parameter tuning procedure.

In 2022, Almuqren, et al., [23] botnet detection using hybrid metaheuristics and machine learning in an IoT context supported by the cloud. The Hybrid Metaheuristics with Machine Learning based Botnet Detection (HMMLB-BND) approach is presented in this paper for the Cloud Aided IoT context. In the context of cloud-based IoT, the proposed HMMLB-BND technique focuses on the identification and categorization of botnet attacks. The Modified Firefly Optimization (MFFO) method is used in the HMMLB-BND technique that is being presented for feature selection. For botnet identification, the HMMLB-BND algorithm employs a hybrid convolutional neural network (CNN)-quasi-recurrent neural network (QRNN) module. Using the chaotic butterfly optimization algorithm (CBOA), the best hyperparameter tuning procedure is carried out.

In 2022, Kumar, et al., [24] early IoT botnet detection based on machine learning and network-edge traffic. We introduce EDIMA, a lightweight IoT botnet detection tool that can be placed at home networks' edge gateways that aims to identify botnets before an attack is launched. A unique two-stage Machine Learning (ML)-based detector designed especially for IoT bot identification at the edge gateway is part of EDIMA. In order to identify individual bots, the ML-based bot detector first uses ML algorithms for classifying aggregate traffic, followed by tests based on the Autocorrelation Function (ACF). A policy engine, a feature extractor, a traffic parser, and a malware traffic database are also included in the EDIMA architecture.

In 2023, Catillo, et al., [25] a deep learning technique for IoT botnet detection that is portable and cross-device. Complex machine learning architectures are used in many of the current intrusion detection system (IDS) concepts for the Internet of Things. These architectures typically offer a single model for each device or assault. The size and dynamic nature of contemporary IoT networks make these methods inappropriate. In order to learn a single IDS model rather than numerous distinct models over the traffic of various IoT devices, this study suggests a novel IoT-driven cross-device technique. Since a semi-supervised strategy is more applicable to unforeseen attacks, it is used. The approach is built on an all-in-one deep autoencoder, which uses regular traffic from many IoT devices to train a single deep neural network. Table I compare the existing papers related to the Botnet attack detection.

TABLE I. COMPARISON OF THE LITERATURE REVIEW PAPERS

| Study | Method | Detection Technique | Advantages | Disadvantages |
|---|---|---|---|---|
| Nookala et al. [16] | Logistic Regression | Botnet detection using frequency counting | Simple and efficient method; good for basic botnet detection tasks | May not handle highly complex attacks well due to the simplicity of the frequency counting method. |
| Alissa et al. [17] | SVM, Random Forest, ResNet50, LSTM | Botnet detection in IoT | Effective for large datasets; can utilize deep learning for more complex attack patterns | Requires large datasets for training; computationally intensive for real-time detection. |
| Al-Fawa'reh et al. [18] | Deep Reinforcement Learning (DRL) | Malware botnet detection | Enhanced generalizability and robustness; adapts dynamically to evolving malware patterns | Complexity of DRL models may lead to high computational cost and long training times. |
| Kalakoti et al. [19] | Statistical ML | Botnet detection | Effective for binary and multiclass classification; good for identifying relevant features | The feature selection process can be computationally expensive and may not generalize well across different datasets. |
| Taher et al. [20] | kNN, Harris Hawks Optimization | IIoT botnet detection | Combines hybrid filter and wrapper methods for better feature selection; effective for IIoT | High computational overhead due to the hybrid approach and complexity of the optimization algorithms. |
| Waqas et al. [21] | Various ML Algorithms (SVM, ANN, DT, RF, etc.) | Botnet detection | Offers a variety of classifiers for different attack types; flexible and adaptable | Limited by the effectiveness of individual classifiers in handling diverse types of botnet attacks. |
| Alrayes et al. [22] | Elman Neural Network (ENN) | Botnet detection in IoT | Efficient in IoT environments; uses BMO for effective feature selection | May struggle with real-time detection and the complexity of feature selection using the BMO method. |
| Almuqren et al. [23] | Hybrid CNN-QRNN | Botnet detection in cloud-based IoT | Combines CNN and QRNN for better detection performance in cloud IoT | High computational demand due to the hybrid neural network and feature selection processes. |
| Kumar et al. [24] | ML-based two-stage detector | Early IoT botnet detection at edge | Lightweight and fast detection at edge gateways; helps in early detection | May not be effective against sophisticated botnet attacks with complex behaviors or new attack patterns. |
| Catillo et al. [25] | Deep Autoencoder | Cross-device IoT botnet detection | Uses semi-supervised learning, which is beneficial for handling unforeseen attacks | Challenges in dealing with unforeseen or novel attack types due to the semi-supervised nature of the model. |
| Study | Methodology | Detection Technique | Advantages | Disadvantages |

The increasing number of Internet of Things (IoT) devices has made them a prime target for botnet attacks, presenting a significant challenge for network security. The detection of botnet assaults in IoT environments is critical, yet existing approaches face various limitations in terms of computational efficiency, adaptability to evolving attack patterns, and the ability to handle complex or unforeseen attack types. Many machine learning (ML) and deep learning (DL) techniques have been proposed for botnet detection, utilizing methods like Logistic Regression, SVM, Random Forest, and deep reinforcement learning. However, these methods often struggle with issues such as high computational demands, limited generalizability, and difficulty in real-time detection. Additionally, feature selection and optimization processes, essential for improving detection accuracy, are computationally expensive and may not generalize well across diverse IoT environments.

Thus, there is a need for more efficient and adaptive botnet detection models that can operate effectively in dynamic and resource-constrained IoT environments. These models should be capable of detecting a wide range of attack types, including novel and sophisticated threats, with minimal computation overhead and in real-time. Developing such a model requires addressing the challenges of feature selection, optimization, and ensuring robustness against evolving malware patterns.

## III. Proposed Methodology

The DenseSE-ASPPNet is proposed as the botnet detection system that combines advanced pre-processing, feature extraction, and optimization techniques. Pre-processing begins with the cleaning of data from entries that may be irrelevant or missing; then Min-Max normalization of features into a consistent scale to efficiently train the model is applied. For feature extraction, we use the DenseNet169 backbone, allowing for feature reuse through dense connections for the extraction of compact informative representations. In addition, RSE blocks improve channel-wise attention recalibration, which helps the model to focus more on important features. ASPP is used to capture multi-scale spatial patterns, which are very important for botnet activity detection at different resolutions. Finally, the hyperparameters of the model are optimized using the CE-HSOA, which combines global exploration and local exploitation to ensure faster convergence and enhanced robustness. Together, these modules enable DenseSE-ASPPNet to effectively detect botnet activities in IoT networks. The proposed Botnet attack detection model is shown in Fig. 1.

### A. Pre-processing

Pre-processing in the DenseSE-ASPPNet architecture consists of two key operations: data cleaning and Min-Max normalization. Data cleaning cleans irrelevant, missing, or erroneous entries from the raw network traffic data so that only valid information is utilized. After data cleaning, all features are scaled within a fixed range by applying Min-Max normalization.

*1) Data cleaning:* The main purpose of data cleaning is to remove unusual data from the original data, such as duplicating, missing, or illegal data. When an experiment is repeated, all duplicate data are eliminated and just the data that appears for the first time are retained. The gaps are filled in by averaging the data from the preceding and subsequent hours. This is shown in Eq. (1),

$$x_i = \frac{x_{i-1}+x_{i+1}}{2} \quad (1)$$

In the padding data, $x_i$ represents the data to be filled, $x_{i-1}$ represents the data from the previous hour, and $x_{i+1}$ represents the data from the next hour. Unlawful data in this experiment are those that have a value of 0 but shouldn't be 0. It is also replaced by the average value of the data from the preceding and following hours, which is determined by Eq. (1).

*2) Min- Max normalization:* In information processing, data normalization is a crucial step. This entails standardizing data in order to reduce complexity, remove redundancy, and enhance data quality. Usually, this method entails scaling numerical data to a uniform range of values in order to standardize it and facilitate comparison and analysis. In this investigation, the min-max normalization method was employed.

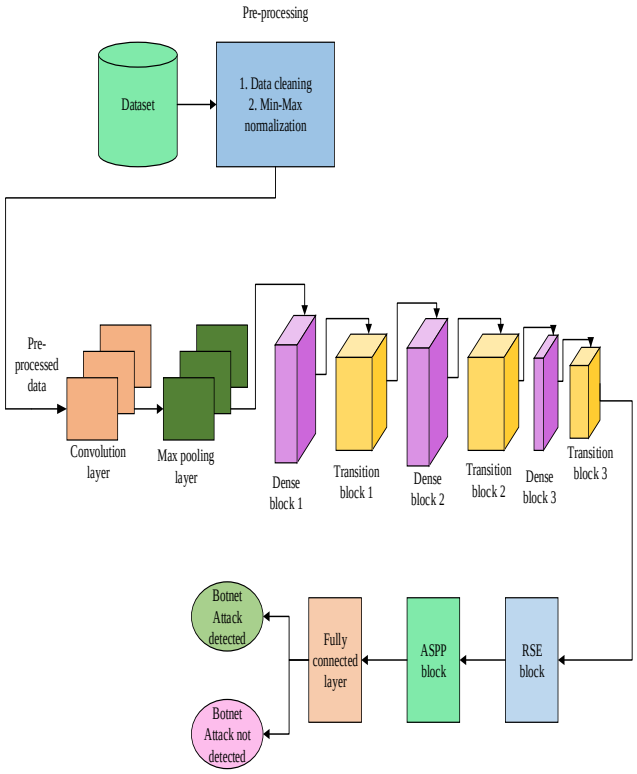

Fig. 1. Block diagram of the proposed Botnet attack detection model.

The initial data is linearly modified using Min-Max normalization. With this method, all scaled data between 0 and 1 is obtained. The following Eq. (2) can be used for this: The relationships between the original data's values are preserved using Min-Max normalization.

$$Z^* = \frac{z-\min(z)}{range(z)} = \frac{z-\min(z)}{max(z)-\min(z)} \quad (2)$$

The minimal value is denoted by min⁡(z), while range (z) denotes the range between maximum and minimum. The breadth of the interval is 1, and the range of Z^* is within the range [0, 1].

### B. DenseRSE-ASPPNet

DenseRSE-ASPPNet is proposed as an effective model for botnet detection using advanced feature extraction techniques. Using the DenseNet169 as the backbone, it explores dense connections that allow feature reuse while learning compact and informative representations for the input data. Furthermore, the RSE blocks enhance feature recalibration capabilities by making the model adaptive to important features while key information is preserved through residual learning. In addition, Atrous Spatial Pyramid Pooling (ASPP) is used to capture multi-scale spatial patterns that are critical for botnet activity detection, which can occur at different spatial resolutions. Combining DenseNet, RSE blocks, and ASPP enables the DenseRSE-ASPPNet model to effectively extract relevant features for accurate and robust botnet detection in IoT networks.

Convolutional layers, max pool layers, transition layers, and dense (fully connected) layers make up the DenseNet. ReLU is used throughout the model's design, whereas SoftMax is used to activate the top layer. The maxpool layers reduce the dimensionality of the input, while the convolutional layers recover the image's characteristics. In the stack, the first flattened layer is followed by the fully linked layers. The flatten layer functions as an artificial neural network and receives a single input array. The DenseRSE-ASPPNet model is shown in Fig. 2.

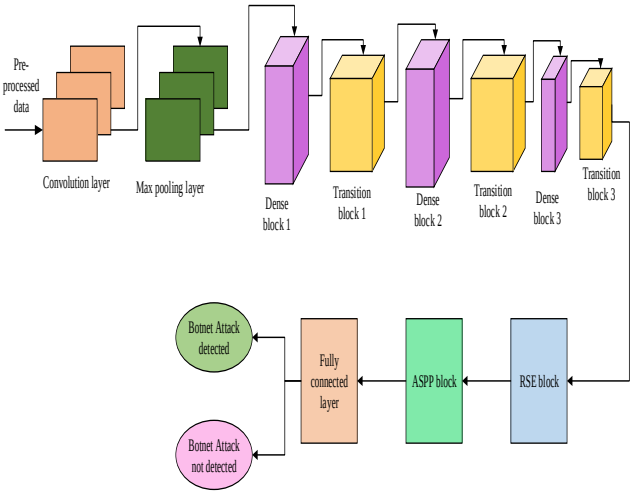

Fig. 2. Architecture of the DenseRSE-ASPPNet model.

*1) Convolution layer:* To put it simply, an activation occurs when a convolutional layer applies a filter to an input. Continuous application of the filter to an input result in a feature map that shows the intensity of the detected features at different locations within the input. ReLU and other activation methods can then be applied to a feature map that has been created using several filters. Often, the operation between these two entities is a dot product since the filter employed in a convolutional layer is narrower than the input data. Assuming a P×P square neuron element, the outcome of this layer would be (P-m+1)×(P-m+1), followed by a filter of size m×m. The nonlinear input to the unit $x_{ij}^{l}$ is determined by summing the inputs from the layer cells preceding them, as per Eq. (3).

$$x_{ij}^{l} = \sum_{a=0}^{m-1} \sum_{b=0}^{m-1} \mu_{ab} y_{(i+a)(j+b)}^{l-1} \tag{3}$$

The convolutional layer's implementation of the identified non-linearity is demonstrated by Eq. (4).

$$y_{ij}^{l} = \lambda(x_{ij}^{l}) \tag{4}$$

*2) MaxPool layer:* Adding a maxpool layer to a CNN is primarily done to reduce the dimensionality of the feature map. The maxpool layer summarizes the features in the region that the pooling layer has filtered, applying a filter on the feature map similarly to the preceding layer. n_h×n_w×n_c, which represent the feature map's height, width, and channels, respectively, are presumed to be present in a feature map. The feature map's dimensions are determined by Eq. (5) when the maximum pooling ( 〖max〗 _p) across the size f and stride s filters is utilized.

$$max_p = \frac{(n_h - f + 1)}{s} \times \frac{(n_w - f + 1)}{s} \times n_c \tag{5}$$

*3) Dense layer:* The fully connected layer is where the majority of classification at the network's end occurs. Unlike pooling and convolution, it is a global procedure. A global analysis is performed on the output of all the preceding layers using the information gathered from the feature extraction steps. By doing this, it creates a non-linear blend of the characteristics that are utilized to classify information. The communication between all neurons in a thick layer and all neurons in the layer above it is referred to as strongly coupling in a neural network. A matrix-vector multiplication occurs whenever each neuron in this layer sends information to its matching neuron in the layer underneath. The formula for matrix-vector multiplication is provided in Eq. (6).

$$M.\lambda = \begin{matrix} m_{11} & m_{12} & \cdots & m_{1y} & p_1 \\ m_{21} & m_{22} & \cdots & m_{2y} & p_2 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ m_{x1} & m_{x2} & \cdots & m_{xy} & p_y \end{matrix} \tag{6}$$

A matrix with dimensions of × y and 1× y, respectively, is represented by the variables M and p in the equation above. Backpropagation can be used to update the previous layer's parameters, which comprise the variable matrix, during training. To backpropagate over the learning rate, which is defined by changing the weights for the layer ly designated by ω^ly and bias represented by the variable B^ly of the neural network, utilize Eq. (7) and Eq. (8) respectively.

$$\omega^{ly} = \omega^{ly} - \alpha \times d\omega^{ly} \tag{7}$$

$$B^{ly} = B^{ly} - \alpha \times dB^{ly} \tag{8}$$

The dω and db are calculated using a chain rule (from the output layer via the hidden layers to the input layer). These are dω and db, which are the partial derivatives of ω and b of the loss function. Eq. (9) through Eq. (12) are utilized to calculate dω and db.

$$d\omega^{ly} = \frac{\partial L}{\partial \omega^{ly}} = \frac{1}{n} dZ^{ly} A^{[ly-1]T} \quad (9)$$

$$\mathrm{dB^{ly}} = \frac{\partial \mathrm{L}}{\partial \mathrm{B^{ly}}} = \frac{1}{\mathrm{n}} \sum_{\mathrm{i=1}}^{\mathrm{n}} \mathrm{dZ^{ly(i)}} \quad (10)$$

$$\mathrm{dA^{ly-1}} = \frac{\partial \mathrm{L}}{\partial \mathrm{A^{[ly-1]}}} = \mathrm{W^{lyT}} \mathrm{dZ^{ly}} \quad (11)$$

$$\mathrm{dZ^{ly}} = \mathrm{dA^{ly}} \times \mathrm{g'(Z^{ly})} \quad (12)$$

As per the previously mentioned equations, the layer ly linear activation is represented by the variable Z^ly, and the differential of the Z^ly-related non-linear function is denoted by g^' (Z^ly). The symbol for the nonlinear activation function at the same layer is A^ly.

*4) Transition layer:* A CNN uses a transition layer to make the model simpler. Usually, a transition layer uses an 11-layer convolution to lower the number of channels and a stride 2 filter to cut the input's height and breadth in half.

*5) SE block with residual connection:* The SE Block is utilized in this situation due to its simplicity in integrating into any model and its capacity to rectify information loss by recalibrating features with a negligible increase in parameters. By passing the input features via the GAP, the SE-Block-based attention module condenses each channel into a single feature, or scalar value. The two phases of the SE Block are excitation and squeezing. Every channel in the image is made one-dimensional during the squeeze stage by using global average pooling, or GAP. A rectified linear unit (ReLU) and a sigmoid are two completely connected layers that the squeezed vector passes through during the recalibration stage. In order to highlight the key information, the flattened vector is then multiplied by the image that has undergone a 1 × 1 convolution and the weight, which represents squeezed information. An SE Block is depicted in Fig. 3. The SE Block's reduction ratio is a hyperparameter that modifies the number of nodes in the ReLU and fully linked layer. The number of parameters rose as the reduction ratio dropped. The number of parameters dropped as the reduction ratio grew. In other words, it is a hyperparameter associated with variations in computing cost and capacity. The recalibrated output and the input layer are connected by a residual connection that is introduced at the recalibration stage. A direct shortcut between a module's input and output is another design element in the residual connection block that improves the gradient flow during backpropagation while maintaining information. Adding the recalibrated feature map back to the input is how a SE Block that uses residual connections is implemented.

The SE channel attention process involves several important equations. The Squeeze operation uses global average pooling to reduce the input feature map (H×W×C) to 1×1 ×C. The height, breadth, and number of channels of the original feature map are denoted by H, W, and C, respectively. This could be shown in Eq. (13),

$$z_c = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} u_c(i,j) \quad (13)$$

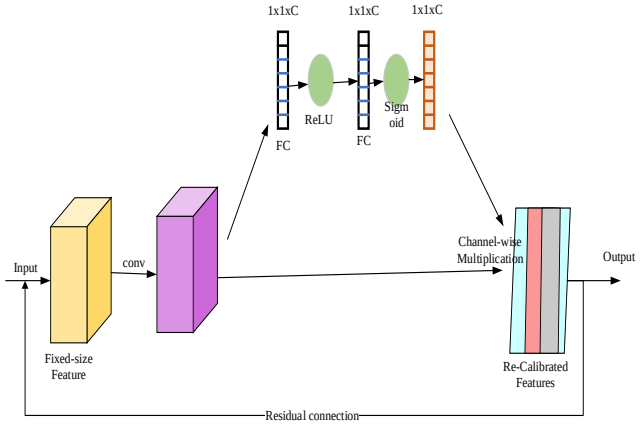

Fig. 3. Block diagram of the RSE block.

In this case, u_c is the feature value of the c^th channel at position (i,j) in the input feature map, and z_c is the Squeeze output of the c^th channel. An activating mechanism and two fully connected layers are used in the Excitation phase to establish channel weights and understand the correlations between channels. In Eq. (14),

$$\mathrm{s} = \sigma(\mathrm{W_2}\delta(\mathrm{W_1 z})) \quad (14)$$

where, z is the Squeeze phase's output, δ is the ReLU value, σ is the Sigmoid function, s is the generated channel weight vector, and $W_1$ and $W_2$ are learned weight parameters. Furthermore, after the SE attention system is executed, the feature specification is obtained by multiplying the channel's weights by the initial features. In Eq. (15), the recalibration procedure is displayed.

$$y_c = s_c . u_c \quad (15)$$

The input features (u_c) are appended to the recalibrated features (y_c) in order to create a residual connection:

$$\hat{y}_c = \mathrm{y_c} + \mathrm{u_c} \quad (16)$$

This equation can also be written as:

$$\hat{y}_c = (s_c . u_c) + u_c \quad (17)$$

The addition ensures that the recalibrated features enhance the input features without overwriting the original information, maintaining a balance between recalibration and preservation.

*6) ASPP module:* The ASPP module's dilated convolution, sometimes referred to as extended convolution or atrous convolution, is distinguished by the addition of gaps between the convolution kernel's constituent pieces. This preserves the original input feature map's height and width while expanding the kernel's receptive field. The convolution kernel's spacing is indicated by the dilation rate. By altering the dilation rate, the filter's receptive field can be adjusted appropriately. Every two convolutional kernel elements are separated by (r-1) zeros, as seen in Fig. 3. k ' = k + (k - 1) × (r - 1) is the kernel's effective

size. Among these, r stands for the dilation rate and k for the convolutional kernel's size. Dilated convolution is the same as ordinary convolution when r=1. It can modify the convolutional kernel's receptive field by varying the dilation rate without requiring additional calculations or parameters. The basic dilation model is shown in Fig. 4.

Fig. 4. 3×3 Filter with different dilation rate as 1, 2, and 3.

An ASPP module is added at the network's bottom to extract multi-scale features that will aid the network in comprehending and capturing data at various scales. Spatial Pyramid Pooling (SPP) is the foundation of the enhanced ASPP module. The use of dilated convolutions in place of ordinary convolutions is where ASPP and SPP diverge. This module uses dilated convolutions with varying dilation rates as the final prediction in order to merge multiple receptive field features. The ASPP module makes use of adaptive average pooling in conjunction with four parallel dilated convolutions (with dilation rates of 1, 6, 12, and 18), as illustrated in Fig. 5. Batch normalization (BN), ReLU activation, and a convolution operation make up each dilated convolution. Concat can be used to join parallel networks. To guarantee that the output image size stays the same as the input image size, use BN, ReLU, and ordinary convolution (with a kernel size of 1×1).

*7) Fully Connected (FC) layer:* The FC layer performs feature aggregation by combining the learned features from different areas of the input image. The network can provide more sophisticated representations by capturing higher-level patterns and correlations between features thanks to this aggregation. In this assignment, the burst assembly is carried out, and the output of the completely linked layer is frequently used to generate final predictions. The proposed model's final layer has two layers, provides the final output for prediction.

*8) SoftMax activation layer:* Deep learning systems commonly use the softmax activation function to address classification issues. In Eq. (18), where, weight is represented by the variable ω and bias by the variable b over an input vector x, defines the general form of a nonlinear activation function.

$$y = f(\omega \times x + b) \tag{18}$$

The output layer of a convolutional neural network employs the softmax function to estimate the likelihood of each output class. According to the softmax function's specifications, each neuron in the output layer receives a single value. Each of these neurons in the output layer determines the likelihood (or probability) that a certain node will reach the output. When applied to the input, the softmax function is defined over the softmax function Θ. According to Eq. (19), v_i relates to the exponential function of the input vector, represented by e^(v_i ), and the exponent function of the output vector, represented by e^(v_o ), with m instances.

$$\Theta(z)_x = \frac{e^{v_i}}{\sum_{y=1}^{m} e^{v_o}} \tag{19}$$

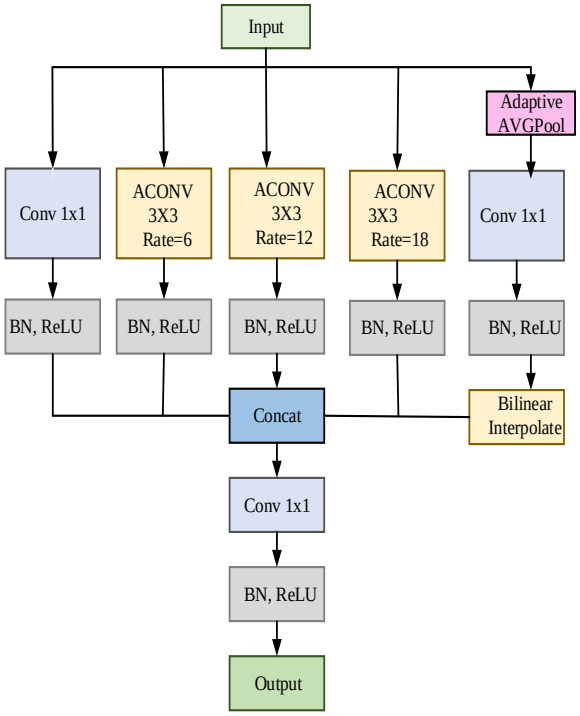

Fig. 5. Structure of the ASPP model.

This work uses softmax as the activation function and the binary cross-entropy loss function as the loss function. Binary cross-entropy has been used in the past to solve binarization challenges. Eq. (20) and Eq. (21) display the binary cross-entropy loss function for a network with n layers.

$$K(\omega, b) = \frac{1}{n}\sum_{i=1}^{n} L(a^{(i)}, a^{(i)}) \tag{20}$$

$$L(\hat{a}, a) = -(a \times \log \hat{a} + (1 - a) \times \log(1 - \hat{a})) \tag{21}$$

With the variable a representing output class 1 and (1-a) representing output class 0, aˆ represents the probability of output class 1 and (1-aˆ) for the class 0 result. The heatmap for the extracted features is shown in Fig. 6.

### *C. Hyper Parameter Tuning of DenseRSE-ASPPNet using CE-HSOA*

Hyperparameter tuning is an important step while optimizing the performance of the model DenseRSE-ASPPNet. The effectiveness of deep learning models, such as DenseRSE-ASPPNet, may be highly reliant on hyperparameters like a learning rate, batch size, number of layers, etc. To effectively find a good combination of hyperparameters, we apply the CE-HSOA.

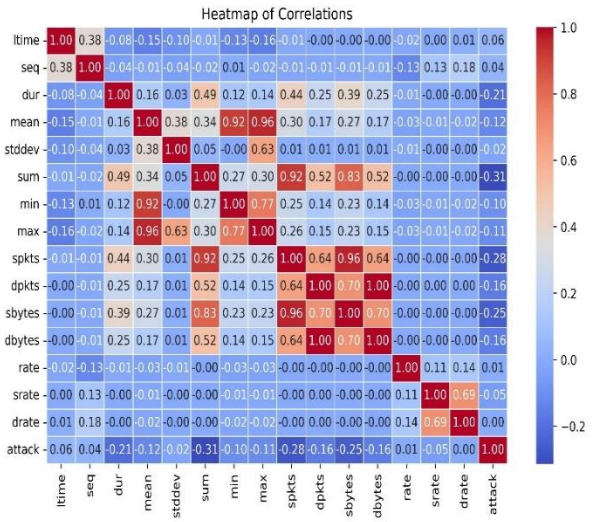

Fig. 6. Heatmap of correlations.

In HSOA, hunting, migration, and mating were important phases. For the search operation, five mechanisms are specified in order to quantitatively model this process. Attacking schools of fish, escaping fish, successfully attacking, attacking smaller squids, and mating Humboldt squids are the components of these methods. As CE-HSOA iterations increase, the search process shifts from exploration to exploitation through mating, bigger squids attacking smaller squids, and fish schools attacking. Fish Escape, however, manages exploration in each iteration.

*1) Generating initial population:* The CE-HSOA population is made up of fish swarms and Humboldt squid. Algorithm 1 is the pseudocode that CE-HSOA employs to create the first population. As may be observed, Humboldt squid are thought to be the best individuals in the population, whereas fish make up the remainder. Since the Hublot squid is larger and more fit than school fish, this problem is in line with nature.

*2) Attack of fish schools:* In CE-HSOA, the attack of fish schools is simulated using Eq. (22).

$$XS^{d}_{new,i} = X_b + V_{jet}.(-XF^{d}_{new,r_1} - PopAll^{d}_{r_2}) \quad (22)$$

According to Eq. (1), $PopAll^{d}_{r_2}$ is the saved $r_2^{th}$ position in the CE-HSOA memory, $XF^{d}_{new,r_1}$ is the position of $r_1^{th}$ fish in $d^{th}$ dimension, $V_{jet}$ is the locomotion velocity parameter, and $XS^{d}_{new,i}$, i is the new position of $i^{th}$ Humboldt squid in $d^{th}$ dimension. Additionally, $r_1$ and $r_2$ are random integer numbers between 1 and the size of the PopAll and the population size of fish, respectively. Responsibility for $V_{jet}$.

*3) Successful attack:* The new position for Humboldt squid ($XS_i$) replaces the existing position for Humboldt squid after the new positions for fish and squid have been updated.

$$XS^{d}_{i} = \begin{cases} XS_i = XS_{new,i}, & if\ FS_{new,i} < FS_i \\ Successful\ escape, & Otherwise \end{cases} \quad (23)$$

The new and current fitness functions of the $i^{th}$ Humboldt squid are denoted by $FS_{new,i}$ and $FS_i$ in Eq. (23).

*4) Successful escape:* When the school of fish is attacked by the squid, the fish flee to a randomly chosen spot. The following equation is used in this escape to update the fish's position and velocity.

$$XF_{new,i} = \begin{cases} XF_i + \overrightarrow{rn}.(P_{best} - XF_i).wf, & if\ nfes < 0.1max_{nfes} \\ XS_i + \overrightarrow{rn}.(ArchiveX_{r_1} - PopAll_{r_2}), & Otherwise \end{cases} \quad (24)$$

The number of function evaluations in Eq. (24) is represented by $nfes$, the maximum number is represented by $max_{nfes}$, $ArchiveX_{r_1}$ is the $r^{th}$ place in the archive of the best results, $XS_i$ is the $i^{th}$ location of the Humboldt squid, $\overrightarrow{rn}$ is the normal random vector, $wf = Fb$, $XF_{new,i}$ is the new position of $i^{th}$ fish, $XF_i$ is the current position of $i^{th}$ fish, and $P_{best}$ is N top of the best positions. The fitness function of $i^{th}$ fish is $F_{f_i}$, while $F_b$ is the best fitness function. If the function evaluation counter is in the first generation of this equation, the fish will migrate toward one of the N best solutions. If not, it shifts to a random location.

*5) Attack of stronger squids to smallest squids:* Fish and Humboldt squid are presumed to be out of the hunt if they are unable to locate a better position in the preceding steps. Thus, the larger Humboldt squid consumes the smaller ones. At this point, the following equation is used to determine the Humboldt squid's location:

$$XS^{d}_{new,i} = XS^{d}_{new,i} + V_{jet_2}.(XS^{d}_{new,i} - X^{d}_{b}) \quad (25)$$

The second velocity parameter in Eq. (25) is $V_{jet_2}$. Based on this connection, it is assumed that the smaller Humboldt squid is in the best position ($X^{d}_{b}$) and that the larger one goes toward it in order to search for the optimum solutions.

*6) Humboldt Squid mating:* In CE-HSOA, the egg position is generated using Eq. (26). It was previously used to improve the deferential evolutionary (DE) method.

$$Eggs = \big(\omega.XS + (1-\omega.P_{best})\big).\gamma + (1-\gamma).pop(r_1,:) + W.(pop(r_3,:) - popAll(r_2,:)) \quad (26)$$

The Humboldt squid egg mass is represented by the variable Eggs in Eq. (27), while the adaptive weights $\omega, \gamma, and\ W$ govern the search procedure. Between 0 and 1 are $\omega\ and\ \gamma$. This equation can be used to estimate $W$:

$$\mathrm{W} = \max\{\omega.\gamma, (1-\omega).\gamma, 1-\gamma\} \quad (27)$$

The current study defines the following equations [Eq. (28) and Eq. (29)] for estimating $\omega\ and\ \gamma$:

$$\omega = \mu_\omega + c_1.x \quad (28)$$

$$\gamma = \mu_\gamma + c_2.\overrightarrow{rn} \quad (29)$$

where, the user determines the constant parameters $c_1$ and $c_2$. Additionally, in the first generation, $\mu_\omega$ and $\mu_\gamma$ are vectors with a value of 0.5, and they are updated in subsequent generations in the manner described below:

$$\mu_{\omega} = \frac{[Diff_F(I).\omega(I)^2]}{[Diff_F(I)].[\omega(I)]} \quad (30)$$

$$\mu_{\gamma} = \frac{[Diff_F(I).\gamma(I)^2]}{[Diff_F(I)].[\gamma(I)]} \quad (31)$$

where, $Diff_F$ is the difference between the fitness of Humboldt squids and their eggs, and I is the index indicating which Humboldt squids are more fit than their eggs in Eq. (30) and Eq. (31). The mating motion in the CE-HSOA is performed multiple times because Humboldt squids mate multiple times during their lifetimes, at each generation. Keep in mind that the γ ought to be higher than zero. Therefore, the following equation is used to rectify the γ value if it falls below zero:

$$\gamma = \mu_{\gamma} + 0.1.\tan(\pi.\mathrm{rnd}) \quad (32)$$

The typical random number rnd in Eq. (32) falls between 0 and 1. The value of x is calculated using Eq. (33):

$$x = \frac{nfes}{max_{nfes}}.\overrightarrow{rnd}^{r.10} \quad (33)$$

In Eq. (33), the normal random vector over right around and the normal random number r are both between 0 and 1, respectively.

*7) Control search process with cyclone foraging:* There are several parameters that influence the CE-HSOA search process, such as $V_{jet}$, $V_{jet_2}$, $x, w_f, W, \omega, and\ \gamma$. To replicate Humboldt squids' shape of locomotion, $V_{jet}$ and $V_{jet_2}$ are used. This is accomplished by using a polynomial function. The third and fourth degrees, respectively, are assigned to the power of this polynomial function for $V_{jet}$ and $V_{jet_2}$. To calculate $V_{jet}$ and $V_{jet_2}$, the following formulas are used.

Incorporating the Cyclone Foraging phase from the Manta Ray Optimization algorithm significantly enhances the CE-HSOA's search process. The movement pattern provided in this phase is that of a spiral, thereby increasing the efficiency of exploring space while also decreasing the chances of falling into a local optimum. This strikes a balance between global exploration and local exploitation, ensuring that it is focused on the promising regions for better refinement of the solution. Moreover, due to its adaptive and dynamic nature, this mechanism accelerates convergence and enhances the algorithm's robustness against premature stagnation. Further improvement of versatility is achieved through incorporation of stochastic movements, thereby making CE-HSOA more effective in solving complex, nonlinear, or multimodal optimization problems.

$$V_{jet} = X_{best} + r.(X_{best} - X_i) + \beta.(X_{best} - X_i) \quad (34)$$

$$V_{jet_2} = (X - a_1).(X - a_2).(X - a_3).(X - a_4) \quad (35)$$

where, $X_{best}$ is the best solution, and $\beta$ is the weight factor. The value of $\beta$ is given by,

$$\beta = 2e^{r\frac{T-t+1}{T}}.\sin(2\pi r) \quad (36)$$

The parameters $a_1$, $a_2$, $a_3$, and $a_4$ of the polynomial function that define its shape are found in Eq. (34) and Eq. (35) and can be used to derive $X$:

$$X = \frac{nfes}{max_{nfes}} \quad (37)$$

where, $w_f$ adjusts the fish's escape radius based on the ratio of the fish's current objective function value to the value of the best objective function. The extent of fish escapement is limited by this parameter during the start of the search, when there are many possible options. However, this parameter approaches one and its effect is mitigated as the number of generations increases. In Eq. (25), the impacts of $XS$ are greater than those of $p_{best}$ because raising the generations in equation 8 raises the value of $x$. The local optima trap is avoided by CE-HSOA with the aid of these factors. In the mating portion, $w_f$, $\omega$ and $\gamma$ oversee preventing the ensuing responses becoming convergent too soon. These settings alter the search range and strike a balance between exploration and exploitation based on the objective function's value and the number of generations.

## IV. Results and Discussions

This section compares the performances of several classification techniques—Proposed Model, CNN, KNN, SVM, and Logistic Regression—across various metrics such as accuracy, sensitivity, specificity, precision, F-measure, NPV, FPR, FNR, and MCC. From the obtained results, the Proposed Model is seen to be performing better than the other techniques across most of these metrics, signifying superior classification performance.

### A. Dataset Description

The N-BaIoT Dataset includes traffic information from nine industrial IoT devices. Of them, seven devices gathered data for eleven classes, while the other two devices gathered data for six classes. The information includes both benign traffic and a range of malicious assaults, including SYN, TCP, UDP, and scan. Within the current version of the dataset, there are 89 csv files totaling 7.58 GB in size, with 1486418 examples of both normal and attack cases. The ten attack and non-attack classifications into which the two botnet attacks, MIRAI and BASHLITE, were divided. These attacks fall into three categories: 1) scan instructions, which are used to identify susceptible IoT devices; 2) ACK, SYN, UDP, and TCP floods; and 3) combo or combination assaults, which are used to establish a connection and send spam to it [26].

### B. Overall Comparison of the Proposed Botnet Attack Detection Model

The Table II compares the performance metrics of the Proposed Model, CNN, KNN, SVM, and Logistic Regression, highlighting the superiority of the Proposed Model across all evaluated criteria.

TABLE II. COMPARISON OF THE PERFORMANCE METRICS

| Techniques | Sensitivity | Specificity | Accuracy | Precision | F-Measure | NPV | FPR | FNR | MCC |
|---|---|---|---|---|---|---|---|---|---|
| **Proposed** | 0.9640 | 0.9995 | 0.9900 | 0.9878 | 0.9842 | 0.9964 | 0.0188 | 0.0548 | 0.9726 |

| **SVM** | 0.9054 | 0.9789 | 0.9484 | 0.9695 | 0.9755 | 0.9800 | 0.0777 | 0.1432 | 0.8760 |
| **Logistic Regression** | 0.8299 | 0.9344 | 0.9219 | 0.8980 | 0.8976 | 0.9769 | 0.0637 | 0.2172 | 0.8092 |

The Proposed Model shows the highest sensitivity, specificity, accuracy, precision, F-measure, NPV, and MCC at 0.9640, 0.9995, 0.9900, 0.9878, 0.9842, 0.9964, and 0.9726, respectively, and lowest FPR and FNR values of 0.0188 and 0.0548, respectively, indicating effective minimization of false classifications. CNN is the second-best performer with high sensitivity of 0.9377, specificity of 0.9940, and accuracy of 0.9744, but higher error rates than the Proposed Model. KNN shows average performance, with acceptable sensitivity (0.9280) and specificity (0.9861), but high FPR (0.0749) and FNR (0.1550). SVM further drops the sensitivity at 0.9054 and specifically at 0.9789, along with a decreased MCC at 0.8760. The Logistic Regression performs the worst, at the lowest sensitivity (0.8299), specificity (0.9344), and MCC (0.8092), and the highest FPR (0.0637) and FNR (0.2172). In general, the Proposed Model significantly outperforms the other alternatives, demonstrating its strength and effectiveness in classification tasks.

### C. Accuracy, Sensitivity and Specificity

The Table II shows a comparative performance of accuracy, sensitivity, and specificity for different classification techniques. The Proposed Model achieves the highest accuracy (0.9900), signifying its superior ability to classify cases correctly, both positive and negative. CNN follows with high accuracy at 0.9744, while KNN, SVM, and Logistic Regression follow with progressively lower accuracies of 0.9600, 0.9484, and 0.9219, respectively.

Sensitivity, measuring the model to correctly identify positive cases is also highest for the Proposed Model (0.9640), as it signifies the efficiency in minimizing the false negatives. On the other hand, CNN indicates a competitive sensitivity of (0.9377), while KNN indicates somewhat lower at 0.9280; whereas SVM, and Logistic Regression indicate extremely poor sensitivity in detecting positive cases at 0.9054 and 0.8299, respectively. Specificity, which measures the accuracy in detection of negative cases, approaches near perfection for the Proposed Model (0.9995), thus reflecting an excellent ability to reduce false positives. CNN (0.9940) and KNN (0.9861) are also highly specific, while SVM (0.9789) and Logistic Regression (0.9344) performed much weaker. Fig. 7 shows accuracy, sensitivity and specificity values.

### D. Precision and F-Measure

The Table II also reports Precision and F-Measure, two important metrics that reflect the performance of a model in handling positive classifications. Precision measures the proportion of correctly identified positive cases out of all predicted positives, which is a measure of the ability of the model to minimize false positives. The Proposed Model has the highest precision at 0.9878, which means it can very well classify true positives while keeping false positives at bay. The accuracy of CNN is 0.9825, whereas, KNN follows with 0.9767 and then comes SVM with 0.9695, and then Logistic Regression shows the least accuracy with 0.8980. The F-Measure is the harmonic means of precision and sensitivity. It offers a comprehensive view of the performance of the model in correctly identifying positive cases by weighing the trade-off between these two measures. The Proposed Model has the best F-Measure of 0.9842, which indicates its excellent balance between high precision and sensitivity. CNN is also performing well with an F-Measure of 0.9856, which is slightly higher than its precision due to its strong sensitivity. KNN and SVM have moderate F-Measure values at 0.9798 and 0.9755, respectively, while Logistic Regression lags far behind at 0.8976. Precision and F-Measure values are shown in Fig. 8.

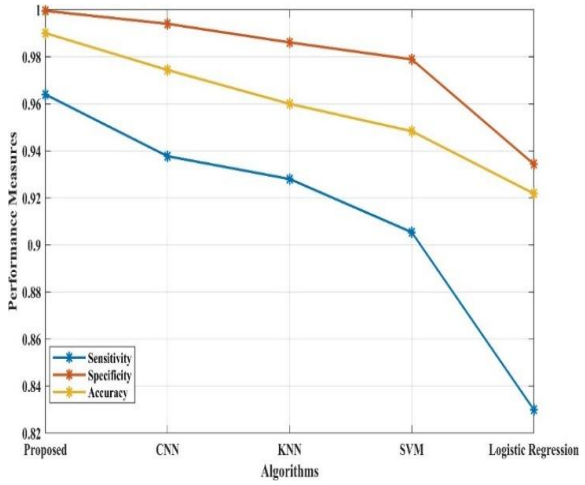

Fig. 7. Comparison of the accuracy, sensitivity and specificity values.

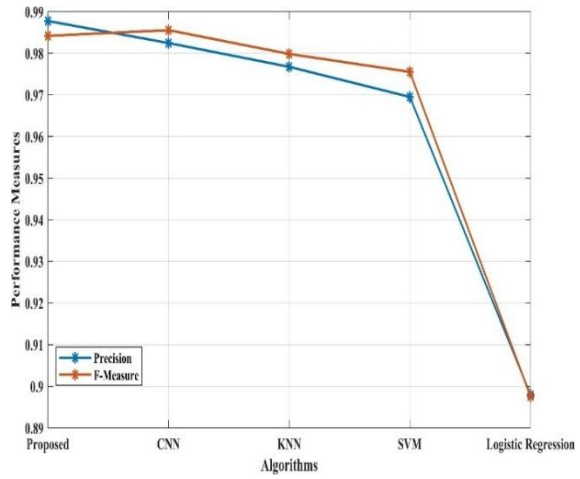

Fig. 8. Comparison of the precision and F-Measure values.

### E. NPV and MCC

The Table II also shows Negative Predictive Value (NPV) and Matthews Correlation Coefficient (MCC), furthering the interpretation of the model's performance. NPV is defined as the proportion of true negatives in all predicted negatives, thus representing how well the model can predict negative cases with minimal false negatives. The Proposed Model attains the highest NPV (0.9964), indicating its high reliability in terms of true negatives. CNN is followed by a strong NPV of 0.9934, followed by KNN at 0.9901, SVM at 0.9800, and Logistic Regression at 0.9769, which means that the performance is declining, and Logistic Regression has the worst ability to classify negative cases. MCC is a comprehensive metric which calculates the correlation between the true and predicted values with all possible outcomes: true positives, true negatives, false positives, and false negatives. The Proposed Model has the highest MCC of 0.9726, which means the model is well-balanced and robust in its prediction. CNN has a high MCC of 0.9608, while KNN and SVM have moderate correlation values at 0.8839 and 0.8760, respectively. Logistic Regression with the lowest MCC is at 0.8092, which reflects the weakest overall predictive power. The NPV and MCC values are shown in Fig. 9.

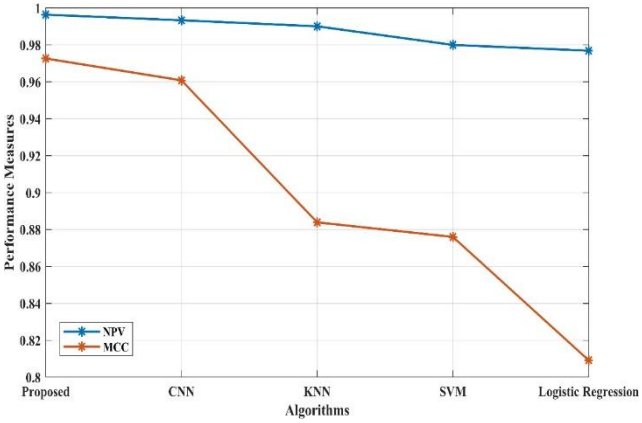

Fig. 9. Comparison of the NPV and MCC values.

### F. FPR and FNR

The Table II evaluates False Positive Rate (FPR) and False Negative Rate (FNR), which evaluate the model's error rates in specific contexts. FPR is the proportion of the false positives to all true negatives, indicating the capacity of the model to get negative cases wrongly classified as positives. The Proposed Model acquired the lowest FPR, which is 0.0188, thereby demonstrating their outstanding capability to minimize false positive and correctly classify negative instances. CNN (0.0283) has an FPR that is slightly above KNN (0.0749), SVM (0.0777), and Logistic Regression (0.0637). Though logistic regression does better than both KNN and SVM in its FPR, it significantly lags behind the proposed model and CNN.

Finally, FNR represents how many of the actual positives in the set were not discovered as positives by the model-thus representing the model's rate of missing true positive occurrences. The Proposed Model has the lowest FNR of 0.0548, indicating its higher efficiency in terms of identifying the right cases with fewer misses. CNN comes next with an FNR of 0.1301, while KNN has an FNR of 0.1550, SVM 0.1432, and Logistic Regression 0.2172, showing higher rates and a greater possibility of missing true positives. FPR and FNR values are compared in Fig. 10.

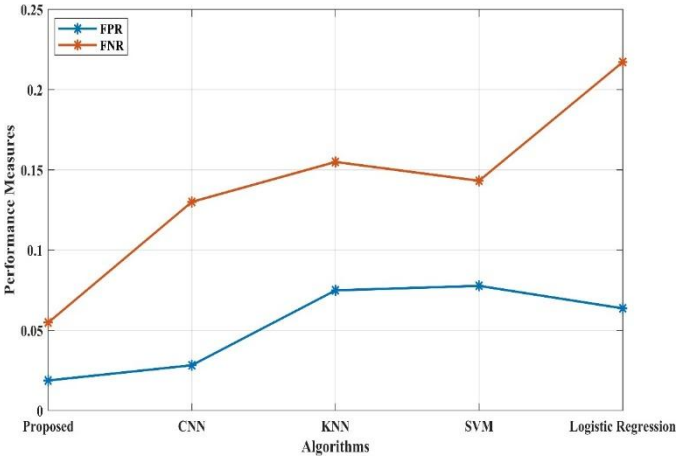

Fig. 10. Comparison of the FPR and FNR values.

## V. Conclusion

In conclusion, the DenseRSE-ASPPNet model gives the best and most efficient approach to botnet detection in IoT networks, surpassing other traditional machine learning techniques. Through the use of advanced methods such as the DenseNet169 backbone, RSE blocks, and ASPP, it can efficiently extract informative features and capture multi-scale spatial patterns. Optimized for hyperparameters of the model, applying the CE-HSOA, which boosts the results to have more robust and faster convergence. Therefore, a model that yields better Metrics and shows a high percentage of correctness for identifying bot activities while having very less errors involving false positives and false negatives.

The performance comparison highlights the advantages of DenseRSE-ASPPNet over other models such as CNN, KNN, SVM, and Logistic Regression. The proposed model achieves the highest Accuracy (0.9900) and Sensitivity (0.9640), demonstrating its strong ability to correctly identify botnet traffic. Its Specificity (0.9995) and Precision (0.9878) further showcase its reliability in minimizing false positives while maintaining high detection performance. In contrast, models like CNN and SVM show lower performance, particularly in terms of FNR, with SVM having an FNR of 0.1432. KNN also struggles with a higher False Positive Rate (FPR) of 0.0749, indicating that it is less effective in distinguishing botnet traffic. Logistic Regression exhibits the lowest performance across most metrics, especially in Sensitivity and Accuracy, underscoring its limitations for complex tasks like botnet detection. Overall, the results demonstrate that DenseRSE-ASPPNet provides a significant improvement in botnet detection performance, making it a highly effective solution for securing IoT networks.

***Abstract*—Evaluating physicians' performance is one of the fundamental pillars of improving the quality of healthcare in medical institutions, as it contributes to measuring their ability to provide appropriate treatment, interact effectively with patients, and work within healthcare teams. This study aims to explore the impact of attribute selection on the accuracy of physician clustering using the K-Means algorithm, to improve physician performance assessment. Three datasets containing professional, medical, and administrative attributes were analyzed, such as age, nationality, job title, years of experience, number of operations, and evaluations from various entities. The optimal number of clusters was determined using the Elbow and Silhouette Score methods. The results showed that the original feature set and Lasso features performed best at k = 3, with a clear distinction between clusters. The "three-star" cluster performed well at k = 2 but lost some fine details. It was also shown that attribute selection directly affects the number and accuracy of clusters resulting from clustering, allowing for a clearer classification of physician categories. The study recommends using either original features or Lasso features to achieve more effective clustering, which supports improved recruitment, training, and management decision-making processes in healthcare organizations.**

## I. INTRODUCTION

Physician performance evaluation is essential for improving the quality of healthcare and ensuring the provision of effective and safe medical services. With the advancement of data analysis techniques, it has become possible to use modern methods, such as clustering, to group physicians based on objective criteria based on professional performance, multiple evaluations, and practical experience. The effectiveness of these methods depends largely on the selection of appropriate attributes that help identify differences between different categories of physicians. Several studies have been conducted on physician performance evaluation. Brennan et al. found that most studies in the healthcare sector relied on manual assessment of physician performance through direct management, encompassing both professional and personal aspects. In their traditional approach, he and Baker used attributes such as physician personal information (age, speciality, gender), medical knowledge, communication skills, peer evaluation, patient satisfaction, and practical experience [1]. Kuemerle demonstrated that these methods, despite their high cost, are comprehensive and effective [2]. Zhang's study relied on several tools, including regression analysis, integrating Norman's theory of action and Reson's theory of human error, as well as developing a medical practice framework, a MOC program, systematic searches of electronic databases, a discretionary survey system, Pearson's correlation coefficient, and linear mixed models [3]. In contrast, another study used artificial intelligence to evaluate physician performance. Shi et al. relied on online text consultations between physicians and patients, using Python programming and a simple partitioning ordinal mapping (SVMOP). Model features included the number of medical terms used by the physician, the number of patient questions, as well as predictive features such as tact and emotional words [4].

With the advancement of data analysis technology, it has become possible to use advanced methods such as clustering to identify hidden patterns within complex data sets. Clustering, according to Xu & Wunsch, is a data analysis technique that relies on dividing data into homogeneous groups, each with similar characteristics [5]. This method can be applied to physician data to extract the most influential attributes in evaluating their performance, thereby improving evaluation quality. The importance of this study lies in exploring the extent to which clustering contributes to improving the accuracy of predictive models for evaluating physician performance. In a study conducted by Ghazzawi et al., different datasets collected from an Egyptian hospital were compared. They sought to identify the attributes that best represent physician performance evaluation criteria using regression analysis. The dataset included various attributes, such as nationality, job title, years of experience, and number of surgeries, as well as multiple ratings from different stakeholders, such as patients, nurses, and supervisors. The results showed that the set of attributes was divided into three groups: the original feature set, the 3-star

feature set, and the best Lasso features [6]. The current study focuses on analyzing the effect of feature selection on clustering accuracy. Several methods for feature selection are compared to determine the most appropriate methods for grouping physicians according to different performance criteria. Regression methods were applied to these attributes in Ghazzawi et al.'s study to identify the most influential attributes, which this study will use in clustering to test the accuracy of the resulting classifications. This research aims to improve administrative decision-making within healthcare organizations by providing more accurate physician ratings. By analyzing this data, a deeper understanding of the differences between physicians and the factors influencing their performance can be achieved, helping to improve decision-making, evaluation strategies, and professional development in healthcare organizations. This study may also contribute to improving predictive models used to evaluate physicians, enhancing the ability to allocate resources more efficiently, guiding training programs, and designing physician evaluation policies based on accurate and reliable data.

### A. Significance of the Study

This study is of great importance in the context of improving physician performance evaluation in healthcare institutions using the clustering method. With the rapid development of technology and big data, it has become necessary to apply advanced data analysis methods such as clustering to better understand the patterns and factors influencing physician performance. This study contributes to:

*1) Improving assessment accuracy:* By analyzing diverse data and using the clustering method, the most influential attributes in physician performance evaluation are identified, enhancing the accuracy of evaluations and helping improve decision-making.

*2) Supporting advanced data analytics in healthcare:* The study promotes the use of big data-based data analytics methods, such as clustering, to improve evidence-based healthcare decisions.

*3) Discovering hidden patterns*: The study helps uncover unseen patterns that may contribute to improving the effectiveness of predictive models, contributing to improving the quality of healthcare.

*4) Achieving strategic improvements:* The study provides strategic insights for improving training programs, allocating resources, and developing effective policies for evaluating physicians based on the most influential attributes.

### B. Objectives

*1) Identifying the most important attributes for physician performance evaluation:* The study aims to identify the key attributes that should be emphasized when applying clustering to improve performance evaluation.

*2) Comparing the impact of clustering on the accuracy of predictive models:* The study aims to compare the impact of clustering on improving the accuracy of predictive models for evaluating physician performance and provide recommendations for its use.

*3) Analyzing the relationship between various traits and physician performance:* The study aims to analyze the relationship between traits extracted from the data (such as years of experience, job title, number of operations) and physician performance in various assessments.

*4) Achieving strategic improvements in healthcare institutions:* The study aims to provide strategic insights for improving resource allocation, training programs, and policy development that impact physician performance evaluation based on clustering results.

*5) Uncovering patterns and factors influencing performance evaluation:* The study aims to uncover hidden patterns that may contribute to improved decision-making related to physician performance in healthcare.

### C. Research Problem

The study's problem is to identify the most appropriate attributes to focus on when evaluating physician performance using the clustering method. There is an urgent need to understand the relationship between various attributes (such as nationality, job title, years of experience, number of operations, and patient evaluation) and physician performance. Furthermore, the study raises questions about the extent to which the clustering method can improve the accuracy of predictive models and discover effective patterns that contribute to making accurate data-driven healthcare decisions. In this context, a set of questions guides this study:

- What are the most important attributes in evaluating physician performance when applying the clustering method?

This question aims to identify the attributes that primarily contribute to evaluating physician performance after analyzing different datasets. This contributes to improving evaluation accuracy and ensuring that the models used reflect the most influential attributes.

- What are the differences between different datasets (original attributes, 3-star attributes, and the Lasso model) in terms of their impact on physician performance evaluation?

This question aims to compare the impact of the original attributes, the attributes extracted through 3-star regression, and the Lasso predictive model on performance evaluation, and to determine which dataset provides more accurate and reliable results.

- Can using the clustering method reveal new patterns in physician performance evaluations that were not apparent using traditional methods?

This question focuses on exploring the ability of the clustering method to discover new patterns in data that may contribute to improving decisions related to physician performance evaluation, which may not be apparent using traditional methods.

- How can clustering results be used to improve physician training programs and resource allocation within hospitals?

This question aims to examine how clustering results can be applied to improve training programs and resource allocation within hospitals, leading to improved physician performance and the delivery of high-quality healthcare.

- What is the relationship between the attributes extracted from the datasets and physician performance in various assessments (such as the evaluations of patients, nurses, and supervisors)?

This question helps examine the relationship between attributes such as years of experience, number of operations, and physician performance as evaluated by different stakeholders, such as patients, nurses, and supervisors.

Through these questions, the study aims to provide a comprehensive vision on how to improve physician performance assessment using the clustering approach, which enhances the ability to make accurate and reliable decisions based on pivotal data, thus improving overall performance in the health system.

### D. Research Contributions

*1) Comparison of different datasets:* This study contributes by providing a detailed comparison between three datasets collected from a hospital in Egypt, including the original attributes, attributes extracted using 3-star regression, and the Lasso model. This helps identify the most effective attributes for evaluating physician performance.

*2) Expanding understanding of clustering in healthcare:* The study provides scientific insights by applying clustering to physician performance evaluation, demonstrating how this approach can improve results by identifying the most influential patterns and attributes.

*3) Analyzing the relationship between different attributes and performance:* By examining the relationship between attributes such as nationality, job title, years of experience, and other attributes, and the varied performance of physicians in different evaluations, this study contributes to providing new insights to support decision-making in healthcare institutions.

*4) Enhancing predictive capability in healthcare models:* By using advanced methods such as clustering, the study contributes to improving predictive models that can support strategic decisions for physicians and hospital management.

### E. Paper Layout

The paper's reminder is organized as follows: in Section II, a Related works is presented; in Section III, the Methodology that includes Datasets Used, Methodology for Determining the Optimal Number of Clusters, Finding the Optimal Number of Clusters, Analysis of clustering results and appropriate decisions, in Section IV, The research work is concluded by expressing direction, in Section V, Study Limitations, in Section VI, Future work, which will open new avenues of exploration and discovery, for upcoming research work.

## II. Literature Review

Many previous studies have focused on evaluating the professional performance of physicians using various data analysis techniques, with an emphasis on selecting the most influential attributes in the evaluation process.

Campbell et al, aimed to evaluate the performance of physicians in the United Kingdom through a cross-sectional survey involving patients and colleagues, and the data were analyzed using principal component analysis and regression. The results confirmed that communication skills, clinical competence, and professionalism, along with age, gender, and specialty, play a fundamental role in assessing medical performance [7]. Mirfat et al. confirmed that individual, psychological, and organizational factors play a crucial role in understanding physician performance. Psychological factors were found to have the strongest direct influence, while organizational factors showed a positive but statistically insignificant effect [8]. On the other hand, Cassel et al. demonstrated that intrinsic motivation, such as achievement and patient appreciation, along with extrinsic incentives such as financial rewards and recognition, significantly influence physician motivation levels [9]. In another study, Cola et al. demonstrated that the success of physician-scientists depends on a range of factors, including role balance, autonomy, organizational support, teamwork, mentorship, and the ability to build relationships. These multidimensional factors are essential for understanding and improving physician performance in academic medical settings [10]. Jin et al. also noted that factors influencing healthcare worker performance, such as burnout and anxiety, were analyzed before and after the COVID-19 pandemic, providing deeper insights into improving physician performance [11]. In addition, William et al. identified 22 key variables that influence medical lecturers' performance, most notably leadership, commitment, and credit scores, reflecting the complexity of the interrelationships that govern the performance evaluation process [12]. Overeem et al, used multi-source feedback (MSF) tools to evaluate physicians based on patient ratings, colleague assessments, and the physicians' self-evaluations. The results showed significant differences between the physicians' self-evaluations and the ratings provided by others, indicating the importance of using multi-source data to analyze performance [13]. Bindels et al, a professional performance evaluation system for physicians was implemented in a Dutch medical center through peer conversations based on the principles of appreciative inquiry and continuous feedback. The study emphasized the importance of continuous professional development and periodic feedback in improving physicians' performance [14]. Study by Ho and Baker: The General Medical Council (GMC) has developed a framework for good medical practice, which includes assessing physicians' performance every five years by measuring knowledge, communication skills, decision-making, and patient-centered medical practice [15]. Dias et al, a systematic review of 69 studies addressing the use of machine learning in evaluating physician competence was conducted, analyzing the impact of various features on professional performance using decision trees, support vector machines, and random forests. The study found that the specialties of surgery and radiology were the most affected by these technologies and emphasized that feature selection significantly impacts the accuracy of the models [16]. As Ghazzawi et al. focused on analyzing data from an Egyptian hospital using regression techniques to examine the attributes that most influence physician performance. The datasets

included attributes related to physicians, such as age, nationality, job title, years of experience, number of publications, and surgeries, as well as various ratings from patients, nurses, and human resources. The first dataset consists of the original dataset, which contains a wide range of attributes potentially relevant to performance evaluation. The second dataset represents a selection of attributes extracted using regression and receiving a 3-star rating. The third dataset includes the most effective attributes in predictive models, such as the Lasso model. The study focuses on this comparison between the different datasets, aiming to highlight the attributes that most significantly influence the clustering results and physician performance evaluation. The results demonstrate that regression analysis can be an effective tool for healthcare administrators to help reduce medical error rates, providing a framework for data-driven decision-making. Table I summarises the results of all the regression models in the Ghazzawi et al. study, which we will rely on in our current study [6].

TABLE I. IMPORTANCE OF FEATURES IN PREDICTING THE THREE MODELS, ADAPTED FROM STUDY [6]

| Attribute/Model | Lasso Regression | Ridge Regression | Linear Regression |
|---|---|---|---|
| Nationality | (+) *** | (+) *** | (+) * |
| Position title | (-) *** | (-) *** | (-) ** |
| Years of Experience | (+) ** | (+) ** | |

| Number of complaints | | (-) * | |

Ghazzawi et al.'s study contributed to the extraction of features, as shown in Table I. All features in the models used, with 3 stars representing the most important, were evaluated with the Lasso model receiving the highest rating. Although previous studies have addressed many factors influencing physician performance, aspects still have not been thoroughly studied, such as the impact of feature selection on classification accuracy using clustering methods. This study seeks to bridge this gap by analyzing different methods to identify the most influential features. This can then cluster and make appropriate decisions for each group, contributing to improved recruitment, professional development, and administrative decision-making within healthcare organizations

### A. Research Gap

*1)* Despite previous efforts to evaluate physician performance using traditional methods such as multi-source (MSF) assessments and questionnaires, there are clear research gaps that warrant further exploration. This study seeks to address these gaps, most notably.

*2)* The Lack of Use of Artificial Intelligence and Machine Learning Techniques in Physician Evaluation.

*3)* Most previous studies focus on traditional assessments such as patient surveys or peer reviews, without incorporating advanced techniques such as clustering to uncover hidden patterns and objectively analyze physician performance.

*4)* Lack of In-Depth Analysis of the Impact of Feature Selection on Clustering Accuracy.

*5)* Although some studies have used data analysis techniques, there is a dearth of research comparing different feature selection methods such as LASSO, regression, and dimensional analysis, and their impact on physician classification accuracy.

*6)* Limited Research on the Application of Clustering in the Healthcare Sector.

*7)* K-Means and other clustering methods have been applied in many fields, but their use in classifying physicians based on professional performance remains limited, leaving a gap in understanding how to improve evaluation quality using these techniques. Failure to Consider External Factors Influencing Ratings.

*8)* Some studies indicate that ratings based on patient and peer feedback may be influenced by socioeconomic factors rather than actual physician performance, calling for the development of more accurate models to mitigate bias.

*9)* Lack of Empirical Validation of the Impact of Ratings on Improving Healthcare Quality.

*10)*Most research is limited to data analysis without examining the actual impact of using the resulting ratings to improve management decisions and develop physician training programs.

### B. Study's Contribution to Bridging the Gap

*1)* Applying the K-Means algorithm to classify physicians based on objective performance criteria.

*2)* Comparing different feature selection methods to determine the most accurate physician classification.

*3)* Studying the impact of various factors on the accuracy of assessments to provide a fairer and more objective model.

*4)* Providing recommendations for the practical application of clustering results to improve healthcare quality and administrative decision-making within medical institutions.

## III. METHODOLOGY

In this study, the K-means algorithm will be applied using Python tools to cluster physician performance evaluation data, relying on three different datasets derived from the regression results in the study [6]. The study aims to analyze the effect of feature selection on the accuracy and effectiveness of the clustering process. The data was extracted from a hospital in Egypt and processed to remove outliers to ensure data quality.

### A. Datasets Used

The study will rely on three sets of features: original features, 3-star-rated features, and Lasso-based features. Each set is detailed below:

*1) Group 1:* Original Attributes: This set contains all the original attributes collected without any dimensionality reduction. The attributes include Age, nationality, job title, years of experience, number of publications, operations, department, patient evaluation, nurse evaluation, human resources evaluation, supervisor evaluation, and complaints.

*2) Group 2:* Selected 3-Star Attributes: This group is based on attributes rated three-star according to their importance in the previous study analysis [6], shown in Table I. They include nationality, job title, number of operations, age groups, department, and HR assessment.

*3) Group 3:* Attributes Selected Using the Lasso Model: Lasso regression analysis was applied to identify the most influential attributes in the model, resulting in the selection of a smaller set of attributes: Nationality, Job Title, Years of Experience, Number of Publications, and Number of Operations.

### B. Methodology for Determining the Optimal Number of Clusters (k)

*1) Elbow method:* This method will be used to analyze the variance within clusters and identify the inflection point that represents the balance between the number of clusters and internal consistency.

*2) Silhouette index:* This method will be used to assess the quality of clustering based on how distinct the clusters are from each other.

### C. Finding the Optimal Number of Clusters

This study will apply unsupervised learning using the k-means algorithm to identify core clusters that may reveal common patterns in professional profiles, practice patterns, or outcomes. The features were divided into three groups, including all original features, 3-star features, and the best Lasso features, as shown in Figures [1], [2] and [3]. This division can provide valuable insights for improving resource allocation and designing effective training programs. Importantly, this approach has the potential to significantly improve the quality of healthcare, positively impacting patient outcomes. To achieve this, a systematic approach based on data-driven clustering techniques was adopted, as described in the following sections.

*a) Using all original features (Optimal k=3):* Fig. 1 presents the number of clusters (k=3). There is a clear distribution of the three clusters. This indicates that all original features carry strong information, allowing for the formation of three distinct clusters. This reflects a strong ability to differentiate between data, achieving high clustering accuracy. The original features are best suited when you have a diverse dataset and need good partitioning between clusters.

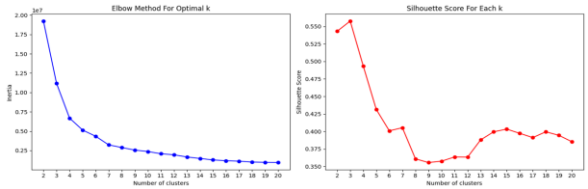

Fig. 1. Elbow Method and Silhouette Scores on original features for finding optimal k.

*b) Using 3-star features (Optimal k=2):* Fig. 2 shows the number of clusters (k=2). There is a less diverse distribution of clusters compared to all original features. The optimal number of clusters is only 2, indicating that the "3-star" features may lack some detail that helps differentiate between data classes. This simplification may be useful in some cases if the goal is to reduce complexity, but at the expense of some accuracy. These features may be useful if you want to simplify data or if you have a complex problem that requires less complex clustering.

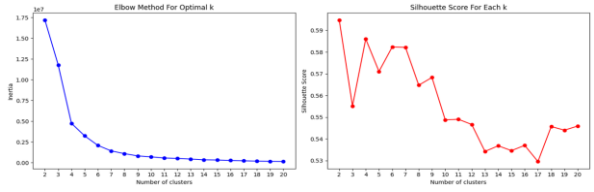

Fig. 2. Elbow Method and Silhouette Scores on 3-star features for finding optimal k.

*c) Using Lasso's best features (Optimal k=3):* Fig. 3 provides the number of clusters (k=3). Like the original features (k=3). The features selected by Lasso appear to select only the most important factors affecting clustering, allowing you to maintain high accuracy while reducing the number of features. It can be argued that Lasso reorders the features in a way that preserves essential details without adding additional complexity.

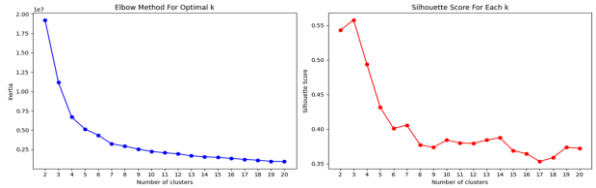

Fig. 3. Elbow Method and Silhouette Scores on Lasso's best features for finding optimal k.

The results show that both the original features and the best features selected by the Lasso model performed best at the optimal number of clusters, indicating their ability to provide accurate data segmentation. The original features provided the best cluster separation, reflecting high clustering accuracy. In contrast, the Lasso features offered an effective balance between reducing complexity and maintaining accuracy, achieving results close to those achieved using all the original features, but with fewer features.

The "three-star" features were simplified and resulted in a smaller number of clusters, which may be useful in some cases where data complexity reduction is required. However, this simplification may result in the loss of important details that may be necessary to understand subtle patterns in the data.

### D. Results

The K-Means algorithm was applied to three different datasets, each with a distinct set of features. The optimal number of clusters was determined using both the Elbow method and the Silhouette index to evaluate the effectiveness of each feature set in the clustering process.

Group 1: Original Features

The results, as shown in Fig. 1, indicate that the optimal number of clusters was k=3. The Silhouette Index also recorded its highest value at this number, indicating that the original features were able to differentiate physicians into three distinct groups.

Group 2: Selected Features (Three Stars)

The results, as shown in Fig. 2 for this group, showed that k=2 was the optimal number of clusters, achieving acceptable performance. However, the Silhouette index was lower than the first group. This indicates that this group tends to oversimplify the data, which may lead to the loss of some fine detail.

Group 3: Lasso Features

The results point as Fig. 3 to k=3 as the optimal number of clusters, with a Silhouette index close to the original grouping. This indicates that the selection of these features reduced the number of variables while maintaining classification quality and accuracy.

Overall, the results indicate that feature selection has a direct impact on the number of resulting clusters and the accuracy of the clustering. Both the original and Lasso features provided accurate and meaningful clustering, while the "three-star" grouping produced a simpler model. These results demonstrate the potential for leveraging feature selection techniques to customize assessment methods more accurately and effectively in healthcare contexts. Based on these results, the study recommends using the original features due to their ability to achieve the highest clustering accuracy and distinguish clusters more clearly, making them the ideal choice when more detailed data analysis is required.

*E. Analysis of Clustering Results and Appropriate Decisions*

Based on The original features were adopted due to their demonstrated remarkable effectiveness in enhancing the accuracy of the clustering process and their ability to more clearly demonstrate the variation between groups, making them the ideal choice for analyzing accurate data and making personalized decisions at the level of each physician. Based on statistical analysis, it was possible to identify distinctive characteristics for each group of physicians, enabling the formulation of administrative and development decisions tailored to the nature of each group's performance.

*1)* Cluster 1 – Young and Mid-Earned Physicians.

Distinctive Characteristics:

Average age: 49.7 years (youngest group).

Average years of experience: 24.7 years.

Average ratings from patients, nurses, and management: High (between 4.44 and 4.84).

Average number of publications: 78.5 papers.

Medicinal error rate: 0.041 (relatively low).

Average number of operations: 800 operations.

Appropriate Decisions:

- Invest in their professional development by providing advanced training courses and mentoring programs from more experienced physicians.
- Encourage scientific research by providing grants and support for the publication of their research, as they have a good publication rate, but lower than the second group.
- Increase their administrative responsibilities, as they have good patient and nurse reviews, potentially qualifying them for future leadership roles.
- Motivate them financially and administratively by offering incentives for excellent performance, as they could be the future of the medical institution.

*2)* Cluster 2 – The most experienced and most surgically active physicians.

Distinctive characteristics:

Average age: 62.1 years.

Average years of experience: 37.1 years (the most experienced group).

Average ratings are very high (between 4.44 and 4.85).

Average number of publications: 136.7 papers (the highest among the three groups).

Medicinal error rate: 0.040 (the lowest among the groups).

Average number of operations: 889 operations (the highest among the groups).

Appropriate decisions:

- Keep them in leadership and supervisory roles given their extensive experience and high ratings.
- Gradually reduce the workload on them and invest their expertise in training younger physicians.
- Encourage them to focus on scientific research and participate in medical conferences to enhance the hospital's standing.
- Developing their incentive programs, such as granting job benefits to highly experienced physicians to increase their loyalty to the organization.

*3)* Cluster 3 – Physicians with the Least Research Involvement.

Distinctive Characteristics:

Average Age: 60.7 years.

Average Years of Experience: 35.7 years.

Average Ratings High (between 4.51 and 4.86).

Average Number of Publications: 39.6 (lowest among the three groups).

Mean Medical Error Rate: 0.047 (higher than the other two groups).

Average Number of Operations: 807.

Appropriate Decisions:

- Increase their participation in scientific research, as their publication rate is lower than that of Cluster 2. This can be achieved by providing research support or imposing research requirements for senior positions.
- Improve their medical skills and reduce errors through specialized training programs.
- Increase their involvement in academic and professional activities such as workshops and medical conferences to enhance their research experience.
- Directing them to supervise new physicians instead of focusing only on surgical procedures, to benefit from their extensive experience in training and guidance.

Finally, this analysis helps guide recruitment, training, and professional development strategies for each group of physicians more accurately. Table II provides a summary of the proposed decisions and appropriate actions for each group of physicians.

TABLE II. A SUMMARY OF THE RECOMMENDATIONS FOR EACH CLUSTER

| Cluster | Main Characteristics | Proposed Decisions |
|---|---|---|
| Cluster 1 (young, intermediate-level physicians) | Younger age, good ratings, moderate number of research assignments, good number of operations | Professional training and development, encouragement of scientific research, management roles |
| Cluster 2 (more experienced and most surgically active physicians) | Highest experience, highest number of operations, highest number of research, fewest errors | Supervisory roles, gradual reduction of operations, promoting scientific research, financial incentives |
| Cluster 3 (physicians least involved in scientific research) | Good experience, lowest amount of research, relatively high number of errors | Professional research encouragement, training to reduce errors, integration into supervision and teaching |

*4) Comparison of clustering performance and results:* Comparing the results, the second cluster (Cluster 2) is the most experienced and most engaged in scientific research, making it ideal for leadership and mentoring roles. The first cluster (Cluster 1) is characterized by physicians in early or mid-career, making it ideal for investing in training and professional development. The third cluster (Cluster 3) includes physicians with extensive experience but less research activity, indicating a need to enhance their involvement in academic research and improve their skills.

## IV. CONCLUSION

This study indicated that selecting appropriate features directly affects the number of clusters resulting from clustering. The results showed that all original features and the best Lasso features resulted in an optimal number of clusters with a value of k=3, indicating that these features retained the essential information needed to distinguish between different physician classes. On the other hand, using simplified features reduced the number of clusters to k=2, which may be useful in some cases, but may result in the loss of some important details. In summary, this study highlights the importance of choosing appropriate features when applying clustering techniques and provides a framework that can be used in future research to analyze staff performance in medical and other fields. Furthermore, the results showed that the original features provide a clear distribution of physicians based on experience, age, and number of operations, facilitating personalized recommendations for each group. The results of this analysis can be used to support hospital decision-making in terms of developing training programs, assigning tasks, and identifying research opportunities for physicians based on their current performance.

Based on these results, the hospital recommends using cluster analysis to improve physician management and develop motivation and training programs tailored to each group, ensuring maximum utilization of available human resources.

## V. STUDY LIMITATIONS

This study focuses on analyzing the impact of feature selection on the accuracy of physician clustering according to different performance criteria, using the K-Means clustering algorithm. However, some limitations should be taken into account:

*1) Data limitations:* The study relies on data from multiple sources, including patient reviews, peer evaluations, and administrative evaluations. This data may not be comprehensive of all aspects of physicians' professional performance, and its accuracy depends on the objectivity of the evaluators.

*2) Sample scope:* The data were collected from a single hospital in Egypt, which may affect the generalizability of the results to other medical institutions with different evaluation systems or work environments.

*3) Influence of external factors:* External factors, such as the socioeconomic environment or the nature of the health system, may affect the clustering results. These factors were not directly considered in this study.

*4) Methodology used:* The study relies on the K-Means clustering algorithm, which requires pre-determining the number of clusters. This may affect the accuracy of the results if the optimal number of clusters is not carefully selected.

*5) Lack of validation of practical impact:* The study is limited to analyzing data and testing the accuracy of the resulting classifications, without empirically validating the impact of these classifications on improving healthcare quality or actual physician performance.

## VI. FUTURE WORK

Further Analysis of Selected Features: Additional studies could be conducted to analyze how the selection of different features affects clustering performance, especially in fields other than the healthcare sector.

Testing advanced clustering techniques: The use of other methods, such as hierarchical clustering or deep learning algorithms, could be studied to improve clustering results.

Scaling up the study: The study could be expanded to include other hospitals and different medical communities to compare the results and determine their generalizability.

Analyzing the impact of behavioral factors: Additional data, such as physician satisfaction and burnout levels, could be incorporated, along with their impact on the performance of different groups.

Combining cluster analysis with classification techniques: A model combining clustering and predictive classification could be developed to improve the accuracy of physician management recommendations.

This study represents a first step toward improving human resource management in hospitals using modern data analysis techniques. Further research is recommended to improve these models and enhance the accuracy of management recommendations in the future.

# Exploring Digital Insurance Solutions: A Systematic Literature Review and Future Research Agenda

Anni Wei, Yurita Yakimin Abdul Talib*, Zakiyah Sharif
Tunku Puteri Intan Safinaz School of Accountancy College of Business, Universiti Utara Malaysia, Sintok, Malaysia

***Abstract*—The purpose of this study is to explore the antecedents for the adoption of digital insurance solutions and to present current research trends and future research agendas based on a systematic literature review. The findings revealed key motivators for the adoption of digital insurance solutions, such as trust, perceived usefulness, ease of use, performance and effort expectancy, social influence, subjective norms, self-efficacy, system quality, and attitudes. Meanwhile, the key inhibitors include perceived risk, privacy concerns, complexity, and technology anxiety. The study shows that current research themes primarily focus on the online insurance sector, while lack of attention to emerging technologies. Although the Technology Acceptance Model (TAM) being the most widely applied theory in digital insurance adoption studies, its explanatory power needs to be enhanced by introducing new theories. Moreover, most research samples consist of insurance consumers, with less attention paid to user groups excluded from financial services. Questionnaires and Structural Equation Modeling (SEM) are commonly used methods, but still have limitations when dealing with large samples and complex behavioral changes. This study provides guidance for governments in promoting the implementation of digital insurance solutions, alongside strategic support for insurers to optimise user experience and enhance industry competitiveness.**

***Keywords*—Digital insurance; Technology Acceptance Model; antecedents of adoption; systematic literature review; future research agenda**

## I. Introduction

As an important pillar of socio-economic and personal well-being, the insurance industry has been at the forefront of technological innovation and digital transformation. With the rapid development of information and communication technology (ICT), insurance companies are actively utilising various digital tools to enhance service quality and market competitiveness [1]. Digital insurance has excelled in areas such as risk assessment, claims processing, and customer interaction. Digital insurance, which refers to the development, delivery, and management of insurance products and services based on digital technology [2], encompasses a variety of digital solutions such as online policy administration, mobile insurance platforms, blockchain-based insurance contracts, and risk assessment powered by artificial intelligence. Nowadays, technology-enabled insurance is an emerging force that drives industry transformation and enhances insurers competitiveness.

At present, the promotion and application of digital insurance still encounter many challenges. Although digital technology has injected innovation into the insurance industry, its development is susceptible to the rapid iteration of new technologies and environmental changes. On the one hand, for the existing user base, consumers experienced difficulties in comparing products or services in previous insurance transactions. The situation has changed with the rapid development of technology. Nowadays, consumers can use digital platforms to compare prices and information anytime and anywhere to make smarter and better choices. Consumers' demand for convenience and real-time interaction is also on the rise, thus increasing the pressure on insurers [3]. Failure to deliver a superior digital customer experience may cause customers to turn to competitors who can better meet their needs. Therefore, for insurers that are seeking rapid growth, deep insights into consumer behavior and preferences as they respond to technological change and evolving needs are key to competitively winning the market. On the other hand, many potential user groups are less receptive to digital insurance solutions, still preferring traditional offline services or transactions through insurance agents [4]. Especially in less-developed regions, the lack of financial inclusion makes it difficult for some groups to access the insurance market. In some emerging markets or remote areas, while digital insurance solutions can overcome geographical constraints, the lack of digital infrastructure is a critical barrier to their further penetration [5]. Thus, the resistance and potential opportunities for digital insurance adoption should be explored in depth.

A systematic literature review (SLR) is necessary in order to address the challenges encountered in the diffusion and adoption of digital insurance solutions. The SLR approach not only provides a comprehensive overview of research trends in the insurance field but also offers strategic reference for the practice of the field. In contrast, singular studies are usually incapable of covering the multidimensional aspects of the field comprehensively. Digital insurance-related research has been ongoing for over a decade. However, there are limited SLRs on the adoption of digital insurance solutions. In addition, emerging technologies such as blockchain, artificial intelligence, and Internet of Things (IoT) are changing the research priorities and directions in the insurance industry [6]. Hence, improving users' acceptance and user experience towards digital insurance solutions remains a priority that needs to be addressed. The authors sorted out and analysed the antecedents of digital insurance solutions adoption through a SLR, aiming to determine the factors influencing consumer acceptance. This study performing topic searches and article screening in mainstream academic databases (i.e., Web of Science and Scopus). A systematic review of relevant literature was conducted to answer the following research questions (RQs):

*Corresponding Author

RQ1: What is the extent of research done to date pertaining to the adoption of digital insurance solutions?

RQ2: What are the key antecedents of the adoption of digital insurance solutions?

RQ3: What is the current research landscape related to the adoption of digital insurance solutions?

RQ4: What are the future research directions in areas related to the adoption of digital insurance solutions?

This study helps to provide a concrete theoretical basis and strategic decision for academics, policymakers, and insurers for deepening their understanding of digital insurance adoption behaviors. The authors believe that this study could inspire more researchers to focus on and explore the different preferences and choices consumers have in relation to digital insurance solutions.

This study is organised into five parts. Section II introduces the literature review methodology; Section III summarises the key results of the literature review; Section IV discusses the findings and proposes a future research agenda; and finally, Section V concludes this study.

## II. Methodology

### A. Review Method

The SLR is a rigorous research methodology that enables a comprehensive analysis and summary of existing research in a structured and transparent manner [7]. It is regarded as one of the most informative and scientifically sound types of literature review methods. Therefore, this study adopted the SLR approach to review the literature in the field of digital insurance adoption.

### B. Review Process and Database Search

The authors searched the articles published from 2000 to 2024, a critical period during which the insurance sector was impacted by technological innovation and digital development. To ensure the quality and representativeness of the articles, the authors focused the searches on Web of Science and Scopus databases. These two databases cover many subject areas and are famous for their high-quality peer-reviewed research articles [8]. The database search for this study was conducted in December 2024.

The literature screening process strictly followed the guidelines of the PRISMA model. This model is widely used in SLR studies due to its advantages in terms of transparency, reproducibility, and methodological consistency [9]. The authors constructed keyword strings based on expert opinions in related fields. Subsequently, articles related to digital insurance adoption were screened by combining synonyms and related terms using Boolean logic operators. Fig. 1 presents the screening process used according to the PRISMA model, alongside the explicit inclusion and exclusion criteria set during the search process. Eventually, the authors obtained 28 articles that fit the study topic.

## III. Results

### A. Most Cited Studies

The citation rate is a key indicator of a study's impact, and a higher number of citations usually indicates that the study has greater influence and visibility in the academic community [10]. To assess the core literature on digital insurance adoption, this study identified the five most highly cited studies by analysing the number of citations. To further quantify the academic impact of the literature, the authors calculated the average number of citations by dividing the total number of citations of a study by the number of years it has been published as a measure of the frequency of citations per year. The review process shows that Heinze et al. [11], is the most cited study in terms of the number and frequency of citations. Table I lists the top five studies with the highest number of citations. The authors believe these studies can serve as a basis for future research in digital insurance.

TABLE I. Five Most Cited Studies in the Field of Adoption of Digital Insurance Solutions from 2000 to 2024

| Authors | Total citations | Citation per year |
|---|---|---|
| Heinze et al. [11] | 96 | 13.71 |
| Gebert-Persson et al. [12] | 50 | 10 |
| Khare et al. [13] | 38 | 3.17 |
| Gowanit et al. [14] | 37 | 4.63 |
| Wang and Lu [15] | 34 | 3.4 |

Source: Based on Google Scholar as of December 2024.

### B. Geographical Location of Previous Studies

Significant geographical differences exist in global research on the adoption of digital insurance solutions, as shown in Fig. 2. Asia, encompassing ten countries or regions such as India, China, and Taiwan, has the leading research concentration. Europe, covering six countries including Spain, Finland, and Germany, has the next highest number of studies. Fewer studies were conducted in Africa and North America. Among the countries or regions, India and Spain have the highest number of studies (n=4). These studies demonstrate the exploration of the insurance industry's digitisation in different regions of the world.

### C. Antecedents of Digital Insurance Solutions Adoption

This study systematically sorted out the antecedents of user acceptance of digital insurance solutions and categorised them into two categories: motivators and inhibitors. While motivators are positive forces that drive users to accept or use digital solutions, inhibitors are negative factors that prevent users from adopting such technology.

*1) Motivators*: Table II presents the top 10 positive factors influencing the acceptance of digital insurance solutions based on the frequency of occurrence. The factors are trust, perceived usefulness, perceived ease of use, performance expectancy, effort expectancy, social influence, subjective norms, self-efficacy, system quality, and attitude.

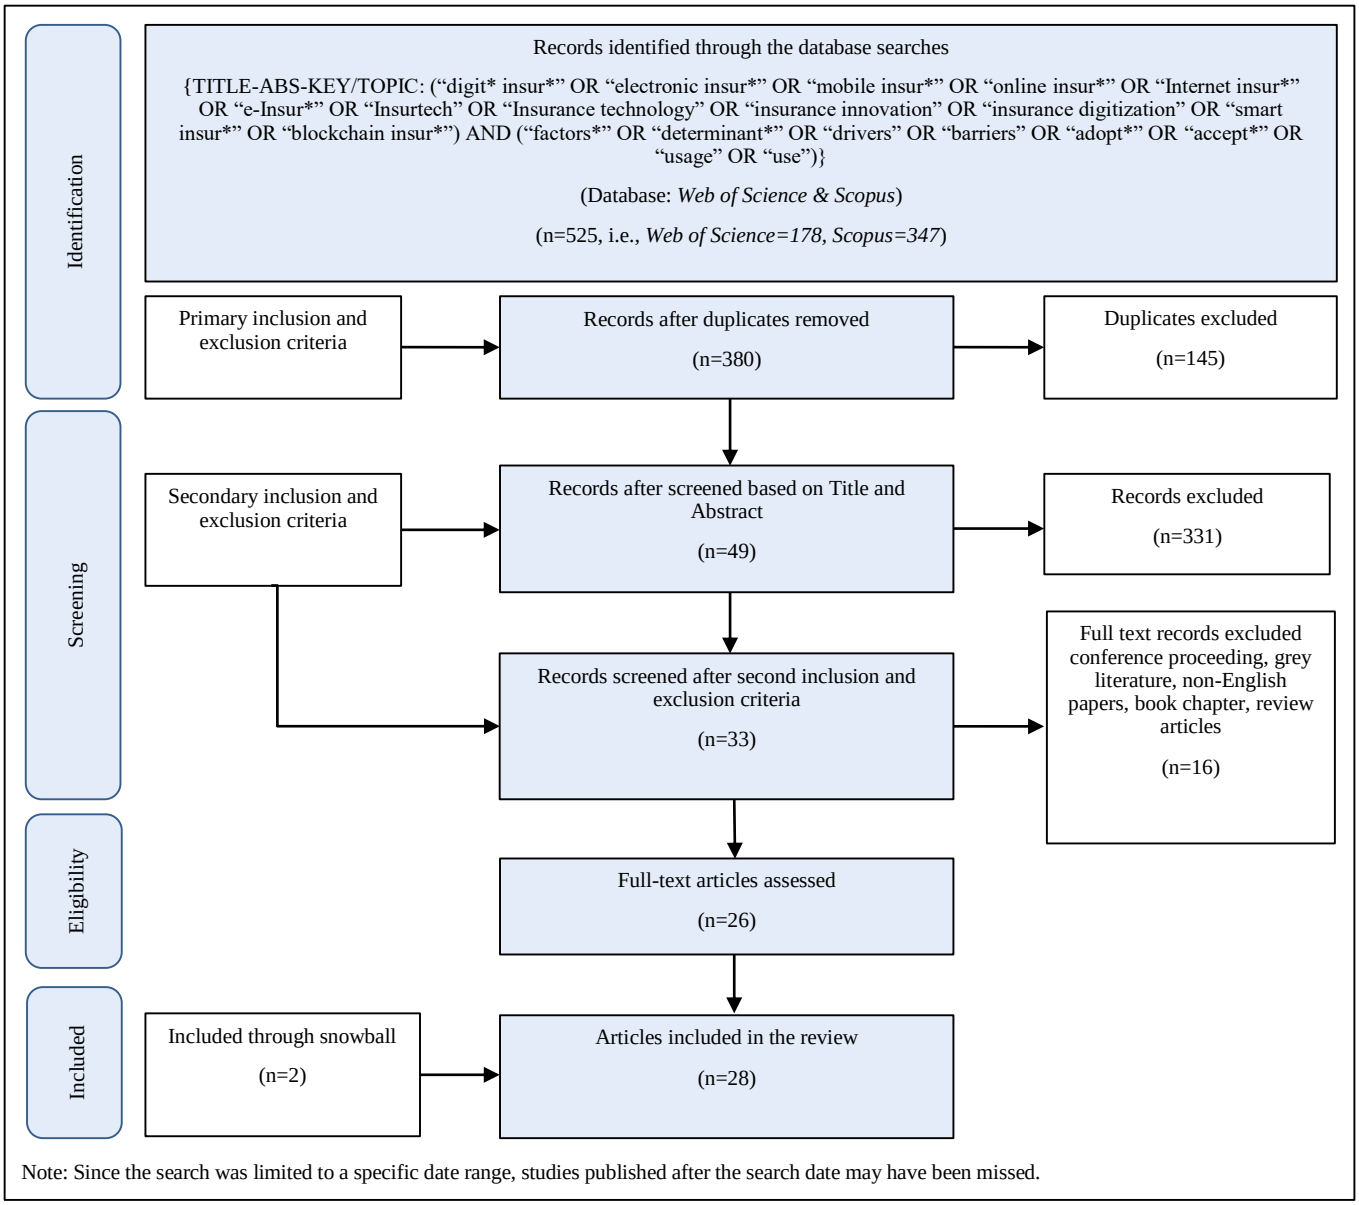

Fig. 1. PRISMA flowchart.

Fig. 2. Geographical locations of the reviewed studies.

*2) Inhibitors*: The factors that negatively affect the acceptance of digital insurance solutions are shown in Table III. Compared to motivators, inhibitors have been less researched and only mentioned in some studies. Therefore, this study lists the top four factors that occur with the highest frequencies, namely, perceived risk, privacy concerns, perceived complexity, and technology anxiety.

### D. Profiles of Studies

*1) Themes of reviewed studies*: Based on the literature review, the authors identified the main trend of research themes in the field of digital insurance adoption, as shown in Fig. 3. Existing research focuses on areas such as online insurance, Chatbot-based insurance, e-insurance, and mobile insurance. However, the research on technologies such as telematics and wearable devices in digital insurance are still relatively less explored.

TABLE II. MOTIVATORS OF DIGITAL INSURANCE ADOPTION

| Factors | Definition | Citation |
|---|---|---|
| Trust | The degree to which an individual perceives and believes in the reliability, integrity and trustworthiness of another person, organization, or system. | [12], [14], [15], [16], [17], [18], [19], [20], [21], [22], [23] |
| Perceived usefulness | An individual's subjective evaluation of whether the use of a particular object, service or technology is perceived as having real value and benefit. | [12], [14], [18], [19], [22], [24], [25], [26] |
| Perceived ease of use | An individual's subjective assessment of how easy or effortless it is to use a particular technology, product, or system. | [12], [14], [18], [19], [22], [25], [26], [27] |
| Performance expectancy | The benefits or performance that an individual expects from the use of a technology or service. | [17], [20], [23], [28], [29], [30] |
| Effort expectancy | The degree to which an individual expects effort to be required to complete a task when using a particular technology, system or service. | [17], [20], [23], [28], [29], [30] |
| Social influence | The impact that the words, attitudes, and behavior of others have on an individual's perceptions, decisions, and behavior. | [17], [20], [23], [28], [29], [30] |
| Attitude | An Individual's positive or negative evaluations of the use of a technology or service. | [12], [16], [19], [22], [26], [31] |
| Subjective norm | An individual's perceived social pressure, i.e. the extent to which others expect them to engage or not engage in a behavior. | [14], [18], [22], [26], [27] |
| Self-efficacy | An individual's understanding and beliefs in his or her skills and capability to perform a task given. | [14], [18], [29], [32] |
| System quality | The overall technical level and performance of an information system in terms of functionality, reliability, usability, and responsiveness. | [15], [28], [29], [33] |

TABLE III. INHIBITORS OF DIGITAL INSURANCE ADOPTION

| Factors | Definition | Citation |
|---|---|---|
| Perceived risk | An individual's subjective perception or awareness of the potential risks associated with a behavior, decision, or product. | [22], [23], [24], [28], [29], [32] |
| Privacy concern | The potential threats and harm that an individual or organization may face when processing, collecting, storing, and sharing personal information. | [14], [21], [30], [33] |
| Perceived complexity | An individual's perceived level of complexity in relation to a thing, concept, or task. | [15], [27] |
| Technology anxiety | The nervousness, anxiety or worry that individuals feel when faced with new technologies. | [21], [27] |

*2) Theories and models*: Based on the literature review, the authors found that 18 of the 28 studies used a theoretical framework or model, as shown in Fig. 4. One of the most used is Technology Acceptance Model (TAM). TAM, a model proposed by Davis et al. is used to explain user acceptance behavior towards new technologies through two core variables: perceived usefulness and perceived ease of use [34]. In addition, the Unified Theory of Acceptance and Use of Technology (UTAUT) proposed by Venkatesh et al. is the second most used theory or model. The UTAUT model integrates multiple technology acceptance theories and emphasises the joint impact of performance expectancy, effort expectancy, social influences, and facilitating conditions on user behavior [35]. DeLone and McLean's Information Systems Success Model (D&M Model) is this field's third most-used theoretical model. The D&M Model, which includes system quality, information quality, and service quality, provides a tool for measuring users' usage of the system and user satisfaction [36]. However, not all studies used existing theoretical frameworks. Some studies did not

cite traditional models, and other studies developed new models based on research needs.

*3)* Methodology Overview

*a) Statistical data analysis tools and techniques*: This study also reviewed the tools and techniques used for statistical analysis in the literature, as shown in Table IV. Structural Equation Modeling (SEM), Partial Least Squares Structural Equation Modeling (PLS-SEM), and Multinomial Logistic Regression are the main data analysis techniques used in the field of digital insurance.

TABLE IV. DATA ANALYSIS TOOLS AND TECHNIQUES USED

| Methods | Citations |
|---|---|
| Structural Equation Modeling (SEM) | [12], [15], [16], [19], [22], [24], [26], [29], [33] |
| Partial Least Squares Structural Equation Modeling (PLS-SEM) | [17], [18], [20], [23], [28], [31] |

*b) Data collection technique and sample size*: The data collection methods and sample size distributions of the studies are shown in Fig. 5 and Fig. 6, respectively. As shown in Fig. 5, questionnaires are the preferred data collection method in this field of research. A small number of studies used interviews and mixed methods. Focused group discussions and experimental research had relatively limited use in this study field. The distribution of sample sizes in Fig. 6 shows that studies with sample sizes of 201 to 300 people are the most numerous, followed by studies with sample sizes of 301 to 400 and 101 to 200. Studies with sample sizes of 1 to 100 people mainly focused on qualitative research methods, such as interviews and focus group discussions. Studies with sample sizes greater than 600 people are rarer. The authors conclude that the existing research primarily relies on questionnaire-based methods conducted on medium-sized samples.

*c) Profile of respondents*: The characteristics of the respondents are shown in Fig. 7. In these studies, insurance consumers were the most frequently investigated target group, followed by policyholders. Mobile users were also included in some studies. In addition, specific groups such as students, car buyers, university staff, disabled persons, farmers, and athletes were mentioned in a limited number of studies.

*d) Comparison of research methods*: To present the similarities and differences in research methodology of the included literature, 28 studies related to the adoption of digital insurance solutions were categorised. As shown in Table V, the data collection methods, analysis methods and sample characteristics used in each study are summarised.

TABLE V. COMPARISON OF RESEARCH METHODS IN THE REVIEWED LITERATURE

| Pranav and Dharmalingam [41] | Online insurance | Questionnaire | Pearson Chi- square | N=168, Insurance consumers |

## IV. FINDINGS, DISCUSSIONS, AND FUTURE RESEARCH AGENDA

To answer the first research question (RQ1), we screened 28 empirical studies related to the adoption of digital insurance solutions from the existing literature. The studies are mainly concentrated in Asia and focus on user adoption of e-insurance, mobile insurance, and online insurance. Europe has the second-highest number of studies, focusing on technology-based insurance and user adoption. Unlike Asia, European studies focus more on cutting-edge technologies, such as chatbots, telematics, and wearable devices, suggesting that the European region is more focused on using advanced technologies in the digital insurance industry. In this region, Spain has the highest number of studies, focusing mainly on the practical application of chatbots in insurance. This finding reflects Spain's prominent role in chatbot technology research within the insurance sector. While the number of studies in India and

Spain is comparable, the exploration of insurance digitisation in India is still in the internet-enabled stage.

The second research question (RQ2) was answered using the literature review results. User adoption behavior towards digital insurance solutions is influenced by motivators and inhibitors. Among the motivators, trust, perceived usefulness, perceived ease of use, performance expectancy, effort expectancy, social influence, subjective norms, self-efficacy, system quality, and attitude were mentioned several times as the key drivers of users' willingness to accept the technology. Specifically, users' trust in digital insurance and positive evaluations of the usefulness of service features contribute to the attractiveness of the technology; perceived ease of use and reasonable effort expectancy reduce the psychological burden of using the technology, thus enhancing adoption intentions. In addition, social influences and subjective norms positively shape user perceptions through external pressures or recommendations, self-efficacy enhances user confidence in the use of the technology, and system quality ensures the reliability of the technology. Moreover, positive user attitudes towards digital insurance further drive their willingness to adopt digital solutions.

On the contrary, perceived risk, privacy concerns, perceived complexity, and technology anxiety are the repeatedly mentioned inhibitors to user adoption in existing studies. Users' negative perceptions of digital insurance technologies' potential risks directly reduce their usage willingness. In addition, doubts about privacy security, concerns about technological complexity, and technological anxiety may further increase user resistance and impede the diffusion of digital insurance solutions. These findings highlight the need to focus on and alleviate user concerns, besides enhancing the positive influences when promoting digital insurance technologies.

The authors answered the third research question (RQ3) by sorting the research topic trends, theoretical frameworks, data analysis techniques, data collection methods, and sample distribution. First, all studies were conducted in different contexts of digital insurance solutions, with online insurance being one of the most popular research areas. Although Insurtech and innovation-based insurance are considered future research directions, the number of related studies is relatively small. The authors find that the existing research themes are mainly focused on the application of early digital insurance solutions (e.g., online insurance and mobile insurance). However, with the rapid development of Industry 4.0 technologies, digital insurance has integrated emerging technologies such as blockchain, artificial intelligence, and wearable devices, which offer greater potential for insurance innovation [6]. This scenario indicates that research on digital insurance adoption still has research gaps, especially in the application of cutting-edge insurance technologies and user behavior analysis. Thus, there is an urgent need to explore these areas in depth in future research.

The existing research on digital insurance adoption has relied heavily on classical theoretical frameworks such as TAM, UTAUT, and D&M models, which have broad applicability in explaining user behavior. However, with the evolving technological environment and user needs, classical theories have limitations in explaining complex and dynamic user behaviors. For example, some previously under-attended theoretical frameworks, such as the cognitive-affective-normative (CAN) model, have also been applied to digital insurance-related research [27]. The CAN model provides a multidimensional perspective of users' decisions and behaviors. This suggests that introducing new research variables or developing new framework structures based on existing theories can help explain user behavior in specific contexts.

The commonly used statistical techniques as data analysis tools in existing studies include SEM, PLS-SEM, and logistic regression. SEM is the most popular technique due to its ability to model complex causal relationships, enabling it to offer a significant advantage in the analysis of multivariate interactions [42]. However, these most used methods also have limitations. For example, SEM and PLS-SEM are highly dependent on model assumptions, which may affect the stability of the analysis results when the data quality is insufficient or the sample size is small [43]. Logistic regression has relatively limited performance in dealing with nonlinear relationships and thus may not be able to reveal the interactions between complex variables comprehensively. Based on these limitations, the authors suggest that future research explore emerging analytical techniques to reveal complex indicators and more accurately predict user behaviors.

Questionnaires were the most used instrument for data collection in these studies. The use of questionnaires corresponds to the distribution of research sample sizes, with medium sample sizes of 201 to 400 people being the most common. While studies with small sample sizes were usually conducted using qualitative analysis methods, large sample sizes were less commonly used due to higher resource requirements. It is worth noting that while the findings of insurance consumer and policyholder studies are highly applicable for most user groups, these studies lack in-depth investigations of specific occupational groups (e.g., farmers, athletes) and special populations (e.g., students, disabled people). These limitations may lead to an inadequate understanding of specific groups' behavioral patterns and needs, thus limiting the accuracy of the research results. Therefore, more attention should be paid to the specific groups in the future to explore their unique behavioral patterns and needs in depth.

For the fourth research question (RQ4), the next section provides the answers by discussion of the future research agenda. Applying the TCM framework is comprehensive and instructive, thus providing a clear direction to researchers [44]. The authors propose a future research direction through the TCM framework to bridge the current research gap.

### *A. Future Research Agenda on Theory*

Future research should explore and introduce new theoretical models to better understand the complexity and diversity of the digital insurance sector. Although traditional theories (e.g., TAM and UTAUT) are important in explaining technology adoption behavior, they may be difficult to fully adapt to the contextual needs in the field of digital insurance.

Alternatively, the CAN model provides a comprehensive framework for understanding individuals' intentions to adopt new products; however, it is rarely applied in the insurance industry. Future research could further validate the new model's applicability in the field of digital insurance.

As the insurance industry's digital transformation accelerates, users' perceptions of technology are becoming more complex, and research models need to be more inclusive and multidimensional. Researchers can enrich the explanatory power of existing models by extending the traditional theoretical framework to include insurance industry-specific factors (e.g., insurance literacy, perceived cost, product portfolio, etc.). Also, the key role of inhibiting factors in influencing user behavior should be explored more in future studies. In addition, the authors encourage future scholars to incorporate moderating or mediating factors into the models they develop.

Moreover, future research could integrate interdisciplinary theoretical frameworks, for example, by combining TAM, TPB, UTAUT, and some finance theories. The authors strongly recommend that future research create an Insurtech acceptance model. The interdisciplinary model can cover multiple dimensions, such as technological features, personal psychology, and social environment. Through interdisciplinary integration, digital insurance research will not only provide more accurate behavioral predictions but also offer a more guiding theoretical basis for industry practice by different stakeholders (e.g., policymakers and insurers).

### *B. Future Research Agenda on Context*

Future research should strengthen the studies on specific regions and groups. The existing studies mostly focus on Asian and European regions, leaving less developed regions such as Africa relatively less explored. Due to the low insurance coverage of low-income groups and underdeveloped regions, these groups have become important targets for promoting digital insurance solutions. However, these populations are still understudied in the existing literature in this field. Future research should focus on differences in user acceptance behaviors across cultures (e.g., collectivist and individualist cultures) and social contexts (e.g., rural and urban). An in-depth analysis of these differences will help policymakers and insurers to develop targeted promotional strategies.

In addition, future research should focus on the potential negative impact of digital insurance solutions. Although cutting-edge technologies show great potential in optimising insurance services, research on the related negative effects is still insufficient. For example, while technologies such as blockchain and artificial intelligence enhance transparency and efficiency, risks such as data breaches and algorithmic discrimination may erode users' trust in technologies. Future research should analyse the potential negative antecedents in depth and propose effective countermeasures to optimise user experience and promote a widespread adoption of digital insurance technologies.

Moreover, future research could explore cross-scenario applications of digital insurance solutions, especially by integrating sustainability themes which have received less mention in previous research, such as carbon emission and technology fairness. In addition, future studies are advised to focus on the application of digital insurance in the healthcare industry, an area that is still under-researched. Currently, technologies such as blockchain and artificial intelligence are used for data sharing and health risk assessment in the insurance and healthcare industries [45]. Future research could further explore user acceptance of these technologies.

### *C. Future Research Agenda on Methods*

Future research can employ longitudinal research methods. The promotion of digital insurance and user behavior may be affected by dynamic changes in policies and regulations. Longitudinal studies can reveal the time-series characteristics of behavioral changes by tracking user behavior in stages, such as initial acceptance, continued use, and potential exit [46]. For example, researchers can design multi-year data collection programs that can be used to analyse how policy interventions affect users' willingness to accept digital insurance. However, cross-sectional studies face difficulties to capture these long-term trends and changes. Existing studies on digital insurance are mostly based on cross-sectional analysis; the authors suggest that future researchers explore longitudinal studies more in order to grasp the dynamic changes in consumer behavior.

Another research agenda is to explore the emerging analytical approaches, such as integrating SEM with artificial neural networks (ANN) to cope with the complexity of user behavior studies. Existing analytical methods have limitations in revealing nonlinear relationships, and SEM-ANN approaches can simultaneously leverage the strengths of SEM in causal inference and the capabilities of ANN in nonlinear pattern recognition. For example, SEM-ANN can analyse digital insurance users' willingness to accept at different times and reveal potentially complex behavioral paths. In addition, social network analysis (SNA) is another method worth exploring to reveal users' relationship patterns and behavioral decisions [47].

Future research should also focus on applying machine learning methods in large-scale data processing and behavioral pattern prediction. Machine learning algorithms (e.g., decision trees, random forests, and deep learning) can efficiently process complex user data and mine hidden behavioral patterns from the data [48]. For example, machine learning allows researchers to predict the acceptance willingness of different groups towards digital insurance solutions and identify possible behavioral differences.

## V. CONCLUSION

Digital insurance solutions provide convenient services to people, especially those who have difficulty accessing the insurance market. In the literature analysis, the authors found that digital insurance research themes focused on insurance sector-related technologies in the early digital transformation era, with less exploration on Insurtech, which incorporates emerging technologies. Among the theoretical frameworks, TAM, UTAUT, and D&M models are widely used, but their limitations suggest the need to introduce new theoretical frameworks to explain user behavior more comprehensively. In

terms of research groups, existing studies focused on insurance consumers in general, with a significant lack of research on consumers from low-income groups or less developed regions. The results show that trust, perceived ease of use, perceived usefulness, performance expectancy, effort expectancy, social influence, subjective norms, self-efficacy, system quality, and attitude are the most frequently cited motivational factors. However, the main inhibitors include perceived risk, privacy concerns, perceived complexity, and technology anxiety.

Despite the initial results of this study in identifying the key antecedents influencing the adoption of digital insurance solutions, there are still some methodological limitations. Due to the relatively limited amount of quantifiable data in the existing literature, it is not yet able to perform meta-regression analyses based on multiple studies to systematically validate statistically the relationship between the identified antecedents and adoption. This is mainly since some of the literature adopts qualitative or mixed research methods, and the small number of quantitative studies involved in the antecedent makes it difficult to fulfil the multi-study validation conditions required for meta-analysis. Therefore, the specific impact of the antecedents proposed on the adoption of digital insurance solutions remains to be further verified through empirical data in subsequent studies. Nevertheless, this study provides practical guidance to the government for the promotion of insurance adoption. Additionally, by offering insights into user needs, this study provides strategic recommendations to insurers for enhancing market competitiveness. Academically, this study clarifies the research direction in the field of digital insurance solutions and provides support for subsequent academic exploration.

## ACKNOWLEDGMENT

The authors would like to thank all researchers, participants, and others who were involved directly or indirectly during data collection and reviewed this manuscript.

# Towards an Optimization Model for Household Waste Bins Location Management

Moulay Lakbir Tahiri Alaoui, Meryam Belhiah, Soumia Ziti
Intelligent Processing and Security of Systems-Faculty of Sciences, Mohammed V University in Rabat, Morocco

***Abstract*—Smart cities require effective, adaptive household waste management systems due to rapid urbanization. Traditional bin placement strategies based on placing bins equidistant among residents fail to account for actual human behavior, leading to overflowing or underused bins. This paper addresses optimizing bin location and capacity through Internet of things (IoT) technologies and data-driven decision-making by deploying LoRaWAN sensors in Tangier City as a case study; real-time usage information was then collected and analyzed. Through statistical analysis and outlier detection techniques, the proposed approach identifies bin placements that are non-optimized by using statistical analysis. It also evaluates data quality and classes bins by their usage level; results show several bins were constantly overused or underused indicating that dynamic placement and capacity adjustment would improve waste collection efficiency, reduce operational costs and enhance citizen satisfaction within a Smart City framework.**

***Keywords*—Smart City; IoT; household waste; LoRaWan; bin location; outlier detection**

## I. Introduction

Cities in developing nations are rapidly expanding, increasing the challenges associated with household waste management. Data collected from networks of IoT sensors placed in waste bins provide valuable data about filling levels and enable dynamic waste collection planning. Leveraging IoT networks to monitor fill rates in real time allows waste collection to be optimized without degrading the quality of service for citizens or wasting resources by emptying half-full bins.

Despite recent advances, several shortcomings remain in existing waste management systems. Many solutions rely on static routing or periodic collection schedules, ignoring real-time variations in bin usage. Prior works often lack robustness against real-world factors such as communication failures, and temporary urban events. To communicate with the servers, some studies use both IOT and GSM [1], which is expensive.

Furthermore, most studies address filling rate without integrating additional factors such as bin moisture and temperature, which are crucial for assessing waste degradation and health risks.

These limitations explain why the problem of dynamic and efficient bin management remains partially unsolved. Existing approaches either oversimplify the complexity of urban environments or fail to incorporate reliable outlier detection, resulting in inefficient resource allocation and increased operational costs [2].

This study proposes a method to optimize bin locations and dimensions based on continuous real-time data collected from sensors embedded in waste bins. The approach also incorporates an optimized routing algorithm for waste collection vehicles, aiming to minimize fuel consumption, travel time, and human resource utilization, which together represent a significant portion of municipal operating budgets [3].

The key contributions of this work are:

- A real-time data analysis framework that integrates fill rate, moisture, and temperature measurements for dynamic waste bin management.
- An outlier detection method designed to distinguish between temporary and permanent bin overflow conditions.
- A system design that considers technical constraints such as energy limitations, frequency interference, and network security in heterogeneous IoT environments.
- An evaluation showing how optimizing bin dimensions and locations can significantly reduce waste management costs.

However, limitations remain. The current system depends on the stability of wireless communication networks and the accuracy of low-cost sensors, which may introduce measurement errors under specific urban conditions.

The remainder of this paper is organized as follows. Section II reviews related works, including the IoT paradigm, IoT network architecture, LoRaWAN technology, and the challenges faced by IoT devices. It also discusses key data quality dimensions and methods to enhance the household waste collection process. Section III presents the proposed optimization model for managing household waste bin locations, including the outlier detection method, comparison metrics, and hyperparameter tuning process. It also describes the case study conducted in Tangier City, detailing data pre-analysis, quality verification, and outlier detection results. Section IV presents and discusses the results, including data pre-analysis, quality verification, outlier detection, and identification of slow- and fast-filling bins. Section V concludes the paper and suggests future research directions.

## II. Related Works

### A. IoT Paradigm

IoT and internet of everything (IoE) refer to a connected world where all objects are interconnected via ubiquitous sensors [4] and devices from different manufacturer's need to

exchange data. The IoT economic impact could grow to $3,352.97 billion by 2030 [5] ; the number of IoT devices may reach 75 billion [6].

Globally dispersed, diverse, and heterogeneous IoT devices provide data that influence interoperability and data quality [6].

Heterogeneous networks and sensors' challenges are the origin of communication problems between multiple nodes and layers. The following sub-chapter delves into the fundamental structure, components, and layers of IoT, exploring their applications and challenges.

### B. IoT Network Architecture

The IoT architecture is divided into several layers [7], each one responsible for different functions within the ecosystem as depicted in Fig. 1:

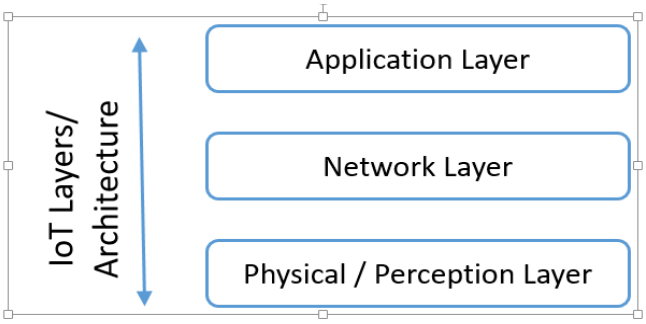

Fig. 1. IoT Architectre [7].

The physical layer, sometimes referred to as the perception layer, is in charge of actuating the environment in real time, measurement, and communication to the next layer, like temperature, bin level filling, moisture, geolocation, etc.

Maintenance of these devices poses challenges in terms of replacement and repair due to potential sensor placement in inconvenient locations [8]. This could lead to operational difficulties and even delays in data collection. Moreover, environmental conditions like high temperatures or humidity can affect sensor performance, necessitating extra care during hardware maintenance procedures. Furthermore, issues with the power supply or connectivity may make it difficult for the physical layer sensors to function. It may be necessary to regularly monitor and troubleshoot these issues in order to ensure accurate and uninterrupted data transmission. Defective equipment can lead to a malfunctioning sensor that produces inaccurate data, affecting service delivery and overall business insights.

Sensors often face limitations: being cost-effective means they aren't of the highest quality and have limited capacities. This includes issues with connectivity and short battery life for various functions, lack of precision, loss of calibration, and keeping up reporting once the device becomes faulty [9].

Noise is a major problem for sensors. The signals they rely on can be seriously disrupted by interference or physical impediments, which results in inaccurate data collection[10].

Network layer: interconnects IoT devices with the next layer [11] using universal protocols.

Application layer: controls sensors, receives data, analyzes them, and takes decisions[12].

In the next subsection, we describe the LoRaWan solution and present its benefits and drawbacks.

### C. LoRaWan

LoRaWan is a member of the Low Power Wide Area Network (LPWAN) family. These devices use the medium access control protocol (MAC) mechanism to communicate with the gateway.

*1) LoRaWAN Dataframe:* Dataframes have the same time duration. To overcome noise and interference, LoRa uses forward error correction (FEC) codes ranging between 4/8 and 4/5 and diagonal interleaving. The symbol rate Sr depends on the bandwith Bw and the spreading factor according to the Formula (1) [13]:

$$S_r = \frac{Sp * B_w}{2^{SF}} \quad (1)$$

*2) LoRaWAN Topology:* LoRaWan has a star topology as per Fig. 2 [14]. Sensors can only communicate with the gateways but not with each other; gateways communicate with the server; they encapsulate raw data received from sensors in UDP/IP packets and send them to the server. The server sends downlink packets and commands. Devices are divided into three classes [15]:

Class A: has basic options needed to join a LoRaWan network. Bidirectional communication can be enabled. Class A devices are most of the time asleep, thus they consume the least of power.

Class B: more receive windows can be scheduled to get synchronized and to inform when devices are ready for downlink traffic; power consumption is higher than the first ones.

Class C: Receive windows are open continuously except during transmission, power consumption is higher for this class.

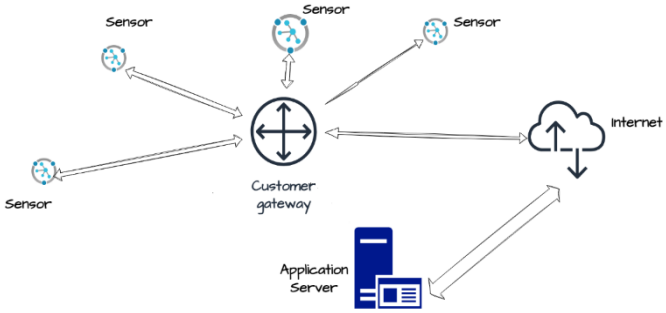

Fig. 2. LoRaWan network topology.

*3) LoRaWAN transmission:* The LoRa physical layer can use 125 KHz channels from the bands 433 MHz, 868 MHz, and 915 MHz to transmit, sensors communicate within 1% of the time only and transmit a small amount of data [16].

To guarantee secure and reliable communication, LoRaWan sets a number of mechanisms and joining procedures for sensors.

Once the sensor joins the network and is activated using over-the-air procedure (OTAA) [17] or by personalization (ABP) [18], the device sends a join or re-join message with needed keys and identifiers and gets a join-accept message from the server. The use of open source protocols helps to reduce the solution fees; the communication protocol MAC [19] is used between the sensors and the gateway; furthermore, to avoid financing frequency license fees, unlicensed bands may be used; the 868 MHz sub-band is unlicensed in Europe [20] and Morocco, according to the frequency regulation center [21].

Numerous technologies, including SigFox, IEEE 802.15.4g, LoRaWAN, and Z-Wave, use the same frequency, which may have an effect on signal quality and interference. In order to overcome interference, European regulations share time resources; a radio transmitting for one second cannot transmit for the next 99 seconds [22].

### D. LoRaWan Solution to IoT Devices Challenges

With the cited information above, the LoRaWan solution overcomes most of the IoT constraints while maintaining the same quality of service:

- *Joining and re-joining procedures:* restrict the sensors allowed to send data to MGWs.
- *Power consumption*: LoRaWan is a low-power area network [15]; sensors are asleep most of the time, especially for class A devices. Sensors contain a solar panel that extends the lifespan of sensor batteries and delivers sufficient voltage to sensor units (low power transmitter). Fig. 3 shows LoraWan Sensor modules. The embedded GPS module in the device helps to inform trucks about exact geolocation and to identify the location of bins. Table I summarizes solutions to most sensor challenges and the reason behind the popularity of this technology.
- Frequency transmission fees: as per [16] free of charge frequency usage to reduce the solution cost.
- Interference using processes like listen before sending or sending 1% of the time reduces considerably the interference. Data control and preprocessing can be done on the application server.
- Distance between the sensors and the gateway can reach 6 km with a high reception rate (more than 90%) [23].
- Synchronization: Is a drawback for LoRaWan [24]
- Access to transmission channels from multiple and heterogeneous sensors is unpredictable which causes collision and loss of frames [25].

TABLE I. LORAWAN SOLUTION TO IOT DEVICES CHALLENGES

| Challenge | Solution | Details |
|---|---|---|
| Power consumption | Low power consumption | Sensors are asleep most of the time |
| Frequency transmission fees | Free of charge frequency usage | Used to reduce charges |
| Interference | Sending 1% of the time reduces considerably the interference | A limited number of devices can transmit in the same time |

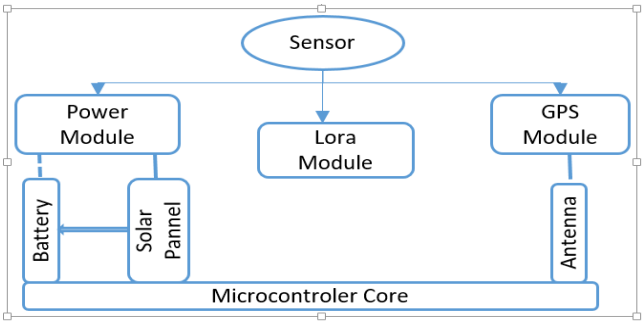

Fig. 3. LoRaWan sensor modules.

In the following section, we will present the most important dimensions regarding data quality.

### E. Data Quality Dimensions

Data dimensions are characteristics of data quality that can reveal the data's overall quality level once they are measured correctly [26]. Data quality is a crucial parameter for services based on IoT; a control and validation of the quality are mandatory before model deployment. Herein we will define the most influencing data quality dimensions:

*1) Accuracy:* Evaluates the reliability, dependability, and certification of data [27]. It represents the degree to which observations are correct, trustworthy, and guaranteed error-free. It can also be defined as how a value 'v' is close to the correct value of the real world.

*2) Completeness:* A «NULL» value may indicate a missing value, which is an existing value in the real world but the observation is lost for a specified reason; those values may exist but are unknown, or they do not exist, or the system does not know if they exist or not [28].

*3) Timeliness, volatility and currency:* The temporal dimensions are sensitive since late data may be unuseful. Timeliness describes how current the data are; it can alternatively be described as the offset between the server time and the received sensor's timestamp. Volatility is a measure of how frequently data changes over time; where currency specifies how fast data are updated, it can be defined as in Formula (2) [29]:

$$\text{Currency} = \text{Age} + (\text{Delivery\_Time} - \text{Input\_Time}) \quad (2)$$

where, "age" indicates the data's original age upon receipt and "Input_time" is the server time when data are observed.

### F. Household Waste Collection Process Enhancement

While the majority of research concentrated on management and trash classification, the current work looks at bin locations and identifies inadequate ones; it also shows outliers, including the most and least used bins; as well as inaccurate data produced by malfunctioning devices. Non-synchronized bins are sorted out to permit a full operational waste collection process. The data control part in our program can be deployed by other IoT services.

## III. Towards an Optimization Model for Household Waste Bins Location Management

### A. Outlier Detection Model Presentation

Outliers represent a rare event in a dataset; this unexpected value may be due to a measurement error or a faulty sensor, but it can also be a valuable insight [27]. In this subsection, we will present the main steps and procedures of our model that detects outliers. Data may be numbers, dates, geo-location values, etc.

Our model is built using Jupyter Notebook with required libraries and dependencies installed, like Pandas, Numpy, Matplotlib, Sickit-Learn, Pyod, Pycaret etc. The model is designed to operate in a variety of fields; it can be adapted according to each domain specification, and the following steps are performed:

- Data collection: supplied data, in text, csv, or other formats, contain multiple columns; it is filtered to keep necessary columns for our model.
- Cleanup: NaN and empty values represent a non-complete observation; it should be detected and cleaned/corrected.
- Preprocessing: data columns are interpreted as object types and need to be converted to appropriate types such as date time, integer, etc.
- Data normalization and feature selection: features should have similar scales with a low correlation level to provide better results. The data show below variables:
  - The server time (servertime) and time of the IoT device related to the observation.
  - Bin_number, Bin_index1 and Bin_index2 represent an identyer of the waste bin used by different layers.
  - Filling_level is a variable measuring the fill level of a Bin.
  - Bin_longitude and latitude represents GPS coordinates.

Time identifiers and Bin indexes are correlated as per Fig. 4. To detect outliers we use the variables bin identifier, time and fill level etc. A new variable will be introduced to classify data per day of the year.

- Data from Bin_index columns are converted to a dictionary to simplify data analysis and allow exploration of data through outlier detection methods requiring numerical values.
- Parameter tuning: we can change the ratio of data to train the model according to the data size, and other parameters can be changed according to our need.
- Pandas library helps to sort out IoT devices that overflow the server and bins rarely transmitting their filling level. We use Pycaret to detect outliers, tune, and compare the models.
- Model comparison: different outlier detection models can be compared using different metrics, as we will present in the next subsection.

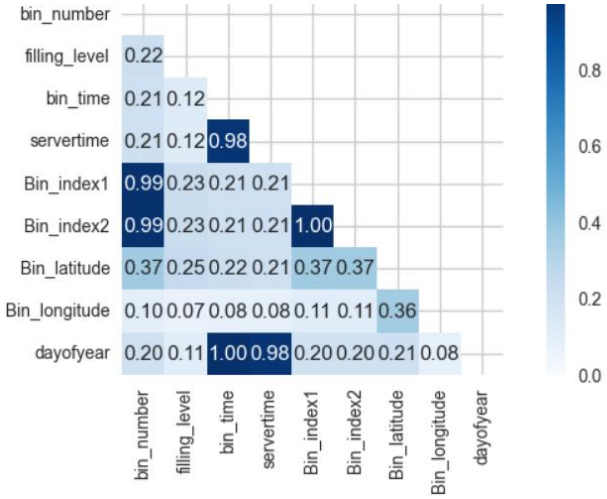

Fig. 4. Correlation matrix.

The Fig. 5 below summarizes different data treatment steps of our program:

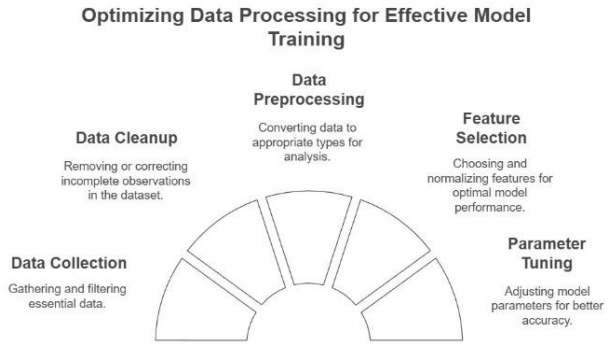

Fig. 5. Data processing.

*1) Comparison metrics:* The model sorts out the best method to detect outliers based on the best metrics. The main metrics used in the case of classification models are [30]:

- Accuracy: it presents the ratio of the correct prediction numbers to all the prediction numbers.

$$\text{Accuracy} = \frac{Number\ of\ correct\ predictions}{Total\ number\ of\ predictions} \quad (3)$$

$$\text{Auc} = \frac{1 + Correct\ positif\ predicts - Incorrect\ positif\ predict}{2} \quad (4)$$

$$\text{Recall:}\quad \text{Recall} = \frac{Correct\ positif}{Correct\ positif + False\ negatif} \quad (5)$$

$$\text{Precision:}\quad \text{Precision} = \frac{Correct\ positif\ results}{Correct + False\ positif\ results} \quad (6)$$

$$\text{F1 Score:}\quad \text{F1} = 2 * \frac{Precision * Recall}{Precision + Recall} \quad [31] \quad (7)$$

*2) Outlier detection using KNN method:* The number of neighbors to be given an integer K, this method calculates the distance to the k nearest neighbors. In a m-dimentional space,

let A and B be two points; they can be expressed as the tulpes: (A[1], A[2],…A[m]) and (B[1], B[2]…B[m]). The distance AB can be : $\sqrt{(\sum(B[i]-A[i])2}$. An object O is an outlier if the number of neighbors within a distance r defined as a threshold is less than K.

To detect outliers, we use Pycaret 3.3.1. Setup function trains the environment, multiple parameters can be specified in this step such us features, thresholds, outlier method, the number of neighbors to be used for KNN method, etc. possible models can be listed, compared, and the best model is identified, the model is tuned and saved for future use.

*3) Hyperparameter tuning:* Finding outliers is not an easy task; it depends on many factors. The model should be well trained, which requires a large dataset with low-correlated features. It also depends on how rare the outliers we are interested in are. Using default parameter values for a model helps to sort out data that are very different; however, to detect outliers that are not completely different, parameter tuning is mandatory [32]. The number of neighbors can be increased and the threshold reduced. The number of dimensions may be large, which increases computational resources and time. Principal Component Analysis (PCA) is used to overcome this issue and convert correlated variables to non-correlated ones.

### *B. Case Study: Household Collection in Tangier City*

This study concerns a part of the Tangier city, one of the biggest cities in northern Morocco; it has undergone an economic and demographic surge empowered by the establishment of the Tangier-Med port, cars and aircraft manufacturers, among other development factors. Like many growing cities, the population has risen significantly; therefore, public services have to follow the pace.

In most cities, household waste collection is planned once a day in low traffic periods. Although this approach appears to be effective, it has a number of drawbacks, and there is more to be done to optimize the collection process. Indeed, time, fuel consumption, and human resources will be overused if we include the total number of bins in everyday travel in order to empty and clean them up.

## IV. RESULTS

This paper aims to sort out the rate at which bins are filling up. Datas are gathered from different LoRaWan sensors placed in all household bins in the studied region.

Data is collected over a 10-day period, sensors calculate bins filling level and send it to a central server, where, GPS location (longitude and latitude), server time, and measurement time are included. It is important to highlight data quality efforts provided in different layers in the network.

### *A. Data Pre-analyzis and Data Quality Check*

*1) Accuracy:* To monitor bin filling level, gathered data from different sensors should be reliable. A sensor hardware or software failure may cause a reduced number of observations or may flood the system with observation signals. Table II shows such abnormal behavior from sensors that need to be checked. The column “Bin Number” is an identifier of bins; “Num of measurements during 10 days” represents the sum of observations during the supervision period, while the other columns show the number of observations for each day of the year (194 refers to 13th July, 195 to 14th July..).

*2) Completeness:* The server discards incomplete frames and missing values; incomplete ones will lead to a « Null » value that will be discarded in our data pre-treatment program.

*3) Timeliness:* Data age is an essential parameter; old data do not reflect reality and cannot be used to make a decision. The time difference between the server and sensors data measurement can indicate rows to exclude from data analysis; this offset will be considered in our program.

- Bins 495 and 529 sent 60982 messages during the ten days.
- Bin 529 sent 33959 during the ten days (33506 during 3 days).
- Bin 495 sent 27007 during 3 days.
- Bins 266, 271, 20, 274, and 274 sent 2 messages each during the whole ten days. Other indicators may help to find faulty devices: 391 reported only 8 measurement values during the 10 days and passed from 10% to 100% within 12 seconds between 2024-07-20 08:58:53 and 2024-07-20 08:59:05.

A normal bin’s data are also included; « bin 28 » sent 1102 observations well spread over the monitored period, with different filling level values; those observations were continually sent to the server, with a minimum of 58 and a maximum of 143 observations per day.

### *B. Outlier Detection*

In this subsection, we will present the result of the computational program that aims to sort out outliers that need to be analyzed and take actions accordingly. Python with machine learning libraries such us Sickit Learn, Pandas, Matplotlib, and PyOD are used to develop our computation software. After data cleanup, training, testing, and evaluation, our model detects outliers. KNN is used since it has the best performing metrics: accuracy, recall, F1-score, and precision, as it is highlighted in Table III.

Found outliers contain a few bins that are 100% filled up and that are mentioned in the above subsections (bin numbers: 121, 516, 304, 503, 200, and 352). Other bins need to be highlighted and studied (bin numbers: 312, 2, 494, 452, 511, 201, 465, 376, 208, 536, 539, 545, 547, 518, 13) as per Fig. 6. More investigations need to be done to check why each of those locations represents an outlier and different stakeholders have to be involved to take a decision according to the analysis results. Other outlier methods with parameter tuning need to be used for more accurate data analysis.

TABLE II. NUMBER OF MEASUREMENTS PER SENSOR DURING THE SUPERVISION PERIOD

| Bin Number | Number of measurements during 10 days | Day of the year | 195 | 196 | 197 | 198 | 199 | 200 | 201 | 202 | 203 | 204 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | 194 | | | | | | | | | | |
| Bin_Number_352 | 8402 | 6 | 2 | 4 | 2 | 1099 | 2658 | 0 | 0 | 1653 | 0 | 2978 |
| Bin_Number_495 | 27023 | 6 | 2 | 4 | 2 | 4015 | 9831 | 13161 | 0 | 0 | 0 | 2 |
| Bin_Number_529 | 33959 | 6 | 2 | 4 | 2 | 439 | 0 | 0 | 0 | 9978 | 11937 | 11591 |
| Bin_Number_266 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| Bin_Number_271 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| Bin_Number_20 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| Bin_Number_274 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| Bin_Number_273 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| Bin_Number_391 | 8 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 6 | 0 | 2 |
| Bin_Number_307 | 16 | 6 | 2 | 4 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| Bin_Number_42 | 16 | 6 | 2 | 4 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| Bin_Number_198 | 16 | 6 | 2 | 4 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| Bin_Number_219 | 16 | 6 | 2 | 4 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |
| Bin_Number_435 | 16 | 6 | 2 | 4 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 2 |

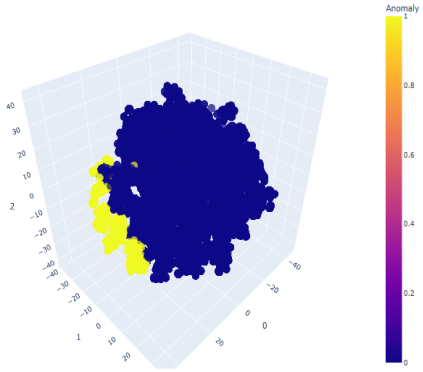

Fig. 6. Outlier bins pertaining to fill level.

The outlier detection can be used as a first step; more analysis follow to check the reasons behind those bins to be outliers. Checking outliers reduces computational resources and filters bins and sensors to monitor.

### C. Slowest Filling Up Bins

Bins that fill up slowly can be deprioritized during waste collection. Unnecessary travels to those bins can be avoided.

Table IV shows multiple bins that did not exceed 30% of their capacity during 2024-07-12. These bins do not require immediate emptying and can be excluded from daily routes. During this day Bin_451 and Bin_225 recorded a 0% fill level, Bin_456, Bin_151, and Bin_44 stayed below 10% and most bins listed remained under 25%.

Table V highlights bins that remained underused over a 10-day period. Specifically, it shows the number of days during which each bin did not reach a 50% fill level.

Bin_Number_44 never reached half capacity during the entire 10-day period, Bin_Number_533, 532, 310, and 120 exceeded 50% capacity only once. Several other bins stayed below the threshold for 6 or 7 days.

Concerned bin sizes and places should be reviewed.

Table VI presents the maximum daily fill levels recorded for Bin_Number_514 over an 11-day supervision period. During 6 of these 11 days, the bin did not exceed the 50% fill threshold. Only between Days 201 and 203 did the fill level rise above 60%, with a peak of 74%. On Day 204, the fill level dropped sharply to 22%, reflecting a possible irregular usage pattern or external intervention such as manual emptying.

TABLE IV. BINS NOT REACHING 30% FILL-UP LEVEL ON 2024-07-12

| bin_num | max_fill up level | bin_num | max_fill up level | bin_num | maxfill_up level | bin_num | max_fill up level |
|---|---|---|---|---|---|---|---|
| Bin_451 | 0 | Bin_412 | 17 | Bin_395 | 22 | Bin_382 | 24 |
| Bin_225 | 0 | Bin_532 | 20 | Bin_533 | 22 | Bin_365 | 24 |
| Bin_456 | 2 | Bin_495 | 20 | Bin_493 | 22 | Bin_524 | 25 |
| Bin_151 | 3 | Bin_224 | 21 | Bin_217 | 23 | Bin_479 | 25 |
| Bin_44 | 9 | Bin_386 | 21 | Bin_508 | 23 | Bin_355 | 25 |

TABLE V. NUMBER OF DAYS /10 THE MAXIMUM FILL LEVEL DID NOT REACH 50%

| Bin Number | N of occurrences | Bin Number | N of occurrences |
|---|---|---|---|
| 44 | 10 | 343 | 7 |
| 533 | 9 | 515 | 7 |
| 532 | 9 | 350 | 7 |
| 310 | 9 | 412 | 7 |
| 120 | 9 | 40 | 7 |
| 488 | 8 | 417 | 6 |
| 506 | 8 | 182 | 6 |
| 535 | 7 | 456 | 6 |
| 467 | 7 | 514 | 6 |

Fig. 7 illustrates the fill level evolution for Bin N44, N532, and N533 over the supervision period. These bins display consistently low filling patterns. Although short spikes are observed, the majority of values remain below the 50% threshold. Bin N44, for instance, shows extended periods near zero. Bin N532 briefly exceeds 60%, then stabilizes below 30%. Bin N533 presents a single peak but quickly returns to lower levels. These trends confirm the underuse highlighted in Table V. They suggest that these bins may not require daily collection. However, the accuracy of the recorded values must be verified before operational adjustments are made.

The map below (Fig. 8) shows the geospatial distribution of bins that consistently reported low fill levels during the 10-day monitoring period in the city of Tangier. These bins, highlighted on the map, rarely exceeded 50% capacity.

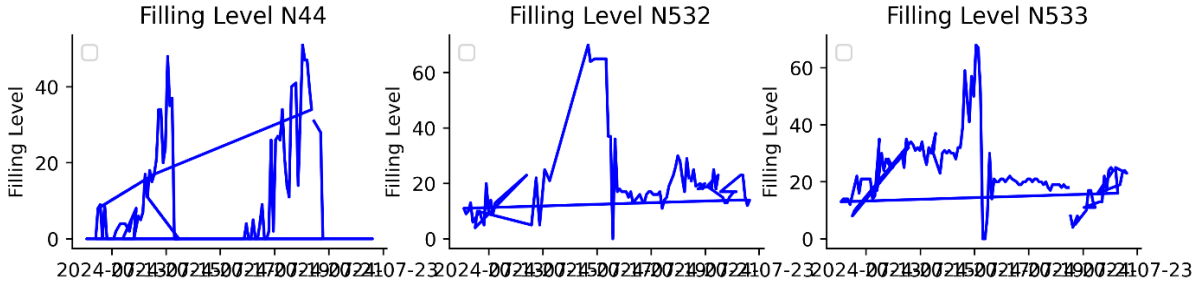

Fig. 7. Bins with a low filling level during the supervision period.

TABLE VI. MAXIMUM FILL LEVEL DURING SUPERVISION PERIOD FOR N514

| day | Bin Num | level | newla | newlo | date | time |
|---|---|---|---|---|---|---|
| 194 | 514 | 34 | 35.767506 | -5.800178 | 12/07/2024 | 21:06:47 |
| 195 | 514 | 37 | 35.767506 | -5.800178 | 13/07/2024 | 23:30:21 |
| 196 | 514 | 37 | 35.767506 | -5.800178 | 14/07/2024 | 21:04:33 |
| 197 | 514 | 54 | 35.767506 | -5.800178 | 15/07/2024 | 19:19:16 |
| 198 | 514 | 52 | 35.767506 | -5.800178 | 16/07/2024 | 21:10:16 |
| 199 | 514 | 48 | 35.767506 | -5.800178 | 17/07/2024 | 21:02:31 |
| 200 | 514 | 40 | 35.767506 | -5.800178 | 18/07/2024 | 18:56:37 |
| 201 | 514 | 64 | 35.767506 | -5.800178 | 19/07/2024 | 18:49:52 |
| 202 | 514 | 68 | 35.767506 | -5.800178 | 20/07/2024 | 18:42:25 |
| 203 | 514 | 74 | 35.767506 | -5.800178 | 21/07/2024 | 12:36:42 |

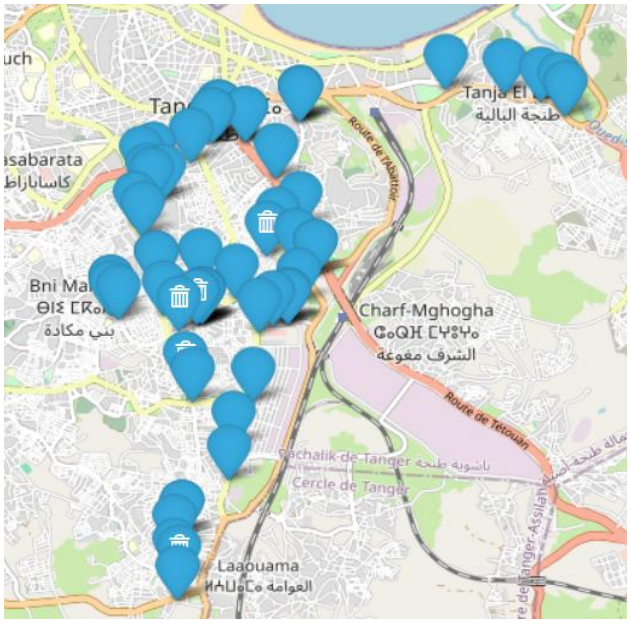

Fig. 8. Bins with a low filling level during the supervision period.

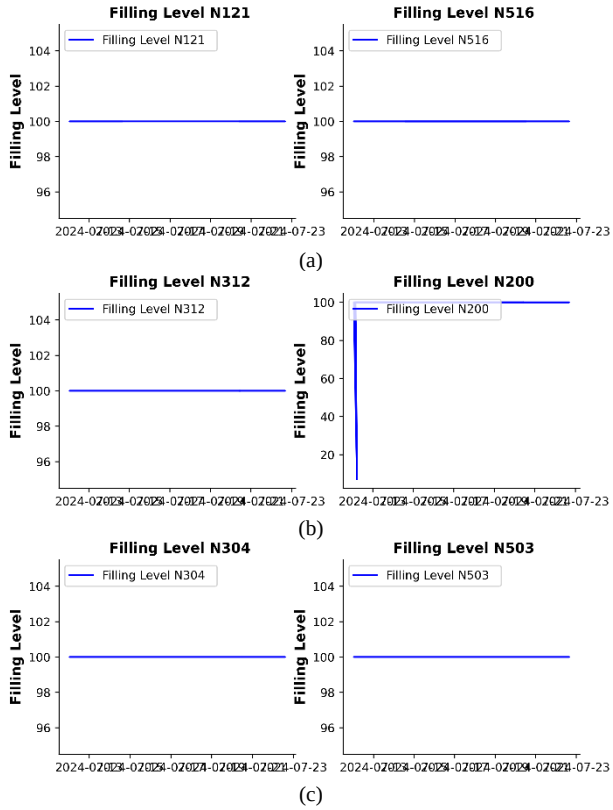
## D. Fastest Filling up Bins

A filled-up bin can emit an unpleasant odor, which impacts the life quality of citizens. In this subsection, we will sort out the fastest-filling bins.



(a)

(b)

(c)

Fig. 9. (a) Bins with abnormal filling level for N121 and N516, (b) Bins with abnormal filling level for N121 and N516, (c) Bins with abnormal filling level for N304 and N503.

Data analysis indicates the following results: Bins 121, 516, 304, 503, 200, and 352, exhibited a constant filling level of 100% throughout the supervision period, following a small number of initial readings below that threshold. For example, Bin 352 recorded only 14 initial values below 100%, followed by 8,388 consecutive values at 100% as per Fig. 9(a), 9(b), and 9(c) which indicates a device failure that needs to be fixed.

The list below presents the quickest filled up bins; Fig. 10 shows their geolocations; those bins should be replaced with bins having a bigger capacity to answer citizens demand: [bin numbers: '121', '516', '312', '200', '304', '2', '503', '494', '452', '511', '201', '465', '376', '208', '536', '539', '545', '547', '518', '13', '541', '542'].

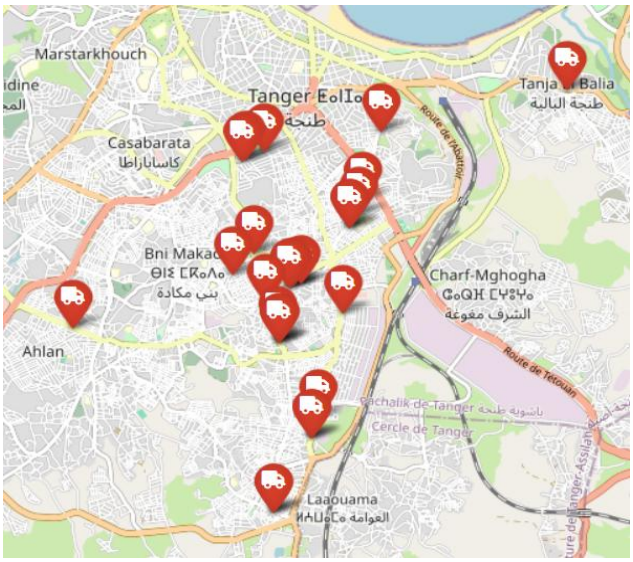


Fig. 10. Bins with a high filling level during the supervision period.

The map below combines both types of bins Fig. 11.

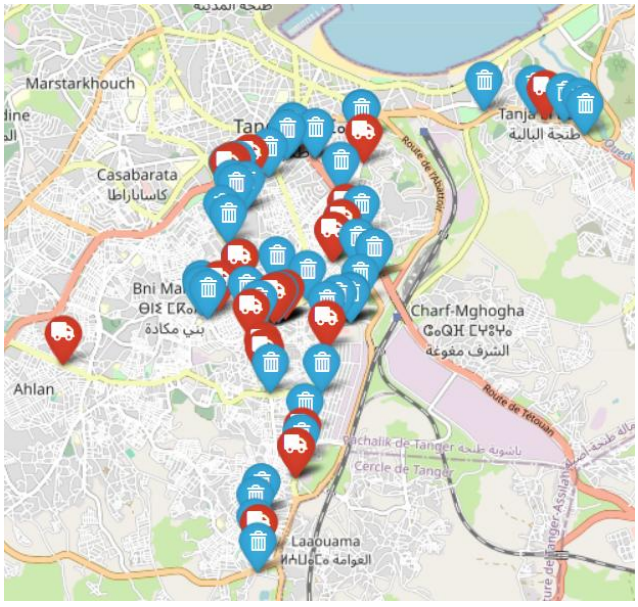

Fig. 11. Bins with a high filling level and the ones with a low filling level.

Fig. 11 presents a combined geospatial representation of waste bins with contrasting usage patterns during the supervision period. Red markers indicate bins with consistently high fill levels, while blue markers represent underused bins with persistently low fill levels.

This dual-layered view enables rapid identification of mismatches between bin capacity and local waste generation dynamics. High-fill bins highlight priority zones for:

- Capacity increase
- Additional bin deployment
- More frequent collection schedules

Low-fill bins suggest potential for:

- Relocation
- Downsizing
- Reduced collection frequency

Such spatial insights are essential for optimizing operational efficiency, minimizing collection costs, and maintaining service quality across the city. Nevertheless, sensor reliability must be verified before implementing adjustments to avoid decisions based on inaccurate data.

### *E. Discussion*

Provided data offers valuable insights about the functional state of LoRaWan sensors, indeed:

- Several IoT-based technologies communicate filling levels via GSM texting. The expense of communication is therefore unsustainable. In just 10 days, Bin_Number_529 sent 33,959 messages. The GSM [1]method is very costly because, at 0.05 USD each SMS, for instance, that amounts to 1,697.95 USD for a single bin. Over the course of 10 days, bins 529, 495, and 352 sent 69384 messages. Scaled to a citywide network, the cost becomes huge, the proposed solution is performing better than [1] and [33] using GSM especially that LoRaWan uses free transmission band.
- Synchronization state of sensors: the dataset shows a big time offset between the server and sensors clock which may lead to incorrect observation.
- Unreliable information as demonstrate by bins 121, 516, and 352 in Fig. 9(a), Fig. 9(b) which were 100% filled up throughout the duration or a brutal filling level from 10 to 100% within 12 seconds. Fig. 9(b) indicating a faulty measure or faulty device: such behavior indicates a faulty device which facilitate the maintenance process.
- An erroneous GPS location of a sensor indicates a displacement of the bin or a faulty device measurement, which allows tracking bins in real time.
- Data control helps to maintain sensors in a healthy state and keeps transmitted data frames accurate. Maintaining IOT devices is easier by measuring data quality and avoiding traffic outage. Suspected faulty devices should be checked which allows a continuous bin fill level check.
- Truck trips can be significantly reduced by avoiding travels to bins not reaching a predefined filling threshold level; this impacts also travel time and man hours; fuel consumption and its impact on the environment can be reduced; more than that, transportation trucks can be reused and their number reduced.
- Hot seasons and special events are another critical context where waste collection efficiency directly impacts service quality and citizen satisfaction. During these periods, waste generation increases rapidly, and delayed responses can degrade urban hygiene and public perception. Monitoring the fill level of all bins in real time, while ensuring data quality, enables timely emptying of full bins. This optimizes collection routes, avoids emptying bins that are not yet full, and reduces unnecessary trips, fuel consumption, and human resource usage.

Supervising the filling level of bins for long periods indicates less used ones; a rarely used bin does not have to be emptied on a daily basis, which minimizes resource usage. The above-listed bin geolocations mentioned in the previous subsection should be reviewed; indeed, it can be displaced to more demanded locations.

On the other hand, dimensions of bins with a high level of fill-up should be resized; bigger bin sizes are needed to answer citizens' demand. Above parameters, among others, are keys of bin geolocation optimization.

There is a limitation to this study in receiving data; indeed, the analysis is impossible without valid and accurate data.

## V. CONCLUSION

This study has enabled us to implement a program that controls IoT data quality, especially the most important dimensions such as timeliness, completeness, and accuracy.

By processing observations collected by the various devices, a full operational IoT network is maintained by early detecting faulty devices. It is possible to reduce the distance covered by bin collection trucks and reduce collection time, as well as fuel consumption and its impact on the environment.

As the location of bins is a key element in the service provided to citizens, this program allows to detect locations that are underused and that need to be displaced to a more demanded area; it also detects bins that are frequently overloaded and for which the size needs to be increased or enhances the emptying frequency, especially in hot seasons or during special events where the demand increases substantially and the service quality KPIs should be higher.

To optimize bin geolocation positions, long-term supervision needs to be put in place. Outlier method results can sort out locations that need to be highlighted. Deeper investigations regarding each outlier needed to be performed to take actions, by either increasing the bin's size, displacing the bin, or keeping the bin under surveillance.

This study focused on optimizing household waste collections based on real-time sensor data and bin usage patterns. Future work will focus on automating recycling integration at waste deposit points.

***Abstract*—Facial identification has emerged as a key research area due to its potential to enhance biometric security. This research proposes an advanced security system for electric vehicles (EVs) based on facial identification, implemented using Raspberry Pi. The system comprises two main modules: Face Detection and Face Recognition. For face detection, the researchers propose using the Viola-Jones algorithm, which leverages Haar-like features to detect and extract unique facial features, such as the eyes, nose, and mouth. MATLAB will be used as the development tool for this module. For face recognition, the proposed approach integrates Principal Component Analysis (PCA) with Support Vector Machine (SVM). PCA is used to extract the most relevant facial information and construct a computational model, while SVM enhances classification accuracy. The system's performance is evaluated using accuracy and the Receiver Operating Characteristic (ROC) curve, with results demonstrating a face recognition accuracy of 95% and an average execution time of 2.32 seconds, meeting real-time operational requirements. These findings confirm the proposed method's reliability in offering advanced and efficient biometric protection for modern electric vehicles.**

***Keywords*—Face recognition; face detection; Principal Component Analysis (PCA); Support Vector Machine (SVM); Raspberry Pi***

## I. INTRODUCTION

In this era of globalization, the rapid growth of modern electrical vehicles (EV) with advanced technologies requires strong security to prevent customer's vehicle begin stolen. Passive Entry Passive Start (PEPS) was introduced to enhance the security of EV by using low-frequency (typically 125 kHz) or ultra-high-frequency signals to exchange unique key access codes between the key and the vehicle. When these codes match and yield the expected value, and the key is within the vehicle's range, the car grants access to the driver [1], [2].

However, the low-frequency or ultra-high-frequency signals can be easily duplicated or coped using a specific hacking device tool especially in this modern era [3]. This situation leads to the risk of EV being stolen.

Therefore, it is necessary to develop a security system to enhance the security of EV. One of the ways is to integrate the EV with biometric which is using facial recognition.

Biometrics are becoming increasingly integral to both personal security setups, providing a strengthen layer of protection. Biometrics use unique body features, such as fingerprints, irises, and facial structures, to authorize access. Thus, one of the biometrics was facial recognition technology. In 1967, Woodrow W. Biedsoe, a pioneer in artificial intelligence, developed a system that can classify photos of face using a graphical computer input device known as RAND tablet. The exponential growth of technology makes facial recognition integral with complex algorithm artificial intelligence, neural network, and machine learning to process, identity, and classify images with a high degree of accuracy.

The problem statement for developing facial recognition using Raspberry Pi module on electrical vehicle (EV) is because there is an increasing number of consumers buying EV as the prices are affordable. However, the EV nowadays uses passive entry passive start (PEPS) system to allow driver access into the vehicle. By using this PEPS system, drivers need to carry the key to unlock their EV. The disadvantage of this system is that driver might lose their key due to the careless behavior causing them need to pay expensive price to replace the key. Furthermore, some EV store their unique code in remote control and driver need to carry it and present in the range of the EV in order to access it, but sometimes the battery of the remote control drain out due to long time in use or the remote control suddenly malfunction. If the key is stolen, the EV can be accessed by who is holding the key.

Given the vulnerabilities of current Passive Entry Passive Start (PEPS) systems and the rising demand for secure keyless access in electric vehicles, it is crucial to explore biometric alternatives that offer both accuracy and reliability. This study seeks to answer the following research question: Can a facial recognition system implemented on a Raspberry Pi using PCA and SVM provide secure and efficient keyless access to electric vehicles while maintaining high accuracy and real-time performance? By addressing this question, the study aims to bridge the gap between low-cost embedded systems and advanced biometric security solutions for EVs.

The solution that is proposed in this project is to implement facial recognition in EV using Raspberry Pi. The Raspberry Pi module is a microcontroller that can configure based on desire function using programming. The module will integrate with

other components such as camera, lock of EV, and engine of EV. The system will provide an interface for driver to use facial recognition to access their EV.

The system of facial recognition in EV will solve the problems of the present EV limited access option and give flexibility. Drivers will be able to access their EV using their facial feature without carrying any key on them. The security system using facial recognition on EV will improve driver experience and simplify the process of unlock EV. The objective for the development of facial recognition in electrical vehicles using Raspberry Pi is to achieve more than 95% accuracy of facial recognition and achieve execution time not more than 3 seconds. To analyze the accuracy and efficiency of the facial recognition system using Receiver Operating curve, and to develop a facial recognition system to access EV with Raspberry Pi. The first step of this project is to create a block diagram to illustrate the facial recognition system in EV. After that, selecting the proper version of microcontroller, sensor, actuator, and other components. The microcontroller will need to program to recognize a person's facial feature and record it into its database then allow access to an authorized person. The microcontroller also needs to control other components such as lock and motor. Decentralized coordination concepts, such as those used in multiarea temperature control systems, can enhance the modular management of EV subsystems [4].

High quality camera module is required in the procedure of facial recognition because it is used to take input (image) from driver. The facial recognition system in EV needs to be programmed using specific algorithm. Thus, a user interface will be necessary for programming and allow users to interact with the system to set up their biometric. Meanwhile, the security system might need to be improved soon. Thus, this requires an LCD panel and a keypad or touch screen panel. In a word, developing a microcontroller-based security system that uses facial recognition in EV required various knowledge, such as microcontroller programming, technical skills, and logic thinking. Iterative design approaches and formal validation techniques, such as model checking, can further enhance the reliability of embedded authentication systems in critical applications [5]. Implementing face detection and recognition technology for unlocking electrical vehicles (EV) has several societal implications. In a word, this technology not only brings convenience it also enhances the security for users. It makes the process of accessing vehicle more simple and easy, reduces the risk of theft, and potentially minimize the chance of losing physical keys. However, societal concerns arise regarding privacy and surveillance. Implementing facial recognition technology may lead to an increase in potential infringing on individual privacy rights. This is because users were concerned about who has access to the facial data and how it is stored.

In terms of health perspective, facial recognition technology may affect user's psychology due to the reason of continuing monitoring by the technology system. Indirectly, this can lead to stress and anxiety among users. The facial recognition in EV must be very sensitive and accurate in detecting user's face to avoid potential safety hazards. It is equally important to address functional safety in the communication layers, especially when facial data is transmitted over embedded networks [6].

System malfunction or misrecognition could lead to unauthorized access or system lock users out of their vehicles. Thus, reliability and accuracy of the facial recognition technology must be considered first before implementing the EV. When it comes into legal issues, engineers must ensure that their systems obey with local, national, and international laws regarding data protection and privacy. Issues such as data permission, storage, and sharing must be addressed in compliance with legal standards. Furthermore, there could be legal liabilities in case of system failures or breaches that lead to unauthorized access or harm. In some cultures, there is a high acceptance and trust in technology. Meanwhile, there is controversy and concern about privacy and surveillance. Engineers must consider these culture differences when designing and implementing facial recognition systems. One of the ways to address these issues is to carry out a survey with communities to understand their concern.

The main contributions of this research are as follows:

- The study implements a face detection and recognition system to enhance biometric security in electric vehicles.
- The proposed system integrates Principal Component Analysis (PCA) with Support Vector Machine (SVM) to improve facial recognition accuracy.
- A real-time face recognition system is deployed on a Raspberry Pi platform, ensuring a cost-effective and efficient security solution.
- The performance of the proposed system is evaluated using accuracy metrics and the Receiver Operating Characteristic (ROC) curve, achieving 95% recognition accuracy.
- The system offers a keyless vehicle access mechanism, improving user convenience while mitigating the risks of key theft and duplication.

The paper proceeds as follows: Section II reviews existing methods relevant to the current study. The proposed approach is presented in Section III. Section IV presents the experimental results, while Section V discusses the findings in detail. Section VI outlines the conclusions drawn from the study, and Section VII highlights the limitations and proposes potential directions for future work.

## II. Literature Review

A literature review is a critical overview and assessment of the body of work such as books, academic articles, dissertations, or conference papers that have already been published regarding a specific subject or research question. It involves reviewing, assessing, combining relevant materials to present a summary of the state of knowledge in a specific field or topic area. In this chapter, reviews on explanation on algorithm used, past studied, and project regarding the implementation of Facial Detection and Facial Recognition and all its component that will be explained.

In this study [7], the author has shown that there are three important stages in the structure of Face Recognition to produce a robust system. The first stage was face detection and obtain input either in image or video to locate the position of human

face. Secondly, the feature extraction was the stage to extract the unique feature of human face such as eyes, nose, mouth, and mustache for any human faces located in the first stage. Lastly, the stage of face recognition uses the features extracted from the human face to compare it with all templates faces in database to decide the human identity. Fig. 1 shows the structure of face recognition by [8].

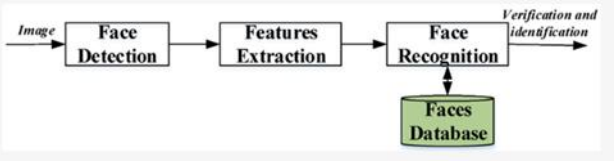

Fig. 1. Structure of face recognition.

### A. Face Detection

Face detection is an algorithm used to detect the presence of a human face, serving as a crucial preprocessing step for face recognition [9]. The system will create a box bounding if the human face is in detection, the box will be in green color [10]. One of the most famous algorithms used in face detection was Viola Jones's algorithm, known as Haar-Cascade algorithm.

### B. Haar-Cascade algorithm (Viola Jones's algorithm)

The algorithm was proposed by Viola and Jones in 2001. The algorithm is used in various applications that apply face detection because it can recognize faces in a real time video [11]. Human's facial features can be differentiated from a set of data image by using Haar feature. Haar features were proposed by Alfred Haar in 1909. The detector of cascade detects the face in the captured mage or real-time and face region is extracted. The face image was normalizing to remove the noise or unwanted information due to other factors while capturing the image [12].

### C. Face Recognition

Face recognition is a process of identifying or giving access to an individual using their face without physical contact with any hardware. Sun and Chen [13], originally proposed a method for face recognition. Today, this approach is widely used in modern systems. Face recognition is mostly used to identify people in photos, videos, or in real-time. In nowadays, the accuracy of face recognition system can be improved using machine learning, the system is trained using images of authorized users, and the accuracy of recognition can be enhanced [14].

### D. Principal Component Analysis (PCA)

PCA was proposed in 1901 by Karl Pearson, who introduced the idea and implemented it to non-random variables [15]. Harold Hoteling extends the concept of Karl Pearson to random variable in 1930. Nowadays the technique is applied in various fields, including mechanics, economics, medicine, and neuroscience. In computer science, PCA is used as a tool for data dimensionality lowering. In the era of Big Data, the data we process was large and complicated. Thus, PCA can reduce computational complexity and save computer storage. Next, face recognition benchmarks that used PCA have been achieved using machine learning and are applied in research and commercial application [16].

### E. Support Vector Machine (SVM)

SVM is an algorithm that was developed in 1990 by Vladimir N. Vapnik and his team [17]. SVM was mostly used in classification problems. The algorithm was recommended in solving binary classification. SVM can differentiate between two classes by calculating the optimal hyperplane that maximizes the margin between the closet data points of opposite classes. Furthermore, SVM can be categorized as a supervised deep learning algorithm, which is frequently used in the process of classification models and regression problems. Recent studies have also demonstrated the potential of SVM for secure, real-time decision-making in intelligent systems, including blockchain-based environments in the Internet of Medical Things (IoMT) [18].

### F. Related Works

In this research paper of using Facial detection and Facial recognition in EV using Raspberry Pi, the important key in this system was the algorithm that implement. Thus, researchers have reviewed several papers that propose different algorithms for face detection and face recognition. One of the papers by Khairul Anuar Ishak [19], presents a system using face detection and face recognition to unlock the door and ignite the engine of vehicle, the algorithm they used for face detection was the combination of Fast Neural Network and Convolution Neural Network while the algorithm used for face recognition was the combination of Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA). The study of the paper aim to improve the accuracy of face detection and face recognition when drivers want to access the vehicle. The combination of the algorithm used in the system shows the highest recognition rate and lowest misclassification rate. The system proposed in this research paper shows the total processing time for driver access to a vehicle with 5.1 seconds and the average recognition rate of 91.43%.

Another research paper by SL LIN and JY WU [20], the facial recognition system used FlagBlock building block program software of Flag Maker. The program creates a website for browser connections to use facial recognition, so that the user can get output and input of the information of D1mini. The author used mobile phone or computer browser as D1mini output interface. Principal Component Analysis (PCA) as the algorithm for analysis through the experiment, two-dimensional PCA was chosen by the author and found out that recognition correctness showed good results compared to the rate of accuracy of original image. 300 face photos were used for training for PCA analysis, and the test was carried out 100 times. The results for recognition rate were 92%. The success rate was dependent on the situations, such as lighting conditions, distance, and the angle of the face.

Next, authors Chaitanya Kolluru, Akhil GV and their colleague propose a research paper "Development of Face Recognition-Based Smart Door Lock System with Remote Servo Control Authentication" [21]. The proposed project used Haar-Cascade for the face detection, OpenCV library was used for image processing to detect the multiple faces. Then the author integrates the system with AdaBoost machine learning, the machine learning chooses the most relevant Haar-like features from a large number of features. The author used Dlib's algorithm for facial recognition, the algorithm uses deep metric learning by using a neural network called Reset. This method

learns a mapping from face image to a high dimensional feature space because some faces will have same feature from different people. The system used Raspberry Pi board with a camera module, Motion sensor responsible for motion detection during low-light condition while the servo motor control for door lock. The proposed system achieved 92.72 % of accuracy when the system was trained with 1000 image and achieve 80.24% accuracy rate in low light.

In [22], the research paper proposed a system to ignite vehicle using facial recognition. The system used Convolution Neural Network (CNN) models as the machine learning for to recognize the authorize person. During the training session, author choose four different people as input image for CNN models, each person has 500 of image. The backbone of the CNN model used for facial recognition have four layers and it will produce stage by stage using the same layer. The first layer was the input layer, this layer carried out images from the pre-processing stage. The second layer was the three stages of convolution layers, each consisting of a convolution operation and a rectified linear unit (Relu). The third layer implemented fully connected layer. The final layer was a dropout layer, utilizing four classes of face images in CNN model for facial recognition. The proposed model has achieved 98.3% of accuracy for face recognition.

The purpose of the project is to enhance the security of the vehicle by using face recognition to ignite the car's engine. The proposed system uses cascade detectors that recognizes the obtaining image and extract the feature of the face region. OpenCV was used for face recognition operation, the operation was done using variety of algorithm, including feature-based and model-based algorithm. The research paper stated that LDA (Linear Discriminant Analysis (LDA)) was better than PCA (Principal Component Analysis) when big training sets was applied in recognition. The accuracy of the proposed system achieved more than 80% when come into confirming the identity of user with the saved image of user in the system [23].

In this research paper [24], author has made an evaluation of the performance of facial recognition model based on multiple algorithms. Algorithms which are used were Support Vector machine (SVM), Local Binary Patterns Histogram (LBPH), Eigen faces (EF), Principal Component Analysis (PCA), and Linear Discriminant Analysis (LDA). The datasets used for the training was from ImageNet and Scikit Learn tool and was used to determine the accuracy, precision, recall, F1-Score and execution time for each method. The execution time for each algorithm can be rated as PCA<SVM<LBPH<LDA<EF. However, from the perspective of precision and accuracy of the algorithms, SVM performs better than another algorithm which are 98% for both perspective.

On the other research paper [25] by Asif Rahim and his team, they enhance the performance of face detection and facial recognition in smart home system by using logistic regression (LR), Hist gradient-boosting classifier (GBCs), and convolutional neural network. The reason for authors to enhance the system was because, the factors of illumination condition, facial expression, pose, occlusions and aging pose affected the accuracy of face recognition. The proposed models also compare with LR-XGB (XGBoost)-CNN, LR-CBC (CatBoost Classifier)-CNN, LR-GBC (GradientBoost)-CNN, LR-ABC(AdaBoost Classifier)-CNN, and LR-LGBM(LightGBM classifier)-CNN, and were evaluated based on their functionality using a dataset containing sensor readings and face images. Among these, the LR-HGBC-CNN model has shown a good results compared with other model because it achieved high scores across multiple metrics such as accuracy, precision, recall, F1 score, and AUC-ROC in both anomaly detection and facial recognition tasks. Specifically, the LR-HGBC-CNN model reached an accuracy of 94% for anomaly detection and 88% for facial recognition, indicating its robust capability in distinguishing normal and abnormal events as well as recognizing authorized faces in smart home environments.

In this research paper [26], the author develops a hardware that can capture image of kidnapper and perform face recognition on the suspect to help victims' family to rescue their children in shortest period. The face detection method used by the author was Viola-Jones algorithm. The author used Convolution Neural Network (CNN) to perform the facial recognition system [27]. The dataset that was used by author was AT&T database, Celab Faces Attributes dataset, and face dataset that are collected by author and the outcomes are 87.50%, 92.19% and 95.93% respectively. Overall face recognition accuracy was 98.48%.

In [28], author had demonstrated the face recognition using algorithm Local Binary Pattern Histogram (LBPH). The objective of the study was to produce a biometric security system for better function. The biometric system was integrated with augmented reality (AR) and the face recognition rate was achieved at 90% in bright lighting conditions.

In this research paper [29], the study focuses on developing a system that can process fast face recognition so that it can monitor student attendance in smart classroom. The proposed method based on Convolution Neural Network (CNN) and able to detect 30 faces out of 35 detected faces [30]. They use Edge Computing for processing the data at the edges of the nodes to reduce the data latency and enhance the real time response. Their proposed system had made accuracy of 85.5% in face recognition and 94.6 % in face detection.

From [31], author had developed a face recognition for absence information system. The study stated that the face recognition system can apply Principal Component Analysis (PCA) and Support Vector Machine (SVM). The author used customize dataset which is 100 facial data for test data and training data. The system test results showed that the use of PCA and SVM as a classifier can achieve a high level of correctness. The training included the facial image, 91% of the identification was correct.

While numerous studies have explored face recognition using PCA, LDA, CNN, and other algorithms, most have focused on controlled environments or high-performance computing platforms. Few have investigated the feasibility of integrating PCA and SVM for real-time face recognition on embedded, low-cost platforms such as Raspberry Pi [32], [33]. Additionally, although prior works achieved recognition accuracies ranging between 85% to 92%, there is a lack of comprehensive evaluations that simultaneously address execution time and recognition accuracy in EV security

contexts. This study aims to fill this gap by implementing and evaluating a PCA + SVM-based face recognition model on Raspberry Pi, emphasizing both security performance and real-time responsiveness, specifically for EV access systems.

## III. PROPOSED METHOD

To develop a system that can recognize human facial using Raspberry Pi module, a hardware device such as Raspberry Pi 4 module, is used to capture the face image of the authorize person, which serve as input image to the facial recognition. A custom face dataset is necessary for training and testing the correctness of the proposal system. The components used for the hardware are the Raspberry pi 4 module, LED light, PIR Motion Sensor, Camera Pi module, breadboard, Lan cable, and power adapter [34]. To make the Raspberry Pi as a standalone hardware for face recognition system, MATLAB software is used for deep learning in facial detection and facial recognition [35]. After the accuracy of the system is reached as our objective which is to achieve more than 95%, the program will be deployed to the Raspberry Pi board through LAN cable. Fig. 2 shows the block diagram of the system. Several studies have explored similar microcontroller-based integrations using ESP32, ESP8266, and Arduino platforms for IoT and control applications [36], [37] and [38], validating their effectiveness in real-time monitoring and system automation.

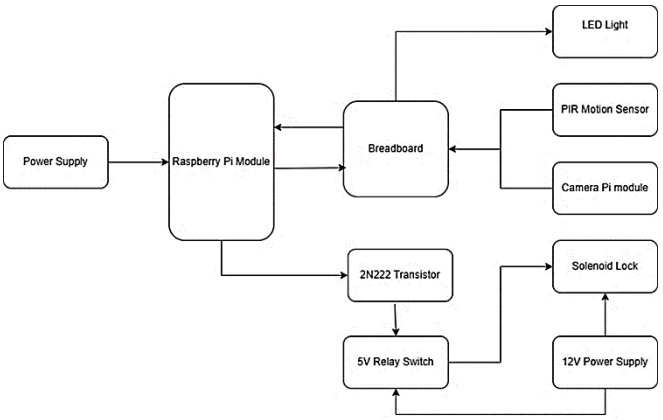

Fig. 2. Raspberry Pi face recognition block diagram.

### A. Programming Flowchart

Based on Fig. 3, the flowchart shows a person's facial feature is set and recorded as a template in the database before the face recognition process start. The system (Raspberry Pi) was powered by a 5V direct current and will always be in the standby mode. The motion sensor will detect the presence of human and turn on the system, the system starts detecting and isolate a human face in a rectangle that indicate the region of interest. After that the camera will capture the image through the camera module (Raspberry Pi Camera module) [39]. If fail to capture the human's face the system will deny the access. After the capturing is successful, the captured human's face will be compared to the face template that is set on the database. After that, the system would make decision, if the face matched with the face template in the database, then the access will be granted. However, for the unmatched face, the system will show a message "Access Denied".

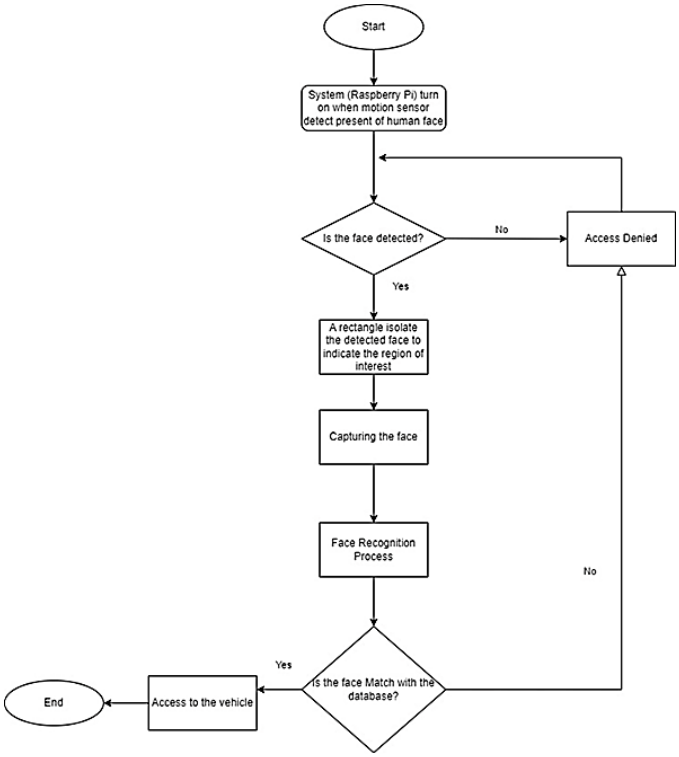

Fig. 3. Programming flowchart.

### B. Dataset

A dataset is important for face recognition system. When it comes to stage for testing the accuracy of the algorithm, a quality dataset ensures that the algorithm is able to differentiate one face from another. This includes understanding in facial features, angle, and lighting conditions. When an algorithm was trained and achieve high accuracy of face recognition, meaning it can accurately recognize faces it has never seen before by using the general features of human faces. To achieve high accuracy of face recognition. Researchers use AT&T dataset which consists of 400 human faces and a custom set of databases which consists of 200 human faces to test the system efficiency.

### C. Algorithm

The method used to design the proposed work was the combination of Principal Component Analysis and Support Vector Machine (SVM) to develop a facial recognition system. Viola- Jones's algorithm is vital in the face recognition as it is the first step in face recognition. This algorithm developed for general object detection, and it can be trained to an algorithm that can detect human face only. According to [40], there are four main steps in Viola- Jones's algorithm which were Choosing Haar-like features, creating an integral image, Running Adaboost training, and Creating classifier cascade. An input data (image) is segmented into tiny of size NxN and convert into rectangle area and features are calculating individually every single rectangle. Human face have shared some similarities, for an instance, the nose region tends to be brighter than the mouth region and the eye region are typically darker compared to the forehead. Fig. 4 shown the basic Haar-like Rectangle features.

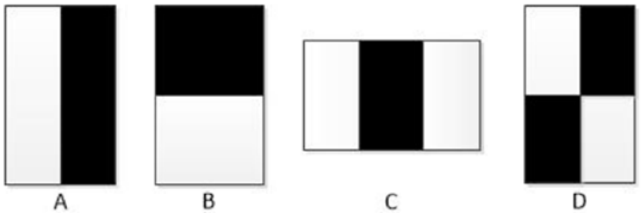

Fig. 4. Basic Haar-like rectangle features.

Haar-like features are efficiently calculated apply an intermediate representation known as the integral image, which accelerates computation. In Eq. (1), it computes the integral images. Total of the pixels above and left of (x, y) was included in the integral image which locate at x, y.

$$(x,y) = \sum_{s=1}^{x}\sum_{t=1}^{y} I(s,t); 1 \le x \le M, 1 \le y \le M \quad (1)$$

The integral image was represented as 'A' as shown in Fig. 5. The original image is represented by 'I'. The rectangular region represents as 'M'. The integral image at location 1 in Fig. 5 equals to the total of the region 'A'; while in location 2, A+B is the sum of pixels in region; the total pixel in region C+A was located at location 3; lastly, the summation of the pixel in the region A+B+C+D is locating at location 4.

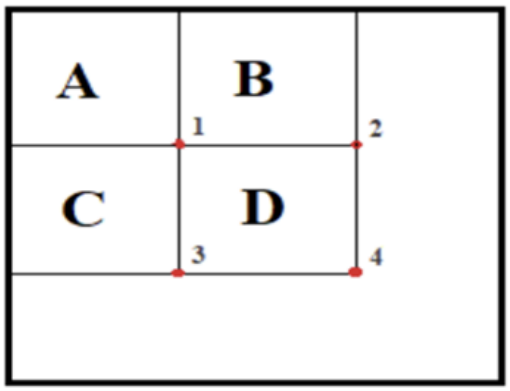

Fig. 5. Integral image formation.

Adaboost algorithm used to reduce the redundancy because the Haar features calculate in every single window is very huge (estimate 180000). The majority of the features are unnecessary. Cascading classifiers [41] will reduce the number of calculated images and selecting the perfect features in every window. PCA is utilized to extract features from the segmented images, serving as the basis for the recognition process by preserving essential information while reducing data dimensionality. To enhance the recognition technology's performance, a beta prior is incorporated, and a full-probability Bayesian model is developed, offering an improvement over the conventional PCA approach. Face recognition technology, as a biometric identification method, leverages computer vision to analyze facial images and identify key feature points such as the eyes, nose, and mouth. Fig. 6 shows the steps for cascaded classification by stages [42].

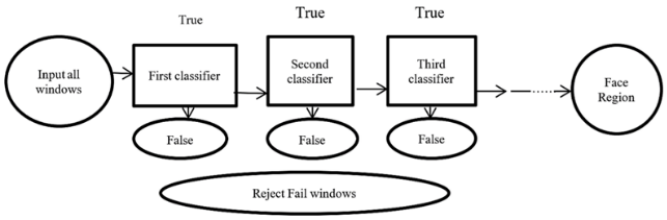

Fig. 6. Steps for cascaded classification by stages.

There are three formulas, Eq. (1), Eq. (2), Eq. (3) used in Principal Component Analysis which were mean, standard deviation and variance.

$$\bar{x} = \frac{\sum_{i=1}^{n} x_i}{n} \quad (2)$$

$$s = \sqrt{\frac{\sum_{i=1}^{n}(x_i - mean)}{n-1}} \quad (3)$$

While the data is often multi-dimensional in computer science. The relationship between two random variables can be described through covariance, Eq. (4):

$$cov(X,Y) = \frac{\sum_{i=1}^{n} X_i - mean\ of\ X(Y_i - mean\ of\ Y)}{n-1} \quad (4)$$

Multiple covariance needs to be calculated as Eq. (5) as the dimension increases. For example, the quantity of covariances required for handling n-dimensionally data:

$$\frac{n!}{(n-2)!*2} \quad (5)$$

Eq. (6) shows the matrix methos give a solution for this solution:

$$C_{n*n} = \left(c_{i.j}, c_{i.j} = cov(Dim_i, Dim_i)\right) \quad (6)$$

Covariance matrix, Eq. (7) was a dataset in three dimensions {x, y, z}:

$$C = \begin{pmatrix} cov(x,x) & cov(x,y) & cov(x,z) \\ cov(y,x) & cov(y,y) & cov(y,z) \\ cov(z,x) & cov(z,y) & cov(z,z) \end{pmatrix} \quad (7)$$

It can be observed that the covariance matrix is a symmetric matrix because the diagonal shows the variance of each dimension. After obtaining the covariance matrix, eigenvalues and eigenvector can be calculated using Eq. (8):

$$A\alpha = \lambda\alpha \quad (8)$$

'A' stands for the original matrix while λ stands for an eigenvalue of A, and α represents the eigenvector according to eigenvalue λ. The study in [43] shows two stages in face recognition using Principal Component Analysis which are training stage and testing stage.

In [44], [45] and [46], Support Vector Machine (SVM) method in machine learning, valued for its capability to handle high-dimensional data and its robustness against noise. Praised for its ability to manage high-dimensional data and its resilience to noise. In the context of a set of training data (Xi, yi), where, Xi represents the feature vectors and yi denotes the class labels, the purpose of SVM is to determine the optimal hyperplane. Below is shown the Eq. (9):

$$W^T x + b = 0 \quad (9)$$

W represents the impact vector, x denotes the input feature vector, b is the bias term. This purpose is to maximize the margin between the hyperplane and the support vector, which are the closet points to the hyperplane form both classes. The optimization problem can be formulated as Eq. (10):

$$\min(w, b)\frac{1}{2}||w||^2 \quad (10)$$

Subject to Eq. (11):

$$y_i(w^T x_i + b) \geq 1 \quad (11)$$

The accuracy of the proposed work can be measured by using the formula, Eq. (12) by [47], [48] which were using True positive, True Negative, False Positive, and False Negative:

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} * 100\% \quad (12)$$

ROC curve represents the curve of sensitivity (True positive rate) against 1-specificity (False Positive Rate) while varying the threshold. Different cut-off points are responsible for generating this graph. The AUC (area under the curve) quantifies the effectiveness across various test thresholds on the ROC curve. Fig. 7 shows an example test with an AUC of 1.0 is very accurate as the sensitivity reaches 1.0 while specificity also archives 1.0.

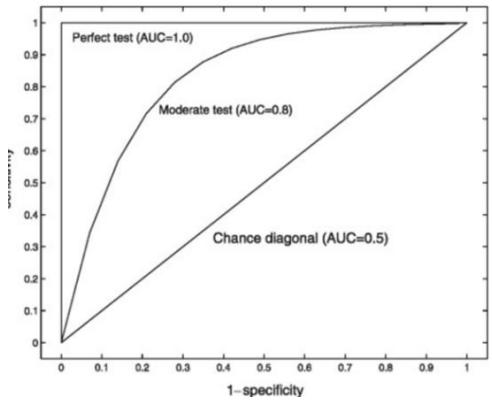

Fig. 7. ROC curve.

### D. Circuit Design

Fig. 8 shows the circuit connection between Raspberry Pi module, Relay Switch, 12V battery, Solenoid lock, Pi Camera Module, and PIR sensors. In this project, researchers use Raspberry Pi GPIO pin to communicate with other components. Below Fig. 9 shows the GPIO pin with label for better understanding.

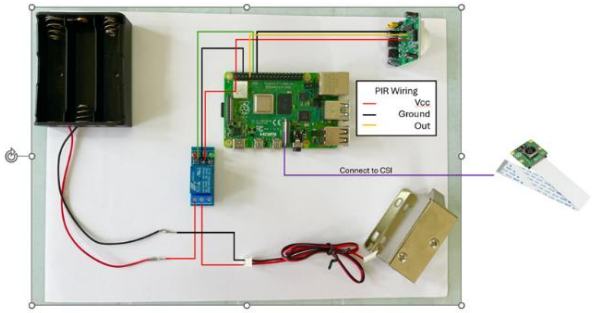

Fig. 8. Circuit design.

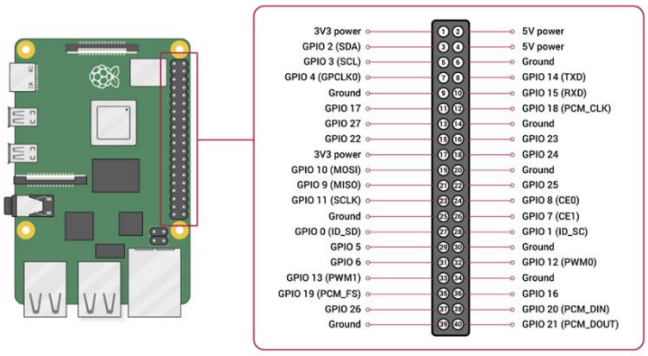

Fig. 9. GPIO pin in Raspberry Pi.

## IV. Result

The proposed work starts with testing the algorithm in MATLAB software by using the application of classification learner. The dataset of 10 people was prepared and divided into classes, each class contain 10 images. After that, the dataset was converted into table firm since the classification learner only accept dataset in table form. The classification learner can analyze the reliability of the input dataset by using the algorithm of PCA and SVM. Fig. 10 shows the results of using classification learner to test the input dataset:

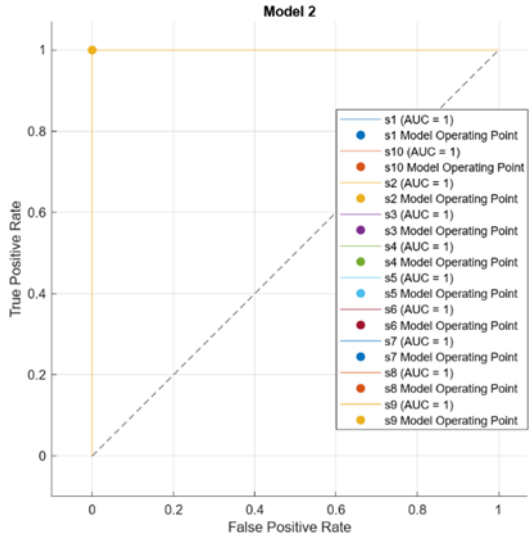

Fig. 10. ROC Curve for 10 people.

From the ROC, each person was named for ‘s’. Thus, there were 10 class, and each class represented a different person. The area under the ROC curve (AUC) represents the probability that the model. From the results, we can conclude that every class where, the area under the curve (AUC) were 1.0, which mean the classifier can perfectly differentiate between positive and negative classes.

### A. Test the Custom Face Database with PCA and SVM

The custom face dataset was needed to pre-process by converting the images into table form before the training session. Before converting the images into table form, the dimensions of images were fixed at 180 (width) x 200 (height). The number of components was a crucial step in determining the accuracy of the model. If fewer components were selected it would reduce

computational complexity but may lose some information. However, more components retain more information but increase complexity. In this part, researchers used 50 components for 250 images to test the performance of the model. The Fig. 11 shows the accuracy of the training results:

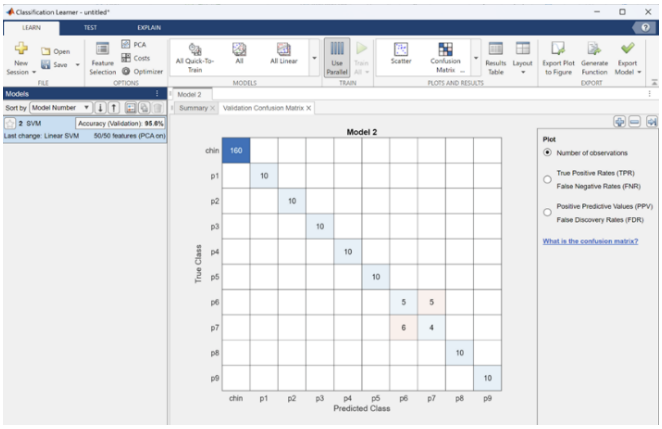

Fig. 11. The Acccuracy using PCA and SVM using 250 images.

To test the accuracy of the proposed face recognition model, the True Positive (TP), True Negative (TN), False Negative (FN), and False Positive (FP) were recorded in Table I. The table shows the value of each class in model training:

TABLE I. FACE RECOGNITION RESULTS OF CUSTOM DATABASE

| Class | Testing Images | TP | TN | FN | FP | Accuracy |
|---|---|---|---|---|---|---|
| chin | 10 | 10 | 0 | 0 | 0 | 100% |
| P1 | 10 | 10 | 0 | 0 | 0 | 100% |
| P2 | 10 | 10 | 0 | 0 | 0 | 100% |
| P3 | 10 | 10 | 0 | 0 | 0 | 100% |
| P4 | 10 | 10 | 0 | 0 | 0 | 100% |
| P5 | 10 | 10 | 0 | 0 | 0 | 100% |
| P6 | 10 | 5 | 3 | 0 | 2 | 80% |
| P7 | 10 | 4 | 3 | 1 | 2 | 70% |
| P8 | 10 | 10 | 0 | 0 | 0 | 100% |
| P9 | 10 | 10 | 0 | 0 | 0 | 100% |
| | Total | 89 | 6 | 1 | 4 | - |
| Average Accuracy | | | | | | 95% |

The table presents the classification performance of a model across ten different classes, each with 10 testing images, totaling 90 images. The model achieved perfect accuracy (100%) for most classes, including chin, P1, P2, P3, P4, P5, P8, and P9, correctly identifying all instances. However, performance dropped for P6 and P7, with accuracies of 80% and 70%, respectively, due to false positives and false negatives. The overall accuracy of the model is calculated at 95%, indicating strong general performance. The errors in P6 and P7 suggest potential challenges in distinguishing these classes, which may require further investigation, such as improving feature extraction, enhancing the dataset, or optimizing the model parameters. Expanding the testing dataset could provide additional insights into performance trends and areas for improvement.

The execution time was measured using the average method, where the test was conducted 20 times to ensure consistency and reliability of the results. Table II shows the recorded time and average time for the code execution:

TABLE II. AVERAGE TIME FOR CODE EXECUTION

| Test | Time (s) |
|---|---|
| 1 | 2.32 |
| 2 | 2.45 |
| 3 | 2.37 |
| 4 | 2.32 |
| 5 | 2.54 |
| 6 | 2.29 |
| 7 | 2.29 |
| 8 | 2.29 |
| 9 | 2.28 |
| 10 | 2.30 |
| 11 | 2.31 |
| 12 | 2.27 |
| 13 | 2.28 |
| 14 | 2.33 |
| 15 | 2.31 |
| 16 | 2.38 |
| 17 | 2.39 |
| 18 | 2.30 |
| 19 | 2.28 |
| 20 | 2.28 |
| Average | 2.32 |

### *B. Test the Face Recognition with Raspberry Pi*

After the testing had done in MTALAB, the proposed work has been moved into Raspberry Pi to test. When there is presence of face, region of interest (ROI) will isolate the face region and capture the image [49]. The purpose of doing this is to carry out a real time facial recognition in Raspberry Pi to let user unlock the vehicle door. Fig. 12 shown the results of using Raspberry Pi execute the command.

Fig. 12 also shows the results when authorized face was detected. While Fig. 13 shows the results when unauthorized face was detected and ‘unknown’ was shown in the window screen.

The time for the system detects the face was 2.32 seconds by using the average method to calculate the time. While the accuracy when compared with previous work had shown that the accuracy has been improve using PCA and SVM. Table III shows the comparison of the accuracy.

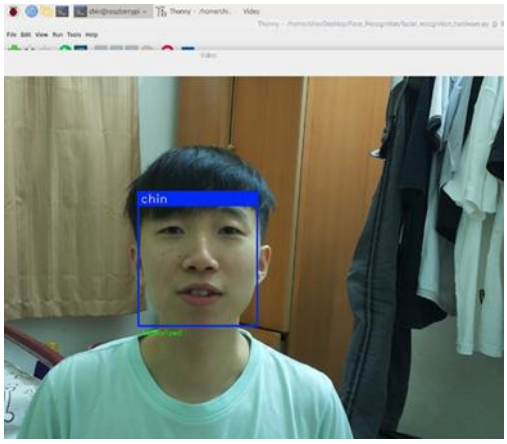

Fig. 12. Face recognize using Raspberry Pi.

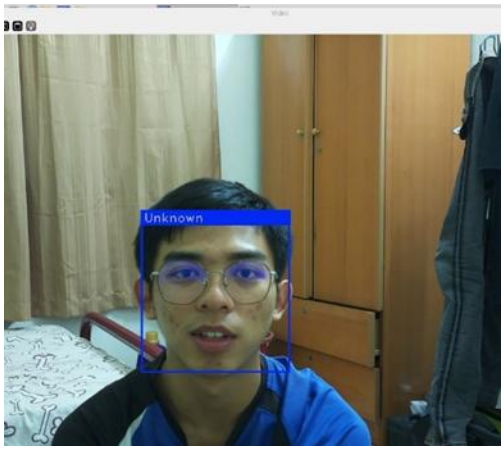

Fig. 13. Unauthorized faces detected.

TABLE III. COMPARISON OF ACCURACY IN FACE RECOGNITION ALGORITHM

| Ref. | Algorithms used in Face Recognition | Database | Accuracy (%) |
|---|---|---|---|
| [15] | PCA + LDA | Customize | 88.75 |
| [16] | PCA | Customize | 92.00 |
| [17] | Haar-Cascade + Dlib's face recognition | Customize | 92.72 |
| [20] | PCA +LDA | Customize | 80.00 |
| [23] | CNN | AT&T | 87.50 |
| [24] | LBPH | Customize | 90.00 |
| [25] | CNN | WILDS | 85.5 |
| [26] | PCA + SVM | Customize | 91.00 |
| Proposed algorithm | | Customize | 95.00 |

The accuracy of facial recognition using a different algorithm and database is recorded in Table III. Compared to existing studies, the proposed PCA + SVM-based facial recognition model offers several distinct advantages. First, it achieved the highest recorded accuracy of 95% among all reviewed works, surpassing traditional PCA + LDA, LBPH, CNN, and Dlib-based methods. Second, the model maintained low execution time (2.32 seconds), demonstrating real-time capability on a resource-constrained Raspberry Pi platform—something not addressed in most prior works. Additionally, unlike many previous implementations that rely on high-performance systems or require complex hardware integration, this model offers a cost-effective and scalable solution suitable for embedded vehicle environments. These advantages validate the practicality and effectiveness of the proposed system for EV security applications.

## V. DISCUSSION

From the outcome, researchers have achieved all the objectives which is to achieve more than 95% accuracy of facial recognition, use ROC curve to analyze the accuracy of the face recognition, and develop the Face recognition using Raspberry Pi. When the system captures the human face, the system will undergo Principal Component Analysis to extract the significant features of the face and undergoes Support Vector Machine (SVM) to improve predictive accuracy. Before the software was implemented into Raspberry pi board, the software was evaluated with Receiver Operating Curve (ROC), the curve uses a graphical to measure the performance of a classification model. It plots the trade-off between the True Positive Rate (TRP) and the False Positive Rate (FRP) at various threshold settings. The environment must have enough lighting to make sure the camera can capture a clear facial image. The average time for the system to recognize an authorized face was about 95% and the time execution was 2.32 seconds.

The theoretical foundation of this work—specifically the use of Principal Component Analysis (PCA) for feature extraction and Support Vector Machine (SVM) for classification—is motivated by the need to implement a high-accuracy, real-time face recognition system on a resource-constrained embedded platform. By validating these algorithms through MATLAB and then deploying them on a Raspberry Pi, the study demonstrates the practical viability of transferring machine learning theory into real-world automotive security systems. This approach not only strengthens biometric security in electric vehicles but also showcases the potential for broader applications in other IoT-based systems requiring fast and reliable biometric authentication.

The validation of the proposed facial recognition system was performed using both a standard (AT&T) and custom dataset. We evaluated the model using precision metrics, including ROC curves and AUC scores. The AUC consistently reached 1.0 across 10 classes in the ROC test, indicating perfect classification performance. Furthermore, Table III provides a comparative analysis of our model against other recent approaches, highlighting superior accuracy and real-time responsiveness.

The accuracy of facial recognition using a different algorithm and database is recorded in Table III. The results show the accuracy of the proposed algorithm has the highest compared to other previous studies. The proposed algorithm proved that the accuracy of the PCA + SVM was improved compared to previous studies. This also shows that the objective number two was achieved by using SVM to analysis the system.

## VI. CONCLUSION

This thesis presents the development and implementation of face detection and face recognition systems using Principal

Component Analysis and Support Vector Machine (SVM). The proposed system was divided into two parts, the first part was to analyze the reliability of the system using MATLAB software. After the system achieved 95% of accuracy above, the system was implemented in Raspberry pi board to test out with the component. The combination of both parts ensured work as a standalone device to let driver using shortest time to access their EV and increase the security of the vehicle.

This research also aimed to identify the best methods for the proposed Principal Component Analysis (PCA) and Support Vector Machine (SVM). To increase the accuracy of the system, the training photo was important, which is the size, number of training images and the resolution choose. At first the system was trained at 100 images and the accuracy was not achieved, then the training image was increased to 200 images, the accuracy improveed to 95% above. This shows that the more training images the higher the accuracy of the system.

## VII. Limitation and Future Works

The limitation of the proposed methodology is that, it is time consuming in creating the face dataset. More images indicate that more individuals are required to create a customized dataset. Next, the quality of the images, the training images must have the same properties in terms of size, resolution and lighting of environment. There is also a limitation for the system which is the system can recognize a photo of an individual which means an individual can use a photo to access the system. The proposed system was aimed at improving the security of nowadays EV. The system can be installed on the door frame of the vehicle. The system ensures that only authorized person can have access to the vehicle. Besides, the proposed system can also be implemented in the home security system.

## Conflicts Of Interest

The authors declare no conflict of interest.

## Acknowledgment

The authors extend their appreciation to Universiti Teknikal Malaysia Melaka (UTeM) and to the Ministry of Higher Education of Malaysia (MOHE) for their support in this research.

## Authors' Contributions

The authors' contributions are as follows: "Conceptualization, Jamil Abedalrahim Jamil Alsayaydeh and Chin Wei Yi; methodology, Fatimah Abdulridha Rashid; software, Jamil Abedalrahim Jamil Alsayaydeh; validation, Fatimah Abdulridha Rashid; formal analysis, Chin Wei Yi; investigation, Jamil Abedalrahim Jamil Alsayaydeh; resources, Fatimah Abdulridha Rashid; writing—original draft preparation, Jamil Abedalrahim Jamil Alsayaydeh and Safarudin Gazali Herawan; writing—review and editing, Chin Wei Yi and Rex Bacarra; funding acquisition, Rex Bacarra and Safarudin Gazali Herawan.

## Data Availability Statement

All the datasets used in this study are available from the Zenodo database (accession number: https://zenodo.org/records/15034216).

***Abstract*—Without the requirement for third-party approval, cryptocurrency enables anonymous, secure, quick, and inexpensive financial transactions. Although cryptocurrency is gaining global popularity, its applications are still limited. This research aims to investigate the factors influencing the acceptance of cryptocurrency as an investment tool, focusing on the moderating role of government policy. Using the Unified Theory of Acceptance and Use of Technology (UTAUT) extended with awareness, security, and trust, a survey was conducted with 220 respondents. Structural Equation Modelling (SEM) was employed to analyse the data. The findings revealed that the usage of cryptocurrencies is significantly affected by performance expectancy, facilitating conditions, social influence, awareness, and security in investment. However, trust does not affect the acceptance of cryptocurrency as an investment. The outcomes generate vital insights and strategies for cryptocurrency users, offering a crucial examination for stakeholders and professionals keen on understanding the underlying dynamics of cryptocurrency acceptance in investment.**

***Keywords*—Cryptocurrency; acceptance; investment; UTAUT; government policy***

## I. INTRODUCTION

Globalisation has recently improved many facets of people's lives, communication techniques, and company processes, bringing about major changes [1]. Although its effects haven't been uniform, humanity's global interconnectedness has opened up new opportunities [2]. Concerns over the impacts of globalisation have been highlighted by a few corporate scandals that have received criticism [3], [4]. Cryptocurrency, also referred to as payment tokens, crypto tokens, electronic currency, cyber currency, virtual commodities, and virtual assets, these digital currencies work similarly to physical currency but conducts transactions via blockchain technology [5]-[7]. Cryptocurrency allows for peer-to-peer transactions directly, circumventing banks and government regulation, in contrast to traditional currency [8], [9]. This gives cryptocurrency users alternatives to fiat money or debit/credit cards [10]. Bitcoin is considered to be the original cryptocurrency, having been created by Satoshi Nakamoto in 2008.

Cryptocurrency is becoming used for more than only small-scale transactions like Bitcoin trading and hiring programmers [11]. Pizzas were purchased for 10,000 Bitcoins, or $25 at the time, in the first known business transaction, which is an interesting turning point in the history of Bitcoin. This transaction signalled the start of the currency's exponential rise in value. Within the category of crypto-assets, digital currency was recognized as an investment and has developed into a speculative tool for short-term trade. Bitcoin, in particular, has become a commonly recognised medium of exchange and transaction currency despite fluctuating significantly [12]. By 2021, the price of a single Bitcoin was about USD 67,000, indicating a significant increase from its launch twelve years earlier. Notably, El Salvador was the first country to officially recognize Bitcoin as a legal tender, which helped it become well-known worldwide [13]. Although its prices are still unregulated, Bitcoin trading works differently because it occurs on licensed exchanges. Since its debut, several new cryptocurrency investment products and exchange-traded funds have been introduced, further solidifying Bitcoin's reputation as a credible trading and investing option. It was thought that cryptocurrency could be a game-changing technology that could solve enduring problems in business and finance [14]. Similarly, as of May 2020, about 5,400 distinct cryptocurrencies were available. Bitcoin has the highest market capitalization at US $160 billion [15]. This translated into around 300 million cryptocurrency users worldwide, with 5.8 to 11.5 million active wallets. These developments highlight the potential for cryptocurrencies to transform the established financial system and establish themselves as a significant medium of exchange [16]. However, despite these achievements, the scope and geographic reach of Bitcoin adoption and spread are still somewhat constrained. [17]. Consequently, cryptocurrency has yet to fully realise its potential, as widespread acceptance is still lacking [18]. Researchers critically studied cryptocurrencies, mostly concentrating on their application in Western settings [19], [20], as such academic research on cryptocurrencies is still limited, particularly in developing nations [21]. Researchers like [22], [23] observed that although cryptocurrencies are growing in underdeveloped countries, they are still in their infancy. Furthermore, only a limited number of stakeholders regularly interact with this currency, even though many have a sufficient understanding of it [24]. The conversation around cryptocurrencies did not take off until 2011, and reputable peer-reviewed journals did not publish articles about cryptocurrency until 2013 [25]. As a result, knowledge about cryptocurrencies is still scarce, especially regarding other well-known financial technologies like internet banking or mobile payments. Furthermore, prior studies on blockchain adoption and cryptocurrencies have mostly concentrated on advanced countries such as the USA and the UK [26], [27].

As a result, a limited amount of literature has been done on the acceptability of cryptocurrencies in the investment field [28], [29]. Likewise, research has frequently disregarded the viewpoints of Bitcoin users [30] and the key determinants of

cryptocurrency acceptance, like risk, trust, and security, which have not received enough attention [31]. Specifically, the acceptance of cryptocurrency in investment remains largely unexplored [32], [33]. Correspondingly, policies are significant in promoting broad acceptance and utilization of new financial technology by increasing consumer confidence and awareness [34]. Thus, adopting cutting-edge technology could improve a nation's economic strength and the independence of its people, especially in emerging nations. People have yet to engage in cryptocurrency trading despite the ban. People who trade cryptocurrencies frequently use foreign brokers or more conventional techniques like sending money to broker accounts or paying cash directly to currency owners electronically. Hence, this study seeks to explore the determinants affecting the use of cryptocurrency in investment. It aims to fill existing gaps in the literature on cryptocurrency acceptance by examining investor behaviour in the context of emerging economies. To address this, the study is guided by the following objectives:

- To examine the influence of performance expectancy, social influence, facilitating conditions, awareness, security, and trust on the acceptance of cryptocurrency in investment.
- To test the moderating effect of government policy on the relationship between performance expectancy and social influence with investment acceptance.

Accordingly, the study seeks to answer the following research questions:

- What are the key factors influencing the acceptance of cryptocurrency in investment?
- Does government policy moderate the relationship between performance expectancy/social influence and cryptocurrency investment acceptance?

## II. Literature Review

The acceptance of cryptocurrencies has been of interest to several literature reviews. The technical components of understanding cryptocurrency acceptance have been the topic of one line of research. Perceived benefits and innovation traits (compatibility, observability, and trialability) impacted attitudes towards Bitcoin and the intention to accept it favourably, according to research that combined the risk-benefit concept, transaction cost theory, theory of planned behaviour, and innovation diffusion theory [35]. It was claimed that the behavioural intention to use cryptocurrency was influenced by performance expectancy, effort expectancy, and facilitating factors, according to [36], who used the UTAUT framework. In addition, another study that employed a multi-method approach found that travellers primarily weighed security, usability, and prices when deciding to use cryptocurrency [37]. Furthermore, related studies have recognised technology attachment and blockchain transparency as essential factors for fostering trust in cryptocurrency and promoting its commercial adoption among the public [38]. Scalability, transparency, privacy, credibility, and ethical issues were noted in a systematic assessment as barriers to crypto adoption [39]. Accordingly, studies on Bitcoin usage indicate they are a good choice for investors who want to increase profits while successfully lowering total risk through sensible diversification techniques.

Equally important, current research indicates that human behavioural factors significantly influence cryptocurrency acceptance. According to a comparative study that used the theory of planned behaviour as a framework, social media use influenced consumers' subjective criteria and opinions about Bitcoin, which influenced the acceptance of the cryptocurrency [40]. Similarly, another study emphasized how crucial the theory of planned behaviour is for elucidating intentions to adopt Bitcoin, with attitude, subjective norms, perceived behavioural control, and trust serving as vital motivators [41]. The fuzzy analytic hierarchy exploration assessed the importance of factors influencing Bitcoin investment. Their analysis identifies social influence as the paramount component, succeeded by favourable situations and perceived usefulness [42]. Recently, a comparable study conducted research focused on identifying factors influencing cryptocurrency within investments made by investors from Malaysia. Compatibility, trialability, ease of use, and complexity positively affected cryptocurrency adoption.

Similarly, cryptocurrencies continue to experience low acceptance in investment, and cryptocurrency awareness is frequently associated with younger generations and lower educational levels. Empirical studies investigating the acceptance of cryptocurrencies in investment are severely lacking in this area. However, the majority of research focused on the fundamental elements that affect Bitcoin adoption. On the other hand, the factors influencing the adoption of cryptocurrencies in investment have been the subject of very few studies. Therefore, this study's primary objective is to explore the underlying dynamics influencing investors' acceptance of cryptocurrencies.

Existing research about cryptocurrency acceptance continues to expand, yet several fundamental barriers still need resolution. Current research mainly examines cryptocurrency usage between peers and general usage while missing its adoption patterns in structured investment frameworks. Most previous research has been conducted in studies of technologically advanced Western economies, which has created a gap in empirical understanding regarding regulatory uncertainty and varied technological readiness between developing nations. Examining government policies' effects on individual cryptocurrency investment behaviour remains scarce in current academic research. Consequently, this study tackles these weaknesses to provide a more contextualized, policy-aware model of cryptocurrency investment acceptance. It extends the UTAUT by combining it with external variables incorporating awareness, security and trust to better model cryptocurrency investment behaviour. The study adopts government policy as a new moderating factor while integrating important external variables such as awareness, security and trust into its empirical model structure. The extension of the UTAUT model with security awareness and trust dimensions delivers a stronger policy-oriented description of cryptocurrency investment behaviours in emerging markets. Subsequently, this study establishes itself as a significant addition that completes theoretical voids while improving real-world understanding.

## III. Research Framework

The most significant determinants of behavioural intention to use technology are the UTAUT characteristics of social influence and performance expectancy [43]. Additionally, little research was carried out on concepts like social influence and conducive conditions [44]. The present study was theoretically grounded in the UTAUT paradigm. Security and awareness were added to the UTAUT model to increase its predictability [45]. Users' security concerns prompted the use of the structures. Performance expectancy, social influence, facilitating conditions, awareness, security, and trust were suggested as predictors of whether or not people would embrace cryptocurrency in investment (ACI), as shown in Fig. 1.

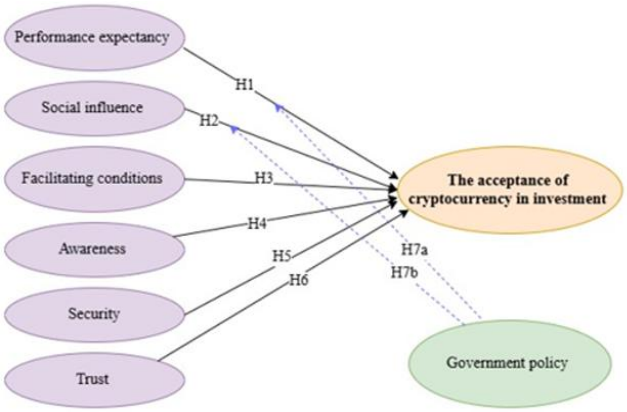

Fig. 1. Research framework.

## IV. Hypotheses Testing

### A. Performance Expectancy

Performance Expectancy (PE) is the level to which individuals believe using cryptocurrencies would help them do their jobs better [46]. Current research on cryptocurrencies indicates that performance expectancy is one important aspect influencing people's use of cryptocurrencies [47]. Cryptocurrencies are structured on the Blockchain technology. In addition to offering more advantages to users, the technology has solved the issues with traditional payment methods like PayPal and credit cards [48]. The introduction of cryptocurrencies is anticipated to increase user convenience in financial transactions. Transaction efficiency, for instance, might be improved [49]. The fund transfer procedure is improved, and transaction costs are reduced when central financial institutions are eliminated [50]. Numerous studies have found that performance expectancy robustly impacts users' behavioural intentions to use Bitcoin [51]. In this regard, performance expectancy was an important driver of behavioural intention to utilise cryptocurrencies [52]. Nonetheless, it was pointed out that performance expectancy had a detrimental effect on behavioural intention to use cryptocurrency [53]. As a result, the findings of the prior investigations contradict one another. The findings are inconclusive. Further research is needed on the relationship between performance expectancy and cryptocurrency acceptance in investment. Thus, this study hypothesises:

H1. Performance expectancy is positively related to the acceptance of cryptocurrency in investment.

### B. Social Influence

Social influence (SI) is related to the degree to which people believe that their family members and peers are influencing them to use cryptocurrencies [54]. According to earlier studies, peer groups, family members, and other current technology users' attitudes greatly impact a person's behavioural intent to use technology [55], [56]. The literature also highlights how effective word-of-mouth is at influencing people's opinions. According to several research studies, the behavioural intention to use innovation is positively influenced by social effects [57]. Similarly, [58] highlighted the impact of social influence as a motivator for users' intent to use cryptocurrency. Therefore, people's inclinations to adopt cryptocurrencies are positively impacted by social influence [58]. However, social influence was reported to have a negligible impact on the acceptance of cryptocurrencies [59]. Social influence significantly impacts consumers' intention to utilize new technology when they know little about it [60]. Since cryptocurrency is a relatively new technology, users don't know much about it. Therefore, it is anticipated that consumers' behavioural intention to embrace Bitcoin as an investment will be positively influenced by friends or loved ones' positive influence regarding the advantages of cryptocurrency. It was claimed that individuals' intentions to adopt cryptocurrencies are positively impacted by social influence [61], [62]. Thus, this study formulates:

H2. Social influence is positively related to the acceptance of cryptocurrency in investment.

### C. Facilitating Conditions

Facilitating Conditions (FC) were characterized as customers' opinions on the accessibility of the technology infrastructure and support required to embrace cryptocurrency [63]. When resources and assistance are available, people are more likely to use technology [64]. Since cryptocurrencies are a quickly developing technology, there isn't enough infrastructure or legal framework to support their use. Additionally, virtual communities centred around cryptocurrencies, such as social media groups and online forums, encourage and counsel people to embrace cryptocurrencies in their financial endeavours. According to earlier research, the conducive circumstance is among the most important predictors of cryptocurrency use intention [65]. However, it has been discovered that the acceptance of cryptocurrencies is not much impacted by facilitating conditions [66]. Consequently, this study proposes:

H3. Facilitating conditions is positively related to the acceptance of cryptocurrency in investment.

### D. Awareness

Awareness (AWAR) is described as a person's understanding of innovation and the advantages of embracing it [67]. According to this study, awareness is the degree to which consumers are aware of cryptocurrencies and their advantages. The significance of awareness in embracing technology was first examined in an innovation diffusion theory [68]. A new technology is cryptocurrency. As a result, users have a limited knowledge of the advantages of cryptocurrencies. Therefore, to increase the perception of its advantages, one must be aware of cryptocurrency services [70]. Several studies have shown that users' propensity to embrace cryptocurrencies is positively

impacted by awareness [28], [28], [33]. User acceptance in a contract may be hampered by ignorance of cryptocurrencies [24]. Thus, this study postulates:

H4. Awareness is positively related to the acceptance of cryptocurrency in investment.

### E. Security

Security (SEC) defines how safe a person feels when applying technology when they are online. People avoid using technology because they are anxious about it [39]. Transactions involving cryptocurrencies are carried out online. Potential financial loss, theft, or failure due to cybercrime may worry users [40]. Because of its security, individuals would feel more comfortable utilizing the technology, enabling it to reach its full potential as a cash substitute [41]. If people believe that cryptocurrencies are a safe form of money, they will be more inclined to utilize them [16]. Prior studies have demonstrated that security has a major impact on people's readiness to use digital currencies [17]-[20]. Similarly, a lack of security has negatively affected the desire to embrace Bitcoins as an investment [16]. As a result, more people see Bitcoin as a safe innovation, and they are more likely to apply it. Hence, the current research constructs:

H5. Security is positively related to the acceptance of cryptocurrency in investment.

### F. Trust

Trust (TR) is the readiness to trust someone or something because you think they are reliable. Trust is the belief that a system will be able to carry out all of its intended tasks. Accordingly, trust was divided into two categories: i) behavioural intentions containing ambiguity and vulnerability, and ii) faith or confidence in the reliability of another individual [47]. According to earlier studies, a person's behaviour varies based on their online purchasing confidence [33]. Due to the financial risk involved, online payment systems demand the highest confidence level [24]. Furthermore, it was found that user commitment to online transactions is increased when trust is present [32]. Furthermore, trust has been shown to predict Bitcoin use positively as a payment mechanism [28]. Thus, this study hypothesizes:

H6. Trust is positively related to the acceptance of cryptocurrency in investment.

### G. Government Policy as a Moderator

Government Policy (GP) is related to the role of the government in motivating the application and utilisation of technology [33]. Government policy can be described in this study as the role of government-related regulations covering different rules that facilitate accepting cryptocurrency in investment. It was found that government policy influences many acceptance decisions [34]. One digital technology used in financial transactions is cryptocurrency. As a result, the features of cryptocurrencies and the function of governmental regulations will determine whether or not a person accepts them. One could argue that government policy may impact how much the government facilitates, oversees, and regulates the potential utility of Bitcoin services [35]. The impact of one variable on another is either increased or decreased by a moderator variable [36]. Government policy has been shown to support people's financial choices, including accepting cryptocurrencies [37]. Government rules, however, make it less likely for consumers to choose to utilize cryptocurrencies [38]. The impact of social influence and performance expectations on adopting cryptocurrencies as investments is then anticipated to be mitigated by government policy. The following theories are investigated:

H7(a) Government policy moderates the relationship between performance expectancy and the acceptance of cryptocurrency in investment.

H7(b). Government policy moderates the relationship between social influence and the acceptance of cryptocurrency in investment.

## V. Research Methodology

### A. Data Collection

Only 220 of the 290 questionnaires designed for the sample were filled out and returned, and the study population comprises people interested in investing in cryptocurrencies. As a result, 76% of the response rate was reached. The survey aimed to collect information on respondents' knowledge of cryptocurrency's features and their propensity to embrace it in the future. This data was measured using a Likert-type scale, where, 1 represents strongly disagree, and 7 represents strongly agree. With the necessary adjustments made for the specific setting of this study, the majority of the 28 items in this section were taken from recent Bitcoin literature as well as from previous studies conducted in different situations. The second section of the questionnaire revealed information about the respondents' age, gender, and level of education. The questionnaire was designed and disseminated in English.

### B. Data Analysis and Results

The gathered data was analysed using SPSS version 29 and SEM. The recommendations of [48], [49] and earlier studies in this area served as an inspiration for the selection of these techniques. Table I shows that 61% of respondents were female and 39% of respondents were male. Regarding age grouping, 45.8% of respondents were in the 25 to 34 age range, 16.8% were in the 35 to 44 age range, 30.4% were in the 18 to 24 age range, and 7% were above 44. Sixty-three percent of the respondents had a Bachelor's degree, sixteen percent had a Diploma, six percent had Certificates, and nine percent had a Postgraduate degree.

TABLE I. Demographic Profile

| Demographics | Categories | (%) |
|---|---|---|
| *Gender* | *Male*<br>*Female* | *39*<br>*61* |
| *Age* | *18-24*<br>*25-34*<br>*35-44*<br>*44 and above* | *30.4*<br>*45.8*<br>*16.8*<br>*7.0* |
| *Educational Background* | *Certificate*<br>*Diploma*<br>*Bachelor's degree*<br>*Postgraduate degree*<br>*Others* | *6.0*<br>*16.0*<br>*63.0*<br>*9.0*<br>*6.0* |

In the same way, several crucial metrics, including nomological validity, convergent validity, discriminant validity, and face validity, were included in the analytic process to evaluate the validity and dependability of the structural model employed in the Structural Equation Modelling (SEM) technique. Convergent validity, which ensures that items evaluating a certain idea have a significant amount of common variation, was evaluated using average variance extracted (AVE), factor loadings, and reliability measures (in this case, Cronbach's alpha). Cronbach's alpha AVE and factor loadings of 0.5 or higher are deemed acceptable, whereas an AVE of 0.6 or higher is deemed acceptable by [49].

Table II indicates a high degree of internal consistency among the measures employed to measure each aspect, with Cronbach's alpha values ranging from 0.839 to 0.895. Furthermore, the AVE values, which range from 0.541 to 0.782, are greater than the 0.5 threshold, suggesting that the underlying constructs explain over 50% of the variance in the observed variables. A strong association between the latent constructs and the observable variables is also indicated by the fact that all factor loadings are higher than 0.5. Overall, these findings demonstrate that all prerequisites for convergent validity have been met, confirming the model's attainment of convergent validity. By showing that the items measuring each construct are indicative of the respective underlying constructs and share a significant amount of common variation, this validates the robustness and reliability of the measurement model.

TABLE II. CONVERGENT VALIDITY MEASURE

| Variables | Cronbach's Alpha | AVE |
|---|---|---|
| *PE* | *0.856* | *0.541* |
| *FC* | *0.864* | *0.661* |
| *SI* | *0.895* | *0.747* |
| *AWAR* | *0.869* | *0.698* |
| *SEC* | *0.874* | *0.543* |
| *TR* | *0.839* | *0.782* |
| *GP* | *0.845* | *0.785* |
| *ACI* | *0.843* | *0.786* |

The discriminant validity of each construct in the model must differ from the other constructions. Relatively, discriminant validity can be evaluated in a variety of ways. The fit indices for the baseline and limited models were then compared, with the connection between the components in this study fixed at 1. Consequently, discriminant validity is attained if there is a significant difference in the fit indicated between the two models. Table III shows that the baseline model's Chi-square (x2) value was 1,449.196 with 643 degrees of freedom, while the limited models' x2 value was 1,607.716 with 545 degrees of freedom (DF). This shows a difference in the degree of freedom of seven and an x2 difference of 1,229.197. The fit indices for the restricted models and baseline models differ dramatically. Accordingly, this model attains discriminant validity, and consulting experts in this field verified the face and nomological validity. Lastly, the findings exposed that the comparative fit index (CFI) is 0.839, and its root mean square error of approximation (RMSEA) is 0.541. For both measures, these levels are acceptable [44], [47], [50]. Therefore, this validates the model as a whole.

TABLE III. DISCRIMINANT VALIDITY MEASURES

| Elements | Chi-square | DF |
|---|---|---|
| *Baseline model* | *1,449.196* | *643* |
| *Restricted model* | *1,607.716* | *638* |
| *Changes* | *158.520* | *5* |

## VI. RESEARCH HYPOTHESES

The hypotheses discussed above are tested through path analysis, as shown in Table IV. The findings illustrated that performance expectancy significantly impacts individuals' acceptance of cryptocurrency in investment. Consequently, Hypothesis 1 is supported ($\beta = 0.052$, $t = 1.142$, $p = 0.127$). This result indicates that the ease associated with cryptocurrency will allow users to accept cryptocurrency when investing. This is supported by [15], who stated that behavioural intention to utilise cryptocurrency is hindered when cryptocurrency is difficult. Moreover, social influence significantly affects an individual's behaviour in accepting cryptocurrency in investment. Thus, hypothesis H2 is supported ($\beta = 0.099$, $t = 2.339$, $p = 0.010$). The results concurred with those of [35], [36], who revealed that behavioural intent toward cryptocurrency acceptance among Saudi Arabian university students is influenced by the views of near and loved ones, such as friends and family, regarding the advantages of cryptocurrencies. Additionally, it was shown that facilitating conditions substantially impacted the adoption of cryptocurrencies in investment. Consequently, ($\beta = 0.101$, $t = 2.116$, $p = 0.017$) support Hypothesis 3. This result is consistent with [20]. It refers to the political climate, the government's desire to encourage the use of cryptocurrencies in investing, and the laws, circulars, and policies that have been put in place to assist cryptocurrency acceptance.

TABLE IV. REGRESSION RESULTS

| Hypothesis | Relationship | ß | T Values | p Values | Result |
|---|---|---|---|---|---|
| *H1* | *PE -> ACI* | *0.052* | *1.142* | *0.127**** | *Supported* |
| *H2* | *SI -> ACI* | *0.101* | *2.116* | *0.017**** | *Supported* |
| *H3* | *FC -> ACI* | *0.099* | *2.339* | *0.010**** | *Supported* |
| *H4* | *AWAR -> ACI* | *0.098* | *2.258* | *0.012**** | *Supported* |
| *H5* | *SEC -> ACI* | *0.276* | *5.775* | *0.05* | *Supported* |
| *H6* | *TR -> ACI* | *0.054* | *1.034* | *0.015*** | *Unsupported* |

Note. ***indicates a significant level at $p < 0.01$.,**indicates a significant level at $p < 0.05$.

All of these characteristics have a major impact on people's decision to embrace cryptocurrencies as an investment. Similarly, people who accept Bitcoin investments were found to be significantly impacted by awareness. Since (β = 0.098, t = 2.258, and p = 0.012), Hypothesis 4 is accepted. This outcome is consistent with [11], who claimed that knowledge and awareness of cryptocurrencies significantly impacted their use. The respondents' ability to obtain general information on cryptocurrencies, including their advantages and potential risks, is a noteworthy indication of awareness.

Regarding the acceptability of cryptocurrencies in investing, the respondents noted a high degree of awareness and expertise, which has positively affected their views of and acceptance of cryptocurrency in investment. Further, security was recognised to significantly affect individuals accepting cryptocurrency in investment. Accordingly, H5 is supported (β = 0.0276, t = 5.775, p = 0.05). This outcome is consistent with Almarashdeh [19], who emphasized users' perceived concerns about the security of financial transactions associated with Bitcoin use.

Nevertheless, trust was found to have no discernible effect on people's behaviour regarding the acceptance of cryptocurrencies in investment, which is contradicted by [8], [9], who noted that users are more likely to trust a currency issued by an authority than a cryptographic currency. As a result, Hypothesis 6 is rejected (β = 0.054, t = 1.034, p = 0.015) in this study for several reasons, including the decentralized nature of the cryptocurrency market, the absence of a central authority in charge of issuance, and the fact that using a reliable third party when transferring money online is not necessary [14]. The findings summarised other determinants rather than trust that could impact individuals who accept cryptocurrency in investments.

Table V shows that the relationship between performance expectancy and the acceptance of cryptocurrencies as an investment is considerably impacted by government regulation. Hypothesis 7a is thus supported (β=0.084, t=2.137, p=0.017). This suggests that government policies significantly shape the influence of performance expectations on the acceptance of cryptocurrencies in investment. This illustrates that the association between performance expectancy and accepting cryptocurrency in investment is strengthened by government policy. This finding could be further explained by the prospect theory, which claims that people make decisions based on how options are framed and are receptive to losses rather than profits [51]. In cryptocurrency, investors who expect positive returns and have high-performance expectations may be more inclined to invest [52]. If considered beneficial in lowering volatility and safeguarding investors, government policy, individuals with high-performance expectancy (positive return expectations) might be more likely to invest [53]. Government policies could enhance this positive perception if perceived as effective in reducing volatility and protecting investors [54]. This would make investors more open to the possible benefits of cryptocurrency, especially in light of restrictions, which could reinforce the positive link between the acceptance of cryptocurrency in investment and performance expectancy [55]. Finally, government policy negatively affected the correlation between SI and the acceptance of crypto in investing.

TABLE V. RESULTS OF GOVERNMENT POLICY ANALYSIS

| Hypothesis | Relationship | ß | T Values | p Values | Result |
|---|---|---|---|---|---|
| *H7a* | *PE > GP* | *0.084* | *2.137* | *0.017*** | *Positively Supported* |
| *H7b* | *SI > GP* | *-0.080* | *1.908* | *0.028*** | *Negatively Supported* |

*Note. **indicates a significant level at p < 0.05.*

Hypothesis 7b is therefore not supported (β=-0.080, t=1.908, p=0.028). Consequently, the analysis's findings show a negative correlation between social impact and investors' acceptance of cryptocurrencies. This illustrates how the presence of governmental regulation may mitigate the relationship between social influence and the adoption of cryptocurrencies as investments. This finding could be explained by Social Learning Theory [56], which posits that individuals learn by observing and imitating others' behaviours. Regarding cryptocurrency, individuals may be persuaded to invest due to the influence of friends, family, or online communities. However, government policy can introduce uncertainty and complexity to the process, making investors less likely to follow the actions of others [60] mindlessly. They might be more cautious and conduct their research before investing, weakening the direct influence of social pressure. The additional justification that may align with this outcome is related to Uncertainty Reduction Theory, which theorises that individuals seek to reduce uncertainty in situations involving risk [58]. Concerning cryptocurrency, a new and complex investment, individuals might rely heavily on social influence to make decisions. Nevertheless, when governments establish policies, it provides a sense of legitimacy and clarity, potentially reducing the reliance on social cues and leading to more independent decision-making.

## VII. DISCUSSION

Using SEM analysis, this study aimed to investigate the factors influencing the adoption of cryptocurrencies in investments. The results showed that users' adoption of cryptocurrencies as an investment is positively impacted by several elements, which aligns with many previous studies. These include performance expectancy [47]-[48], facilitating conditions [63], social influence [55]-[56], and awareness [67]. However, the acceptance of cryptocurrencies was not much impacted by trust, which has failed to be replicated in past studies [28], [32], [69]. Conceptual hurdles exist in cryptocurrency because its decentralized and pseudonymous systems function without standard trust components like banks or regulators. This can probably be explained by Gunawan and Achmad [39], who noted that new users of decentralized platforms face challenges due to the absence of trusted identifiable entities on these platforms.

## VIII. CONCLUSION

The insights obtained by this study hold considerable value for practitioners, academics, and policymakers, shedding light on aspects of cryptocurrency in investment behaviour that may not align with users' cultural and social values. Consequently, the findings contribute to gaining a deeper comprehension of the dynamics of cryptocurrency acceptance. The study's findings also serves as a basis for promoting user involvement with cryptocurrencies for financial investment. This study explores a topic that has not been experimentally investigated before using

the UTAUT model in a new setting. Furthermore, this study offers practitioners and regulators information on crucial elements to encourage cryptocurrency investment and adoption among stakeholders. Cryptocurrencies and similar digital assets offer the potential for more efficient exchange methods than traditional currencies, highlighting the need for further investigation. With swift progressions in financial innovation, fiscal advisors and users should remain current regarding the latest developments in both knowledge and skills. Traditional financial institutions face a serious challenge if they do not adjust to these changes. Users can choose alternative advice platforms that offer more effective, flexible, and affordable services. The results might also lead people to consider cryptocurrencies a good investment choice.

## IX. Limitations and Future Research

It is essential to consider this study's various possible limitations. First, a self-report survey and cross-sectional research design may restrict causal inferences and miss gradual changes over time [69]. Future research could use experimental designs to overcome this restriction. Second, a complete collection of factors impacting the adoption of cryptocurrencies in investment is not included in the study's suggested model. Consequently, this model needs to be seen as a starting point for additional study in order to create a more thorough understanding of cryptocurrency acceptance in investment. Since many users engage with cryptocurrencies as investment assets, future research would benefit from incorporating inherent features and risks specific to cryptocurrency in investment, such as traceability, price value, and sustainability, and examining their influence on user attitudes toward cryptocurrency acceptance.

Thirdly, although structural equation modelling (SEM) was used in this investigation, alternative theoretical perspectives and methodological approaches could produce additional insights, potentially enriching our understanding of the phenomenon. Lastly, longitudinal research on cryptocurrency adoption could offer valuable perspectives on the evolving dynamics of acceptance behaviour, particularly as it responds to shifts in market trends, regulatory developments, and technological advancements. By addressing these shortcomings, future studies could advance a more sophisticated comprehension of cryptocurrency investment behaviour and its wider ramifications for stakeholders and international financial markets.

## Acknowledgment

This research was supported by the Ministry of Higher Education (MoHE) of Malaysia through the Fundamental Research Grant Scheme (FRGS/1/2022/ICT03/UUM/02/3).

***Abstract*—Oil palm trees are the world's most efficient and economically productive oil bearing crop. It can be processed into components needed in various products, such as beauty products and biofuel. In Malaysia, the oil palm industry contributes around 2.2% annually to the nation's GDP. The continuous surge in demand for oil palm worldwide has created an awareness among the local plantation owner to apply more monitoring standards on the trees to increase their yield. However, Malaysia's cultivation and monitoring process still mainly depends on the labor force, which caused it to be inefficient and expensive. This scenario served as a motivation for the owner to innovate the tree monitoring process through the use of computer vision techniques. This paper aims to develop an object detection model to differentiate healthy and unhealthy oil palm trees through aerial images collected through a drone on an oil palm plantation. Different pre-trained models, such as Faster R-CNN (Region-Based Convolutional Neural Network) and SSD (Single-Shot MultiBox Detector), with different backbone modules, such as ResNet, Inception, and Hourglass, are used on the images of palm leaves. A comparison will then be made to select the best model based on the AP and AR of various scales and total loss to differentiate healthy and unhealthy oil palm. Eventually, the Faster R-CNN ResNet101 FPN model performed the best among the models, with AParea = all of 0.355, ARarea = all of 0.44, and total loss of 0.2296**

***Keywords*—Component oil palm detection; deep learning models; object detection; Faster R-CNN; drone imagery analysis***

## I. INTRODUCTION

Palm oil is the most productive oil crop and can be processed into various products, such as soap, vegetable oil, beauty products, etc. In Malaysia, palm oil has been regarded as Malaysia's golden crop. The oil palm industry has always been one of the most important agricultural exports for the nation. In 2022 alone, palm oil contributed 66.1% of the nation's total export earnings, which amounted to MYR 44.63 billion this year [1]. Besides, the demand for palm oil continues to surge due to the growing population and the shortage of sunflower and rapeseed oils in recent years. It is estimated that the annual production will be quadrupled, reaching 240m tons by 2050 [2]. To benefit from this scenario, Malaysia's oil palm industry has to be able to increase its yield. As a result, the monitoring process of oil palm trees has become important to ensure a continuous supply of palm oil.

One of the main focus or projects involves differentiating and detecting healthy and unhealthy oil palms in the plantation. This task is particularly important because insects can transmit the disease affecting an oil palm tree to its surrounding trees. Also, it is important to provide timely treatment to the infected unhealthy oil palm trees.

However, the problem for the Malaysian oil palm industry has always been labor shortages as it heavily depends on foreign labor to carry out the monitoring task. Nevertheless, the situation worsened when coronavirus hit the globe in early 2020, which caused the border between countries to close. Foreign laborers are not able to enter Malaysia to fulfill the labor shortage faced by the industry. Fortunately, this crisis has successfully prompted the industry player to innovate and implement some automation, such as object detection techniques, to overcome the problem. With object detection techniques put in place, it can help the plantation owners to shorten the time in detecting unhealthy and healthy oil palm trees, thus increasing the efficiency of the task as the traditional way of oil palm tree monitoring is too labor-intensive and inefficient. Once this project is successful, it will provide a reference for other researchers to improvise further and develop the detection model. Besides, it also acts as a starting point for the companies in this industry to utilize this method to overcome the labor shortage, further helping them increase their crop yield moving forward. Lastly, it is also believed that this project can help to share awareness and gather the attention of other companies of different crops, apart from oil palm, to utilize the object detection technique in their crop plantation and management process.

Object detection is an important computer vision task that detects instances of visual objects of a particular class (such as humans, animals, or cars) in digital images [3]. The idea and early design of object detection started in the 1900s. In recent years, the evolution of GPU architecture and deep learning techniques have generalized the usage of object detection techniques in many sectors. Autonomous driving, defect detection, and traffic monitoring are real-world applications that use object detection models. There are two types of object detection frameworks, which are region-based, and regression/classification based. Region-based frameworks are commonly referred to as two-stage detectors, while regression/classification-based frameworks are referred to as one-stage detectors.

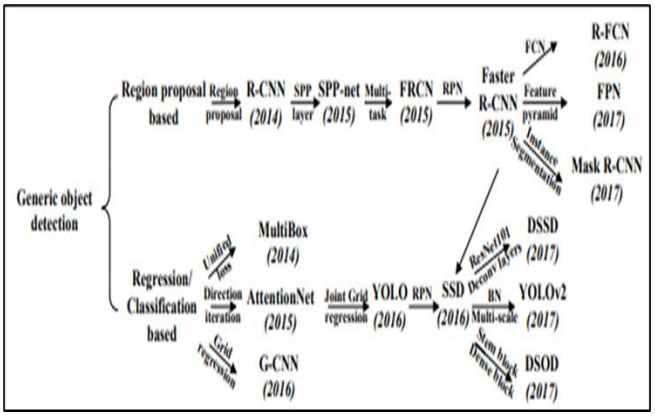

Fig. 1. Development of object detection frameworks [4].

Two-stage detectors will first generate region-based proposals, then classify each proposal into different classes. The typical examples of two-stage detectors are R-CNN, SPP-Net, Faster R-CNN, and FPN. Meanwhile, one stage detectors view object detection as a regression or classification problem, adopting a unified framework to achieve final results (categories and locations) directly [4]. Single-shot MultiBox Detector (SSD), You Only Live Once (YOLO), and CenterNet are some of the models that use regression/classification-based frameworks. Fig. 1 summarizes the development of two object detection frameworks.

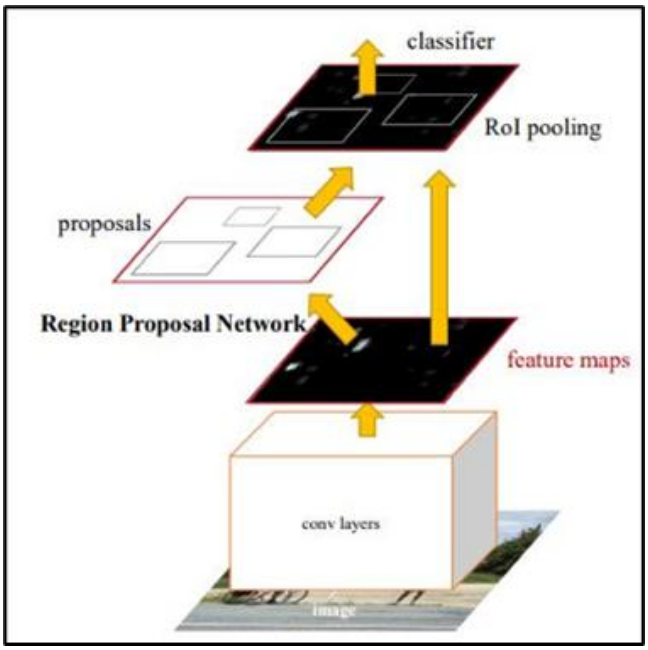

Fig. 2. RPN module [5].

Faster R-CNN is the abbreviation of Faster Region-based Convolutional Neural Network. It combines the algorithm of RPN (Region Proposal Network) and Fast R-CNN as shown in Fig. 2. It can be viewed as an updated version of Fast R-CNN, where, RPN replaces the Selective Search method. RPN is a fully convolutional network, which slides over the convolutional feature map and simultaneously predicts object boundary and object-ness scores at each position [4]. As a result, the model performs better in speed and accuracy and consumes fewer computational resources. In a paper published in [6], the authors applied Faster R-CNN on high resolution imagery for automatic detection and health classification of oil palm trees. There are two backbones selected for Faster R-CNN, which are ResNet-50 and VGG 16. The model with ResNet-50 as the backbone obtained F1 scores of 95.09%, 92.07%, and 86.96%, respectively, for oil palm tree detection, healthy tree identification, and unhealthy tree identification. Overall, the ResNet-50 model yielded a better F1 score than the VGG-16 model.

RetinaNet is a one-stage object detection model first published in a paper by Lin et al. The development of RetinaNet is aimed at overcoming the problem of class imbalance and robust estimation in Single-Shot MultiBox Detector (SSD) during training by utilizing a focal loss function. Class imbalance problem in SSD leads to many easy negatives appearing when the detector is evaluating the object locations, overwhelming the loss function and causing a degeneration in the model performance. With focal loss function, it helps to down-weight those easy negatives and thus focus training on hard negatives as shown in Fig. 3.

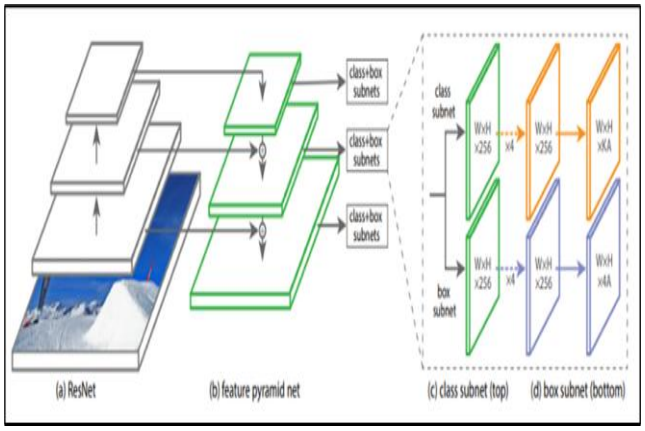

Fig. 3. RetinaNet architecture [7].

An optimized palm tree inventory model based on a RetinaNet object detector and high-resolution RGB images is proposed in 2021 to classify and locate palm trees in different scenes with different appearances and ages [8]. The dataset has a spatial resolution of 25cm. The detection model for palm tree inventory achieved a precision of 89.3% on the validation dataset and 76.9% on the test dataset. Both precision values are on the mAP@IoU = 0.50 category. CenterNet is an anchorless object detection model published [9], entitled "Objects as Points" in 2019. The idea of anchorless in this model is to replace Non-Maximum Suppression (NMS) algorithm used in SSD or YOLO. NMS algorithm functions as a filter to select one single bounding box out of the many overlapping bounding boxes in the post process. For example, YOLOv3 generates more than 7k bounding boxes in its prediction for each image, mostly considered garbage predictions, and the NMS algorithm will need to run pairwise checks for those overlapping bounding boxes [10]. Fig. 4 shows a CenterNet algorithm. This method increases the complexity of the model when the number of bounding boxes (predictions) increases. It also forces the model to consume more computational power and time in clearing those irrelevant predictions.

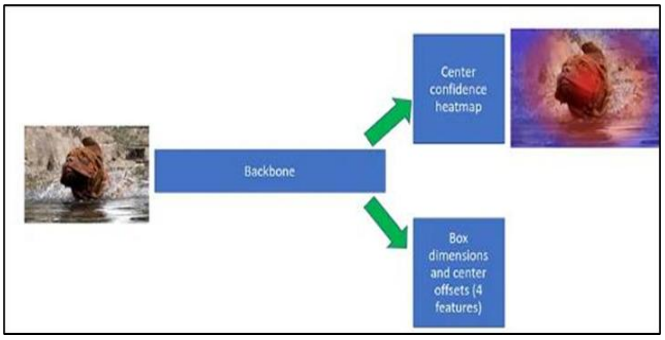

Fig. 4. CenterNet algorithm [10].

Meanwhile, CenterNet predicts a box center for an object and uses the center point to regress the value for its box dimensions and offsets, directly removing irrelevant predictions without any decoding process. An anchor-free deep learning model, CenterNet, is used to detect individual crown locations and regions from dense 3D terrestrial laser scans [11]. There are 1181 crowns from twelve plots. The author used eight plots for training, and four plots for testing. The model is trained over 40k iterations. The maximum training F1-score and IoU were 0.881 and 0.670, while testing result showed a F1-score of 0.754 and IoU of 0.583. The result also showed that a taller, larger, smoother, less crowded, and less overlapped tree was found easier to be detected by the model. Table I shows a comparison of object detection models for two stage and one stage of model. ResNet, Inception, and HourGlass Network are all convolutional neural networks widely used for image classification tasks. However, each contains its design specification to optimize the deep neural network as it goes deeper.

TABLE I. COMPARISON OF OBJECT DETECTION MODELS

| Model | | Innovations | Strength | Limitations |
|---|---|---|---|---|
| Two Stage | Faster R CNN | The RPN module helps to generate high-quality region proposals and saves time compared to the Selective Search method. | Higher accuracy | Complicated training with high memory consumption |
| One Stage | RetinaNet | Focal loss function – down weight the easy negatives and focus on hard negatives | Stable training for class imbalance | Lower accuracy compared to a two-stage detector |

Before ResNet was invented, researchers tended to design deep learning networks by increasing their layers and depth as shown in Fig. 5. However, it comes to a limitation where the train and test errors increase when it goes even deeper. In a paper published by [12], it is believed that this degradation in performance is not caused by overfitting, and indicated that not all networks could be optimized easily by making it deeper. As a result, a deep residual learning framework has been proposed by [12] to address the degradation problem. ResNet learns residual functions with reference to the layer inputs instead of learning unreferenced functions. Thus, it makes it possible to train a much deeper network while minimizing the error value.

Next, Inception Network as shown in Fig. 6 is designed to decrease the computational cost and burden to run a deep neural network. Besides, it also helps to better optimize parallel computing. The network performs max pooling and a convolution on an input with three different sizes of filters (1x1, 3x3, and 5x5), rather than stacking them in sequence. As the network progress, it will grow wider and not deeper. This also help to reduce vanishing gradient problem [14]. Meanwhile, HourGlass Network consists of multiple stacked hourglass modules, which allow for repeated bottom-up, top-down inference [15]. It is specially designed for predicting human poses. The advantage of this network is that it captures and consolidates information across all scales of the image [15].

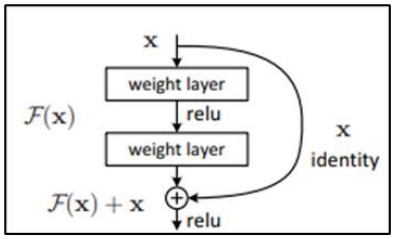

Fig. 5. Residual learning [12].

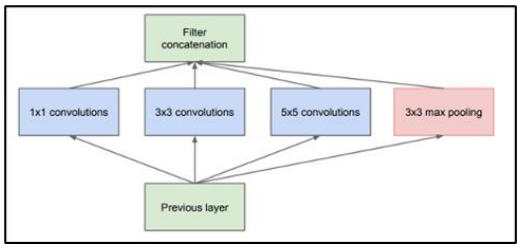

Fig. 6. Inception module [13].

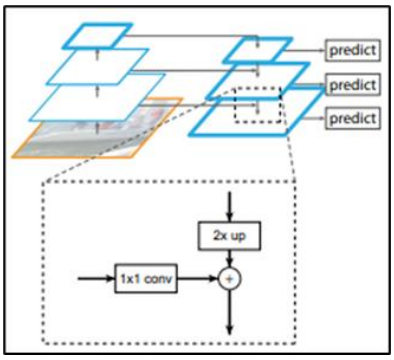

Fig. 7. Building block of FPN [16].

The Feature Pyramid Network is published by Lin et al. in 2017. FPN can be seen as an updated version of ConvNet's pyramidal feature hierarchy. FPN takes a single-scale image of an arbitrary size as input, and outputs proportionally sized feature maps at multiple levels, in a fully convolutional fashion. This process is independent of the backbone convolutional architecture [16]. As shown in Fig. 7, the building block involves a bottom-up pathway, a top-down pathway, and lateral connections. The result from the paper showed that average precision of a Faster R-CNN ResNet50 with FPN, goes up by 7.6%, from 26.3% to 33.9%. The evaluation of the model is made on COCO minival set.

A standard implementation, which can be used as a benchmark among different datasets is published in 2020. One of the famous metrics used for model evaluation is called average precision (AP) and average recall (AR). Before going deeper into how metrics works, it is also wise to understand the concept of intersection over union (IOU). It is a measurement based on Jaccard Index, a coefficient of similarity for two sets of data [17]. For object detection model, IOU measures the overlapped area between two bounding boxes, one from prediction, and one of ground-truth, divided by the area of union between them. With a given threshold, if the IOU is bigger than the threshold, then the detection is considered valid and vice versa. With IOU in place, AP and AR can be evaluated in different variations as mentioned in Table II.

TABLE II. PERFORMANCE METRICS [17]

| Metrics | Meaning |
|---|---|
| AP@50:5:95 | AP of 10 IOUs varying from range of 50% to 95% with steps of 5%. |
| AP50 | AP of IOU of 50% |
| AP75 | AP of IOU of 75% |
| AP-S | AP for small sized objects (area < 322 pixels) |
| AP-M | AP for medium sized objects (322 < area < 962 pixels) |
| AP-L | AP for large sized objects (area > 962 pixels) |
| AR@50:5:95 | AR of 10 IOUs varying from range of 50% to 95% with steps of 5%. |
| AR-S | AR for small sized objects (area < 322 pixels) |
| AR-M | AR for medium sized objects (322 < area < 962 pixels) |
| AR-L | AR for large sized objects (area > 962 pixels) |

The loss function is a common but essential metric in deep learning. It provides a numerical representation of how well a model performs on a particular task. It helps the researchers to evaluate and fine-tune the model to achieve a better result. If the model predicts poorly, the loss function will output a higher number and vice versa. In object detection, the loss function can be categorized into two parts; one is classification loss, another one is localization loss. The former is applied to train the classification head for determining the target object type, and the latter is used to train another head for regressing a rectangular box to locate the target object [18]. Once these two categories adds on, it is called a total loss for the object detection model.

## II. RESEARCH METHOD

A standard object detection workflow has been presented to create a deep learning-based object detector in a paper published in [19] and the workflow as shown in Fig. 8. The workflow starts with the dataset acquisition process, followed by data annotation. The images will then be augmented into different sizes and split into training and test sets according to a selected ratio. Next, the training and test set will be fitted and trained in an object detection algorithm. Once the training is done, the best model will be saved. Finally, the best model will be used to infer the test dataset or new images for evaluation purposes. The evaluation process will be based on the selected metrics, such as mAP, AP, and AR. If the model performs well, it can be deployed into a real-case scenario.

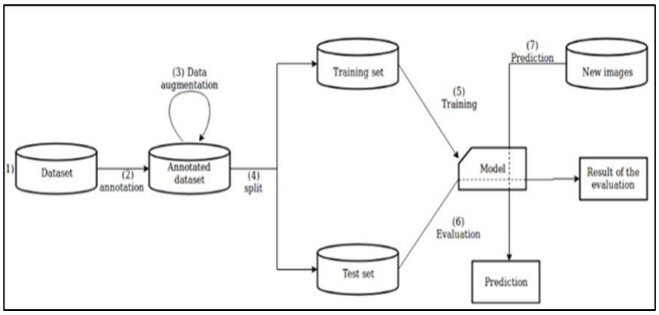

Fig. 8. Workflow for object detection project [19].

Fig. 9 illustrates the overall lifecycle of the object detection project, and it will only cover performance evaluation. The model's deployment for real-case scenarios will depend on the client's needs. The cycle consists of 6 stages: problem understanding, data collection, data annotation and augmentation, data transformation, modelling, and model evaluation. During the early stage of the problem understanding, one discussion session was held with the client, and the problem faced was identified. The problem is due to the client's lack of domain knowledge to develop a proper object detection model. Next, several meetings were held to discuss the desired outcome and expectations from the client. The goal was then set: to develop a prototype model which can make a good prediction on healthy and unhealthy oil palm trees on aerial images captured by drone.

The next stage in the project lifecycle is data collection. It is also known as data acquisition in the object detection workflow. The client provides the image dataset for this project. It consists of 90 images, which are collected from an oil palm plantation in Perak, based on the coordination stored in the metadata of the image. The images are collected during sunny and cloudy weather with different aerial angles. Multiple trees can be seen in an image with tree crowns overlapping each other. Some are unhealthy trees as shown in Fig. 10, and some are healthy trees as shown on Fig. 11. The health of the oil palm trees can be differentiated using crown color. Most healthy trees have green crowns, while the unhealthy ones tend to have yellow and brown crowns [20]. All the images are captured through a drone and stored in 32-bit PNG format. The image size ranges from 8 MB to 12 MB, while the image size is fixed at 2982-pixel x 1694-pixel. All the images have a resolution of 144 dots per inch (DPI).

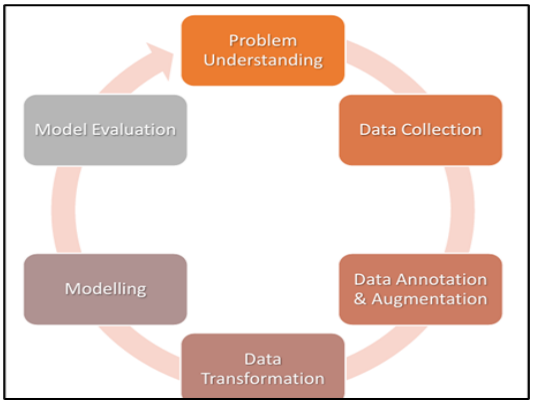

Fig. 9. Project lifecycle.

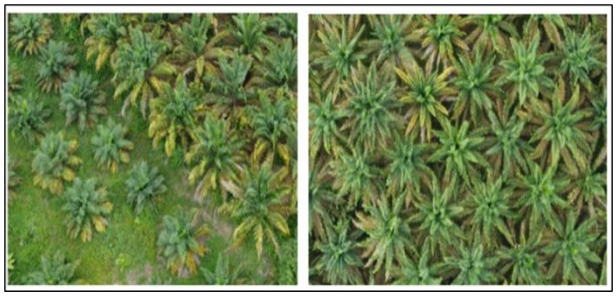

Fig. 10. Tree crown of unhealthy oil palm tree.

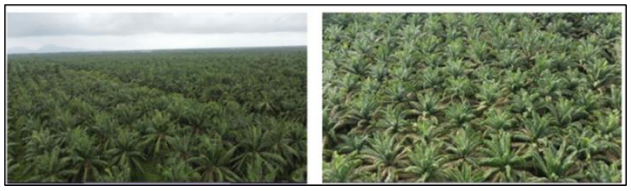

Fig. 11. Tree crown of healthy oil palm tree.

Next, the images were manually annotated using an open-source tool called 'Labellmg' as shown in Fig. 12. The software is written in Python format and uses Qt for its graphical interface [21]. The bounding box was drawn on the visible objects. Each bounding box represents the object's coordinate in the image with four axis: xmin, xmax, ymin, and ymax. Two classes, 'Healthy' and 'Unhealthy', are used to annotate each object in the images. The annotations are saved in Pascal VOC XML format.

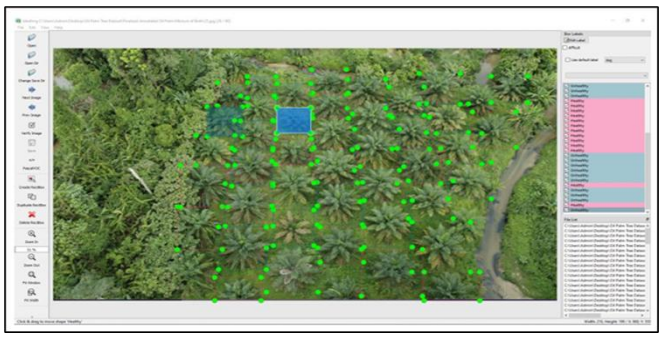

Fig. 12. LabelImg.

The images were once trained using one of the selected object detection models. However, the image size is too big for the GPU to handle. The GPU on Google Colab is the Nvidia Tesla T4, which has 16GB of memory. As a result, the images must be rescaled and reduced in size. The images were augmented or rescaled to 1024 x 1024 pixels. The bounding boxes also shrank according to the rescale ratio using a python script found in a GitHub repository. Italo José codes the script [22].

The image dataset is then split randomly into training and validation sets with a ratio of 8:2 as shown in Fig. 13. Once the splitting process is complete, the respective annotations are split into two folders, training and validation set accordingly. The dataset will need to train in different models. Some models are stored in different model zoos of different platforms, such as TensorFlow, PyTorch, and Detectron2. The model zoo is a repository where companies or open-source institutions store machine learning and deep learning models. Object detection models, stored in TensorFlow and PyTorch model zoo, are developed by Google and Linux Foundation (previously Meta AI). Those models are trained on the PASCAL VOC dataset, and the annotation needs to be in XML format. Meanwhile, models in the Detectron2 platform are maintained by Meta AI, and the models are trained on the COCO dataset. Thus, the annotation needs to be in JSON format. As a result, the annotations in XML format are converted into JSON format using a script found in the GitHub repository. A person develops the script with a pseudonym called fam_taro [23]. Meanwhile, a script developed by Dat Tran in GitHub is being used to generate TFRecord format for TensorFlow object detection models [24]. The Fig. 14 shows the dataset directory structure for the project.

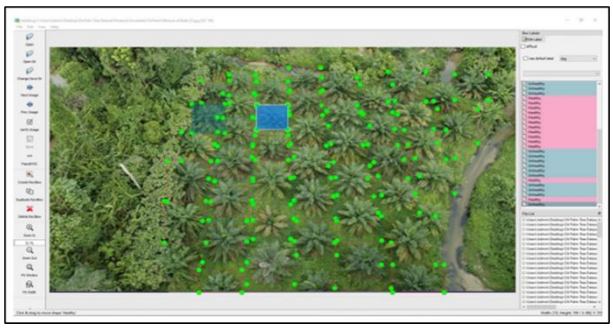

Fig. 13. Original size image vs resized image.

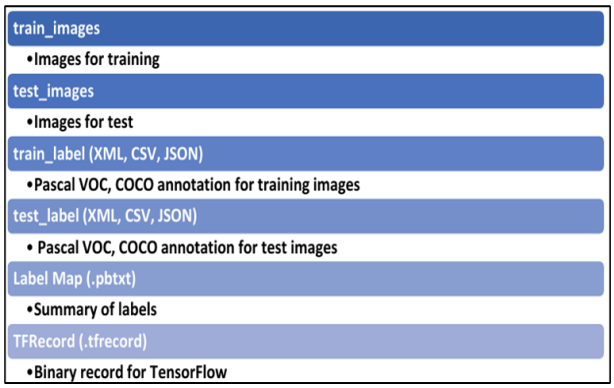

Fig. 14. Dataset directory structure.

TABLE III. MODEL SPECIFICATION

| Specification | Faster R-CNN | | RetinaNet | | CenterNet |
|---|---|---|---|---|---|
| Model Zoo | TensorFlow | Detectron2 | TensorFlow | Detectron2 | TensorFlow |
| Annotation Format | XML | JSON | XML, | JSON | XML |
| Backbone | Inception-ResNet | ResNet-50/101 | ResNet-50/101 | | HourGlass |
| FPN | No | Yes | Yes | | No |
| Anchor | Yes | | Yes | | No |
| Input Image Size | 640 x 640 | | 640 x 640 | | 512 x 512 |

Several models are being selected for training. The justification of the advantages and disadvantages of each model is written in previous discussion. Table III summarizes the specification of the selected models.

Besides, several settings need to be configured in the config file of each model before the training process starts. Table IV summarizes the basic settings in the config file.

TABLE IV. CONFIG SETTINGS

| Settings | Options |
|---|---|
| num_classes | 2/3* |
| Path to train_images/ test_images/ labelmap | Path to the working directory in Google Drive |
| fine_tune_checkpoint | Checkpoint of pre-trained model downloaded from the model zoo of the respective platform |
| fine_tune_checkpoint_type | Detection |
| batch_size | 2/4 |
| num_steps/iter/epoch | 50000/3600/100 |

Many pre-trained object detection models are available in the model zoo of different platforms. However, every platform requires a library version to be installed before the model can be trained on the custom dataset. In addition, the TensorFlow library, Colab, and Drive are all developed by Google. As a beginner, it is reasonable to consider models from the TensorFlow library as the first choice due to compatibility issues. Unfortunately, TensorFlow models are computationally expensive to train and consume much time. A Faster R-CNN model took up to 9 hours to train. Due to cost concerns, other alternatives, such as PyTorch's TorchVision library and Detectron2 library, are being considered. The models in PyTorch take much lesser time and are easier to train. PyTorch's Faster R-CNN model only took an hour to train on the same model. However, only a limited variety of models are available to train on the platform, which is the main disadvantage of the PyTorch platform.

For Detectron2 library, it contains a variety of models that are available for training. Most models are trained with the 3x schedule (~37 COCO epochs). A Faster R-CNN model only takes an hour to train on the same dataset. It has much more model variation and consumes less time in training. As a result, the Detectron2 library is selected for the rest of the training process to produce a standardized result.

Object detection has recently been deemed feasible due to the rapid development of GPU parallel computing. GPU parallel computing allows the model to split the training process into thousands of tasks and process it simultaneously. It is much more efficient and timesaving than the CPU, which only processes one task simultaneously. Unfortunately, there is no GPU hardware available on the laptop. Specification of project setup as shown in Table V. One of the alternatives available online is the Cloud GPU Platform. Some examples of these platforms are Google Colaboratory, Paperspace, Microsoft Azure, and Kaggle.

In order to stay competitive, every platform offers similar GPU devices and only differs by the subscription plan. As a result, it is really up to user preferences and usage. For this project, Google Colaboratory has been selected due to several reasons. The user interface is also not much different from Jupyter Notebook. Lastly, it allows the users to link to their Google Cloud storage, keeping the whole process on the cloud. Thus, it is easier and more flexible for beginners and students.

TABLE V. SPECIFICATION OF PROJECT SETUP

| Types | Specification |
|---|---|
| CPU | Nvidia Tesla T4 (16GB memory) |
| Storage | Google Drive (100GB) |
| IDE | Google Colab (Python) |
| RAM/ Disk Space | 12.7 GB/ 107.7 GB |

## III. RESULTS AND DISCUSSION

The models selected are CenterNet HourGlass104 512x512 and Faster R-CNN Inception ResNet V2 640x640. The basic settings of the model as shown in Table VI and Table VII, the results, and the inference images as shown in Fig. 15 and Fig. 16.

TABLE VI. BASIC SETTINGS FOR TENSORFLOW MODELS

| Settings | Options |
|---|---|
| num_classes | 2 |
| fine_tune_checkpoint_type | Detection |
| batch_size | 2 |
| num_steps | 50000 |

TABLE VII. RESULT FOR CENTERNET & FASTER R-CNN

| Model | CenterNet HourGlass104 512x512 | Faster R-CNN Inception ResNet V2 640x640 |
|---|---|---|
| Average Precision (AP) @ [IoU-0.50:0.95 \| area= all] | 0.372 | 0.351 |
| Average Precision (AP) @ [IoU=0.50:0.95 \| area= small] | -1 | -1 |
| Average Precision (AP) @ [IoU=0.50:0.95 \| area= medium] | 0.194 | 0.157 |
| Average Precision (AP) @ [IoU=0.50:0.95 \| area= large] | 0.408 | 0.405 |
| Average Recall (AR) @ [IoU=0.50:0.95 \| area= all] | 0.542 | 0.475 |
| Average Recall (AR) @ [IoU=0.50:0.95 \| area= small] | -1 | -1 |
| Average Recall (AR) @ [IoU=0.50:0.95 \| area= medium] | 0.366 | 0 275 |
| Average Recall (AR) @ [IoU=0.50:0.95 \| area= large] | 0.576 | 0.516 |
| Total Loss | 5.196 | 1.788 |

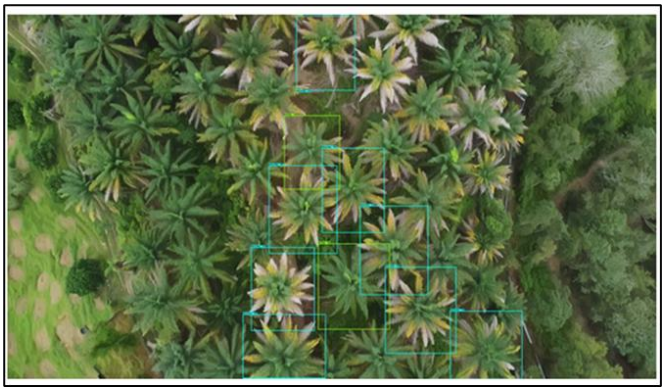

Fig. 15. Inference image of centernet hourglass104.

Fig. 16. Inference image of faster R-CNN inception ResNet V2.

In this evaluation, the inference image is a new test image with an image size of 3840 x 2160 pixels. In the image, most of the oil palm trees are considered medium or large objects, as the area of the big tree crown is above 962 pixels, and the medium one is around 322 and 962 pixels. In Table VI, the evaluation metrics shows that CenterNet with HourGlass104 backbone achieved a higher average precision (AP) for all, medium and large area categories, compared to Faster R-CNN with Inception ResNet backbone. A higher value of AP indicates that when the algorithm detects an object as healthy or unhealthy, it has a high possibility that it is correct. Furthermore, the metrics also show that the average recall rate (AR) of all, medium, and large area categories are higher in the CenterNet model than in the Faster R-CNN model. It means that the CenterNet model has fewer false negative predictions. Meanwhile, there are no small tree crowns under 322 pixels in the image that can be detected. Thus, the metrics show a value of 1 in both AP and AR for the small area category. Lastly, CenterNet achieved 5.196 in total loss, while the Faster R-CNN model only achieved 1.788. This problem can be seen in the inference image as well. Many tree crowns are left undetected in CenterNet's inference image, compared to the one in the Faster R-CNN model. This scenario also means that the CenterNet failed to predict many tree crowns, which means fewer false negative instances are being predicted (higher AR). However, those predicted ones are highly likely to be correct (higher AP). Thus, the metrics proved that the CenterNet model is not robust enough to locate the tree crowns and has a high localization loss compared to Faster R- CNN. In conclusion, both models did not produce a satisfactory result and took a very long time to train around 5 hours. As a result, a decision has been made to stop the training process for other TensorFlow models. The models in the Dectectron2 platform will be used as an alternative.

Four pre-trained models are being selected from the Detectron2 Model Zoo. The models selected are RetinaNet ResNet-50, RetinaNet ResNet-101 FPN, Faster R-CNN ResNet-50 FPN, and Faster R-CNN ResNet-101 FPN. The basic settings of the model as shown in Table VIII and Table IX, the result, and the inference images as shown in Fig. 17, Fig. 18 and Fig. 19.

Fig. 19. Inference image of faster R-CNN ResNet101 FPN.

The batch size and the number of max iterations have been selected for the fine tuning process. These two parameters are essential and will significantly impact the result if the value is fine-tuned correctly. Batch size refers to the number of training images utilized in one iteration, while max_iter refers to the maximum cycle for the training process. The settings of the model as shown in Table X and Table XI, the result and the inference images as shown in Fig. 20, Fig. 21, Fig. 22, Fig. 23 and Fig. 24.

Fig. 20. Benchmark from preliminary result.

Fig. 21. Batch size of 4 and 3600 iterations.

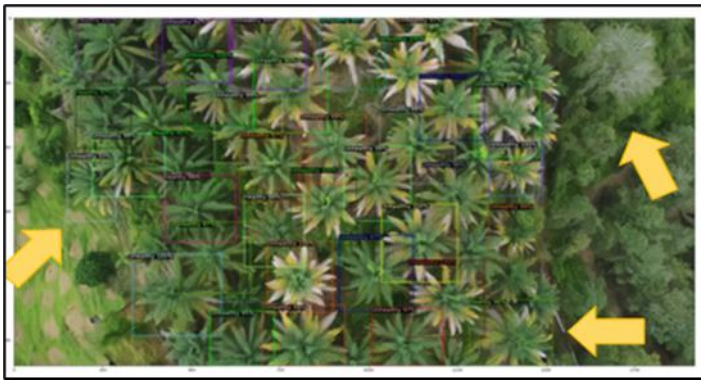

Fig. 22. Batch size of 2 and 7200 iterations.

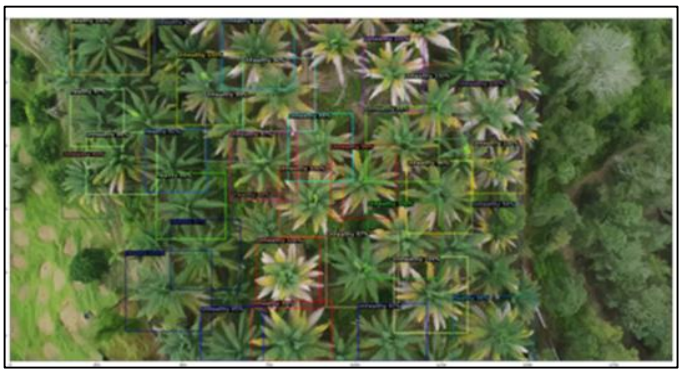

Fig. 23. Batch size of 2 and 9000 iterations.

Fig. 24. Batch size of 2 and 10800 iterations.

The fine-tuning process starts with model A by increasing the batch size to 4 while maintaining the max_iter value at 3600. These settings are made to explore the impact on model performance by increasing the batch size. The process is then continued with another three models of B, C, and D with different iterations, which are 7200, 9000, and 10800, while the batch size is kept constant at 2. The reason is to understand the effect of different numbers of max iteration on the model performance. Table X shows the performance metrics of a benchmark model from the preliminary stage and four other fine-tuned models. The model did not perform significantly better by increasing the batch size to 4. The performance metrics show that model A has a lower total loss and a slight increase in value for AP and AR in the medium area category, while the other metrics of model A dropped when compared with the benchmark model. The inference image also did not show any significant improvement in detection, as there is still a false positive detection on the top right corner of the image. Next, model B has settings of 7200 iterations and batch size of 2. The table shows that there is only a slight increase in value for AP and AR in the medium area category and a lower value of total loss (0.2853). Besides that, it did not show any significant increase in other performance metrics. However, there is an improvement in model B when comparing the inference image with the one of the benchmark model. It is shown with an arrow at the area of improvement. The false positive detection on the top right corner of the image is gone, and the undetected trees at the left side and the bottom part of the image are now detected. For model C, the max iteration is increased to 9000 iterations, and the batch size is kept constant at 2. The result shows that model C achieved the highest AP value of 0.355 for all area category, and the highest AR value of 0.44 and 0.487 for all and large area categories, respectively. Meanwhile, the total loss of model C is 0.2296, which is the second lowest among the models. The inference image of model C has no differences when compared to the one of model B. Lastly, the max iteration is set to 10800, and the batch size is kept constant at 2 for model D. Even though model D achieved the lowest value of total loss and the highest value in AP and AR for the medium area category, the value for other performance metrics dropped compared to model C of 9000 iterations. The value of AP for all and large area categories hits the lowest among all models. The inference image of model D also started to show the symptoms of overfitting as the false positive detection reappeared in the top right corner of the image. In conclusion, the Faster R-CNN ResNet101 FPN model with 9000 iterations and batch size of 4 performs the best. This experiment also shows that a two-stage detector, like the Faster R-CNN model, is better at classifying and locating the object than a one-stage detector, like RetinaNet and CenterNet. In addition, it also proved that a deeper backbone module would yield a better result.

There are some challenges throughout the project execution. The data annotation process was a challenging one. The oil palm trees are tough to label as it contains much ambiguity. Some tree crowns are yellowish because of sunlight reflection, but it does not mean the tree is unhealthy. Besides, oil palm tree crowns overlap, making it hard to determine the correct boundary for each crowns during annotation. Thus, constant communication is made with the clients on this issue so that a standardized dataset can be produced. Lastly, another challenge is the time consumption in training the TensorFlow models. The longest time to train a TensorFlow is around nine hours for the Faster R- CNN model. It is also tough to train the model as the training process disconnected from the server several times, and it will be retrained again. Thus, object detection models from alternative platforms like PyTorch and Detectron2 are being used and the training time significantly reduces to less than two hours.

## IV. CONCLUSION

As mentioned in Section III, the Faster R-CNN ResNet101 FPN model performed the best among all the models. It is then fine-tuned to achieve a better result. Batch size and max iteration are the parameters used to fine tune the model. As a result, the Faster R-CNN ResNet101 FPN model with 9000 iterations and batch size of 2 achieved the best performance compared to its

benchmark model with 3600 iterations and batch size of 2. Suggestion for future work, to explore the method of taking a picture by combine using multi modal fusion and sensor. The data might be useful by combining sensors such as lidar, hyperspectral, and SAR (Synthetic Aperture Radar) with RGB imagery to improve detection under varying the environment from different perspectives.

***Abstract*—Chord prediction plays a key role in the advancement of musical technological innovations, such as automatic music transcription, real-time music tutoring, and intelligent composition tools. Accurate chord prediction can assist musicians, educators, and developers in constructing tools that help in learning, playing, and composing music. Background noise and audio distortions may have an impact on chord prediction accuracy, particularly in real-world situations. Chords can have distinct voicings or finger positions on the guitar, resulting in slight variations in audio representation. This study focuses on the classification of guitar chords using techniques of deep learning. There are eight major and minor guitar chords in the dataset. They have been turned into spectrograms, chromagrams, and Mel Frequency Cepstral Coefficients (MFCC) so that features can be extracted. Various deep learning architectures, including CNN, ResNet50, AlexNet, and VGG, were employed to classify the chords. Experimental results demonstrated that the spectrogram-based AlexNet model outperforms others, achieving good accuracy and robustness in chord classification. The proposed study demonstrates the efficiency of spectrograms and advanced deep learning models for audio signal processing in music applications. By automating chord detection, this study provides beneficial resources for music learners as well as educators, enabling more efficient learning and real-time feedback during practice sessions.**

***Keywords*—Chords; prediction; spectrogram; chromagram; Mel Frequency Cepstral Coefficients; AlexNet**

## I. Introduction

Nowadays people prefer to learn music online, particularly through video lessons. There is a growing demand for systems that can provide real-time feedback and support. Many aspiring musicians struggle to assess their own skill level, especially while learning to play musical instruments such as the guitar. The demand for an automated system capable of effectively identifying and classifying guitar chords is rising, as it can assist learners in determining whether they are performing the chords correctly [1].

A guitar typically contains six wires or strings stretched across the neck and body, each tuned to a distinct pitch, which makes sound when plucked or strummed [2]. The standard tuning of a guitar, from the lowest (thickest) to the highest (thinnest) string, is EADGBE. Frets are metal strips that run horizontally across the guitar neck. The frets separate the neck into parts. When you press a string against a fret, it shortens its vibrating length and changes its pitch. Theoretically, there are endless chords on a guitar due to changes in tunings, fingerings, and voicings [3]. Typically, guitarists utilize a more manageable set of chords. Based on the 12 notes of the chromatic scale, there are 12 distinct major and minor chords. Major chords, which include the root note, major third, and perfect fifth, are known for their bright, happy sound. Minor chords are typically described as having a darker, sadder sound, and they are made up of the root note, minor third, and perfect fifth [4]. The list of 12 major and 12 minor chords is presented in Table I.

TABLE I. Guitar Basic Major and Minor Chords

| Major Chords | Minor Chords |
|---|---|
| A major (A) | A minor (Am) |
| A# major (A#) or Bb major (Bb) | A# minor (A#m) or Bb minor (Bbm) |
| B major (B) | B minor (Bm) |
| C major (C) | C minor (Cm) |
| C# major (C#) or Db major (Db) | C# minor (C#m) or Db minor (Dbm) |
| D major (D) | D minor (Dm) |
| D# major (D#) or Eb major (Eb) | D# minor (D#m) or Eb minor (Ebm) |
| E major (E) | E minor (Em) |
| F major (F) | F minor (Fm) |
| F# major (F#) or Gb major (Gb) | F# minor (F#m) or Gb minor (Gbm) |
| G major (G) | G minor (Gm) |
| G# major (G#) or Ab major (Ab) | G# minor (G#m) or Ab minor (Abm) |

In our research, we demonstrate the 12 major and minor guitar chords with a standard notation system that incorporates the 6-string arrangement, fret numbers, and finger locations. This diagram is commonly used by guitarists to learn how to play each chord on the guitar. For each chord, the string number (ranging from 1 to 6, with string 1 being the thinnest and string 6 being the thickest) is specified along with the fret numbers that correspond to where the fingers should press on the fretboard [5]. For example, in the A Major (A) chord, String 6 (E) is not played, String 5 (A) is played open, String 4 (D) is pressed at the second fret with the third finger, String 3 (G) is pressed at the second fret with the second finger, String 2 (B) is pressed at the second fret with the first finger, and String 1 (E) is played open [6]. Fig. 1 presents a representation of a few chords.

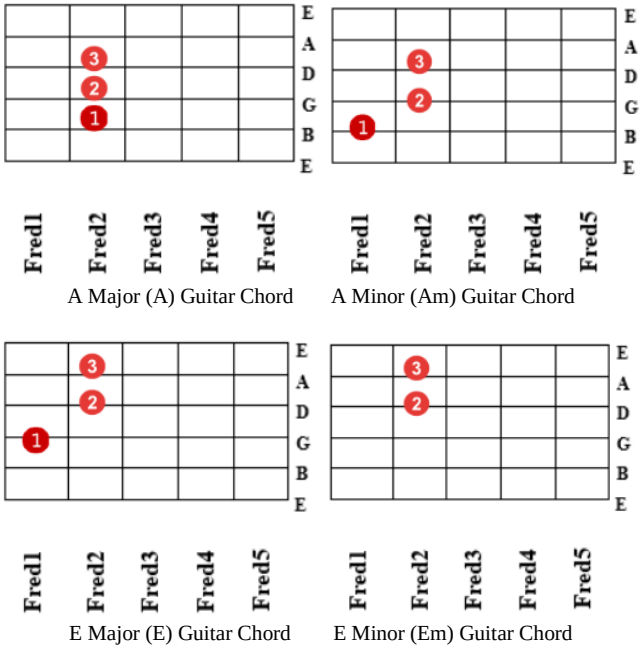

Fig. 1. Representation of chords.

To investigate the most effective representation of audio data for chord classification, we examined three extensively used feature extraction techniques: spectrogram [7], chromagram [8], and Mel-Frequency Cepstral Coefficients (MFCC) [9]. The model trained on spectrogram data outperformed the others in effectively predicting chords, demonstrating its capacity to capture pitch and harmonic relationships that are important for chord differentiation. Several deep learning architectures, such as CNN, ResNet50, AlexNet, and VGG-19, were used to perform the classification challenge [10, 11]. When trained on a limited dataset, AlexNet outperformed the other models, providing the highest accuracy while utilizing the fewest computational resources and training time. This makes AlexNet ideal for cases in which data availability is limited or rapid deployment is required. The approaches applied in the present research included preprocessing audio files to generate chromagrams, which were then scaled to standard dimensions. These representations were then utilized to train the classification models. The precision, recall, F1-score, and accuracy metrics were used to assess the performance of each architecture, ensuring an accurate assessment of its effectiveness. By evaluating the audio input from the learner's performance, it can provide immediate feedback, measure progress, and recommend areas for growth. This approach can be a useful aid for beginners studying guitar, allowing them to rapidly recognize and correct errors while practicing chords. It can function as a virtual tutor, providing assistance when a live instructor is unavailable.

The structure of this research article is outlined as follows: Section Two examines the most recent investigations on music categorization and discusses significant research gaps. Section Three illustrates the methodology, comprising details regarding the dataset, the feature extraction method, the architecture of the AlexNet model, and the assessment criteria used. Section Four discusses the performance of various feature extraction techniques and models in predicting chords based on the selected metrics. Finally, Section Five presents the conclusion, followed by a list of references used.

## II. Literature Survey

Automated chord recognition is an essential aspect of music information retrieval (MIR) that assists with applications such as music transcription, evaluation, and production. The work describes a chord detection method that combines a revised Pitch Class Profile (PCP) feature with Support Vector Machines (SVM) for classification. The PCP feature enhances music chord recognition by efficiently capturing harmonic structures while reducing noise and octave-related ambiguity. SVM is employed as it has high categorization proficiency, allowing precise chord detection across varied musical works. The methodology was evaluated on four songs: *Good to Be Alive*, *Ghost*, *The Royal Wedding Song*, and *Trouble I'm In*, with accuracy rates of 91%, 93%, 95%, and 98%, respectively. Investigations reveal that the approach performs well at detecting chord progressions, with satisfactory outcomes. Employing PCP as a classifier allows for evaluating a song's emotional undertones quickly and accurately, with broader ramifications. It enhances the comprehension of musical concepts by providing essential insights into theoretical frameworks [12].

The traditional methods for characterizing audio signals use handmade features such as MFCC, spectral centroid, or zero-crossing rate (ZCR). The recent improvements have centered on DL approaches and intelligent feature extraction to boost performance. The investigation explores the implementation of textural features and Mel-spectrograms produced from the short-time Fourier transform to capture the frequency content of an audio signal for accurate music identification. Texture features, primarily utilized in processing images, produced promising results in audio analysis by capturing patterns and fluctuations in representations of spectrograms. A diversified song recording dataset of 404 audio files from four unique classes of Arabic music has been gathered and transformed into Mel-spectrograms, using which various texture features are extracted. Each Mel-spectrogram undergoes a two-dimensional Haar wavelet processing before feature extraction with Local Binary Patterns (LBP), Histogram of Oriented Gradient (HOG), and Gray Level Co-occurrence Matrix (GLCM). To assess classification performance, several machine learning methods were used, and the proposed approach was evaluated on two datasets: the recently collected Arabic music dataset and the commonly utilized GTZAN dataset. Using five-fold cross-

validation, the research findings demonstrated that the XGB classifier performed better, giving 97.8% accuracy, 97.7% F1- score, 97.7% recall, and 97.8% precision [13].

Folorunso et al. explore the understudied topic of automatic genre categorization for Nigerian traditional music utilizing the ORIN dataset, which comprises 478 music with five genres: Apala, Fuji, Waka, Juju, and Highlife. The Librosa Python package has been utilized to retrieve timbral texture and tempo information for 30-second portions of each song. The study employed the global mean (Tree SHAP) method to assess feature significance and its impact on the model for classification. Timbral features of texture allow for differentiation between comparable beats and melodies. The timbral texture can be used to compute a variety of properties such as MFCC, spectral centroid, tempo, flatness, bandwidth, contrast, sample-silence, zero-crossing-rate, and so on. After the extraction, information about the level of variance and dispersion is extracted, including mean, skewness, kurtosis, standard deviation, minimum, and maximum values. The methodology, which combines feature extraction with classifiers, delivers insights into the performance of several models for genre categorization. The Tree SHAP method is based on Shapley Additive Explanations (SHAP), a game-theoretic strategy for assigning importance scores to input data in interpreting tree-based model predictions. Four classifiers were implemented for genre classification, and among these, the XGBoost classifier has an outstanding accuracy of 81.9% and recall of 84.5% [14].

Categorizing music genres can be automated, and many approaches have been presented in recent years for accomplishing this objective; however, analysis shows that there is still an inequality between the observed outcomes and an optimal categorization approach. The Teng Li presented an approach that involves preprocessing the input signals and then demonstrating the properties of each signal using a combination of MFCC and STFT features. The proposed technique combines two independent CNN models optimized with black hole optimization (BHO) to evaluate MFCC and STFT data, and the results of the two models are integrated to identify the music genre by applying a SoftMax classifier. The GTZAN and Extended-Ballroom datasets were used for assessing the performance of the suggested technique for categorizing music genres. Test outcomes revealed that the suggested approach obtained a classification accuracy of 95.2% on GTZAN and 95.7% on Extended-Ballroom datasets [15].

Carsault et al. investigate the real-time evaluation and forecasting of musical chord patterns to improve innovative methods in composing music and performance. The chords have inherent hierarchical and functional linkages that are critical for comprehending and anticipating musical forms. The input is an audio real-time recording of a musician, which is processed in order to produce a time-frequency representation assisting in the identification of chord sequences. Each beat of the music is then tagged with a chord, and the prediction module makes use of these chords in recommending what might occur next in the sequence. Chord prediction employs several loss functions, such as Tonnetz and correct notes, for boosting accuracy in both diatonic and non-diatonic music. The Bi-LSTM model is utilized in chord prediction because it retains past and future interdependence in chord sequences, making it ideal for sequential music prediction services. This method provides a deeper understanding of the model's performance than typical accuracy measurements [16].

Deep learning models substituted earlier ML approaches that relied on hand-crafted features and transformed the area of music classification by allowing pattern features to be learned automatically. Researcher Jiyang Chen stated that CNNs face challenges in accurately simulating global features that are essential for identifying music signals with temporal properties due to the influence of the local receptive field. The proposed hybrid architecture based on CNN and Transformer encoder worked on transforming audio signals into mel spectrograms. The CNN architecture consists of four 2D convolutional layers, followed by batch normalization, max pooling, and ReLU as the activation function. The transformer encoder has two layers, each of which has multi-head attention, a multi-layer perceptron, and two normalizing layers. The CNN primarily captures low- level and localized features from the spectrogram, followed by the transformer encoder, which processes these features globally to extract high-level and abstract semantic information. The approach is evaluated on the GTZAN with 100,000 tracks and FMA datasets, contains 8000 music clips, and produces amazing outcomes with lower parameters and an increased inference speed, with accuracy 87.41, precision 87.93, recall 87.58, and F1 score 87.28 [17].

As music is a sort of time-series data, which makes it difficult to build a robust MGC, Zhiqiang Zheng introduced the DL-Enabled MGC approach, which aims at boosting the precision and effectiveness of genre categorization work. The proposed strategy extracts significant features from raw musical data by converting pitches from input Musical Instrument Digital Interface (MIDI) files into vector sequences employing the Pitch2vec method. A hybrid model employs bidirectional long short-term memory optimized using cat swarm optimization to successfully capture temporal dependencies in music data. CSO is a swarm intelligence-based optimization technique that fine-tunes hyperparameters, including learning rate, number of hidden layers, and activation functions, resulting in improved model convergence. BiLSTM analyzes data both forward and reversed, facilitating the model to capture past and future dependencies concurrently. The DLE-MGC technique was examined using the MIDI music dataset containing thirteen types of music utilizing 1000 and 2000 epochs. The results demonstrate that with 1000 epochs, the DLE-MGC methodology has offered a precision, recall, F1-score, and accuracy of 94.97%, 95.97%, 96.53%, and 95.42%, and with 2000 epochs, 95.84%, 95.93%, 96.71%, and 95.77%, respectively [18].

Yu-Huei Cheng presents an experimental approach for recognizing genres of music that employs graphical representations of sound data and effective ML algorithms. To achieve excellent classification accuracy, the visual Mel spectrum was employed as a feature representation, together with the YOLOv4 neural network architecture. The visual Mel spectrum, which captures both temporal and spectral aspects of the music, is provided as input for the classification model, allowing for the extraction of rich, discriminative properties relevant to several music genres. The YOLOv4 architecture has

been chosen as its potential to effectively handle visual data makes it suitable for interpreting visual Mel spectrograms, resulting in effective feature learning and categorization. The 1.6 GB GTZAN dataset was used for the assessments, and the proposed technique achieved 91.49% accuracy for training and 97.93% for testing. This study uses YOLO, which has never been utilized for music genre classification, and it has research significance [19].

A review of previous studies indicates that the majority of music analysis research focuses on genre classification rather than chord prediction. There is a significant gap in research on automatic chord recognition. The majority of studies use CNN for music classification tasks like genre and instrument recognition. While deep learning models are commonly used for classification, the effect of various feature extraction methodologies (such as chromagram, spectrogram, and MFCC) on model performance has not been thoroughly investigated. Most research does not examine how different feature representations impact classification accuracy, leaving a gap in determining the optimal characteristics for chord recognition.

## III. Methodology

We loaded the chords dataset containing .wav audio files for different chord categories and extracted the Chromagram, spectrogram, and MFCC features. The normalization is performed on each extracted feature to ensure that all features are on the same scale [20]. Each feature set was used to train and evaluate several deep learning models in order to determine the most effective feature extraction technique and chord prediction model. PyAudio was used to capture live audio from the guitarist while he performed in order to figure out chords in real time. The selected deep learning model was then used to determine the correct chord [21-23]. The proposed methodology is described in Fig. 2.

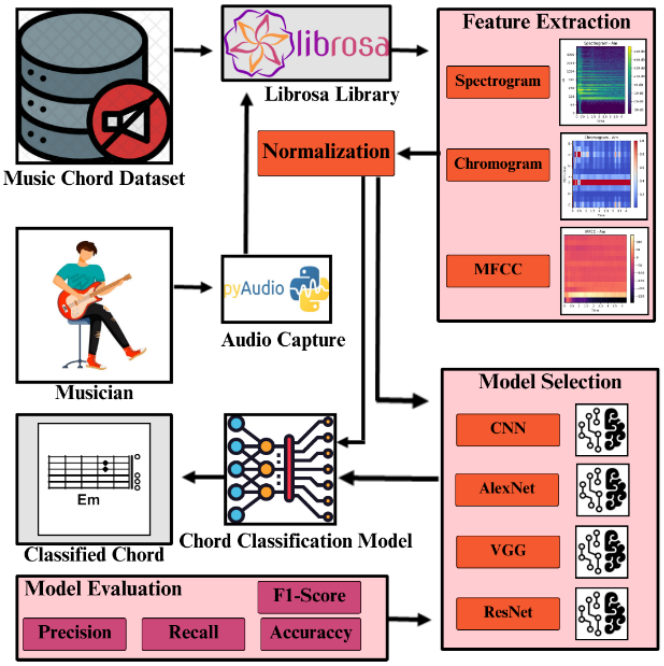

Fig. 2. Proposed methodology.

### A. Dataset

We collected a dataset of 1440 audio files in .wav format, each representing eight distinct guitar chords: [Minor: {Em', 'Dm', 'Am', 'Bdim'}, Major: {G', 'C', 'Bb', 'F'}]. Each chord was played on a guitar by hand, with speed and duration variations to imitate several acoustic aspects associated with performances in real time. This variation in playing approach promises that the dataset covers a wide range of musical expressions, which enhances the robustness of the chord prediction model. The dataset establishes a robust foundation for constructing and evaluating deep learning models for real-time chord recognition in music. The 1,152 .wav files, representing 80% of the chord dataset, were employed to train the chord prediction model, while the remaining 288 files, which is 20%, were used to test its accuracy and effectiveness.

### B. Feature Extraction

Feature extraction is a critical step in chord prediction because it transforms raw audio data into meaningful representations that can be used by machine learning algorithms. We employed three fundamental feature extraction strategies: chromagram, spectrogram, and MFCC, each of which captured a different aspect of the audio stream. Fig. 3 demonstrates the representation of the chromatogram, spectrogram, and MFCC for chords Am and C.

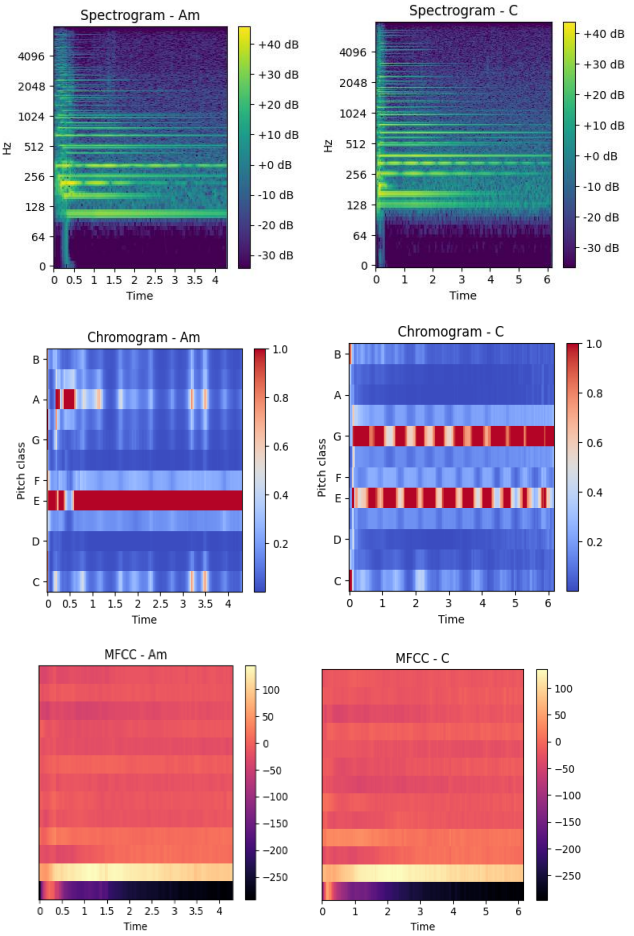

Fig. 3. Representation of chromagram, spectrogram, and MFCC for chord Am & C.

*1) Spectrogram*: Spectrograms are extensively utilized in domains such as machine learning, voice analysis, audio processing, and seismology, particularly in applications like environmental sound classification and recognition of speech. A spectrogram is a two-dimensional graph where a third dimension is represented by color. Time is represented by the horizontal X-axis, which moves from left to right, while frequency is represented by the vertical Y-axis, which goes from low at the bottom to high at the top [24]. A frequency's amplitude or loudness at a given moment is indicated by its color intensity; brighter colors imply higher, louder amplitudes, while darker shades suggest lower amplitudes. A signal is usually broken down into its frequency components over short time intervals using the Short-Time Fourier Transform (STFT) expressed in Eq. (1), which serves as a foundation for building spectrograms [25]. Eq. (2) uses the squared magnitude of the STFT to derive the spectrogram.

$$S(t,f) = \int_{-\infty}^{\infty} x(\tau)\omega(\tau - t)e^{-j2\pi f\tau}\, d\tau \quad (1)$$

$$Spectrogram(t,f) = |S(t,f)|^2 \quad (2)$$

The sliding window current time location represented by t and f represents the frequency being analyzed. The input signal as a function of time is represented by x(τ). A window function w(τ−t) centered at time t isolates a segment of the signal to analyze. The Fourier kernel $e^{-j2\pi f\tau}$ that transforms the signal into the frequency domain.

*2) Chromagram*: A chromagram is a representation in the form of an image of the intensity or energy of the pitch classes or musical notes in a signal, irrespective of their octave. As it can capture the melodic and harmonic elements of audio signals, it is frequently utilized in music information retrieval (MIR). The vertical Y-axis represents musical notes that are classified into twelve pitch classes (e.g., C, C#, D, ..., B) in the Western music system, and the horizontal X-axis represents the time evolution of the signal [26]. The color or brightness of a cell in the chromagram represents the energy or intensity of a specific pitch class at a given time. The audio signal x(n) (where n represents discrete time samples) is transformed into the frequency domain using the STFT using Eq. (1). The Eq. (3) translates frequencies in the spectrum to one of the twelve pitch classes [27].

$$p = mod\left(\left\lfloor 12.log_2\left(\frac{f}{f_{ref}}\right)\right\rfloor, 12\right) \quad (3)$$

where, p is Pitch class ranges from 0 to 11, corresponding to C, C#, ..., B. The f represents frequency in Hz, and $f_{ref}$ refers to reference frequency, typically 440 Hz. The $\lfloor\cdot\rfloor$ symbol represents the floor function, which truncates to the largest integer less than or equal to the value. For each pitch class p, the total energy over all octaves at time t is calculated. The chromagram C(t,p) can be calculated as follows:

$$\mathrm{C(t,p)} = \sum_{f\in F(P)}|X(t,f)| \quad (4)$$

where, |X(t,f)| represents the magnitude of the STFT at time t and frequency f. The set F(p) contains all frequencies f that correspond to the pitch class p. To achieve uniform representation across time frames, normalization is employed, expressed in Eq. (5) [28].

$$NC(t,p) = \frac{C(t,p)}{max_p C(t,p)} \quad (5)$$

where, *NC(t,p)* is the normalized chromagram, and maximum chromagram intensity over all pitch classes for a particular time frame t is represented by $max_pC(t,p)$.

*3) Mel-frequency cepstral coefficients (MFCC)*: MFCCs are created by translating an audio signal into a set of coefficients that represent the signal's short-term power spectrum on the Mel frequency scale, which is commonly utilized in speech and audio signal processing operations [28]. MFCCs give a concise representation of an audio signal's spectrum features and have been designed to represent the human auditory system's perception of sound. To amplify high frequencies and balance the spectrum, pre-emphasis is applied to the signal, assisting to retain key information for analysis.

$$Y[n] = X[n] - \alpha \cdot X[n-1] \quad (6)$$

where, X[n] represents the original signal, Y[n] represents the pre-emphasized signal, and α is the coefficient for pre-emphasis, usually 0.95. To examine short-term features, the signal is separated into small overlapping frames spanning about 20-40 milliseconds. Each frame represents a quasi-stationary segment of the signal. To eliminate edge effects, a window function w[n] (especially Hamming) gets applied to each frame 1 to N expressed in Eq. (7) [29].

$$w[n] = 0.54 - 0.46 \cdot cos\left(\frac{2\pi n}{N-1}\right) \quad (7)$$

The number 0.54 ensures that the window has a "base value" at its center, while -0.46 multiplied by the cosine function modifies the form of the window, regulating how quickly the window tapers to zero at its edges. The power spectrum is obtained using the Fourier transform, which transforms the windowed frame into the frequency domain.

$$X[k] = \sum_{n=0}^{N-1} x[n] \,.\, e^{-j2\pi kn/N} \quad (8)$$

where, X[k] is frequency components and k represents the frequency bin index. To map the power spectrum to the Mel scale m(f), it first passes through a Mel filter bank (MFB) expressed in Eq. (9). The scaling ratio 2595 was used to translate frequencies from the Hertz scale to the Mel scale, and the constant 700 is a reference frequency at which the Mel scale begins to diverge significantly from linear scaling. Triangular filters concentrate distinct frequency bands to replicate human hearing. The energy S[m] for each Mel filter is calculated using Eq. (10), where Weight of the $k^{th}$ frequency in the $m^{th}$ filter. Logarithmic scaling L[m] is used to simulate the human auditory system's perception of sound expressed in Eq. (11) [30].

$$m(f) = 2595.log_{10}\left(1 + \frac{f}{700}\right) \quad (9)$$

$$S[m] = \sum_k |X[k]|^2 . H_m[k] \quad (10)$$

$$L[m] = log(S[m]) \quad (11)$$

The Discrete Cosine Transform (DCT) is used to decorrelate log Mel energy and compress them into MFCC coefficients

using Eq. (12), where M is number of Mel filters and n is the coefficient index.

$$MFCC[n] = \sum_{m=0}^{M-1} L[m] \cdot cos\left(\frac{\pi n(2m+1)}{2M}\right) \quad (12)$$

The overall process for MFCC computation C(t, n) is represented in Eq. (13), where t is the time frame index and n is the MFCC coefficient index.

$$C(t,n) = DCT\left(log\left(MFB\left(FFT(x(t))\right)\right)\right) \quad (13)$$

### C. Model Selection

Several deep learning architectures were employed to evaluate the chord prediction performance, including CNN, AlexNet, VGG-19, and ResNet-50. The best models were picked based on their demonstrated effectiveness in audio categorization tasks utilizing assessment measures. CNN is a fundamental deep learning model that can extract hierarchical features from input data while accurately capturing spatial patterns, making it suitable for a wide range of classification applications [31]. AlexNet is a deep CNN architecture designed for rapid feature extraction and classification. It employs stacked convolutional layers, ReLU activation, and dropout to improve generalization. A VGG-19 is a deeper convolutional network with 19 layers known for its identical design and potential to capture intricate patterns with small receptive fields and dense layers. ResNet-50 is a residual learning framework that uses skip connections to address the problem of vanishing gradient, resulting in deeper network training and improved classification accuracy [32].

*1) AlexNet*: AlexNet is a foundational baseline in deep learning for image classification. AlexNet consists of five convolutional layers for feature extraction and three fully connected layers for classification. AlexNet additionally uses max-pooling for spatial dimensionality reduction and GPUs for parallel processing, allowing for effective training on big datasets. It employs ReLU activation functions to incorporate nonlinearity, dropout to reduce overfitting, and data augmentation to improve generalization [33]. The acceptable input image shape is 224×224×3. The first convolution layer extracts low-level characteristics such as edges and corners using 96 filters of size 11×11 with a stride of 4 and an output of 55×55×96. The second convolution layer captures more detailed features and applies local response normalization (LRN). It uses 256 filters of size 5×5×96 with a stride of 1 and generates an output of 27×27×256. Fig. 4 presents an in-depth description of the AlexNet architecture layers, including filter size, filter number, stride, input and output sizes [34].

### D. Model Evaluation

*1)* Various metrics for assessment, such as accuracy, precision, recall, and F1-score, were employed for evaluating the feature extraction technique and model's performance in music chord prediction. These metrics provide an extensive assessment of the model's potential to accurately categorize chords while balancing false positives and false negatives [35-37]. The TP represents the instances where the model correctly predicts the positive class, and TN are the Instances where the model accurately identifies the negative class. The FP is the number of instances for which the model incorrectly classifies it as positive, and the FN is the number of instances for which the model incorrectly classifies it as negative.

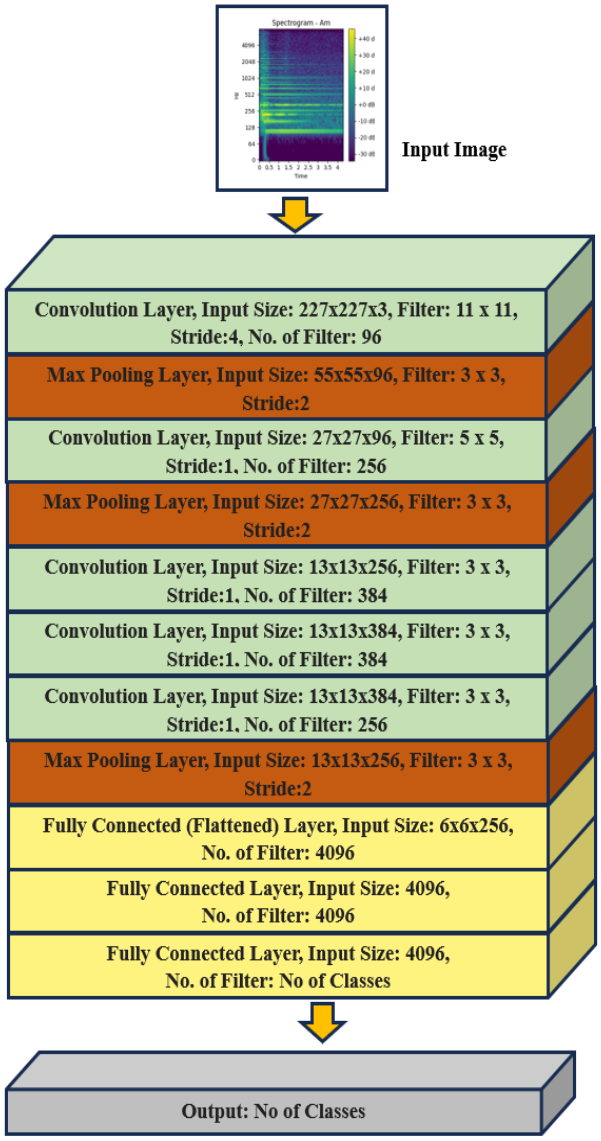

Fig. 4. AlexNet architecture.

$$\text{Accuracy} = \frac{Sum\ of\ Accurately\ Forecasted\ +ve\ samples\ [TP]\ and\ -ve\ Samples\ [TN]}{Total\ Samples(N)} \quad (14)$$

$$\text{Precision} = \frac{Accuately\ forecasted\ +ve\ samples\ [TP]}{sum\ of\ Accuatly\ forecasted\ +ve\ samples\ [TP]\ and\ incorrect\ forecasting\ as\ +ve\ [FP]} \quad (15)$$

$$\text{Recall} = \frac{Accuatly\ forecasted\ +ve\ samples\ [TP]}{Sum\ of\ Accuatly\ forecasted\ +ve\ samples [TP]\ and\ incorrect\ forecasting\ as\ -ve\ [FN]} \quad (16)$$

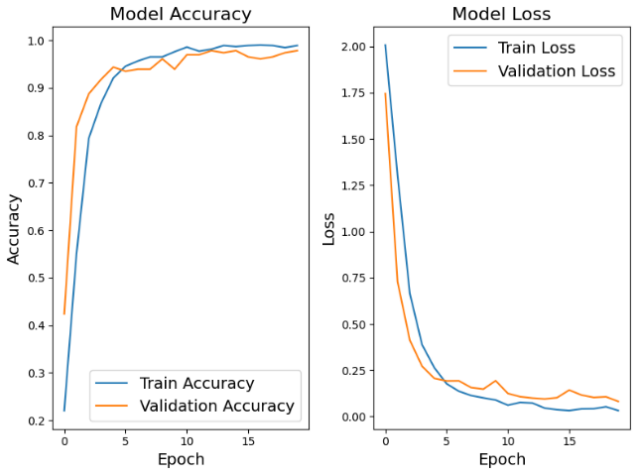
$$\text{F1Score} = 2 * \frac{[\text{Precision} * \text{Recall}]}{[\text{Precision} + \text{Recall}]} \quad (17)$$

## IV. Result and Discussion

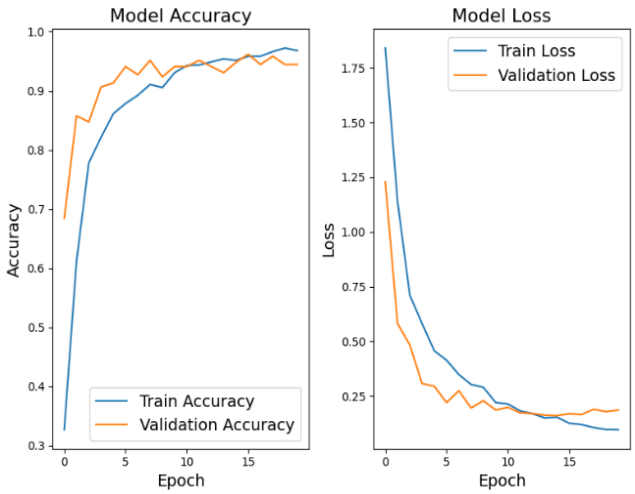
The research study has been carried out on Google Colab, using a T4 GPU for accelerated training. The chords dataset is stored on Google Drive and mounted with the Colab notebook for simple retrieval. Librosa is used for feature extraction, and Keras is utilized to build the CNN model and its variants.

### A. Evaluation of Spectrogram, Chromagram, and MFCC Features

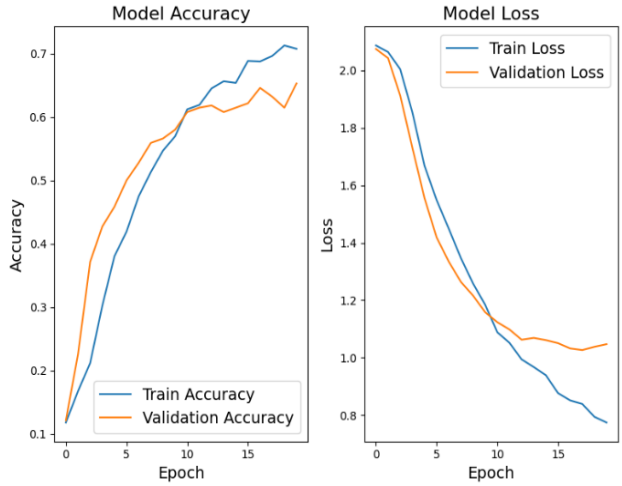
The dataset contains 1440 .wav audio files representing eight different major and minor chords, split into training and testing sets in an 80:20 ratio. To assess the effectiveness of feature extraction approaches, a CNN is trained on each method employing a similar training set. The effectiveness of CNN models trained using different feature extraction techniques was evaluated by plotting training & validation accuracy and loss against the number of epochs. Fig. 5 demonstrates the performance of each feature extraction strategy during CNN training.



Spectrogram



Chromagram



MFCC

Fig. 5. Performance of CNN model trained on spectogram, chromagram and MFCC.

CNN trained on MFCC features has less satisfactory accuracy (65%) than spectrogram and chromagram models. The loss reduction is not as smooth, demonstrating that the model has difficulty with feature representation. The model does not fully converge within 20 epochs, indicating the need for additional training or hyperparameter adjustment. CNN models based on spectrograms and chromagrams outperform MFCC-based CNN models. The spectrogram-based CNN is more accurate, converges in fewer epochs, and has closely aligned training and validation accuracy and loss values, indicating stable learning. In comparison, the chromagram-based CNN takes considerably more epochs to converge, achieves slightly reduced accuracy compared to the spectrogram-based model, and has a greater gap between training and validation accuracy and loss values. The performance of each feature extraction strategy for the test. WAV sound files are presented in Table II.

TABLE II. Performance of CNN on Different Feature Extraction Techniques

| Model | Feature Extraction Techniques | Accuracy | Precision | Recall | F1-Score |
|---|---|---|---|---|---|
| CNN | Spectrogram | 0.94 | 0.95 | 0.94 | 0.94 |
| | Chromagram | 0.93 | 0.94 | 0.93 | 0.93 |
| | MFCC | 0.65 | 0.67 | 0.65 | 0.65 |

The results demonstrate that the spectrogram-based CNN model delivers the highest accuracy of 94%, with other assessment measures at 0.94 each. This shows that spectrograms efficiently capture the time-frequency representation of audio inputs, resulting in reliable feature extraction for chord categorization. The chromagram-based CNN model likewise revealed strong performance, with an accuracy of 93%. However slightly less accurate than the spectrogram-based model, the chromagram technique accurately represents harmonic content, offering it as an acceptable alternative for chord detection tasks. MFCCs primarily capture spectral envelope information and are frequently employed in speech processing; however, due to their limited ability to represent harmonic structures, it may be inefficient for musical chord classification.

### B. Evaluation of Spectrogram Based Deep Learning Architecture

Choosing an appropriate architecture capable of effectively capturing the extracted feature for accurate chord detection is a vital component of the chord prediction problem. In this experiment, we trained CNNs and their variants, such as AlexNet, VGG-19, and ResNet-50, on spectrogram-based features and evaluated their performance using standard metrics. Table III summarizes the performance of each spectrogram-based model.

TABLE III. PERFORMANCE OF SEVERAL CNN VARIANTS ON SPECTOGRAM

| Model | Accuracy | Precision | Recall | F1-Score |
|---|---|---|---|---|
| CNN [38-40] | 0.94 | 0.95 | 0.94 | 0.94 |
| AlexNet | 0.96 | 0.97 | 0.97 | 0.97 |
| VGG-19 | 0.77 | 0.80 | 0.77 | 0.77 |
| ResNet-50 | 0.91 | 0.92 | 0.91 | 0.91 |

AlexNet consistently outperformed the other models examined, revealing its potential to capture pertinent information in the spectrogram and being well-suited for the chord prediction task, offering a balanced performance in both detecting and properly classifying guitar chords. The result shows that ResNet-50 and VGG-19 are deeper architectures having more parameters. These deeper models are more suitable for larger datasets, where they may learn from a diverse set of features. With a limited dataset of 1440 samples, these architectures may struggle to generalize successfully, resulting in overfitting. On the other hand, AlexNet and CNNs are less likely to overfit due to their more compact structure, and they can extract useful information from a smaller dataset without becoming overly specialized in it. Fig. 6 demonstrates the performance of AlexNet trained on spectrograms. The confusion matrix demonstrates in Fig. 7 the performance of AlexNet on the testing dataset.

## V. CONCLUSION

Intelligent guitar chord categorization is a significant advancement towards improved music transcription processes, assisting musicians and growing music learning tools. Implementing deep learning approaches can build a robust system that appropriately recognizes chords from audio signals, eliminating the need for manual intervention and strengthening real-time chord recognition. The experimental results reveal that spectrogram-based models provide the best classification performance, accurately discriminating distinct chords as compared to chromagram and MFCC-based approaches. AlexNet performed outstandingly on a smaller dataset with minimal training time, making it suitable for low-data scenarios in comparison with CNN, VGG-19, and ResNet-50 architectures. The investigated training and validation accuracy/loss curves, confusion matrices, and key classification metrics demonstrate that spectrogram-based AlexNet architectures outperform other architectures trained on several feature extraction methods for chord categorization. Future studies might concentrate on expanding the dataset to foster model generalization and incorporating transformer-based designs for better feature extraction. Furthermore, incorporating the trained model with real-time applications for live chord detection and music analysis can increase its practical applicability. Future research will also concentrate on further enhancing computing efficiency in mobile and embedded devices.

# Portable and Lightweight Signal Processing Approach for sEMG-Based Human–Machine Interaction in Robotic Hands

Ngoc-Khoat Nguyen
Faculty of Control and Automation, Electric Power University, Hanoi, Vietnam

***Abstract*—Surface electromyography (sEMG) presents a viable biosignal for the control of robotic prosthetic hands, as it directly correlates with underlying muscle activity. This study introduces an efficient, computationally lightweight signal processing methodology designed for real-time embedded systems. The proposed methodology comprises a preprocessing pipeline, incorporating bandpass and notch filtering, followed by segmentation via overlapping sliding windows. Time-domain features, specifically Mean Absolute Value (MAV), Zero Crossing (ZC), Waveform Length (WL), Slope Sign Change (SSC), and Variance (VAR), are extracted to characterize relevant muscular activation patterns. By prioritizing computational efficiency and embedded system feasibility, this method establishes a practical framework for user intent recognition and real-time control of wearable robotic hands, particularly within assistive and rehabilitative applications. The experimental findings clearly indicate that the extracted features effectively differentiate between various hand gestures, allowing for accurate, real-time control of the wearable robotic hand. The system's high responsiveness, low latency, and resilience to noise underscore its suitability for assistive and rehabilitative applications. With its focus on computational simplicity and feasibility for embedded implementation, the proposed method provides a practical basis for recognizing user intent in human-machine interaction systems.**

***Keywords*—sEMG; myo-prosthesis; myosignals; human–prosthesis interface; signal processing**

## I. Introduction

The upper limb plays a crucial role to a wide spectrum of daily human activities, encompassing both intricate manipulations, such as object grasping and writing, and complex movements requiring multi-joint coordination [1]. Anatomically, the upper limb comprises distinct segments-the hand, forearm, and upper arm-functioning through the coordinated interaction of the central nervous system, musculoskeletal system, and environmental sensory feedback. This inherent complexity presents substantial challenges in the design of artificial prosthetic systems, particularly robotic hands, where dexterity, precision, and user-intent-driven control are paramount. The partial or complete loss of an upper limb, resulting from trauma, disease, or other etiologies, can significantly impair an individual's quality of life, self-care capabilities, and social integration.

In recent years, a growing number of studies have explored the use of bio-signals originating from the human body to control prosthetic limbs, due to their rich information content regarding motor intentions. Among these, electromyography (EMG) signals have been extensively investigated for their ability to reflect muscle activity [2]-[4]. However, raw surface EMG (sEMG) signals cannot be directly used for motion recognition or robotic control due to their inherent spatial and temporal complexity [5]. Factors such as electrode displacement, muscle fatigue, variability in contraction intensity, and inter-subject differences contribute to reduced accuracy and repeatability in EMG-based control systems [6], [7].

Various techniques have been employed to process EMG signals, yet the core processing pipeline remains largely consistent. Initially, EMG signals are amplified and filtered after acquisition. This is particularly crucial in clinical or rehabilitation scenarios where residual muscle strength may be weak, resulting in significantly lower sEMG amplitudes compared to those in healthy individuals. Proper filter and amplifier design not only improves the signal-to-noise ratio (SNR) but also enhances the reliability of extracting relevant motor information from the signal [8].

Following preprocessing, sEMG signals are segmented using time windows, dividing the continuous data into short, fixed-length segments. Overlapping windowing is the most commonly adopted method, with the choice of window size and stride length being critical for balancing latency and accuracy. Each segment is then used to extract features that characterize muscle activity over the corresponding time interval [9].

Extracted features can belong to the time domain (TD), frequency domain (FD), or time–frequency domain (TFD). Time-domain features are directly calculated from raw sEMG signals and are functions of time [10]. TD features are widely favored due to their simplicity and computational efficiency, making them well-suited for real-time control systems. Common TD features include Mean Absolute Value (MAV), Zero Crossings (ZC), Waveform Length (WL), Slope Sign Changes (SSC), and Variance (VAR), which reflect the intensity, shape, and variation of the EMG signal. These features serves as useful inputs for subsequent classification or control stages, and have been extensively studied for EMG recognition tasks [11]–[13]. For instance, in [11], six TD features (MAV, WL, RMS, AR, ZC, SSC) were used to classify seven hand gestures, with Support Vector Machines (SVM) achieving the highest accuracy (95.26 per cent) compared to LDA (92.58 per cent) and k-NN (86.41 per cent).

In addition to TD features, FD features also play a key role in describing the spectral properties of EMG signals [14]. By

applying spectral analysis techniques such as the Fast Fourier Transform (FFT), indicators such as spectral energy, Mean Frequency (MNF), and Median Frequency (MDF) can be extracted. FD features are commonly used in fatigue analysis or combined with TD features to improve classification performance [13]. Time–frequency domain transformations such as the Short-Time Fourier Transform (STFT), FFT, and wavelet transforms preserve both TD and FD characteristics of the signal. However, TFD-based methods remain relatively underexplored due to their complexity and limited interpretability [8].

After extracting EMG features from one or more domains, the next step is to classify or recognize the user's intended movements. This is a crucial stage that translates physiological signals into control commands for robotic hands. Numerous machine learning algorithms have been successfully employed for EMG classification, ranging from traditional methods such as k-Nearest Neighbors (k-NN) [15], Linear Discriminant Analysis (LDA) [16], [23], and Support Vector Machines (SVM) [11], [17]–[19], to advanced deep learning models such as Convolutional Neural Networks (CNN) [20], [21] and Recurrent Neural Networks (RNN) [22]. Simpler models like LDA and SVM are often preferred in real-time systems due to their low computational overhead and effectiveness with linearly or near-linearly separable features. On the other hand, deep learning models can directly learn representations from raw or time–frequency-transformed data such as spectrograms or scalograms, yielding higher accuracy at the cost of increased computational requirements.

This study focuses on the preprocessing and feature extraction stages of sEMG signals as a foundation for recognizing user intent in robotic hand control. The signal undergoes preprocessing steps, including high-pass filtering, notch filtering, and low-pass filtering, to reduce noise and normalize data. Subsequently, time-domain features such as MAV, ZC, WL, SSC, and VAR are extracted using a sliding window technique, providing the necessary inputs for later classification and control stages.

The main contribution of this paper is the proposal and evaluation of a simple yet effective sEMG signal processing method that can be integrated into real-time embedded systems such as microcontrollers or wearable robotic control devices. This research lays the groundwork for incorporating machine learning techniques that enable more intuitive and adaptive robotic control. Additionally, it contributes to the development of user-intent-based control systems for robotic hands, targeting applications in rehabilitation and assistive technologies.

The subsequent sections are organized as follows: Section II covers the materials and methods used for sEMG signal acquisition and processing, detailing the signal conditioning and feature extraction steps. Section III explains the integration of the proposed method for real-time robotic hand control and describes the validation experiments performed across diverse hand gestures. Section IV presents a discussion centered on the results of these experiments, including an analysis of the proposed method's benefits and drawbacks. Lastly, Section V summarizes the key findings and identifies potential avenues for future work.

## II. Materials and Methods

### A. Signal Analysis

*1) sEMG acquisition hardware*: In this study, the surface electromyography (sEMG) sensor module DFRobot – OYMotion (Product Code: SEN0240) was employed to acquire electromyographic signals generated by muscle contractions of the user. The overall structure of the SEN0204 sensor module is illustrated in Fig. 1. This analog sEMG module, co-developed by DFRobot and OYMotion, integrates essential functional blocks including signal amplification, noise filtering, and primary signal conditioning.

One of the most notable advantages of this module is its capability to operate with dry metal electrodes, eliminating the need for conductive gel typically required by conventional medical electrodes. This feature significantly simplifies the setup process, enhances durability, and improves user convenience, particularly in non-invasive human–machine interaction (HMI) applications. The use of dry electrodes allows for flexible deployment on both static and dynamic muscle regions while maintaining reliable signal quality.

The sensor is capable of amplifying small sEMG signals in the range of ±1.5 mV up to 1000 times. It utilizes differential input combined with an integrated analog filtering stage to effectively suppress noise, particularly power line interference at 50/60 Hz. The sensor operates optimally within a frequency range of 20 Hz to 500 Hz, which corresponds to the primary spectral band of sEMG signals. The output is provided as an analog voltage signal with a reference level of 1.5 V and a swing range from 0 to 3.0 V, making it well-suited for digitization via analog-to-digital converters (ADCs) in microcontroller-based embedded systems.

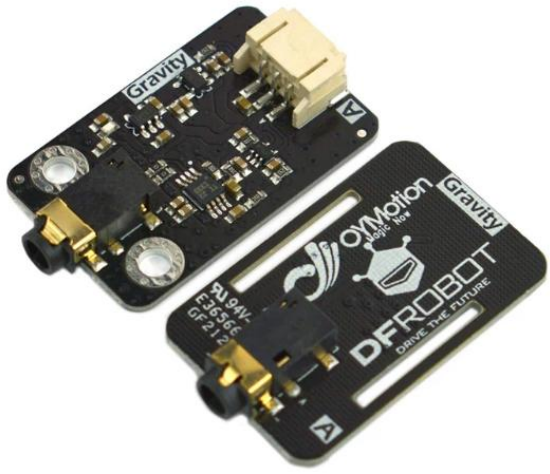

Fig. 1. SEN0204 analog EMG sensor by OYMOTION [24].

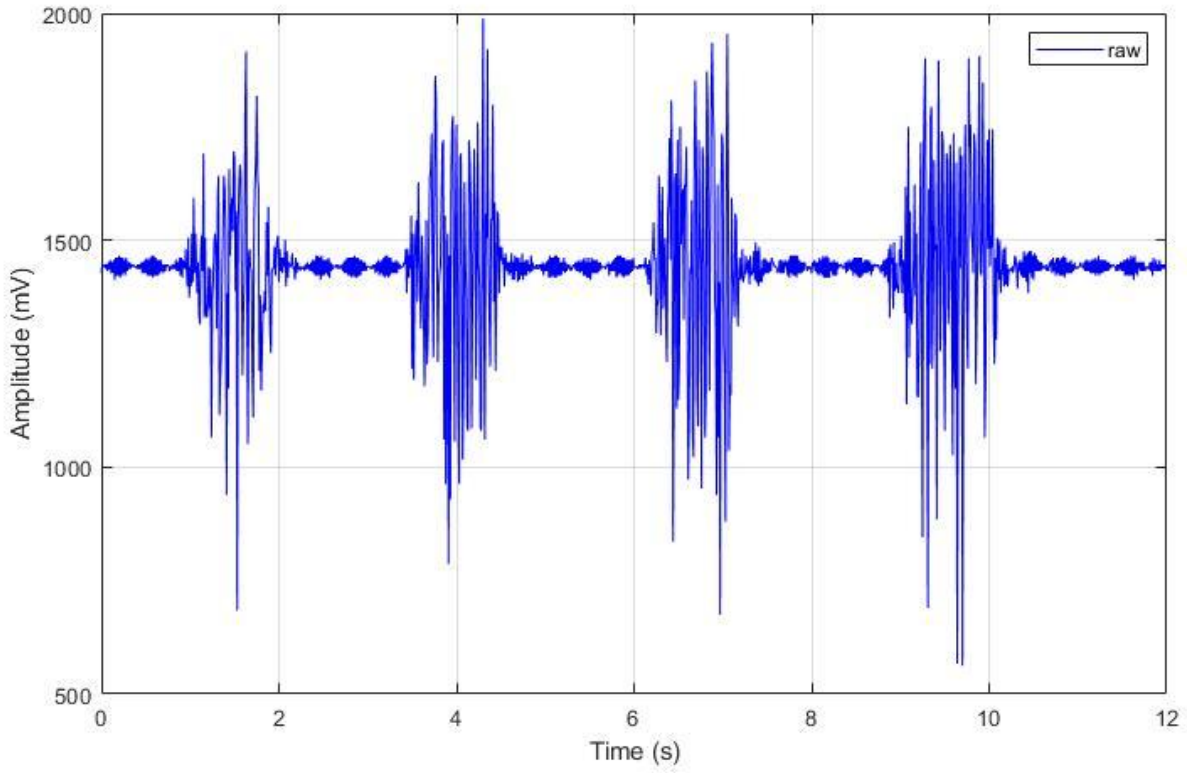

Fig. 2. An illustration of a raw sEMG signal.

Fig. 2 illustrates a raw sEMG signal acquired from the SEN0240 sensor using a 10-bit ADC. The signal was sampled at a frequency of 1000 Hz. The output amplitude fluctuates within the range of approximately 500 mV to 2000 mV, with an average baseline (offset) value around 1.5 V (1500 mV), consistent with the sensor's technical specifications. The signal clearly demonstrates alternating phases of muscle contraction and relaxation, characterized by high-amplitude fluctuations during active periods and near-flat regions during rest. Notably, strong muscle contractions occur at approximately 1.5s, 4.5s, 7s, and 9.5s, with signal amplitudes spiking significantly above the baseline level. During the resting intervals, the signal oscillates mildly around 1.5 V, indicating minimal muscle activity. The presence of power line interference (50 Hz) or high-frequency noise components is noticeable, particularly in the low-activity segments.

*2) Signal preprocessing*: The surface electromyography (sEMG) signal was acquired from the SEN0240 sensor using a three-electrode configuration: two electrodes placed over the muscle and one reference (GND) electrode. The output signal is in the form of an analog voltage within the 0–3.0 V range, with a baseline level of approximately 1.5 V. The amplitude fluctuations of the signal reflect the level of muscle activity.

A sampling frequency of 1000 Hz was selected, which is suitable for the effective bandwidth of sEMG signals (20 to 500 Hz) [25], [26] and satisfies the Nyquist sampling theorem to prevent aliasing. After acquisition, the signal values were converted from raw ADC units to millivolts (mV) to facilitate further processing.

Raw sEMG signals are often contaminated by various noise sources, such as power line interference during acquisition and poor electrode-skin contact, which introduces additional artifacts [27]. Therefore, a signal pre-processing stage is essential. De Luca et al. [28] emphasized the use of high-pass filters to eliminate low-frequency noise, recommending a cutoff frequency of 20 Hz for natural movements and higher values for intense physical activity. Conversely, a low-pass filter with a cutoff frequency between 400 and 500 Hz is recommended. One of the most widely adopted solutions for EMG signal filtering is the use of a Butterworth band-pass filter with a typical passband ranging from 20 to 450 Hz.

In this study, the sEMG signal was pre-processed using a three-stage filtering approach. First, a high-pass filter with a cutoff frequency of 20 Hz was applied to remove low-frequency drift and DC offset while preserving relevant muscle activity components. Next, an IIR notch filter centered at 50 Hz was used to suppress power line interference, which typically appears as a dominant peak in the EMG frequency spectrum [29]. Finally, a low-pass filter with a cutoff frequency of 450 Hz was employed to eliminate high-frequency noise, including impulsive and RF interference. Both the high-pass and low-pass filters were implemented as second-order Butterworth filters to ensure a flat frequency response in the passband and minimal signal distortion. The filtering process was performed using the zero-phase filtfilt method to avoid phase delay.

*3) Overlapped sliding window segmentation*: The sEMG signal is segmented into smaller portions to facilitate time-domain feature extraction. The choice of segment length must be carefully considered: overly long segments may increase computational load, whereas segments that are too short can result in inaccurate feature extraction. In real-time applications in particular, segment lengths exceeding 200 milliseconds often require the use of overlapping techniques to ensure continuity and responsiveness in system feedback [30].

This method divides the signal into fixed-length windows (w), with each window being shifted by a smaller step size (s). This results in overlapping segments, meaning that a single signal sample may appear in multiple consecutive windows. The window length (w) determines the amount of EMG data used for feature extraction, while the step size (s) defines the temporal distance between windows and controls the sliding rate. A smaller step size leads to increased overlap and provides more data for analysis [37]. Selecting an appropriate window and step size is a crucial factor. Larger window sizes allow for more comprehensive information capture and lower variability in extracted features. However, excessively large windows can introduce perceptible delays, which may negatively impact the user experience when using assistive devices. Therefore, as suggested in [38], the optimal window length is typically in the range of 150 ms to 250 ms.

In this study, the window size (w) is set to 200 ms, and the step size (s) is set to 50 ms, as illustrated in Fig. 3. With a sampling frequency of 1 kHz, each window corresponds to 200 samples. As each window shifts by 50 samples, there is a 75 per cent overlap between consecutive windows.

This sliding window-based segmentation effectively captures the temporal characteristics of the sEMG signal, thereby enhancing the accuracy and robustness of the gesture recognition system [36].

*4) Feature extraction*: The sliding window-based signal analysis method not only ensures the ability to continuously monitor muscle activity over time but also facilitates the subsequent feature extraction stage. The segmented signal obtained through this technique exhibits a stable format and well-defined structure, which enhances the accuracy of feature computation and meets the real-time requirements of human–machine interactive robotic control systems.

Extracted features can be categorized into time-domain, frequency-domain, or time–frequency domain features [31]-[34]. Frequency-domain features help identify the frequency components of muscle activity, providing insights into muscle activation levels and the ability to suppress noise. The signal is transformed into the frequency domain using the Discrete Fourier Transform (FFT). Commonly used frequency-domain features include Mean Frequency (MNF), Median Frequency (MDF), Mean Power Frequency (MNP), Peak Frequency (PKF), and Total Power (TTP) [Phinyomark, Yinfeng]. The combination of information from both time and frequency domains is defined as time–frequency features. Common techniques used in this category include Discrete Wavelet Transform (DWT), Short-Time Fourier Transform (STFT), and Wavelet Packet Energy [34].

Frequency-domain features are often used to study muscle fatigue or in motor unit analysis; however, they are generally not suitable for EMG signal classification [32], [33]. In addition, the high computational load may pose challenges for real-time control applications. Time-domain feature extraction, by contrast, is a widely adopted and effective approach for characterizing sEMG signals with low computational complexity, making it well-suited for real-time control systems. These features are directly derived from the amplitude values of the signal within each sliding window.

In this study, the selected time-domain feature includes:

*a) Mean absolute value (MAV)*: The average of the absolute values of the EMG signal within a window, representing the intensity of muscle activity.

$$MAV = \frac{1}{N}\sum_{i=1}^{N}|x_i| \tag{1}$$

*b) Waveform length (WL)*: The cumulative length of the EMG signal waveform within a segment, representing the signal's variability and complexity [35].

$$WL = \sum_{i=1}^{N-1}|x_{i+1} - x_i| \tag{2}$$

*c) Variance (VAR)*: The statistical dispersion of the EMG signal within a segment, reflecting its energy level.

$$VAR = \frac{1}{N-1}\sum_{i=1}^{N} x_i^{\,2} \tag{3}$$

*d) Zero crossing (ZC)*: The number of times the EMG signal amplitude crosses the zero-voltage level within a segment. To avoid counting low-voltage fluctuations or background noise, a threshold condition is implemented. The calculation is defined as:

$$ZC = \sum_{i=1}^{N-1}[\mathrm{sgn}(x_i \times x_{i+1}) \cap |x_i - x_{i+1}| \geq threshold] \tag{4}$$

sgn(x) = 1, if x ≥ threshold

sgn(x) = 0, otherwise

*e) Slope Sign changes (SSC)*: This feature is used to represent the frequency-related information of the EMG signal. It counts the number of times the slope of the signal changes sign, which helps detect abrupt variations and transitions in the signal.

$$SSC = \sum^{N-1}[\, f[(x_i - x_{i-1}) \times (x_i - x_{i-1})]] \tag{5}$$

f(x) = 1, if x ≥ threshold

f(x) = 0, otherwise

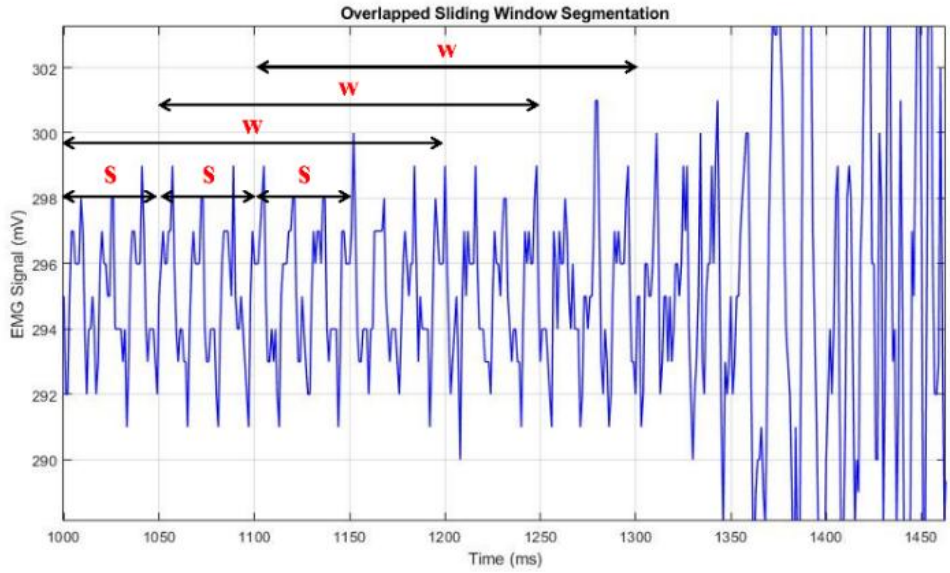

Fig. 3. Window segmentation of the sEMG signal.

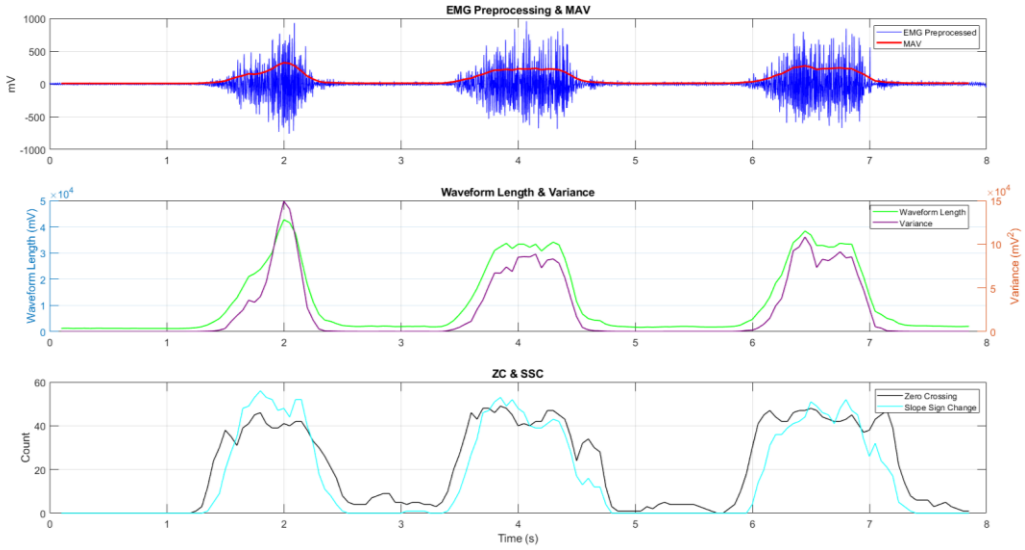

Fig. 4. An example of an EMG signal recorded with MAV, WL, VAR, ZC and SSC features.

During the sEMG signal analysis as shown in Fig. 4, time-domain features are extracted to characterize muscle activity. The Mean Absolute Value (MAV) reflects the level of muscle contraction through the signal amplitude. Waveform Length (WL) and Variance (VAR) indicate the signal's complexity and variability, while Zero Crossing (ZC) and Slope Sign Change (SSC) provide insights into the frequency of waveform transitions. These features enable clear discrimination between rest and contraction states, forming a foundation for motion recognition and robotic control.

### *B. Application in Artificial Hand Control*

*1) Sensor location*: The placement of EMG electrodes plays a critical role in distinguishing the performance across different finger movement patterns. Achieving this requires a solid understanding of the underlying muscular structure responsible for finger control, particularly when selecting optimal sEMG electrode positions. Within the forearm region, two major muscle groups are primarily involved in finger movement control: the flexor muscles and the extensor muscles. These muscle groups are situated on both sides of the wrist and run along the length of the forearm.

The flexor muscles, located on the anterior side of the forearm, such as the Flexor Digitorum Profundus (FDP) and Flexor Digitorum Superficialis (FDS), are responsible for flexing the wrist and fingers. In contrast, the extensor muscles, situated on the posterior side, including the Extensor Digitorum

(or Extensor Digitorum Communis – EDC) and Extensor Digiti Minimi (EDM), control the extension of these joints. These two muscle groups operate in opposition: when one contracts, the other relaxes. Therefore, to effectively capture EMG signals associated with finger activity, it is essential to position sEMG electrodes over both the flexor and extensor muscle regions.

Fig. 5 illustrates the electrode placement strategy. Electrode position 1 targets the activity of the ring and little fingers; position 2 corresponds to the index and middle fingers; and position 3 captures movements of the thumb. The electrodes are aligned centrally along the muscle fibers and spaced approximately 2.5 cm apart to ensure optimal signal acquisition.

*2) Artificial hand control*: Fig. 6 illustrates the overall control diagram of the artificial hand system based on surface electromyography (sEMG) signals. The system utilizes three sEMG sensors placed on the user's arm to acquire bioelectrical signals generated by muscle activity. These signals are preprocessed to remove noise and normalized before feature extraction. The extracted features are then classified to identify the user's intended motion. The classification results are used as input for the controller to actuate the robotic hand accordingly. A human-machine interface (HMI) is integrated to visualize sEMG signals and system status in real-time. Additionally, the system supports communication with a computer for monitoring, data analysis, and parameter adjustment.

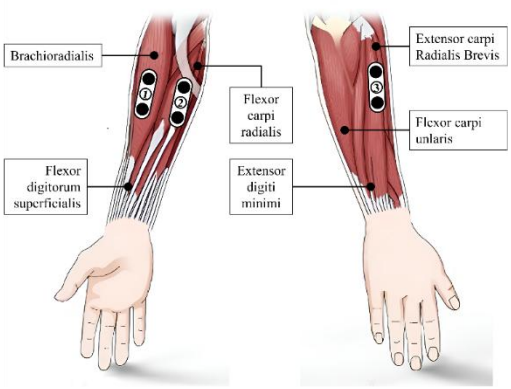

Fig. 5. Human hand muscle structure and electrode placement.

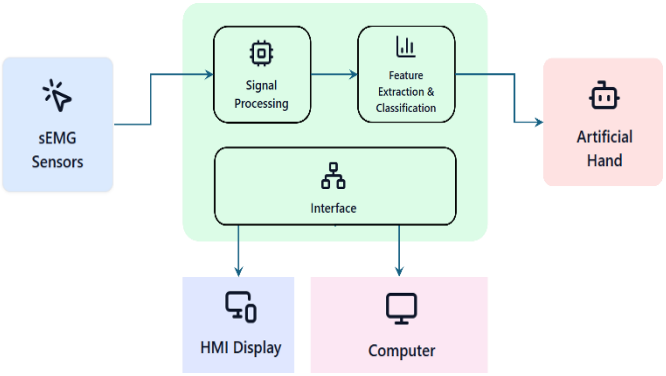

Fig. 6. The control system overview diagram.

## III. Experimental Results

To evaluate the effectiveness of the proposed EMG-based control system, both signal processing results and real-time robotic hand responses were analyzed. Fig. 7 illustrates the EMG signals from three channels, along with the extracted features: Mean Absolute Value (MAV), Variance (VAR), and Waveform Length (WL). These features were computed in real-time over a sliding window and are visualized to correlate with the four distinct muscle activation segments corresponding to different gestures.

The MAV feature showed consistent performance in highlighting the onset and duration of muscle activation across all channels. On the other hand, VAR and WL provided additional sensitivity in distinguishing gestures with similar EMG amplitudes but different signal complexities. The combination of these three features thus offers a robust representation of muscle activity, suitable for classifying and interpreting user intentions.

Fig. 8 demonstrates the practical implementation of the control system, where each user gesture (e.g., wrist extension, flexion, or grasping motion) was successfully translated into the corresponding movement of the robotic hand. The robotic hand responded in real-time with clear alignment to the user's intended actions.

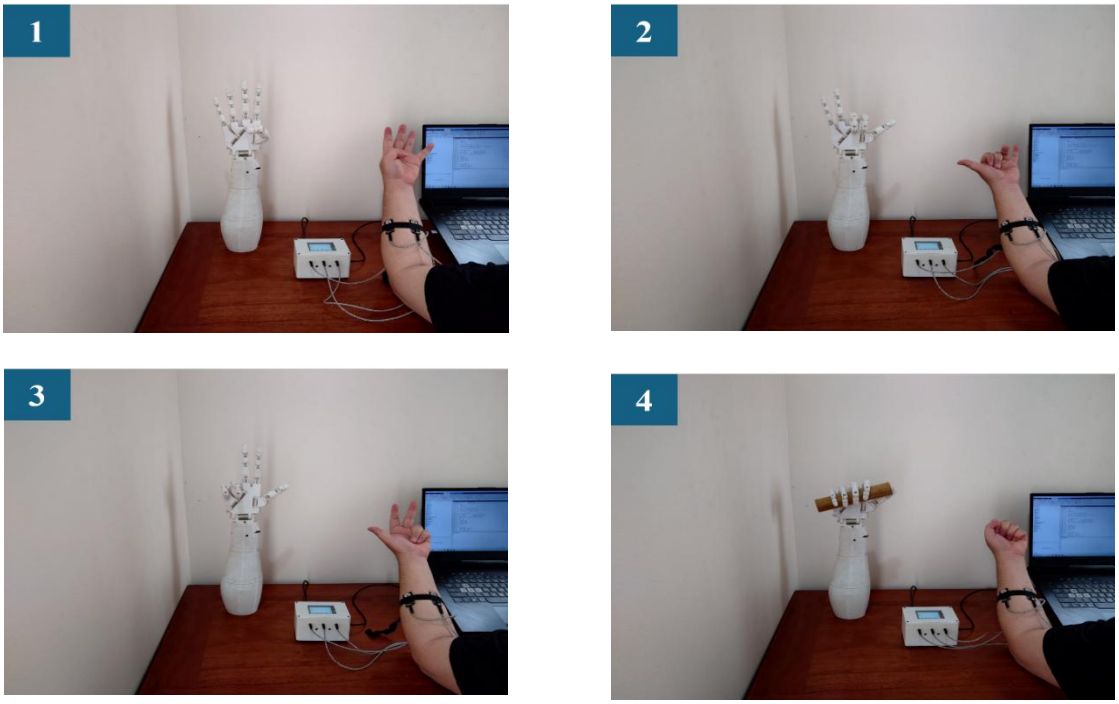

Fig. 8. Real-time EMG-based control of a prosthetic hand using four distinct hand gestures.

## IV. Discussions

The experimental results illustrated in the previous section confirm that the EMG signals acquired from the forearm can effectively control a wearable robotic hand in real time. The proposed system offers low latency and high responsiveness, critical for natural human-machine interaction.

Furthermore, the feature extraction and segmentation pipeline proved reliable in isolating intentional movement from resting or noise-dominant periods. Although the system currently operates on predefined gestures, it provides a foundation for further development involving real-time classification algorithms such as Support Vector Machines or Neural Networks.

Despite the promising results, this study has some limitations. First, the system currently relies on a limited number of predefined hand gestures, which restricts its general applicability. Second, the experiment was conducted with a small number of participants under controlled conditions, which may not fully represent real-world variability in sEMG signals across different users or usage scenarios. Additionally, although the proposed method is optimized for embedded implementation, further evaluation on various hardware

platforms is needed to assess performance consistency. Addressing these limitations will be a key focus in future work.

## V. CONCLUSION

This study presents a preliminary investigation into the processing of surface electromyography (sEMG) signals for the control of wearable robotic hand systems. A foundational signal processing framework, suitable for real-time applications, was developed, encompassing filtering, window-based segmentation, and the extraction of relevant time-domain features, including Mean Absolute Value (MAV), Waveform Length (WL), Variance (VAR), Zero Crossing (ZC), and Slope Sign Changes (SSC).

The implementation of sliding window segmentation and feature extraction from strategically positioned sEMG electrodes over both flexor and extensor muscles demonstrated efficacy in capturing muscle activity associated with finger movements. These extracted features serve as input vectors for subsequent classification and control algorithms.

This work constitutes an initial phase in the development of a comprehensive human–machine interface. It establishes a basis for future research focused on the integration of advanced classification algorithms, such as Support Vector Machines (SVM), k-Nearest Neighbors (k-NN), or deep learning methodologies, for accurate gesture recognition and adaptive robotic hand control. The findings of this study are anticipated to contribute to the advancement of intuitive, responsive, and user-centered assistive robotic systems, particularly for rehabilitation and prosthetic applications.

## ACKNOWLEDGMENT

This work is funded by Electric Power University, following University Project in 2025. The author wishes to acknowledge Mr. Nguyen Van Kien, B.A., for his support in validating the experimental results presented herein.

Centre For Artificial Intelligence & Data Science, Universiti Malaysia Pahang Al-Sultan Abdullah, Lebuh Persiaran Tun Khalil, Yaakob, 26300 Gambang, Kuantan, Pahang[2]

***Abstract*—Generic Code Clone Detection (GCCD) is a code clone detection model that use distance measure equation, enabling detection of all types of code clones, naming clone Type-1, Type-2, Type-3 and Type-4 in Java programming language applications. However, the detection process of GCCD did not focus on detecting clones of Type-3 and Type-4. Hence, this paper suggested two experiments to incorporate enhancements to the GCCD in order to improve the detection rate of clone Type-3 and clone Type-4. The implementation of Chi-square distance in the match detection process produced a significant result increase in the experiment specifically on clones Type-3 and Type-4, in comparison with the Euclidean distance in GCCD, which allows the increase of detection rate due to the dissimilarity of the distance measures. Based on the results, the suggested enhancement using Chi-square distance on match detection process outperforms GCCD in terms of improving code clone detection results based on clone Type-3 and Type-4, as the objectives for each experiment are carried, contributes to the research on improving the code clone detection result.**

***Keywords*—Code clone detection; distance measure; Java language; Chi-square; computational intelligence***

## I. INTRODUCTION

The practice of copying code is known as code cloning and the clone being duplicated is a code clone [1]–[3]. 60% developers went on searching code examples every day as to reduce the development time process [4] and which leads to code cloning. However, the integrity of certain developer cannot be underestimated as code examples could be implemented to the system instead of coding a new code fragment which lead to code cloning. Cost and programmer's limitation, templating and many more could also be the reasons for code cloning [4]–[6]. These reasons for code cloning could lead to drawbacks on software development and maintenance. The increase of maintenance cost, bug propagation, computational complexity and vulnerability proneness [5]–[8]. The inadequacy of programming language could also affect the code cloning [9], [10]. Java is a free programming language that developed open-source software applications. A study mentioned that 6% of 512000 lines of codes in Java applications are code clones [11]. The study concluded that the reason of code clones was the stake-holder's demand and deficiency in Java generic modules.

Code clones are generally categorized into four distinct types [12]–[14]; Type-1, Type-2, Type-3 and Type-4 (Fig. 1). Clone Type-1 is known for exact matches. These are code fragments that are identical, except for differences in whitespace and comments. Type-1 clones are the simplest to detect since they involve straightforward duplication without any modifications to the actual code logic. Clone Type-2 is renamed clones. In these clones, the code fragments are identical except for variations in identifiers, literals, types, or other superficial changes. While the overall structure and logic remain the same, these changes can make detection more complex than Type-1 clones. Clone Type-3 is modified clones. These are more complex clones where the duplicated code has undergone modifications such as adding or removing lines of code, altering control structures, or making other significant changes. Despite these modifications, the underlying logic or functionality of the code remains similar, making Type-3 clones challenging to detect. Finally, clone Type-4, the semantic clones. The most difficult to detect, Type-4 clones involve code fragments that perform the same functionality but are implemented using entirely different syntax or structures. These clones require deep semantic analysis to identify, as they do not share visible structural similarities with the original code.

Several major code clone approaches are prior to undertaking. The six major code clone approaches include text-based approaches, token-based approaches, metric-based approaches, tree-based approaches, graph-based approaches, and hybrid approaches. However, most approaches are incapable of recognizing all code clones [15]. For instance, token-based approach code detection tool such as NiCad [16],[17] detect the lexical part of the source code without considering the semantic information, which then prompted a poor detection result of clone Type-3 [18]. As a response, a code clone detection model was built for detecting code clones effectively. A model for the detection of the code clone incorporates structural process that combine several approaches or tools for the detection of clones. Several models that have existing in the code clone domain are the Generic Clone Model [19], the Generic Pipeline Model [20], Unified Clone Model [21], as well as the Generic Code Clone Detection (GCCD) Model [11]. Multiple researchers studied these four models in order to develop an effective code clone detection model. For instance, an enhancement was made in a

study on Generic Pipeline Model whereby they concatenated the source code file through Divide and Conquer method to enhance the load processing speed, by dividing the file into sub files [22]. They managed to decrease the model's runtime performance and increase the model's performance fully. Another study is on the GCCD model where they enhanced the pre-processing and parameterization process of GCCD [9], [23]. They managed to reduce the pre-processing rules and finding the best weightage to produce a better code clone detection model.

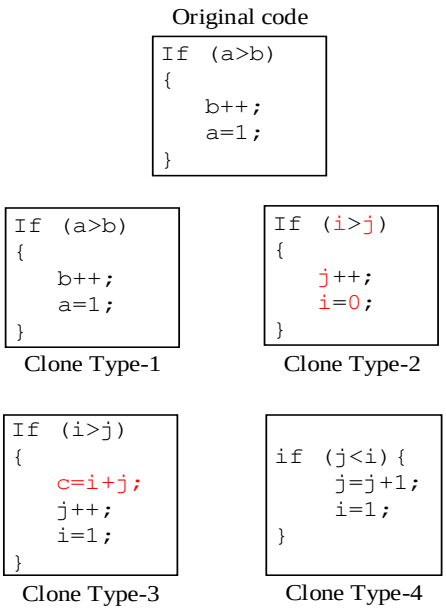

Fig. 1. Example of code clone Type-1, Type-2, Type-3 and Type-4.

The preliminary goal of this work is for enhancing the GCCD in order to produce a reliable code clone detection result, specifically Type-3 and Type-4. Therefore, this work will focus on;

- The experiment is an enhancement on match detection process using different distance measure equation such as Manhattan distance, Squared Euclidean distance, Half-squared Euclidean distance, Chi-square distance, in order to find the highest detection result of Type-3 and Type-4.
- The comparative analysis of the result between GCCD as an existing model and the proposed enhancement towards GCCD in terms of Type-3 and Type-4.

## II. Related Works

Generic Code Clone Detection (GCCD) is a tool commenced for an aim to detect code clones in Java language application [11]. This model was developed targeting to detect code clone Type-1, Type2, Type-3 and Type-4. The purpose of GCCD is to provide a generality approach for identifying all sorts of code clone. GCCD is constructed with a structure of five processes (Fig. 2). The processes are pre-processing process, transformation process, parameterization process, categorization process and match detection process.

### A. Pre-Processing Process

This process standardizes the source code as input for the detection process. There are five pre-processing rules applied to the source code in order to remove unnecessary elements that may conflict with the code clone detection result. The first pre-processing rule removes packages and import statements from the source code. Then, the second pre-processing rule is followed by removing comment lines as the comments are considered as instruction or guidance to the programmer only, which is not conflicting with the source code. The third pre-processing rule removes empty lines, which normally do not hold any source code and act as a method to visualize a clean look in coding. After that, the code is then regularized in the fourth pre-processing rule by replacing all function access modifier to public access modifier. This part of the rule act as a constant value for producing metrics in parameterization process. The fifth rule is to convert all uppercase letters in the original source code to lowercase letters for reducing the difference for detecting code clones. The essence of the source code has been filtered and the source code has become source unit.

### B. Transformation Process

This process converts the source units into measurable units by substituting the source units with numerical value. The source unit is substituted one by one based on the position of alphabets. For instance, the alphabet *p* is substituted to 16 as the numerical value. Taking an example of word of the source unit from the Fig. 3, we can see that 'public' is substituted with value 162102120903.

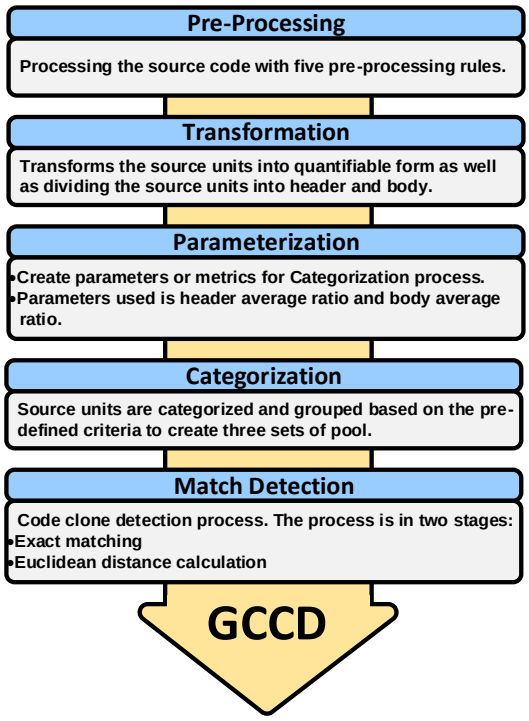

Fig. 2. Structure process of GCCD.

This substitution method allows the source unit to be valued as measurable unit. After that, the measurable source units are divided into header (*h*) and body (*b*) to become a transformed source unit. Header is the first line of a function source code and body is the next line of a function source code after the first line. In the Fig. 3, the lines of source unit public *boolean hasmoreelements* is the first line of function where this line is considered as the header. The rest of the lines are considered as body. This unit will become transformed source unit which is the output of this process.

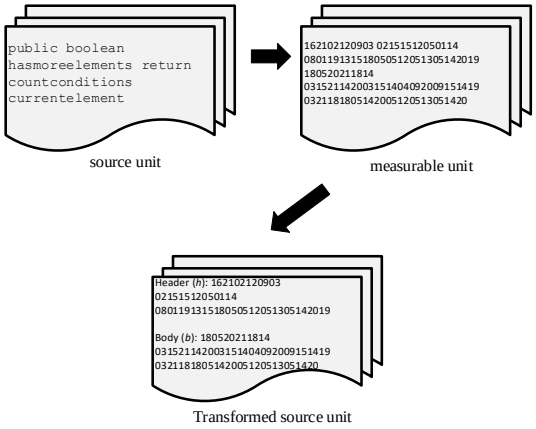

Fig. 3. Snippets of source unit is substituted and grouped to become a transformed source unit.

### C. Parameterization Process

This stage will set up the parameters that would be utilized throughout the categorization process from the transformed source unit (*TSU*). The *TSUs* are in the form of transformed source unit header (*TSUh*) and transformed source unit body (*TSUb*). The parameters involved are average ratio header and average ratio body. Table I shows the parameters involved in getting the average ratio header and body and its description. In order to gain average ratio header and average ratio body, *TSU*s are calculated to gain ratio header along with ratio body. Both ratios require *TSU* to be calculated using this:

$$TSUh_n = A_1 + A_2 + A_3 + \cdots + A_n \quad (1)$$

$$TSUb_n = B_1 + B_2 + B_3 + \cdots + B_n \quad (2)$$

Since all functions have been transformed into a standardize value of public, all the source units have similar access modifier value. Therefore, these *TSU*s are divided with public access modifier weightage value (*P*). The *P* is gain through the substitution of word 'public' into162102120903 as the weightage value. The calculation of ratio header and ratio body can be visualized in equation:

$$Rh_n = \frac{TSUh_n}{P} \quad (3)$$

$$Rb_n = \frac{TSUb_n}{P} \quad (4)$$

where $n$ = 1, 2, 3. After ratio header and ratio body is calculated, the process is tried with finding average ratio header together with average ratio body for each source unit. Ratio header and ratio body is divided with count header as well as count body respectively using this equation:

$$AVRh_n = \frac{Rh_n}{Ch_n} \quad (5)$$

$$AVRb_n = \frac{Rb_n}{Cb_n} \quad (6)$$

From here, the output of transformation process is represented in metric form as parameters.

TABLE I. DESCRIPTION OF PARAMETERS INVOLVED IN PARAMETERIZATION PROCESS

| Parameters | Description |
|---|---|
| Transformed source unit header (*TSUh*) | Value of transformed source unit in header |
| Transformed source unit header (*TSUb*) | Value of transformed source unit in body |
| Ratio header (*Rh*) | The ratio of headers of the transformed source units |
| Ratio body (*Rb*) | The ratio of body of the transformed source units |
| Count header (*Ch*) | Code count of source code header in the source units |
| Count body (*Cb*) | Code count of source code body in the source units |
| average ratio header (*AVRh*) | The average ratio of header (*h*) |
| average ratio header (*AVRb*) | The average ratio of body (*b*) |

### D. Categorization Process

The categorization process occurs by comparing between two *TSU*. Assuming there are *TSUX* and *TSUY*, they are categorized into the first pool as they have the similar *AVRh*. The process of categorizing *TSU* into the first pool runs until every *TSU* with similar *AVRh* is grouped. Then, the *TSU* continue its categorization process together with the remaining from first pool to group *TSU* with similar *AVRb* into the second pool. Once the categorization process reaches its ends for the second pool, the categorization process moves to the third pool, grouping the remainder of *TSU* that cannot match to the first pool and the second pool. This process produces three pools as the output, bringing them to the final process which is match detection.

### E. Match Detection Process

Finally, the pools are screened for Type-1, Type-2, Type-3, and Type-4 clones using match detection process. There are two stages of match detection for detecting code clones. The first stage is exact matching where clone Type-1 and clone Type-2 are detected from the first two pools. The match is considered as Type-1 when two average ratio header and body are identical, following the next pair of matches during the first two pool is processed. As for clone Type-2, certain pairs compared is considered as clone Type-2 when they have similar *AVRhx* and *AVRhy* but different *AVRbx* and *AVRby*, or vice versa. The second stage implements the Euclidean distance measure formula to determine the remnants from the first two pools and the third pool. Assuming the calculation involves two source units' *X* and *Y*. Each source unit consists of average ratio header and average ratio body. The formula of Euclidean distance (ED) is as follows:

$$ED = \sqrt{(AVRhX - AVRhY)^2 + (AVRbX - AVRbY)^2} \quad (7)$$

The outcome from Euclidean distance calculation is then determined its value. The value that fits within 0.85 and 1.00 is

classified as Type-3, while the remainder value is classified as Type-4.

## III. Proposed Enhancement

The proposed enhancements are focusing on two processes from GCCD, which are the match detection process. The dataset for these experiments is similar to the dataset from GCCD, which is Java applications of Bellon's benchmark dataset [28]. This dataset is a benchmark in code clone domain that consists Java applications with medium size to larger size. It also provides the details to the four Java applications involved.

Previously in GCCD, the process of match detection implements Euclidean distance on to the three pools from the categorization process, in order to gain the clone Type-3 and clone Type-4. Once calculated, the value that falls between the ranges 0.85 to 1.00 is considered as clone Type-3 and suchlike is considered as clone Type-4. In comparison to previous GCCD outcomes, the aim of the first experiment is to produce a greater detection result for code clone Type-3 and code clone Type-4, by utilizing different distance measures [24]. Four distance measures were discovered for which the parameters generated from prior processes of GCCD could be applied to achieve. The distance measures are referred in Table II Manhattan distance [25], Squared Euclidean distance [26], Half-squared Euclidean distance [27], and Chi-square distance [28].

TABLE II. Equations Involved in Experiment 1

| Equation Name | Equation |
|---|---|
| Manhattan distance | $d(x,y) = \sum_{i=1}^{n} \mid x_i - y_i \mid$ |
| Squared Euclidean distance | $d^2(x,y) = \sum_{i=1}^{n} (x_i - y_i)^2$ |
| Half-squared Euclidean distance | $d^2(x,y) = \sum_{i=1}^{n} (x_i - y_i)^2$ |
| Chi-square distance | $\chi(x,y) = \sqrt{\frac{1}{2}\sum_{i=1}^{n} \frac{(x_i - y_i)^2}{(x_i + y_i)}}$ |

Manhattan distance calculates the absolute difference between corresponding components of two vectors, offering a simple yet effective way to assess similarity when the changes between code fragments are predominantly additive or subtractive. Squared Euclidean distance is an extension of the standard Euclidean distance, this formula squares the differences between corresponding components before summing them, placing greater emphasis on larger deviations, which may be particularly useful in distinguishing more pronounced differences in code structure. Meanwhile, half-squared Euclidean distance measures halves the squared differences, providing a balance between the sensitivity of the Squared Euclidean Distance and the simplicity of the Manhattan Distance, potentially offering a more nuanced assessment of similarity. Finally, Chi-square distance, a statistical measure that compares the observed and expected frequencies of occurrences, this formula is particularly suited for detecting differences in distributions, making it a promising candidate for identifying Type-4 clones where the code fragments may function similarly but differ significantly in their structural composition. The aforementioned equations will replace the Euclidean distance in the match detection process. The pseudocode 1 shows the pseudocode on the implementation of Chi-square distance into GCCD as an example.

**Pseudocode:** Match Detection Process using Chi-square distance

Pool 1, $PL_1$
Pool 2, $PL_2$
Pool 3, $PL_3$
Chi-Square Distance, *CSD*
Average ratio header, [$AVRh_1, AVRh_2, AVRh_3, \ldots AVRh_n$]
Average ratio body, [$AVRb_1, AVRb_2, AVRb_3, \ldots AVRb_n$]

```
Read [AVRh1, AVRh2, AVRh3, ... AVRhn] and [AVRb1, AVRb2, AVRb3, ... AVRbn] in PL1 and PL2
    Compare AVRh1 and AVRb1 with AVRh2 and AVRb2 using exact matching technique
        If AVRh1 and AVRb1 are same with AVRh2 and AVRb2
            Group as Type-1
        Else If AVRh1 and AVRh2 are same but AVRb1 and AVRb2 are different
            Group as Type-2
        Else If AVRh1 and AVRh2 are different but AVRb1 and AVRb2 are same
            Group as Type-2
        Else
            AVRh1 and AVRh2 are different but AVRb1 and AVRb2 are different
Move into PL3
Read remaining [AVRh1, AVRh2, AVRh3, ... AVRhn] and [AVRb1, AVRb2, AVRb3, ... AVRbn] in PL3
Apply CSD between the remaining [AVRh1, AVRh2, AVRh3, ... AVRhn] and [AVRb1, AVRb2, AVRb3, ... AVRbn]
    If distance is between 0.85 to 1.00
        Group as Type-3
    Else
        Group as Type-4
```

By using the similar assumption from Section II(E) where there are two source units *X* and *Y*, the calculation of the match detection process can be visualized in the chi-square equation where the average ratio header and average ratio body is used:

$$CSD = \sqrt{\frac{1}{2}\left(\frac{(AVRhX - AVRhY)^2}{(AVRhX + AVRhY)} + \frac{(AVRbX - AVRbY)^2}{(AVRbX + AVRbY)}\right)} \quad (8)$$

## IV. Result Analysis

The result from the experiment is recorded in two elements namely overall total clone pairs in Java applications and total clone pairs based on clone types. This section is divided into three subsections where the first subsection describes the result of overall total clone pairs and the second subsection is about the total clone pairs based on clone types, which resulted from the experiment. The final subsection analyzes and discusses the outcome from the result to pinpoint the difference between the existing GCCD and the enhancement made to GCCD.

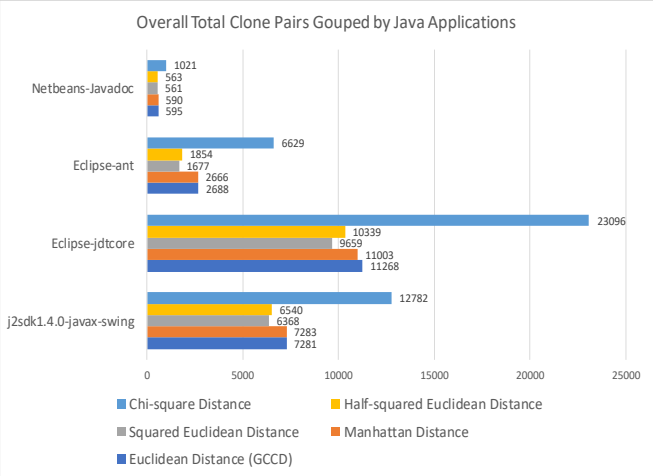

Fig. 4. Overall total clone pairs based on java applications from bellon's benchmark data.

### A. Overall Total Clone Pairs in Java Applications

Fig. 4 illustrate the results of overall total clone pair in Java applications. The first Java application is j2sdk1.4.0-javax-swing. Based on data presented, Chi-square recorded the most total clone pair with 12782 clone pairs. The second most total clone pair is from Manhattan distance with a total of 7283 clone pairs. This puts the difference between the most clone pairs and the second-most with a total of 43.02%. Thirds go to the Euclidean distance with a total of 7281 clone pairs. This total clone pair is lower by 43.04% from the highest total clone pair by Chi-square distance. Total clone pair from Half-squared Euclidean distance recorded the fourth with a total of 6540 clone pairs. The difference between Half-squared Euclidean distance total clone pairs and the highest total clone pair is 48.83%. J2sdk1.4.0-javax-swing has lowermost total clone pair detected by Squared Euclidean distance with 6368 clone pairs. It is 50.18% less than the highest total clone pair by Chi-square distance.

The second Java application for detecting overall total clone pair is Eclipse-jdtcore. The top result for total clone pair is by the Chi-square distance with a total of 23096 clone pairs. The next in order is by Euclidean distance with a total of 11268 clone pairs. The gap between the highest and the second-highest overall total clone pair is 51.21%. Manhattan provides the third-most total clone pair with 11003 clone pairs. This is 52.36% lower than the highest overall total clone pair detected in Eclipse-jdtcore. The fourth result of total clone pair is Half-squared Euclidean distance with 10339 clone pairs. The difference between overall total clone pair from Half-squared Euclidean distance with the most total clone pair from Chi-square distance is 55.23%. The last from Eclipse-jdtcore is by Squared Euclidean distance with a 9659 total of clone pairs. This put the difference between the lowest and the highest from Eclipse-jdtcore with a difference of 58.18%.

The third Java application is Eclipse-ant. Overall total clone pair by Chi-square distance recorded the highest value with 6629 clone pairs. The second is followed by Euclidean distance where it gained a total of 2688 clone pairs, which left the gap of 59.45%. The third for overall total clone pair of Eclipse-ant is Manhattan distance which turned in a total of 2666 clone pairs. This put a 59.78% difference between the first and the third overall total of clone pair in Eclipse-ant. The fourth for Eclipse-ant is Half-Squared Euclidean distance, which has a total of 1854 clone pairs. This is 72.03% lower than the highest overall total clone pair in Eclipse-ant, which is the Chi-square distance. The last formula that detects a total of 1677 clone pairs is Squared Euclidean distance. This has made a 74.70% gap with Chi-square distance, the highest for Eclipse-ant.

As for Netbeans-javadoc, the most prominent total clone pair is by Chi-square distance with 1021 clone pairs. The subsequent total clone pair is by Euclidean distance. It recorded a total of 595 clone pairs, leaving the gap of 41.72% lower than the highest overall total clone pair result in Netbeans-javadoc. Next, Manhattan distance set a total of 590 clone pairs. This overall total clone pair value is lower than the highest value which is 42.21% difference. The fourth total of clone pairs is Half-squared Euclidean distance with a total of 563 clone pairs. The difference between the fourth and the first value of overall total clone pair in Netbeans-javadoc is 44.86%. 561 clone pairs are the final overall total clone pair by Squared Euclidean distance. The difference between the least and the most overall total clone pair detected in Netbeans-javadoc is 45.05%.

### B. Total Clone Pairs Based on Clone Types

This part of the result is discussed based on each Java applications by Bellon's benchmark data, based on Table III.

*1) j2sdk1.4.0-javax-swing*: Table III depicted the result of total clone pairs for each Java application. In j2sdk1.4.0-javax-swing, the detected clone pairs Type-1 is by Half-Squared Euclidean distance with 892 clone pairs. The second highest value of detecting clone Type-1 is by Chi-square distance, with 891 clone pairs, preceding about 0.11% difference from the highest clone pair Type-1 value. The third highest is by Manhattan distance with 889 clone pairs. The gap difference from the highest value of clone pair Type-1 detected in j2sdk1.4.0-javax-swing is 0.34%. The fourth value of clone pair Type-1 detected in this application is 888 clone pairs by Squared Euclidean distance, with 0.45% gap difference. Finally, Euclidean distance recorded the lowest value of clone Type-1 detected by 877 clone pairs, leaving percentage difference of 1.68%. Code clone Type-2 detection clone pair for Half-Squared Euclidean distance keep as highest value recorded with 3725 clone pairs. It is then followed by Manhattan distance with 3716 clone pairs, leaving a percentage difference of 0.24%. The third most value of clone pair Type-2 detected in j2sdk1.4.0-javax-swing is by Euclidean distance with 3697 clone pairs. The percentage difference between Euclidean distance's value and the highest value of clone pair Type-2 is 0.75%. The fourth value is by Squared Euclidean distance with 3695 clone pairs and percentage difference of 0.81%. The least clone pair Type-2 detected is by Chi-square distance with 3684 clone pairs. The percentage difference is 1.10%. Meanwhile, Chi-square distance gained the highest total clone pair Type-3 with 3633 clone pairs. This was followed by Half-squared Euclidean distance with a value of 1773 clone pairs. It is 51.20% less

than the Chi-Square distance result. The third and fourth total clone pairs Type-3 are Manhattan distance (1727 clone pairs) as well as Squared Euclidean distance (1718 clone pairs), with each gap difference of 52.46% and 52.71% respectively. The lowest total clone pair Type-3 is by Euclidean distance with a total of 1710 clone pairs, leaving a 52.93% lower than Chi-square distance. Next, Chi-square Distance was the highest in j2sdk1.4.0-javax-swing code clone Type-4, with a value of 4574 clone pairs. The Euclidean distance, which detected 997 clone pairs, is the second highest for clone Type-4. It is 78.20% lower than the highest value of clone Type-4 detected. Manhattan distance is the thirds with 951 clone pairs of Type-4, a 79.21% lower than Chi-square distance. The fourth value is by Half-squared distance with 150 clone pairs (96.72%) and the least value is from Squared Euclidean distance with a value of 67 clone pairs (98.54%) for clone Type-4.

TABLE III. TOTAL CLONE PAIRS BASED ON CLONE TYPES FOR EACH DISTANCE MEASURES

| Bellon's Benchmark Data Java Applications | Clone Type | Total clone pairs based on clone types | | | | |
|---|---|---|---|---|---|---|
| | | ***ED**** *(GCCD)* | ***MD**** | ***SED**** | ***HSED**** | ***CSD**** |
| ***j2sdk1.4.0-javax-swing*** | T-1* | 877 | 889 | 888 | 892 | 891 |
| | T-2* | 3697 | 3716 | 3695 | 3725 | 3684 |
| | T-3* | 1710 | 1727 | 1718 | 1773 | 3633 |
| | T-4* | 997 | 951 | 67 | 150 | 4574 |
| ***Eclipse-jdtcore*** | T-1* | 626 | 627 | 627 | 627 | 627 |
| | T-2* | 2886 | 2884 | 2887 | 2887 | 2886 |
| | T-3* | 4265 | 3880 | 3782 | 4564 | 7576 |
| | T-4* | 3491 | 3612 | 2363 | 2261 | 12007 |
| ***Eclipse-ant*** | T-1* | 185 | 185 | 185 | 185 | 185 |
| | T-2* | 552 | 650 | 650 | 650 | 650 |
| | T-3* | 581 | 562 | 535 | 585 | 2061 |
| | T-4* | 1370 | 1269 | 307 | 434 | 3733 |

| | T-3* | 102 | 102 | 102 | 104 | 197 |
| | T-4* | 53 | 51 | 22 | 23 | 387 |

[a.] *T-1 = clone Type-1, T-2 = clone Type-2, T-3 = clone Type-3, T-4 = clone Type-4, ED = Euclidean Distance, MD = Manhattan Distance, SED = Square Euclidean Distance, HSED = Half-squared Euclidean Distance, CSD = Chi-square Distance

*2) Eclipse-jdtcore*: Moving forward with the second Java application, which is Eclipse-jdtcore. The overall total clone pair Type-1 detected is consistent for each distance measure with a value of 627 clone pairs. The exception is from Euclidean distance, which detected 626 clone pairs, leaving a 0.16% gap difference from other distance measure formula. In regards to clone Type-2, the highest value went to Squared Euclidean distance as well as Half-Squared Euclidean distance, with each distance measure, scored a total clone pairs of 2887. The second greatest value for Type-2 clone is by Chi-square distance and Euclidean distance (2886 clone pairs). The lowest value is by Manhattan distance (2884 clone pairs). Both with the percentage difference of 0.03% and 0.10% from the highest value. Next, the Chi-square distance gained the highest value of 7576 clone pairs Type-3 for Eclipse-jdtcore. Half-squared Euclidean distance recorded the second-highest Type-3 value of 4564 clone pairs. It is 39.76% lower than Chi-square distance. The next distance measure followed is Euclidean distance with 4265 clone pairs of Type-3, marking a 43.70% gap from Chi-square distance. The fourth and the lowest Type-3 clones are Manhattan distance (3880 clone pairs) together with Squared Euclidean distance (3782 clone pairs). The Manhattan distance and Squared Euclidean distance are 48.79% as well as 50.08% lower than Chi-square distance. Then, clone detection for Type-4 by Chi-square distance in Eclipse-jdtcore, is the highest with a total of 12007 clone pairs. This is followed by the second highest with a value of 3612 clone pairs Type-4 by using Manhattan distance. It is 69.92% lower than Chi-square distance. The third and fourth for Type-4 in Eclipse-jdtcore are recorded by Euclidean distance (3491 clone pairs) along with Squared Euclidean distance (2363 clone pairs). They have 70.93% and 80.32% lower than Chi-square distance. The lowest value of clone pair Type-4 for Eclipse-jdtcore is by Half-squared Euclidean distance, with 2261 total clone pairs and 81.17% gap difference.

*3) Eclipse-ant*: Total clone pairs Type-1 in Eclipse-ant showed concordant outcomes for every experimented distance measure which is 185 clone pairs along individually. For Type-2, the highest clone pair value detected is by each distance measure with 650 clone pairs, except for Euclidean distance with 552 clone pairs, which is 15.08% lower than the highest value. Meanwhile, Chi-square distance showed the highest total of 2061 clone pairs Type-3, followed by Half-squared distance with a total of 585 clone pairs. Half-squared distance has 71.62% lower than Chi-square distance. The third value for clone Type-3 is by Euclidean distance with a total of 581 clone pairs and 71.81% gap difference from highest value. The fourth value is by Manhattan distance with 562 clone pairs. It is 72.73% lower than Chi-square distance. The lowest value for Type-3 clones in Eclipse-ant is Squared Euclidean distance with 535 clone pairs and 74.04% lower than Chi-square distance. Next, the Chi-square distance for clone Type-4 in Eclipse-ant has the greatest value of 3733 clone pairs. The second-highest total clone pairs are 1370 clone pairs Type-4 by Euclidean distance, with 63.30% lower than Chi-square

distance. The third and fourth values are shown by Manhattan distance (1269 clone pairs) as well as Half-squared Euclidean distance (434 clone pairs). Both has 66.01% and 88.37% lower than Chi-square distance. The least value of total clone pairs Type-4 in Eclipse-ant is by Squared Euclidean distance with 307 clone pairs. It is 91.78% lower than the highest value by Chi-square distance.

*4) Netbeans-javadoc*: The Netbeans-javadoc application was also revealed to have concordant outputs when it comes to clone Type-1 for each distance measure which is 99 clone pairs. Euclidean distance recorded the highest Type-2 value with 341 clone pairs. Other distance measures detected 338 clone pairs, 0.88% lower than Euclidean distance. For Type-3, Chi-square distance recorded the highest with 197 clone pairs, followed by Half-squared distance with 104 clone pairs. It is 47.21% lower than Chi-square distance. Euclidean distance, Manhattan distance as well as Squared Euclidean distance showed the lowest which is 102 clone pairs. It has 48.22% lower than Chi-square distance. For Type-4 in Netbeans-javadoc, the Chi-square distance also showed the highest value with 387 total clone pairs. The second highest is by Euclidean distance which is 53 clone pairs (86.30%) of Type-4, followed by the third value by Manhattan distance which is 51 clone pairs (86.82%). The fourth value is 23 clone pairs by Half-squared distance and the lowest Type-4 clone value is 22 clone pairs by Squared Euclidean distance. Both distances have 94.06% and 94.32% gap difference from Chi-square distance.

## V. Discussion

The experiment is concentrating on enhancing match detection process of GCCD by substituting the Euclidean distance to different distance measures. The enhancement on match detection process should be affecting the detection result on clone Type-3 and Type-4, as clone pairs is calculated using the distance measure formula. In this experiment, Chi-square distance has shown a significant increase on the overall total clone pairs that is detected in Java applications of Bellon's benchmark data. Moreover, Chi-square distance shows an improvement in total clone pairs based on clone types, which detected the highest value for each clone Type-3 as well as Type-4 in Eclipse-ant and Netbeans-javadoc application, respectively. Chi-square distance managed to keep the similar value of total clone pairs Type-1 other distance measures in the Eclipse-jdtcore, Eclipse-ant and Netbeans-javadoc. Chi-square distance also able to maintain the similar clone pairs Type-2 value with other distance measures for Eclipse-ant and Netbeans-javadoc. However, Chi-Square is placed as the second highest total clone pairs based on clone Type-1 and the least value in j2sdk1.4.0 – javax-swing. Another difference is in Eclipse-jdtcore application, where Chi-square distance detected the second highest value of clone pair Type-2. Based on this experiment, Euclidean distance and Chi-square distance both embody the similar structure formula. Nonetheless, Chi-square distance divides the upper value with a frequency inverse using the weightage summation of both header and body. As for the difference in result on clone Type-1 and Type-2 in two of the mentioned Java applications, runtime performance during the pre-processing process and transformation process might have affected the detection result. Thus, Experiment 1 concludes that the implementation of Chi-square distance increases the clone pair detection result specifically in Type-3 and Type-4, respectively.

## VI. Conclusion

In this paper, we introduced an improvement that is to the GCCD for detecting code clones in each clone type, specifically Type-3 and Type-4, due to the earlier result from GCCD implicit the inconsistency of the clone detection result in Java applications in Bellon's benchmark dataset. The enhancement that proposed the detection result of clone pair Type-3 and Type-4 can be improved by enhancing match detection process of GCCD, through modifying the distance measures. Result from the experiment revealed that the implementation of Chi-Square provides a higher code clone detection result as the GCCD is enhanced using Chi-square distance in match detection process. The improvement can be seen specifically when it has overruled GCCD by detecting the highest clone pairs Type-3 and Type-4.

The model currently supports clone detection within Java applications as the dataset is limited to the Bellon's benchmark dataset Java application. As a future enhancement, experiment on detecting and analyzing clone pairs in Python applications will be conducted.

## Acknowledgment

The authors would also like to thank the Malaysian Higher Education Ministry and Universiti Malaysia Pahang Al-Sultan Abdullah for their support for this project through the Fundamental Research Grant Scheme (FRGS Grant ID: FRGS/1/2024/ICT01/UMP/02/1).

# Transforming Internal Auditing: Harnessing Retrieval-Augmented Generation Technology

Professor Olive Stumke, Mr Fanie Ndlovu
Faculty of Accounting and Informatics-Department of Auditing and Taxation
Durban University of Technology, Durban, South Africa

***Abstract*—The advent of cloud-based Generative AI models, such as ChatGPT, Google Gemini, and Claude, has created new opportunities for improving education through real-time, adaptive learning experiences. Despite their widespread use globally, their application in South African higher education remains limited and underexplored, resulting in an application gap. This paper, as Phase 1 of a larger project, addresses this gap by focusing on the development of a Retrieval-Augmented Generation (RAG) web application designed to enhance Internal Auditing education at the Durban University of Technology. This is achieved by integrating three powerful Generative AI models—OpenAI GPT-4o-mini, Google Gemini-1.5-flash, and Anthropic Claude-3-haiku—into a single educational platform that will enable lecturers to manage and augment lecture materials while allowing students to access personalized, AI-generated content. This paper presents the design considerations, architecture, and integration techniques employed in the development of the RAG web application, offering insights into the potential of adaptive learning, personalized learning, and AI-driven tutoring in South Africa's educational landscape. This paper demonstrates how a RAG web application can provide the building blocks for future Generative AI applications that could enhance teaching and learning with minimal effort from lecturers and learners in the South African context.**

***Keywords*—*Adaptive learning; Anthropic Haiku; benefits; challenges; Generative AI; Google Gemini API Pro; higher education; internal auditing; OpenAI GPT-Turbo; personalized learning; RAG (Retrieval-Augmented Generation); South Africa***

## I. Introduction

This study represents Phase 1 of a broader research initiative. In Phase 1, we focus only on developing the RAG web application—integrating a database with advanced prompting strategies and Generative AI capabilities to support accounting education. Successive phases of this research, namely Phases 2 and 3, are considered for future execution as part of the continuing investigation. Phase 2 will involve piloting the application with Internal Auditing lecturers and students, where the impact of prompt formatting techniques and key model parameters—such as temperature, top_p, and max_tokens—will be examined. During this phase, feedback on the accuracy and relevance of AI-generated outputs will be collected, along with a cost-benefit analysis across OpenAI GPT-3 Turbo, Google Gemini API Pro, and Anthropic Haiku. Phase 3 will compare effectiveness metrics and provide recommendations on the most suitable and cost-effective Generative AI model for educational use.

Since the release of advanced Generative AI models like OpenAI's GPT-3 and GPT-4, Generative AI has rapidly gained prominence across various domains, including education. These AI-powered tools have the potential to revolutionize how knowledge is disseminated, particularly in complex fields such as Internal Auditing. The literature outlines that artificial intelligence (AI) models like OpenAI's GPT-3 Turbo, Google's Gemini API Pro, and Anthropic's Haiku are now being leveraged to enhance educational outcomes by providing real-time, personalized academic support. Studies have demonstrated the effectiveness of these models, with GPT-4, for example, showing superior performance over GPT-3.5 in answering complex questions from the Turkish Medical Specialization Exam, highlighting its potential in medical education [11]. Despite challenges such as the occurrence of false positives and negatives in AI detection tools, the value of Generative AI in education and research continues to be recognized [3]. This study is guided by the following research question: Can a RAG application integrating multiple Generative AI models be developed to support the teaching and learning experience in an Internal Auditing module at a South African university?

Regardless of the transformative potential of AI in higher education, its use in South Africa remains underexplored. Universities are in the early stages of integrating AI-driven solutions, which offer tailored learning experiences and can improve student outcomes. However, significant challenges persist, including the lack of digital infrastructure and insufficient training on AI technologies [8][18]. Furthermore, ethical considerations surrounding AI integration—such as data privacy, the handling of sensitive information, and inherent biases in AI models—complicate its adoption [20]. These concerns are particularly acute when public AI services are used, where the risks of data misuse and compromised privacy are heightened.

These issues become more pressing in an educational context as AI systems interact with sensitive student data, academic performance records and personalized learning pathways. Ensuring that AI systems do not compromise the confidentiality and integrity of this data is essential. Additionally, any cognitive biases embedded in AI models can affect the fairness of assessments, feedback and learning outcomes, which could exacerbate existing educational inequities. Addressing these challenges is critical to ensuring that AI systems are deployed responsibly and equitably in educational settings, safeguarding both student privacy and academic integrity [1],[6],[8],[9],[17].

Regardless of these hurdles, AI has the capacity to enhance educational content delivery, making learning more accessible and personalized. For instance, AI can support adaptive learning environments where students receive individualized instruction based on their performance, helping to bridge educational gaps [8]. Additionally, AI can automate administrative tasks such as grading and feedback, allowing educators to focus more on engaging with students and developing interactive learning experiences. These technologies have the potential to not only reduce the workload of educators but also to significantly enrich student learning through real-time access to global academic resources and dynamic, data-driven insights.

In South Africa, the challenges are compounded by the need for cost-effective and reliable AI solutions that can be scaled across diverse educational settings. This study seeks to fill the gap in research by developing a Retrieval-Augmented Generation (RAG) web application that integrates three leading Generative AI models: OpenAI GPT- Turbo, Google Gemini API Pro, and Anthropic Haiku. This application will be designed to support an Internal Auditing module at the Durban University of Technology, providing real-time, global insights on academic topics.

To address the potential risks associated with AI usage, this study also emphasizes the importance of incorporating advanced prompting techniques, such as Chain of Thought (CoT), Tree of Thought (ToT), and Rephrase and Respond (RaR). These techniques are intended to guide AI models to generate more accurate and contextually relevant outputs, thereby enhancing the reliability of the AI-generated content and ensuring academic trustworthiness.

In the next section, the current literature on Generative AI models in education is reviewed, followed by a discussion of the requirements and design considerations for the RAG web application. Subsequently, the implementation process is detailed, including the integration of advanced prompting techniques and the evaluation of the application's effectiveness. The paper concludes with a discussion of the findings, implications for higher education, and recommendations for future research.

## II. Generative AI Research

The advent of Generative AI models, particularly in educational settings, has garnered significant attention, with various studies highlighting their potential and challenges. The application of AI in education spans multiple domains, from language learning [8] to tutoring systems [6], each utilizing AI's capabilities to enhance learning outcomes. However, the deployment of AI in specialized fields like Internal Auditing is still emerging. The themes evident from the literature on AI in education discussed in this paper are AI in language learning, Generative AI in higher education and existing AI-powered platforms.

### *A. AI in Language Learning*

Existing research on AI-powered language learning platforms and chatbots demonstrates a wide range of applications [23]. One prominent application is in personalized learning systems, which utilize adaptive algorithms to cater to individual learners' needs. For example, such systems can dynamically adjust learning content based on students' performance and engagement [12]. This personalized approach has been shown to improve learning outcomes, particularly in language learning environments where learners benefit from real-time feedback and tailored support [8],[14],[19].

Validation tests for AI-driven educational platforms, such as those used in language learning, have shown significant improvements in training accuracy and reduced error rates [5]. Specifically, these reduced error rates refer to the system's ability to produce more accurate responses compared to human-provided answers. In this context, “error rates” represent the frequency of incorrect responses generated by the AI during assessments. As the system refines its models over time, adapting to the learning data, it becomes more precise, reducing the occurrence of mistakes and improving overall reliability in real-world applications [5].

### *B. Generative AI in Higher Education*

While the use of AI in language learning is well-documented, its application in higher education, particularly in specialized fields like Internal Auditing, remains underexplored. Studies have shown that Generative AI models like GPT-3 and GPT-4 significantly enrich learning by offering real-time, personalized academic support [8]. However, the adoption of such technologies in South Africa's higher education system is still in its infancy. For example, AI integration in legal education has improved student engagement, with learners achieving faster grade improvements by utilizing AI tools to tackle complex topics such as case analysis [4],[15]. Furthermore, the integration of AI in journalism education is also being explored. AI has the potential to improve productivity in news production, leading to curriculum adaptations to incorporate AI usage, ethical considerations and its applications in modern newsrooms [13].

The introduction of newer Generative AI models like OpenAI GPT-4, Google Gemini, and Anthropic Claude has expanded the potential of AI in educational environments. OpenAI GPT-4, widely recognized for its application in autodidactic learning, supports self-directed learners by providing personalized guidance, real-time feedback, and interactive assistance [7]. Anthropic Claude, with its focus on ethical AI, has shown promising results in educational applications. For example, Claude was tested alongside GPT models in creating virtual patients for medical education, offering scalable and low-cost simulations that improve clinical reasoning and decision-making skills [2]. Claude's design emphasizes transparency, ethical deployment, and minimizing harmful biases, making it a reliable tool for equitable educational environments. These attributes, alongside its role in AI governance and accountability, make Claude particularly well-suited for educational institutions prioritizing responsible AI deployment [21].

Google Gemini, a multimodal AI system, has demonstrated significant advancements in real-time processing of diverse data types such as text, images, audio, and video, making it particularly suitable for dynamic, multidisciplinary academic environments. Its unique mixture-of-experts architecture allows for highly efficient processing, enabling greater scalability and

adaptability in educational applications, especially in fields like law, science and healthcare, where handling multimodal information is crucial [16]. These capabilities position Gemini as a capable tool for providing enriched, interactive learning experiences in higher education.

### C. Existing AI-Powered Platforms

Several AI-powered platforms have been developed for language learning, such as Duolingo and Cleverbot, focusing primarily on vocabulary and grammar drills. Duolingo, which utilizes gamification and adaptive learning techniques, enables learners to manage their pace and content through structured modules but often lacks the depth needed for more specialized fields like Internal Auditing [10]. Similarly, Cleverbot, a chatbot-based platform, engages users in conversational exchanges by learning from past interactions. However, its primary strength lies in mimicking human conversation rather than offering adaptive or context-aware learning experiences that could evolve based on the user's subject matter expertise [22]. In contrast, the proposed RAG-based system in this study aims to address these limitations by offering tailored academic support for Internal Auditing, providing specialized and personalized learning paths for students at the Durban University of Technology at the directive of the lecturer and in line with the module outcomes.

This study builds on the existing body of research by exploring the application of Generative AI models in a new context, higher education in South Africa, specifically within the Internal Auditing module. By leveraging the strengths of OpenAI GPT-4-mini, Claude-3-haiku-20240307, and Google Gemini-1.5-flash, this study aims to develop a RAG web application that not only enhances learning outcomes but also addresses the unique challenges faced by educational institutions in South Africa.

## III. Research Methodology

This section details the methodology employed in the development of a RAG web application designed to enhance the learning experience for students in an Internal Auditing module at the Durban University of Technology. The methodology integrates multiple cutting-edge Generative AI models into a Python Flask web application, supported by SQLite for data management. The process follows a structured approach to ensure the application is functional, scalable, and suited to the educational context. Fig. 1 provides a visual representation of the workflow, showing the interaction between lecturers, students, AI models, and the SQL database. Lecturers create and manage lecture content, while students access both lecture content and AI-generated materials. The flow of data between the users, AI models, and the database supports dynamic and personalized learning experiences.

### A. Web Application Development with Python Flask

The web application was developed using Python Flask, a lightweight framework ideal for the pilot of our educational application that requires real-time user interaction.

*1) Authentication and user management:* The authentication system supports login, signup, and logout functionalities with role-based access control. During the signup process, users are assigned roles: lecturer or student. Lecturers use the system to manage lecture content, while students access lecturer and AI-generated materials.

*2) Lecture management:* Lecturers can create, edit, and manage lecture questions and answers through a set of web forms. This content is stored in an SQLite database, ensuring that all data is securely saved and retrievable for AI-driven content generation.

Fig. 2 illustrates the list view of the Lecture Management interface, where lecturers can view all previously created lecture questions. The list includes columns for the topic, question, answer, and focus, along with action buttons to view details, edit, or delete content. The TutorAI button allows lecturers to invoke AI to generate content based on existing questions and answers. This streamlined interface helps lecturers keep track of lecture materials and manage them efficiently.

Fig. 3 illustrates the creation form where lecturers can add new lecturer questions. The form includes fields for entering the overarching lecture topic, desired question, expected answer, and focus area (industry, local, global, etc.), allowing lecturers to define the specific content they wish to include in their lecture. Once submitted, the new question is added to the list, as seen in Fig. 2, where it can be managed further through the available actions.

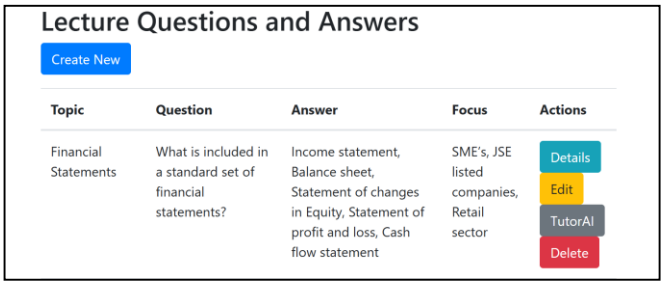

Fig. 1. Lecture management - List view (add, edit, delete questions and answers).

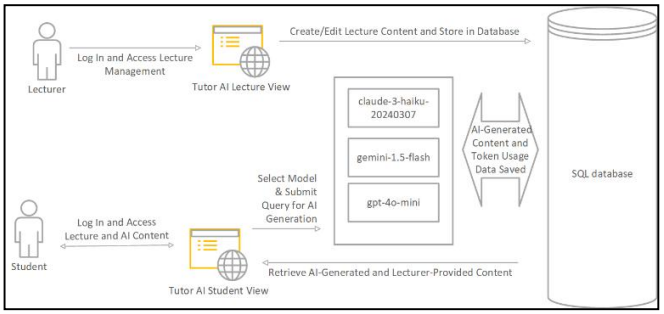

Fig. 2. Application flow.

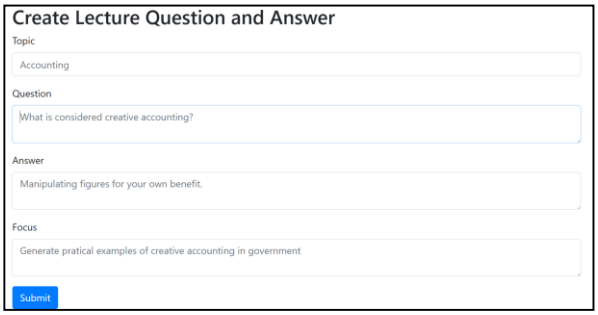

Fig. 3. Lecture management: Create lecture question and answer screen.

## B. Integration of Generative AI Models

The RAG web application integrates three Generative AI models to provide students with dynamic and personalized educational content based on the lecturer-provided lecture questions. This functionality allows students to enhance their understanding by accessing AI-generated answers and examples directly aligned with their course materials.

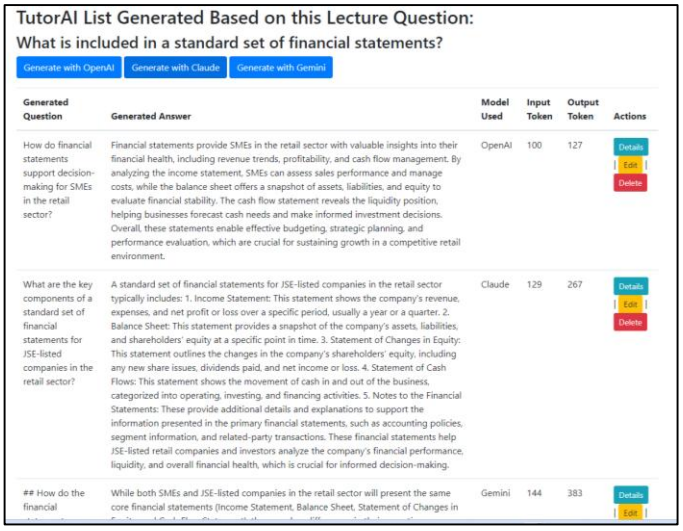

Fig. 4. TutorAI integration of Generative AI models for students.

Fig. 4 illustrates how students can interact with the TutorAI system by generating additional questions and answers related to their lecture materials. Students have the option to select from three AI models, 1) OpenAI GPT-4o-mini, 2) Anthropic Claude-3-haiku, and 3) Google Gemini-1.5-flash, based on their content needs.

*1) OpenAI GPT-4o-mini:* This model generates in-depth answers and explanations related to the lecture material. When a student clicks "Generate with OpenAI," the model processes the lecture question and returns detailed responses. The input and output tokens (reflecting the number of tokens used for generating content) are tracked to monitor how much content is generated for each query.

*2) Anthropic Claude-3-haiku-20240307:* Students can select this model for more creative and comprehensive explanations. By choosing "Generate with Claude," students receive answers that delve into broader interpretations or applications of their lecture content, which helps deepen their understanding.

*3) Google Gemini-1.5-flash:* This model is ideal for concise, fact-based content. When students click "Generate with Gemini," they get brief, straightforward answers, which are useful for summarizing or revisiting key lecture concepts. Token usage data is also tracked here.

The generated content is displayed in a structured table, which includes the question, the AI-generated answer, the model used, and token usage statistics. Students can also view more details and edit or delete the generated content, providing them with flexibility in managing the information they receive.

By offering these AI models, the system empowers students to explore multiple perspectives and explanations on lecture topics, enhancing their learning experience through AI-generated content that is tailored to their academic needs.

## C. Data Management with SQLite

SQLite is used for data storage, providing a secure and scalable solution for managing user data, lecture materials, and AI-generated content. Data management for this study is discussed under database configuration, data security, and token usage tracking.

*1) Database configuration:* The SQLite database serves as the primary repository for lecture content, user data, and AI-generated responses. A structured database schema ensures easy retrieval of data for both lecturers and students.

*2) Data security:* The application employs secure connection strings to SQLite, with strict role-based access control to protect sensitive data.

*3) Token usage tracking:* In order to manage the costs of using external AI APIs, the system tracks token usage (input and output) for each AI model. This data is stored in the database to monitor efficiency and manage costs.

## D. Workflow and System Architecture

The architecture supports seamless interaction between users, AI models, and the database. User interaction, AI content generation, and response delivery are considered at this stage.

*1) User interaction:* Lecturers and students interact with the system through web interfaces: Lecturers manage lecture content and students access AI-generated content. These interfaces are user-friendly and responsive.

*2) AI Content generation:* When a user submits a query, the system constructs a prompt using stored lecture data and sends it to the selected AI model. The AI model generates content, which is stored in the database for future access.

*3) Response delivery:* The generated content is then delivered to the user in a formatted and accessible manner, providing real-time feedback and enhancing the learning experience.

## E. Implementation Challenges and Solutions

Several challenges were encountered during development and are summarized under model integration, data privacy, scalability and cost management.

*1) Model integration:* Managing multiple AI models requires careful handling of API keys and response formats. Standardized prompts and consistent response parsing were implemented to ensure coherence across models.

*2) Data privacy:* Protecting user data was a top priority. The system uses encrypted connections to SQLite and strict access control to safeguard sensitive information.

*3) Scalability and cost management:* By tracking token usage across the AI models, the system monitors API efficiency and manages costs, ensuring scalability as user activity grows.

## IV. Findings and Implications for Higher Education

The development of the RAG web application demonstrates the successful integration of multiple Generative AI models to enhance the educational experience for students in an Internal Auditing module at the Durban University of Technology. By leveraging cutting-edge AI models, OpenAI GPT-4o-mini, Google Gemini-1.5-flash, and Anthropic Claude-3-haiku, the application provides dynamic, personalized content to support both lecturers and students.

Lecturers can efficiently manage their lecture materials, create and update content, and utilize AI-generated enhancements to enrich their teaching. Meanwhile, students are empowered with tailored AI-generated responses, offering multiple perspectives and deeper insights into the course material. The system architecture, built on Python Flask and supported by Azure SQL, ensures that the platform is scalable, secure, and cost-effective, addressing the specific needs of the academic environment.

The integration of role-based access control, seamless data management, and AI-driven content generation allows for an interactive and flexible learning experience. As AI technologies continue to evolve, this application sets the stage for further innovations in educational tools, offering a model for how institutions can harness the power of AI to improve academic outcomes.

## V. Conclusion

The RAG web application not only integrates multiple Generative AI models to support the teaching and learning experience but also provides a blueprint for future applications of AI in higher education, transforming traditional learning methods into more interactive and personalized experiences. Higher education institutions can leverage the RAG web application to drive and support more effective and real-world student solutions.

Although the development of the RAG shows promise, the accuracy and relevance of the Generative AI outputs necessitate further research to be performed on the implementation of the application. As Phase 2 of a broader research initiative, this needs to be done through a pilot study. During this phase, feedback on the accuracy and relevance of AI-generated outputs will be collected, along with a cost-benefit analysis across OpenAI GPT-3 Turbo, Google Gemini API Pro, and Anthropic Haiku.

Given the use of AI applications and the associated costs, a cost-benefit analysis must be carried out. Phase 3 of a broader research initiative will entail the comparison of costs, relevance and accuracy associated with OpenAI GPT-3 Turbo, Google Gemini API Pro, and Anthropic Haiku. The most cost-effective and accurate Generative AI model for educational purposes among the three AI platforms will need to be determined. This will entail the analysis of the feedback and cost data collected. Researchers and developers can warrant the responsible, positive and cost-effective disposition of a RAG web application in various disciplines at a higher education setting while shielding against likely risks.

# Development of an Interactive Oral English Translation System Leveraging Deep Learning Techniques

Dan Zhao[1], HeXu Yang[2*]
School of Foreign Studies, Ningxia Institute of Science and Technology, Shi Zuishan 753000, China[1]
School of Mechanical Engineering, Ningxia Institute of Science and Technology, Shi Zuishan 753000, China[2]

***Abstract*—An advanced interactive English oral automatic translation system has been developed using cutting-edge deep learning techniques to address key challenges such as low success rates, lengthy processing times, and limited accuracy in current systems. The core of this innovation lies in a sophisticated deep learning translation model that leverages neural network architectures, combining logarithmic and linear models to efficiently map and decompose the activation functions of target neurons. The system dynamically calculates neuron weight ratios and compares vector levels, enabling precise and responsive interactive translations. A robust system framework is established around a central text conversion module, integrating hardware components such as the I/O bus, I/O bridge, recorder, interactive information collector, and an initial language correction unit. Key hardware includes the WT588F02 recording and playback chip (with external flash) for audio recording and NAND flash memory for efficient data storage. Noise reduction is achieved using the POROSVOC-PNC201 audio processor, while the aml100 chip enhances audio detection capabilities. The extensive neuron network testing using a dataset of 1.8 million translation samples demonstrates the system's superior performance, achieving an impressive success rate exceeding 80%, a rapid translation time of under 50ms, and a remarkable translation accuracy of over 95%. This state-of-the-art system sets a new benchmark in interactive English oral translation, achieving a success rate exceeding 80% (a 10% improvement over existing methods), a rapid translation time of under 50ms (a 30% reduction), and a remarkable translation accuracy of over 95% (a 5% improvement), by combining deep learning advancements with high-performance computing and optimized hardware integration.**

## I. Introduction

Artificial intelligence big models are "large parameter" models trained using large-scale data and powerful computing power. With their high versatility and generalization capabilities, these models have shown extraordinary potential in many fields such as natural language processing, image recognition, and speech recognition. Artificial intelligence big models can be subdivided into big language models, big visual models, multimodal big models, and basic big models, which are constantly promoting technological innovation and progress in their respective fields.

Computer science is a practical technical discipline that systematically studies the theoretical basis of information and computing and how these theories can be implemented and applied in computer systems. Computer science not only covers systematic research on algorithmic processing for creating, describing, and transforming information, but also includes many branches. From computer graphics that emphasizes the calculation of specific results, to computational complexity theory that explores the nature of computational problems, to programming language theory and program design that focus on realizing calculations, and human-computer interaction that is committed to improving the usefulness and usability of computers and computing, computer science provides a solid theoretical foundation and rich technical means for the development of artificial intelligence.

Oral translation, as a type of instantaneous interactive learning, has high requirements for the accuracy and adaptability of translation systems. Regarding the issue of interactive English oral translation, scholars in related fields have conducted in-depth research. For example, in [1] proposes an interactive oral machine translation system based on semantic analysis, which uses semantic analysis technology to convert source speech into text and improve translation quality by analyzing language texts. However, this system requires extremely high logical compilation and has poor translation accuracy. In [2], designed a bidirectional English online auxiliary translation system based on human-computer interaction, which displays translation results based on the similarity between words analyzed by a corpus. This system can evenly distribute the frequency of markers, but its dependence on the corpus is too high, resulting in a low success rate of translation. In [3], designed an automatic calibration system for English spoken pronunciation based on speech perception technology, which achieves high accuracy in correcting English spoken pronunciation but has a long calibration process and poor instantaneous translation ability. In contrast, our proposed system leverages advanced deep learning techniques to address these limitations.

Deep learning technology, as a type of machine learning, combines grassroots features to obtain a more abstract high-level representation of attribute categories or features, thereby more clearly discovering distributed features of data. It has strong analytical capabilities for both sound and text. Deep learning technology can achieve information learning by establishing an appropriate number of neural computing nodes and a multi-layer computational hierarchy and further optimizing the data characteristics to detect text data features. After detecting the functional relationship between input and

*Corresponding Author.

output, the correlation between texts is determined to achieve information exchange. Therefore, this article designs a new interactive English oral automatic translation system based on deep learning algorithms, optimizes the system hardware and software, uses deep learning technology to transform features layer by layer, enriches the internal information of the data based on learning features, and tests the actual application effect of the interactive English oral automatic translation system designed in this article through experiments. Therefore, this article designs a new interactive English oral automatic translation system based on deep learning algorithms. The objectives of this study are to propose an efficient and accurate translation system, optimize its hardware and software components, and evaluate its performance through experiments. The rest of this study is organized as follows: Section II describes the framework design of the proposed system, Section III details the hardware design, Section IV presents the software design, Section V reports the experimental study, Section VI presents results, and Section VII concludes the study.

## II. Framework Design of Interactive Oral English Automatic Translation System Based on Deep Learning

### A. Principles of Deep Learning

The interactive spoken English is automatically translated using deep learning technology. The translation model is shown in Fig. 1:

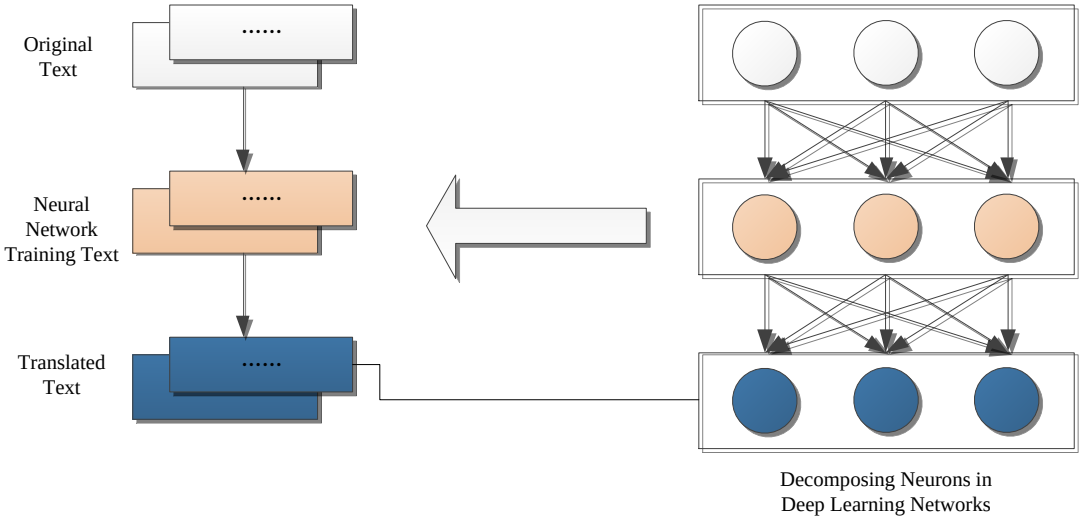

Fig. 1. Deep Learning translation model.

Set $x$ as input information text and $y$ as output text, $\theta$ as a conversion function, a linear model of input information text is established according to the characteristics of language structure, as shown in Formula (1):

$$P(y|\ x;\theta)=\sum_{z}\frac{\exp(\theta\cdot\phi(x,y,z))}{\sum_{y'}\sum_{z'}\exp\left(\theta\cdot\phi\left(x,y',z'\right)\right)} \tag{1}$$

wherein, $P(y|\ x;\theta)$ is the obtained logarithmic linear model mapping, the implicit language structure phrase is set as the basic translation unit, and the input text information is set as the target neuron. The activation function of the target neuron is decomposed in the relevant neurons of the neural network. The decomposition process is as follows:

$$f_m=\sum_{u\in C(f_m)}\sum_{n=1}^{N}r_{u_n\leftarrow f_m} \tag{2}$$

$$f_1=\sum_{n=1}^{3}r_{u_n\leftarrow f_1} \tag{3}$$

wherein, $f_m$ is the target neuron to be decomposed; $C(f_m)$ is the collection of neurons; $N$ is the number of neurons; $r_{u_n\leftarrow f_m}$ is the corresponding relationship; $f_1$ is the data value after decomposition.

After decomposing the activation function value, the neuron level correlation is calculated. The calculation method selected in this study is a backward propagation recursive algorithm. The calculation process is as follows:

$$r_{u\leftarrow f}=\sum_{o\in \mathrm{OUT}(u)}w_{u\to o}r_{o\leftarrow v} \tag{4}$$

wherein, $r_{u\leftarrow f}$ is the neuron-related data after recursion; $o$ represents the target neuron selected in the recurrent neural network.

While using backward propagation recursively to calculate neuron level correlation, the weight ratio of current neurons is calculated through forward propagation as follows:

$$w_{u\to f}=\frac{\mathbf{W}_{u,f}u}{\sum_{u'\in \mathrm{IN}(f)}\mathbf{W}_{u',f}u'} \tag{5}$$

The data are labeled according to the weight ratio to obtain small-scale labeled data. Other data are large-scale unlabeled data. The semi-supervised learning is completed by using the deep learning network. The calculation process is as follows:

$$J(\vec{\theta},\overleftarrow{\theta})=\sum_{n=1}^{N}\log P\left(y^{(n)}|\ x^{(n)};\vec{\theta}\right)+\sum_{n=1}^{N}\log P\left(x^{(n)}|\ y^{(n)};\overleftarrow{\theta}\right)$$
$$+\tau_1\sum_{t=1}^{T}\log P\left(y^{'}|\ y^{(t)};\vec{\theta},\overleftarrow{\theta}\right)+\tau_2\sum_{s=1}^{S}\log P\left(x^{'}|\ x^{(s)};\vec{\theta},\overleftarrow{\theta}\right) \quad (6)$$

Among them, $\sum_{n=1}^{N}\log P\left(y^{(n)}|\ x^{(n)};\vec{\theta}\right)$ indicates the possibility of translating the original text into the target text, and the translation mode is forward translation; $\sum_{n=1}^{N}\log P\left(x^{(n)}|\ y^{(n)};\overleftarrow{\theta}\right)$ indicates the possibility of translating the target text into the original text, and the translation mode is backward translation [4-5]; $\tau_1\sum_{t=1}^{T}\log P\left(y^{'}|\ y^{(t)};\vec{\theta},\overleftarrow{\theta}\right)$ is the original text neural network; $\tau_2\sum_{s=1}^{S}\log P\left(x^{'}|\ x^{(s)};\vec{\theta},\overleftarrow{\theta}\right)$ is the target text neural network.

The translation content is determined by comparing the vector-level relevance to achieve Interactive Oral English Translation. The mathematical model of translation is as follows:

$$R_{u\leftarrow f}=\sum_{m=1}^{M}\sum_{n=1}^{N}r_{u_n\leftarrow v_f} \quad (7)$$

Formula (7) represents the translation result [6].

### B. Frame Structure Design

The automatic translation system of spoken English designed in this study has strong interactive ability. After obtaining the real-time voice, it can convert the voice into text. The correction module is set inside the system, which can well ensure the accuracy of spoken English translation. The framework of the translation system is shown in Fig. 2:

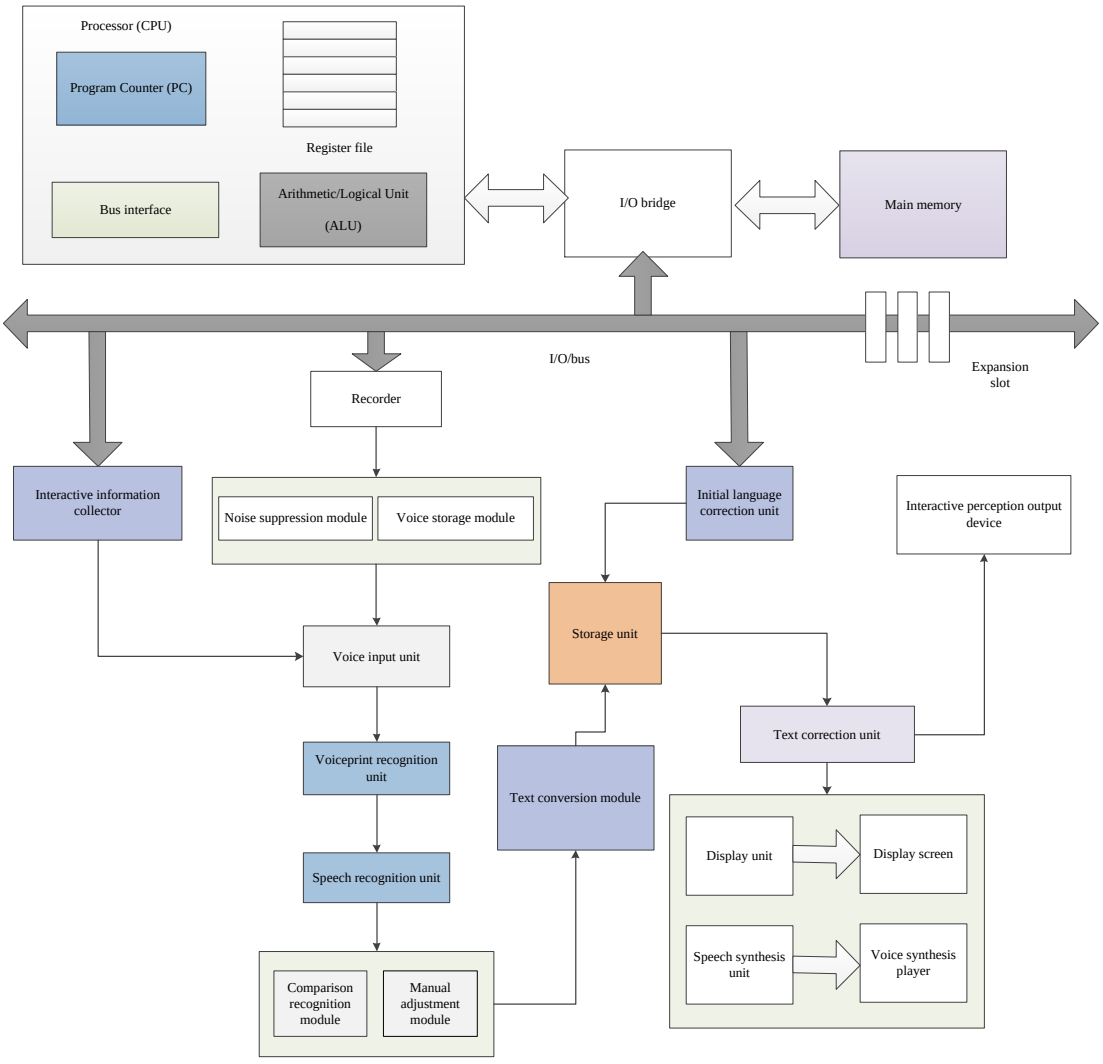

Fig. 2. Framework of translation system.

According to the Fig. 2, the internal bus of the translation system framework in this study connects the I/O bridge, recorder, interactive information collector, and initial language correction unit. The bus word length is 8 bytes (64 bits), and the bus is responsible for information interaction. The central processing unit (CPU) inside the system is mainly responsible for sending, interpreting, or executing the instructions inside the system. The program counter (PC) is the core device of the CPU, with a size of 1 byte. During the operation of the system, the PC always points to various machine language instructions. When

the CPU receives the instructions, it will continuously update the program counter to execute the instructions of the processor. After completing an instruction, the PC will point to the next instruction. The CPU will then carry out new work. The working process of the processor mainly includes loading, operation, storage, and jump. The specific execution process is as follows: after receiving the translation command, the system will automatically collect the target text, copy a byte of the target text from the main memory to the register, and use the copied content to replace the original content of the register. When the two-word contents of the two registers are copied to the arithmetic logic unit (ALU), the ALU will perform operations on the two words copied and store the operation result in the original register to complete the operation. After the register runs for a period of time, it will copy an internal byte or a word to a location in the main memory. Through this operation, the content in the original location of the main memory will be overwritten to complete the storage. After the storage is realized, the CPU needs to start a new instruction, extract a word from the original instruction [7]-[8], and copy the extracted content to the PC. After overwriting the original value of the PC, start a new command.

The I/O bus is connected to the interactive information collector and recorder at the same time. The voice information to be converted is collected through the above equipment. The collected information will be transmitted to the voice input unit at the same time. The in-depth detection of voice will be carried out through the double recognition of voiceprint recognition and voice recognition. Under the work of the comparison recognition module and the adjustment module, the transferred information will be automatically converted. After the converted text and the corrected information of the initial language enter the storage unit, the correction is implemented in the text correction unit, the translation results are displayed by the display and voice synthesis player, and the output content is backed up in the interactive perception output device.

## III. Hardware Design of an Interactive Oral English Automatic Translation System Based on Deep Learning

An automatic translation system is established under the deep learning network. The hardware structure of the system (Fig. 3) is as follows:

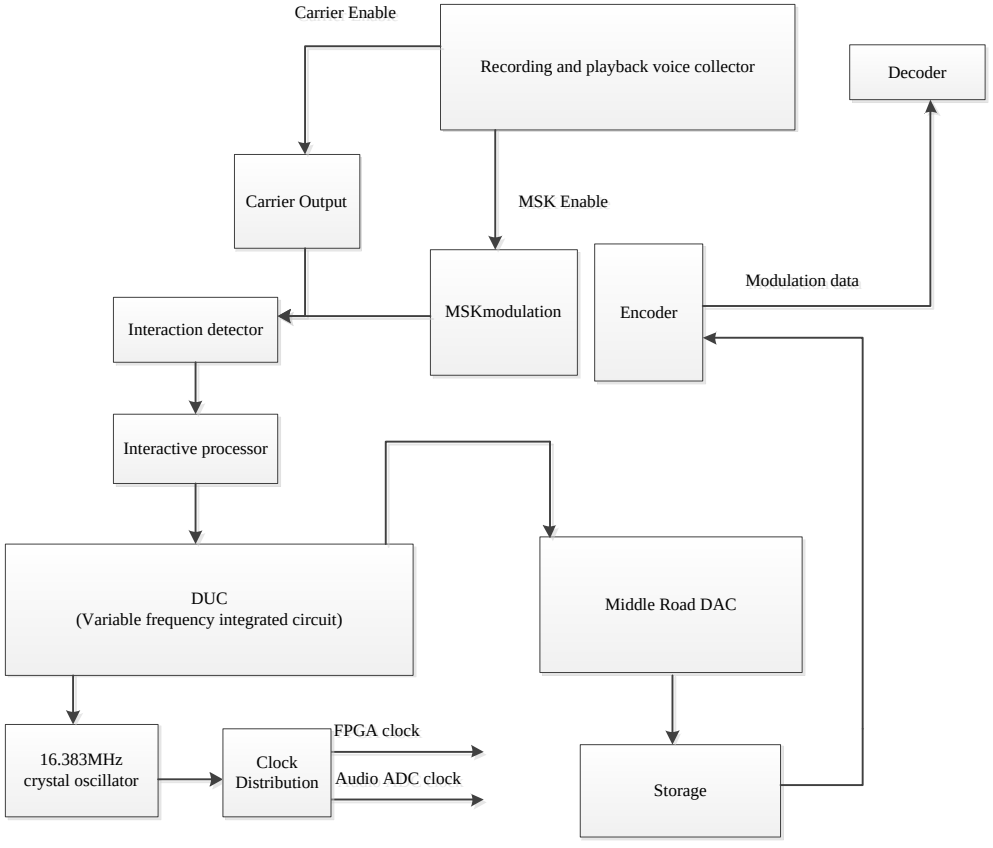

Fig. 3. Hardware structure of automatic translation system.

It can be seen from Fig. 3 that the collector outputs signal through carrier enable and MSK enable and performs carrier output processing and MSK modulation processing, respectively. The processed text data successively enters the interaction detector and interaction processor. The frequency conversion integrated circuit and crystal oscillator are used to complete clock distribution. The allocated data enters the memory and is modulated by the encoder. In the process of translation, when the encoder is in a working state, the decoder must keep waiting until all the encoders have finished their work. The decoder uses the parallel technology of a deep neural network to realize translation and output the final translation results.

### A. Recording and Playing Voice Chip

The audio recording and playback chip selected in this study is the Wt588f02 audio recording and playback (external flash) chip. The working voltage of the chip is 2.0 to 5.5V. The internal low-voltage reset (lvr=1.8v) watchdog has a strong timing function. Even if there is a vibration inside, it will float at +/-1%. It is controlled by a serial port and can sample 16KHz recording at most. The built-in 2M bit flash of the chip has a self-healing function. The main program data and flash data in the voice chip can be erased and then burned [9]. The chip and pin are shown in Fig. 4.

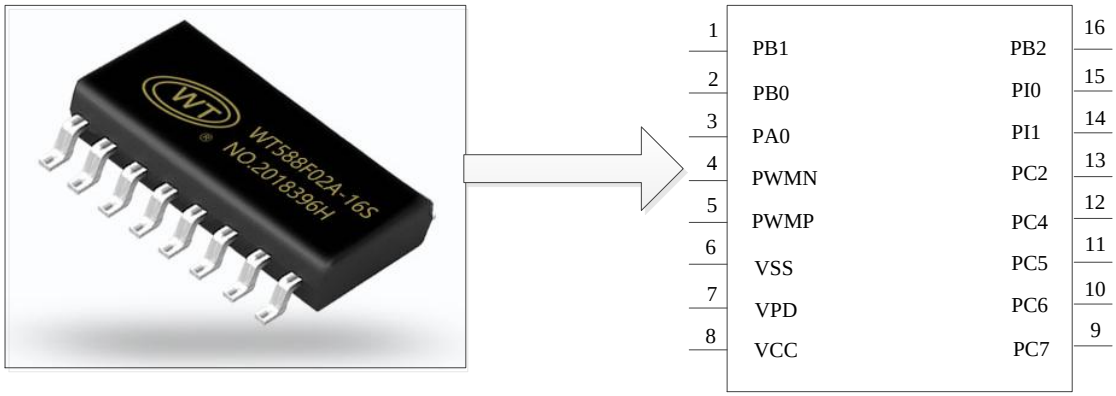

Fig. 4. Wt588f02 recording and playback chip and pin.

The Pin description is shown in Table I:

TABLE I. PIN DESCRIPTION

| Name | Serial number | Attribute | Describe |
|---|---|---|---|
| PB1 | 1 | I/O | SPI communication pin |
| Pb0 | 2 | I/O | SPI communication pin |
| PA0 | 3 | I/O | Data |
| Pwmn | 4 | Out | Horn port |
| Pwmp | 5 | Out | Horn port |
| VSS | 6 | Power | GND |
| VPD | 7 | Power | Internal power supply and discharge |
| VCC | 8 | Power | Power supply positive pole |
| PC7 | 9 | I/O | Mic interface terminal (refer to the reference circuit for connection) |
| PC6 | 10 | I/O | Mic interface terminal (refer to the reference circuit for connection) |
| PC5 | 11 | I/O | Mic interface terminal (refer to the reference circuit for connection) |
| PC4 | 12 | I/O | —— |
| PC2 | 13 | NC | —— |
| PC1 | 14 | I/O | SPI communication pin |
| P10 | 15 | I/O | Busy |
| PB2 | 16 | NC | SPI communication pin |

### B. Memory

The memory selected in this study is NAND flash memory, and the memory structure is shown in Fig. 5.

As a kind of flash memory, NAND flash memory uses a nonlinear macro cell mode internally, with a maximum bandwidth of 100GB per second. The internal cell density is extremely high, which can ensure the storage of a large number of voice text information, ensure the storage density, and effectively improve the writing and erasing speed. Since the input translated text data is saved in array mode, after consolidation and management, the storage array runs in a pool, which can reduce the amount of calculation during operation, and the response time is less than 50 μ s. The processor inside the memory is Intel Ice Lake, and the maximum port of the front-end host is 48. The prediction and analysis technology inside the memory can monitor the storage state well and [10], optimize the storage state at any time so as to ensure storage efficiency.

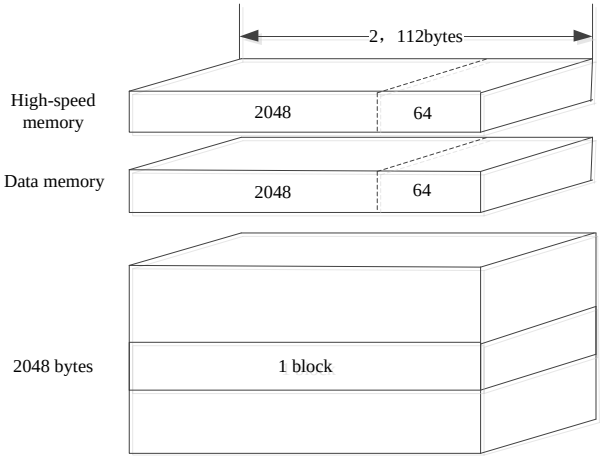

Fig. 5. NAND flash memory structure.

### C. Audio Processor

The audio processor selected in this study is the POROSVOC-PNC201 audio processor. The processor uses the DNN neural network noise reduction algorithm, deep neural network echo cancellation algorithm, AGC automatic gain adjustment algorithm, howl suppression, reverberation elimination and other technologies, AI algorithm+embedded SOC chip deep fusion technology. Under the deep learning technology, it completes sample training, eliminates various noises in the external environment, and realizes blind source separation, ensuring that the input sound source is valid information. The processor has a professional DSP instruction
