set, which can process signals well. The FPU operation unit enables the processor to support floating-point operation and cooperate with the FFT accelerator to ensure the processing speed.

### D. Audio Detector

The audio detection chip selected in this study is the aml100 chip, which uses digital analog technology to complete machine learning and data calculation to ensure that the data calculation results are closer to the data source. The chip is composed of a group of independent configurable analog modules, which can support various audio detection functions through software programming technology. Compared with the traditional single mode, the aml100 chip is more flexible. Using 7mm x 7mm 48-pin QFN package, it can effectively reduce power consumption and ensure that the power consumption operation process is less than 20 μ A. The field programmable function enables the chip to meet the requirements of different occasions.

## IV. Software Design of Interactive Oral English Automatic Translation System Based on Deep Learning

After completing the hardware design, the interactive spoken English automatic translation system software is designed by using the deep learning algorithm. In the process of translation, the gradient of deep learning neural network will gradually disappear with the deepening of time dimension. Therefore, the translation system software designed in this study introduces the attention mechanism, uses the attention mechanism to identify the original information characteristics of spoken English, uses the encoder to obtain the data correlation, and obtains the probability distribution state according to the correlation analysis results. The gradient disappearance problem is solved through the residual network, by default, one layer of neural network calculates an identity function to calculate the performance of different weights at different levels when expressing the identity function. The calculation process is as follows:

$$\begin{gathered} d_1 = f_1(x) + x \\ d_2 = f_2(d_1) + h_1 = f_2 d(h_1) + f_1(x) + x \\ d_3 = f_3(d_2) + d_2 = f_3(d_2) + f_2(d_1) + d_1 = f_3(d_2) + f_2(d_1) + f_1(x) + x \\ d_n = x + \delta_1 + \delta_2 + \cdots + \delta_n \end{gathered} \tag{8}$$

where, $\chi$ is the input information; $f_1$ is the identity function of the first layer neural network; $d_1$ is the output result of the first layer neural network. By analogy, when the neural network is a $\eta$ layer [11]-[13], the output result is the neural network output data and of each layer.

The software workflow of Interactive Oral English automatic translation system based on deep learning neural network parallel algorithm and residual network is shown in Fig. 6.

### A. Sound Acquisition Model

Using deep learning algorithms to recognize interactive oral information, establish a sound acquisition model, input the collected acoustic features into the neural network in image mode, set the size of the acoustic feature map $g$ to $a \cdot b$, and process the input acoustic feature map $g$ through an excitation function. The output results of the acquisition model are as follows:

$$F_{a,b} = f\left( \sum_{m=0}^{k=1} \sum_{n=0}^{k=1} =1\left( \kappa_{m,n} g_{a+m,b+n} \right) + \kappa_e \right) \tag{9}$$

Among them, $F_{a,b}$ represents the position of the output neuron in the feature map, which is row $a$ and column $b$; $k$ represents the number of layers in the neural network; $\kappa_{m,n}$ represents the weight values of row $m$ and column $\eta$, and the weight values of the acoustic acquisition model are calculated using unsupervised and training methods; $\kappa_e$ represents the deviation value generated during the training process.

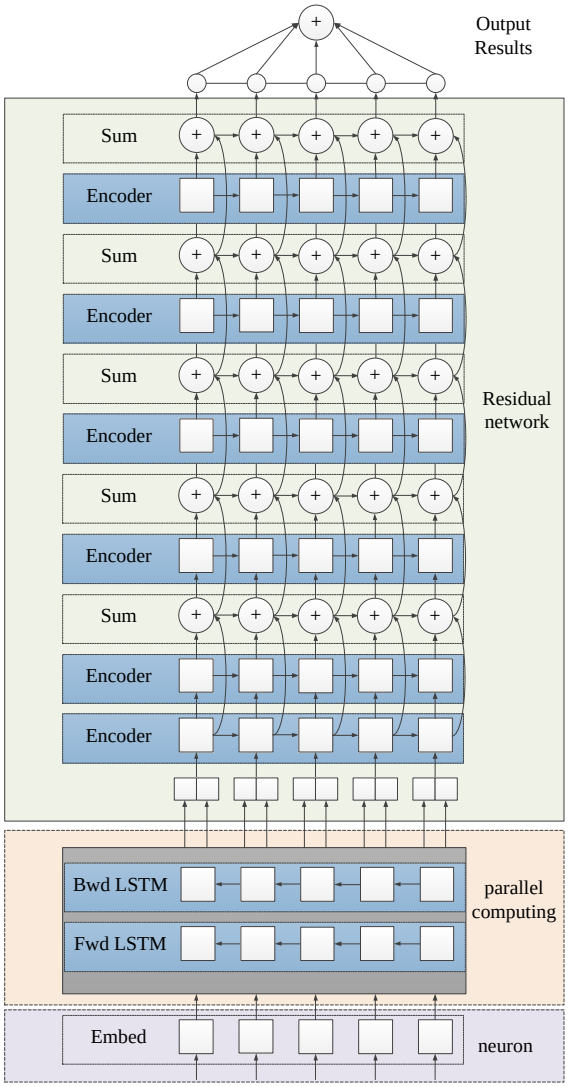

Fig. 6. Software workflow of Interactive Oral English automatic translation system.

After the output results are obtained, the backpropagation technology is used to realize the training. The neural network will produce losses in the interaction process, and each node will have errors, so the loss amount needs to be calculated. Set the node to $i$ ,the loss amount is:

$$\delta_i = -O_i\left(I_i - O_i\right)\left(1 - O_i\right) \tag{10}$$

where, $\delta_i$ represents the calculated loss result; $O_i$ represents the weighted output value; $I_i$ represents the weighted input value.

Analyze the gradient of $\kappa_{m,n}$ and complete weight iteration using gradient descent technique. The calculation process is as follows:

$$\kappa_{m,n}{}' = \kappa_{m,n} - \eta \frac{\delta}{\partial \kappa_{m,n}} \tag{11}$$

where, $\kappa_{m,n}{}'$ is the weight value after iterative update; $\eta$ represents the learning rate of the neural network; $\partial$ represents the offset value.

The acoustic acquisition model is trained through the above calculation to improve the robustness of the model [14]-[16].

### B. Feature Recognition Based on Deep Learning

Feature recognition is realized through the attention mechanism of deep learning neural network. The recognition process is shown in Fig. 7:

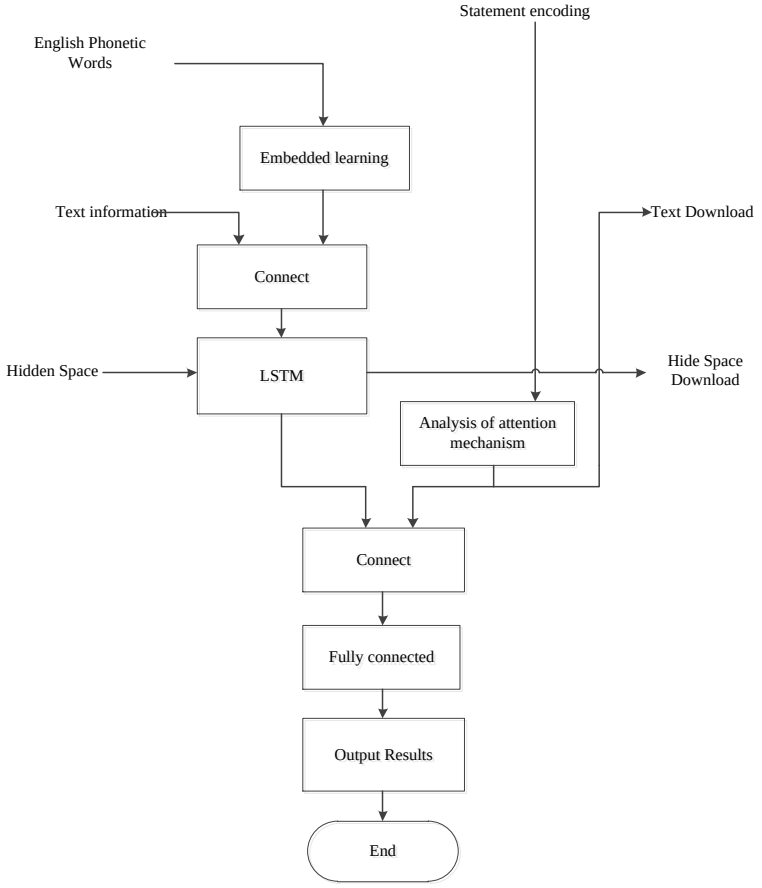

Fig. 7. Feature recognition process based on deep learning.

Select the training sample in the sound acquisition model, set the trained sample as $\wp$ , the position coordinate in the neural network as $X_\wp(x_{\wp 1}, x_{\wp 2}, \cdots x_{\wp n})$ , the learning frequency in the training process as $V_\wp(v_{\wp 1}, v_{\wp 2}, \cdots v_{\wp d})$ , the best training position of $\wp$ as $P_\wp$ , the best training of all learning particles in the training sample as $P$ , and iterate the learning particles in the deep learning space. The iterative results are as follows:

$$v_{\wp d}^{k+1} = v_{\wp d}^{k} + c_1 R\left(P_\wp^k - x_{\wp d}^k\right) + c_2 R\left(P^k - x_{\wp d}^k\right) \tag{12}$$

$$x_{\wp d}^{k+1} = x_{\wp d}^{k} + v_{\wp d}^{k+1} \tag{13}$$

where, $c_1$ represents the training depth coefficient of the optimal training position $P_\wp$ $c_2$ represents the training depth coefficient of the optimal training position $P$ . When learning particles need to consider semantic features, it is necessary to focus on the deep learning coefficient and control the training

intensity through the deep learning coefficient; $R$ represents the dynamic coefficient generated during the training process [17], and the range is (0,1).

After repeated training, the learning particle will reach the maximum training frequency $V_{\max}$ . When this value is reached, the frequency of the subsequent training process will remain constant. The depth threshold is obtained by analyzing semantic features, and the optimal solution obtained by attention detection is $S$. The result is semantic features [18].

### C. Interactive Processing of Translation Information

The obtained optimal solution $S$ is expressed through probability distribution. If the label sequence is set to $l$, the probability distribution is expressed as $p(l|\ s)$ . Translation information features are input into the neural network model to calculate the output sequence with the highest probability,

$$R(s) = \arg\max\ p(l|\ s) \tag{14}$$

optimizing maximum output sequence $R(s)$ using decoder. When predicting the information of each frame, the blank tag is inserted, and the path that can be consistent with the tag sequence is added. The noise in the sound is eliminated by the sequence, and the information is filtered. The processing result is obtained through bidirectional coding. The filtering process is as follows:

$$\ell_s = \vec{\ell}_s \oplus \overleftarrow{\ell}_s \tag{15}$$

$$\vec{\ell}_s = f\left(\vec{\ell}_{s-1}, e_s\right) \tag{16}$$

$$\overleftarrow{\ell}_s = f\left(\overleftarrow{\ell}_{s-1}, e_s\right) \tag{17}$$

wherein, $\ell_s$ represents the result of joint processing of forward encoding $\vec{\ell}_s$ and reverse encoding $\overleftarrow{\ell}_s$; $\overleftarrow{\ell}_s$ represents the activation function of neural network; $e_s$ indicates hidden status.

Delete the useless information in the voice information through interactive processing, record the standard vector after summarizing the remaining information, use the decoder to decode the data [19]-[20], and output the information iteratively after matching with the context. The interactive processing flow of translation information is shown in Fig. 8:

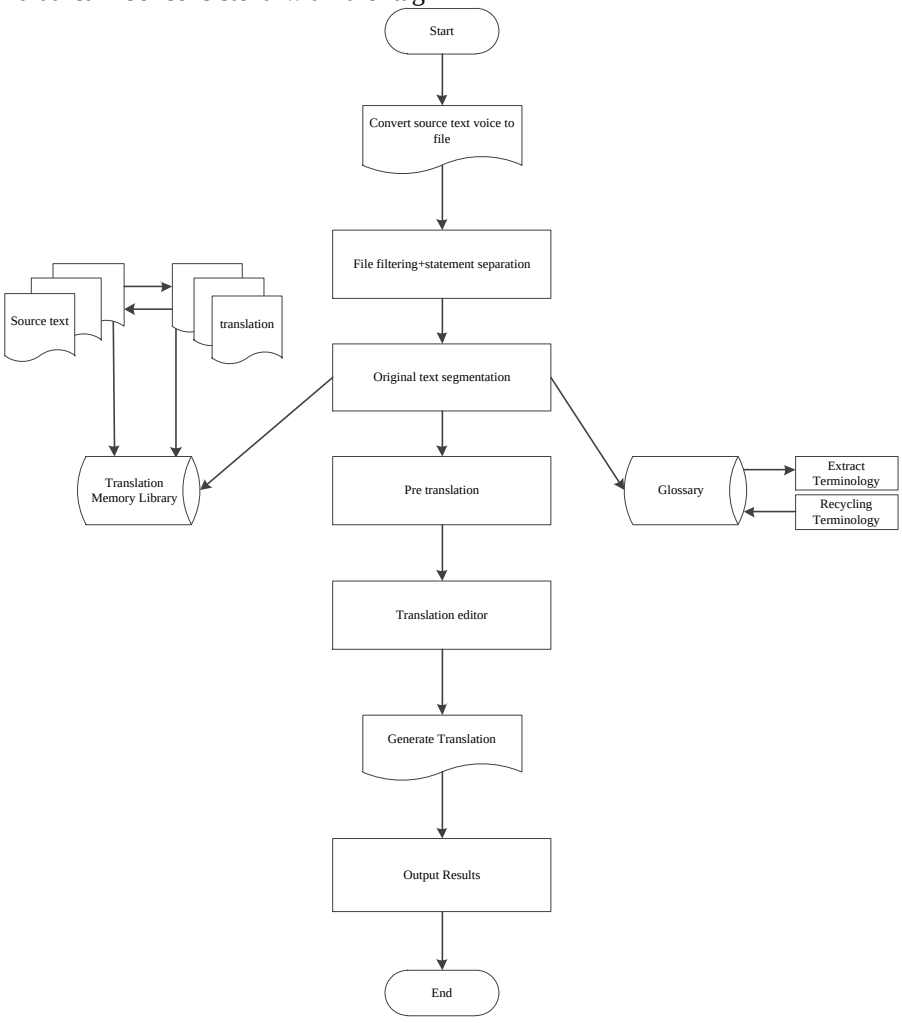

Fig. 8. Interactive processing flow of translation information.

## V. Experimental Study

In order to verify the practical application effect of the Interactive Oral English automatic translation system based on deep learning designed in this study, a comparative experiment was set. A total of 1.8 million sentences were set to be translated, including 600000 spoken words, 600000 spoken short sentences, and 600000 spoken long sentences. The system was compared with a semantic analysis translation system, human-computer interaction translation system, and language perception translation system. The translation time and translation accuracy were studied in depth. The detection time was 24hours, and the detection results were recorded every 10 minutes.

The experimental results of the translation success rate are shown in Fig. 9:

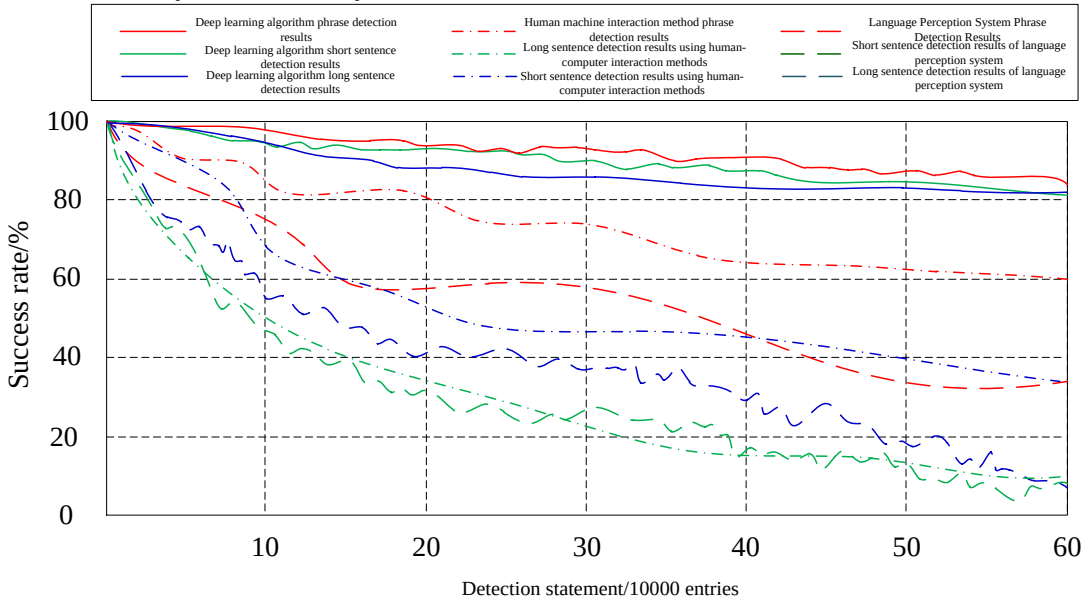

Fig. 9. Experimental results of translation success rate.

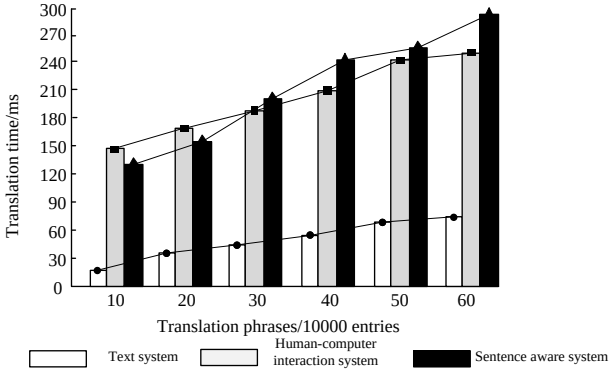
According to the above Fig. 9, as the number of detected entries/sentences increases, the success rate of translation also decreases. The three methods have the highest success rate of phrase translation and the lowest success rate of long sentences. In the process of translation, the deep learning algorithm adjusts the weights through neural network training to ensure that the output results can achieve the expected results. Therefore, the success rate of the Interactive Oral English automatic translation system based on deep learning for detecting entries/sentences is always above 80%, which is always higher than the traditional human-computer interactive translation system and language-aware translation system.

The experimental results of translation time are shown in the following Fig. 10:



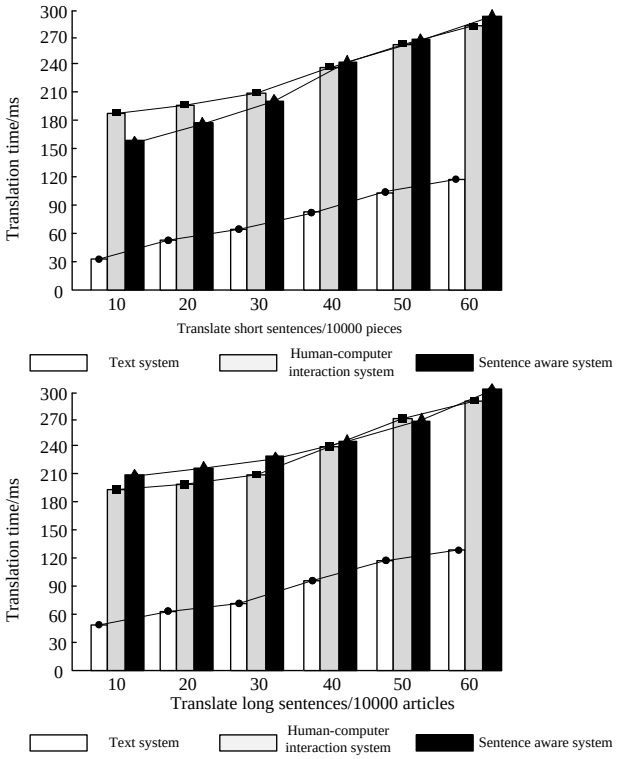


Fig. 10. Translation time experimental results.

It can be seen from the above Fig. 10 that in terms of translating phrases, short sentences and long sentences, the translation process time of the translation system proposed in this study is far less than that of the traditional translation system. When the number of translated phrases is 600000, the translation system time proposed in this study is 50ms, when the number of translated short sentences is 600000, the translation system time proposed in this study is 90ms, and when the number of translated long sentences is 600000, the translation system time proposed in this study is 105ms. It can be translated in a short time to meet the requirements of instant translation.

The experimental results of translation accuracy are shown in Table II:

TABLE II. EXPERIMENTAL RESULTS OF TRANSLATION ACCURACY

| | Number of translations/10000 | Phrase accuracy/% | Accuracy rate of short sentences/10000 | Accuracy of long sentences/% |
|---|---|---|---|---|
| Text system | 0-20 | 98.21 | 97.43 | 96.23 |
| | 20-40 | 96.44 | 96.81 | 95.67 |
| | 40-60 | 95.93 | 95.32 | 95.24 |
| Human-computer interaction system | 0-20 | 94.66 | 92.18 | 91.98 |
| | 20-40 | 91.09 | 86.64 | 88.76 |
| | 40-60 | 89.34 | 81.93 | 86.32 |
| Sentence aware system | 0-20 | 93.67 | 91.04 | 89.74 |
| | 20-40 | 90.25 | 87.29 | 85.64 |
| | 40`60 | 88.44 | 83.45 | 80.98 |

According to the above table, the translation accuracy of the translation system proposed in this study is always above 95%. Through the deep learning algorithm for oral interaction, data mining and phrase training are used to better detect the meaning of phrases and sentences so as to achieve accurate translation.

## VI. RESULTS

The extensive neuron network testing using a dataset of 1.8 million translation samples demonstrates the superior performance of the proposed system. The key results are as follows:

*1) Translation success rate:* The system achieves a success rate exceeding 80%, significantly higher than traditional translation systems.

*2) Translation time:* The translation time is under 50ms for phrases, 90ms for short sentences, and 105ms for long sentences, ensuring instant translation capabilities.

*3) Translation accuracy:* The translation accuracy exceeds 95%, outperforming existing techniques by at least 5%.

These results validate the effectiveness and efficiency of the proposed interactive English oral automatic translation system.

## VII. CONCLUSION

Aiming at the problem of interactive spoken English translation, this study designs a new automatic translation system based on deep learning algorithm, optimizes both hardware and software, and mainly completes the following research:

Establish a deep learning translation mathematical model, and use the bus to connect the I/O bridge, recorder, interactive information collector and initial language correction unit to build a framework. The arithmetic logic unit (ALU) has extremely strong computing power and can calculate data information in a short time.

The hardware design is completed through the collector, encoder, interactive detector, interactive processor and decoder. The NAND-flash memory adopts nonlinear macro unit mode and has extremely high storage efficiency.

By using deep learning and a residual network to realize software translation, use the decoder to optimize the maximum output sequence, and insert blank tags in each frame of information to ensure that the information can be translated more accurately.

Experiments show that the translation system designed in this study can achieve accurate translation in a short time, and the translation success rate is higher than that of the traditional translation system. Although this study has the above advantages, it still faces many challenges, mainly in the following aspects:

Attribute mutations may occur during the process of customizing parameters, which may affect the operation sequence of training functions and calling functions.

Since the control flow logic cannot be completely recorded in the intermediate expression, the instant translation accepts fewer Python native statements. If this problem can be solved, the framework's expressiveness will be significantly improved.

For future work, we plan to investigate more advanced deep learning algorithms to further improve the translation accuracy and speed. Additionally, we will explore the integration of more sophisticated hardware components to optimize the system's performance.

# Impact of Cryptocurrencies and Their Technological Infrastructure on Global Financial Regulation: Challenges for Regulators and New Regulations

Juan Chavez-Perez, Raquel Melgarejo-Espinoza, Victor Sevillano-Vega, Orlando Iparraguirre-Villanueva
Facultad De Ingeniería, Universidad Tecnológica Del Perú, Chimbote, Perú

***Abstract*—The rise of cryptocurrencies is transforming the landscape of global finance, but their very decentralized nature is triggering unprecedented challenges for regulatory systems. This systematic literature review (SLR) aimed to gather and synthesize information to understand the functioning of cryptocurrencies in relation to their regulatory challenges. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) methodology supports the rigor of the research, where 50 studies published between 2022 and 2025 were selected in databases such as Scopus, Web of Science, IEEE Xplore and Science Direct. Among the results, it was observed that the continents with the greatest contributions were Europe and Asia, representing 60% and 25% of the studies analyzed, respectively. Likewise, the period with the highest scientific production was the year 2024, with 50% of the manuscripts published. Regarding the analysis of keyword co-occurrence using VOSviewer, it was found that "blockchain" and "cryptocurrency" were the most predominant terms, with 18 and 16 mentions, highlighting their centrality in the academic discussion. Ultimately, the research highlights that cryptocurrencies bring with them major regulatory challenges, such as money laundering and lack of legal clarity, while blockchain emerges as an essential tool to improve the transparency and operability of financial regulation.**

***Keywords*—Cryptocurrencies; financial regulation; blockchain; regulatory challenges; cryptocurrency laws**

## I. Introduction

For some years now, digital transformation has been playing a major role in the global economy. One of the emerging trends is cryptocurrencies, a new tradable asset capable of revolutionizing the way payments are made [1]. The innovation of its technology and its growing popularity are capturing the attention of the mainstream media and investors [2]. By 2023, more than 23,000 types of cryptocurrencies had been registered [3]. Their growth has exposed various regulatory challenges globally. According to the United Nations (UN), the decentralization of the network in which cryptocurrencies operate makes it difficult to regulate them within the existing legal framework and highlights the lack of legal clarity on procedural issues affecting transactions involving different countries [4]. Similarly, the World Health Organization (WHO) emphasizes the importance of establishing unambiguous measures as new technologies such as cryptocurrencies emerge, to develop functionalities that ensure security and accessibility [5]. The cryptocurrency market is positioning itself as a profitable activity for investors, as they find it very beneficial to acquire this asset class at relatively low prices for subsequent sales at higher values [6]. This type of web-based digital exchange has now become a popular commodity and an attractive source of trading [7].

The cryptocurrency landscape is very broad, within it, "Bitcoin", one of the most popular cryptocurrencies for being the pioneer in the field, reached in less than a decade a capitalization value of one trillion dollars and boosted the creation of more than 10,000 additional cryptocurrencies [8]. The secret of the success of this technology lies in its cryptographic protection, derived mainly from the combination of cutting-edge technologies and decentralized systems, such as blockchain [9]. Blockchain technology also provides a secure and verifiable system of record [10] allowing individuals to interact with electronic wallets that make it possible to store and manage their cryptoassets independently [11]. This type of technology allows the creation of a peer-to-peer network, which acts in combination with a cryptographic algorithm, distributed data storage and a decentralized consensus mechanism. On the other hand, there are also technologies such as artificial intelligence (AI), which is playing a remarkable transformation in financial systems, since they allow optimizing critical processes, as well as handling incidents by 63%, decreasing resolution time and improving operational effectiveness to increase user satisfaction by more than 50% [12]. These technological advances, although promising, pose regulatory challenges like those of cryptocurrencies, such as the need to monitor algorithms and ensure transparency in automated decision making.

The rapid increase in the diversification of cryptocurrencies has represented a deficiency in studies on their economic and regulatory impact. Currently, financial regulation does not adequately address key aspects such as digital wallet software, which has generated risks in terms of security and financial crime [13]. A worrying example is the use of cryptocurrencies in dark web markets, which have become the main means of payment for illicit activities, because various features allow instant payments without major costs, their addresses can be easily obtained and modified, transactions are highly anonymous, a feature that complicates the identification of individuals [14]. This situation has generated new regulatory challenges in terms of personal data management standards, trust and traceability of financial events [15].

This study is justified by the need for research that addresses the global regulatory challenges associated with

cryptocurrencies and explores the impact of blockchain technology on evolving financial regulations. The objective is to compile and synthesize recent scientific evidence to understand the risks inherent in these digital assets, identify emerging regulations, and propose recommendations for a more effective regulatory framework tailored to the dynamics of the global financial system.

This paper is organized as follows: Section II presents a literature review, focusing on the challenges and financial regulations related to cryptocurrencies. Section III describes the methodology used for the review, based on the PRISMA method. Section IV presents the main findings obtained. Section V discusses the results, and finally, Section VI presents the conclusions of the study.

## II. Literature Review

### A. Regulatory Challenges for Cryptocurrencies

Several studies have analyzed the impact of cryptocurrencies on global financial regulation. In the study [16], we evaluated the dynamics and risks associated with cryptocurrencies to explore the stylized facts, volatility and risk measures in the performance of digital assets, by using daily data of bitcoin, ripple and Ethereum, and their comparisons with technology stocks, risk measures such as Value-at-Risk (VaR) and Expected Shortfall (ES) were applied. The results confirmed that cryptocurrencies present high volatility, dependencies between cryptocurrencies, volatility clusters and arbitrage opportunities, highlighting that cryptocurrencies are riskier than technology stocks.

Similarly, in [17], evaluated the presence of speculative bubbles in the cryptocurrency market during the COVID-19 pandemic, analyzing the gregarious behavior of investors and factors such as Google searches and transaction volume, using probit regressions in time series and panels, together with alternative measures of liquidity and volatility. It was determined that all the cryptocurrencies analyzed presented bubbles, and that explosive behavior in one cryptocurrency affects others, contradicting the efficient market hypothesis. Complementarily, in [18], hybrid models combining forward propagating neural networks (DFFNN), and long term memory networks (LSTM) with generalized autoregressive conditional heteroskedasticity (GARCH) models were evaluated in three types (GARCH, EGARCH and APGARCH) with the objective of predicting the volatility associated with 27 cryptocurrencies, employing the outputs of the GARCH models as inputs to the neural networks, demonstrating that the hybrid models outperform the GARCH and deep learning (DL) models separately, significantly improving the accuracy in predicting volatility.

In [19], they analyzed tail risk in cryptocurrencies, non-fungible tokens (NFTs), stocks and gold, using conditional VaR-based models, showing that there is no superior model to capture tail risk, but non-Gaussian distributions better modeled skewness and heavy tails, which is crucial for risk management and portfolio diversification. In the same vein, in [20], the ability of volatility models to predict downside risk in cryptocurrency trading was explored by applying models such as conditional autoregressive VaR (CAViaR), dynamic quantile rank (DQR), GARCH and generalized autoregressive score (GAS) to five cryptocurrencies (Bitcoin, Ethereum, Ripple, Litecoin and Stellar), evaluating forecasts using backtesting techniques and model confidence sets (MCS). The result showed that quantile-based models combined with a weighted aggregation method were the most effective in predicting downside risk.

### B. Financial Regulations Through the Influence of Cryptocurrencies and Blockchain

In the study [21], they sought to promote a greater focus on the analysis of cryptocurrencies as money within international political economy (IPE), employing monetary theories, such as the "commodity theory of money" and the "state theory of money", concluding that cryptocurrencies represent a challenge to traditional monetary theories and suggesting that their development as money is influenced by political dynamics that deserve further investigation. Likewise, in research [22], examined the existence of seasonal patterns in cryptocurrency returns, through data analysis of 500 cryptocurrencies, focusing on the Monday effect and trading activity during weekends. As a result it was found that the positive Monday effect on Bitcoin did not persist after 2015, and that there is no robust evidence of anomalies in returns, although trading activity was lower on weekends.

Consequently, in [23], explored the transmission of extreme risks between NFTs, DeFi tokens and cryptocurrencies, using the quantile connectivity technique to analyze volatility conditions was able to identify that NFTs offer greater diversification opportunities, with lower risks compared to other blockchain markets, making them an attractive option to reduce extreme risks. Complementarily, in [24], they analyzed how climate shocks affect extreme risks in cryptocurrency markets, for which they built risk contagion networks using a TVP-VAR model to measure the sensitivity of cryptocurrencies to climate, political and financial factors, finding that extreme risks in cryptocurrencies are highly sensitive to climate shocks, and that global financial markets are the main transmitters of risks. Furthermore, in [25], addressed the comparison of herding behavior in "clean" low-energy and "dirty" high-energy cryptocurrency markets, using the method of collecting data on market returns and activity, and by using value-weighted and equally-weighted portfolios, it was found that herding behavior is more pronounced in "dirty" markets, especially in bearish market conditions, while "clean" cryptocurrencies only showed herding behavior when both markets were rising. Table I shows the main findings and limitations of the reviewed studies.

TABLE I. CONCLUSIONS AND GAPS FOUND IN THE REVIEWED PAPERS

| Refs. | Main results | Limitations |
|---|---|---|
| [16] | Identify higher risk in cryptocurrencies using VaR and ES | It does not explore how financial regulations could mitigate these risks. |
| [17] | Detects speculative bubbles during COVID-19 using probit models and Google Trends | It does not analyze regulatory mechanisms to prevent bubbles. |
| [18] | Hybrid GARCH-LSTM models improve volatility prediction in 27 cryptos | It does not consider emerging regulations in the models. |
| [19] | Non-Gaussian distributions better model tail risk in cryptos vs. traditional assets | Does not discuss application to regulatory capital requirements. |
| [20] | CAViaR models outperform GARCH in predicting downside risk backtesting with MCS | Does not integrate with regulatory oversight systems. |
| [21] | Evidence of contradictions between cryptos and traditional monetary theories | It does not propose an adapted regulatory framework. |
| [22] | Refutes seasonal patterns in yields (500 cryptos analysis) | Does not evaluate the impact of market regulations. |
| [23] | NFTs show lower systemic risk than DeFi | It does not address specific regulation for NFTs. |
| [24] | Climate shocks increase systemic risk according to the TVP-VAR | It does not consider regulatory climate disclosure. |
| [25] | Increased gregarious behavior in "dirty" crypts (high energy consumption) | Does not analyze the impact of environmental policies. |

## III. METHODOLOGY

The study was guided by the PRISMA 2020 statement, widely recognized for its requirement in terms of rigor, transparency and relevance in conducting systematic reviews. The framework describes a concrete structure for identifying, selecting and synthesizing relevant studies, ensuring that the process is fully replicable and free of bias [26]. The application of PRISMA 2020 is essential to answer the research questions formulated, focusing on the regulatory challenges associated with cryptocurrencies and their influence on the evolution of international financial regulation. Complementarily, a graphical representation tool based on an R programming language and its Shiny package was used to build the flowchart. This allowed us to elaborate a clear visualization of the different phases of the process, covering from the initial collection of the studies to the final selection of the included documents, facilitating the comprehensive understanding of the procedure [27].

The research questions were developed based on a methodical and strictly structured process. The first step was to conduct a preliminary review of the existing literature regarding the subject matter of cryptocurrencies and financial regulatory standards, with the objective of identifying those trends, gaps and potential areas of interest. After this initial exploration it was detected that, although there are studies about the impact of cryptocurrencies on financial markets, there is a lack of publications addressing global regulatory challenges and the contribution of blockchain to the evolution of regulations in the field.

Based on this review, issues of current relevance were prioritized, and questions were formulated that not only reflect the most current problems in the field but also help to fill gaps in literature. The following are the research questions that were formulated to guide the study:

- What are the main regulatory challenges faced by the bodies in charge of supervising cryptocurrencies at a global level?
- How have cryptocurrencies and blockchain technology influenced the evolution of international financial regulations?

To ensure the suitability and quality of the selected studies, it was necessary to establish the relevant criteria to incorporate in-depth and specific research. These considerations are presented below:

### A. Inclusion Criteria

Studies that explore the regulatory challenges associated with cryptocurrencies or analyze the impact of blockchain technology on global financial regulation.

Research published in academic databases related to the topic, peer-reviewed journals or presented at recognized international conferences, ensuring academic rigor.

Publications between the period 2022 and 2025, to capture the most recent developments and debates in the field.

Articles written entirely in English, due to their international scope and standardization in the academic community.

### B. Exclusion Criteria

Studies published before 2022, as they may not reflect current developments and challenges in the cryptocurrency and blockchain ecosystem.

Research that does not directly address the main regulatory and technological aspects central to the study.

Articles that are not peer-reviewed or lack clear methodology and solid empirical evidence.

Papers that do not provide relevant information to answer the research questions posed.

The search for publications was carried out within academic databases relevant to the focus of the study, including Scopus, Web of Science, Science Direct and IEEE Xplore. Likewise, employing keywords such as cryptocurrencies, financial regulation, blockchain, regulatory challenges and cryptocurrency laws, together with Boolean operators and the period between 2022 and 2025, made it possible to ensure recent developments in the field and to gain insight into the various perspectives. The result of this process provided the compilation of an initial set of studies. Fig. 1 shows the distribution of these studies according to the source of origin, providing a complete overview of the number of publications identified.

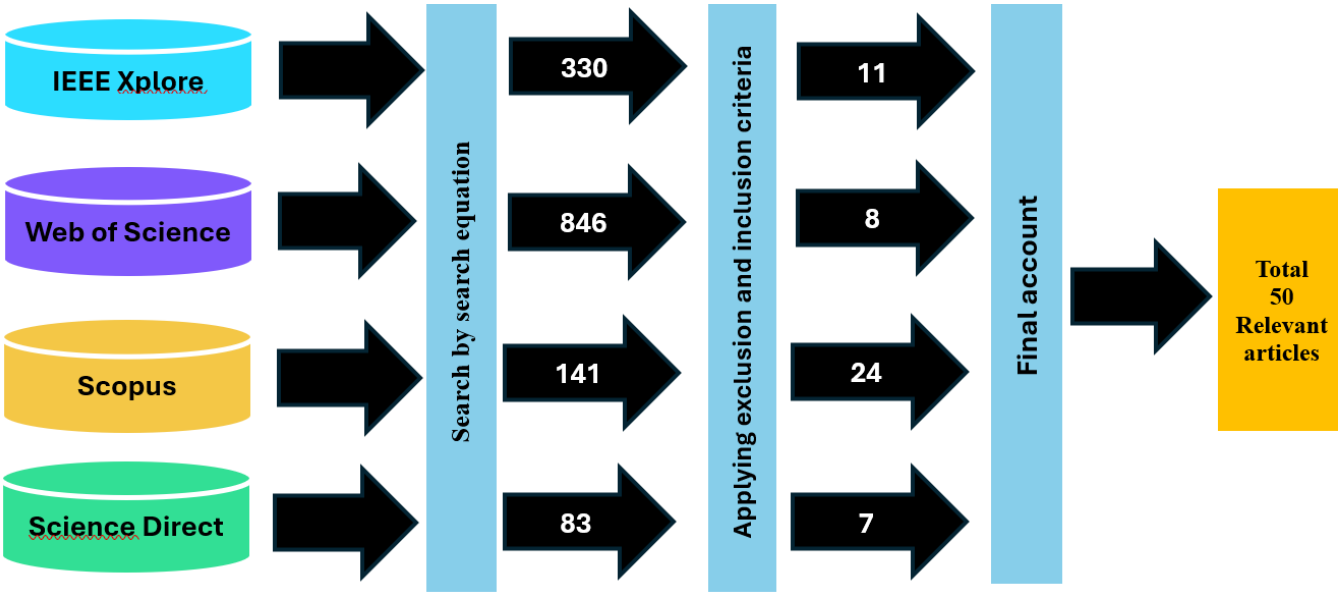

Fig. 1. Distribution of studies per database.

The PRISMA 2020 guidelines guided the process comprehensively, aligning under the framework is necessary to organize the SLR in four main phases, which are mentioned below:

- Identification: rigorous search of selected databases to identify potentially useful studies for addressing research questions.
- Selection: Filters were applied among the articles obtained, starting from the elimination of duplicate works and performing reviews based on title and abstract.
- Eligibility: To verify their relevance and materiality, the papers that passed the screening phase were subjected to an in-depth evaluation, in which it was verified that they adequately answered the research questions.
- Inclusion: The selection to be included for the review had to meet all the defined criteria, standing out for the finding in its literary information.

Fig. 2 illustrates in a synthesized way the selection process based on PRISMA 2020, mainly highlighting its organization in three key stages: identification, selection and inclusion. This visual representation expresses the sequential progression from the initial collection of studies to obtaining the final sample of those included, showing the gradual reduction of studies after the application of the established criteria.

Several computer tools were essential in the processing of the studies collected, since each of them played a strategic role throughout the different phases of the work. The Mendeley software made it possible to store and classify the documents according to their origin in the databases, contributing to the initial structuring of the set. The stored files were then exported in ".RIS" format and imported into Rayyan, a specialized resource platform for research work, whose incorporation made it possible to detect duplicities, create filters and apply them in an evolutionary manner. Through this tool it was possible to identify and eliminate 87 duplicate articles and discard 125 documents that did not meet the eligibility criteria, including systematic reviews, meta-analyses and other types of secondary literature. Subsequently, the selected studies to be included in the SLR were classified in Microsoft Excel, organizing them in a data matrix, recording key information such as the database of origin, title, year of publication, type of document, country of origin, methodological approach classified as qualitative, quantitative or mixed, and the answers to the research questions. This structure enabled a more thorough analysis of the 50 studies chosen, allowing the identification of patterns and trends relevant to the development of the research.

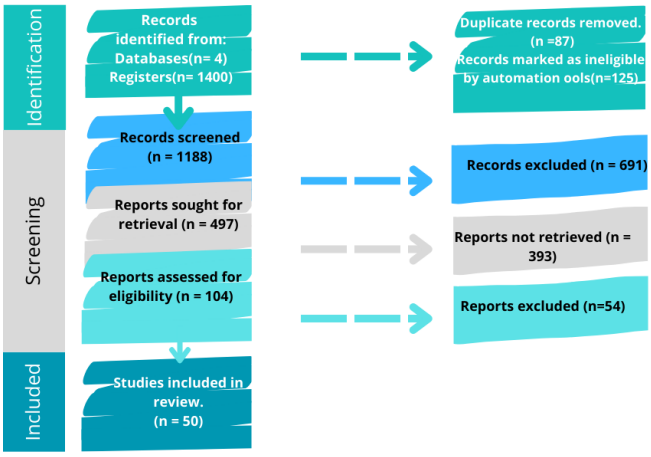

Fig. 2. PRISMA 2020 methodology.

## IV. Results

The results obtained provide a detailed overview, forming the basis for understanding how the latest scientific literature addresses the regulatory challenges of cryptocurrencies and their impact on the evolution of financial regulations. The

development of the stages of the screening process under PRISMA 2020 standards gradually contributed to improving the collected documents, so that it has been ensured that the final studies are the most relevant to represent the review. The initial compilation, presented in Table II, reflects the diversity of the sources consulted, laying a solid foundation for the subsequent analyses.

TABLE II. INITIAL DISTRIBUTION OF STUDIES BY DATABASE

| Database | Quantity | Percentage |
|---|---|---|
| Scopus | 141 | 10.07% |
| Web of Science | 846 | 60.43% |
| Science Direct | 83 | 5.93% |
| IEEE Xplore | 330 | 23.57% |
| | 1400 | 100% |

After collecting the studies, they were classified within collections created according to their source of origin provided by the academic databases. From that process, the exhaustive analysis of the documents began, starting the filtering phases for inclusion and exclusion.

### A. Phase 1: Elimination of Duplicates and Initial Filters

The first phase develops the debugging of duplicates and secondary documents that could have been included after compilation. Therefore, the full detection functionality provided by Rayyan is run, resulting in the consolidation of a refined set of 1,188 unique studies, excluding 212 non-representative ones. The reduction allowed optimizing the database, eliminating redundancies that could distort the analysis, in addition, it was possible to highlight Web of Science as the most representative source in the set, thanks to its high percentage value, followed by IEEE Xplore, Scopus and Science Direct, as detailed in Table III, which reflects the first significant transformation in the analyzed dataset.

TABLE III. DISTRIBUTION OF STUDIES AFTER ELIMINATION OF DUPLICATES AND INITIAL FILTERS

| Database | Quantity | Percentage |
|---|---|---|
| Scopus | 119 | 10.02% |
| Web of Science | 732 | 61.62% |
| Science Direct | 70 | 5.89% |
| IEEE Xplore | 267 | 22.47% |
| Total | 1,188 | 100% |

### B. Phase 2: Review of Titles and Keywords

The review of the 1,188 documents remaining up to this stage, using titles and key words, made it possible to identify those that maintained an evident and concrete link with the research questions posed. As a result of this analysis process, 691 documents were discarded because they did not address the central theme of the focus of the study, since they were outside the limits established in the framework. As a result of this filtering, the set of documents was reduced to 497 records. Table IV shows the updated distribution of the studies after this phase, showing the new proportional configuration between the databases.

TABLE IV. DISTRIBUTION OF STUDIES AFTER REVISION OF KEY TERMINOLOGY IN TITLES

| Database | Quantity | Percentage |
|---|---|---|
| Scopus | 70 | 14.08% |
| Web of Science | 225 | 45.27% |
| Science Direct | 29 | 5.84% |
| IEEE Xplore | 173 | 34.81% |
| Total | 497 | 100% |

Subsequently, we proceeded to a more exhaustive review of the 497 documents, focusing objectively on the analysis of the summaries provided by the studies, but full texts were addressed in those that presented little information in their abstracts.

### C. Phase 3: Review of Abstracts and Full Text

From this process, the analysis had to check those studies that accurately addressed the regulatory challenges of cryptocurrencies and how the impact of blockchain technology was affecting financial regulations. To do so, strategic keywords had to be used such as: cryptocurrencies, blockchain, digital currencies, regulatory challenges, DeFi and empirical study.

The result was the exclusion of 393 studies for not meeting the criteria, so that the set was reduced to 104, firmly refining the literature base for the final analysis. In this line, it was highlighted that the evolution of the studies belonging to Scopus for this stage showed that their content was relevant after their respective evaluation, thus emerging as the one that eliminated the least number of documents. Table V presents the updated distribution of the studies after this phase, reflecting this transformation in the composition of the final sample.

TABLE V. DISTRIBUTION OF STUDIES AFTER ABSTRACT AND FULL TEXT REVIEWS

| Database | Quantity | Percentage |
|---|---|---|
| Scopus | 26 | 25% |
| Web of Science | 41 | 39.42% |
| Science Direct | 14 | 13.46% |
| IEEE Xplore | 23 | 22.12% |
| Total | 104 | 100% |

### D. Phase 4: Final Inclusion

The last selective procedure, aimed at closing the studies for definitive inclusion, consisted of assessing the depth of the content, specifically the degree of complementarity with the methodological soundness and relevance of the contributions to the research approach and the questions formulated. Thus, 54 studies were excluded because they failed to provide substantial evidence and because they presented methodological limitations that compromised their validity in the context of the present study. Therefore, the final set was composed of 50 studies that rigorously met the established criteria, ensuring a robust and representative database for subsequent analyses.

TABLE VI. FINAL DISTRIBUTION INCLUDING STUDIES

| Database | Quantity | Percentage |
|---|---|---|
| Scopus | 24 | 48% |
| Web of Science | 8 | 16% |
| Science Direct | 7 | 14% |
| IEEE Xplore | 11 | 22% |
| Total | 50 | 100% |

Regarding the final distribution of the chosen studies, the Scopus source predominated, followed by IEEE Xplore, Web of Science and Science Direct, reflecting a diverse and balanced composition of the specialized literature. Table VI illustrates this final distribution, consolidating the result of the systematic selection process.

To complement the collection of the 50 studies chosen in this review, a visual representation of the complete distribution is included through a bar graph, showing the numerical data for each academic database selected for the work. Fig. 3 not only facilitates the interpretation of the final set of data but also provides a clear and accessible perspective on the provenance of the selected literature.

Once the final studies were obtained, processes were carried out to determine certain aspects of relevance for the research. Starting with the temporal distribution, which covered the period from 2022 to 2025, where an increasing trend in academic production related to the subject of study was evidenced. Likewise, by 2022, 8 studies were identified, representing 16%. On the other hand, the number increased significantly in 2023, with a value of 13, representing 26%. The trend continued to increase in 2024, with the highest production of 25% of the set, equivalent to 50%. In contrast, in 2025, 4 studies were disclosed, representing 8% of the total. It is important to note that, as 2025 progresses, an increase in the number of published studies is expected. Fig. 4 illustrates this temporal distribution, highlighting the evolution of academic production and the importance of the studies published in the most recent period.

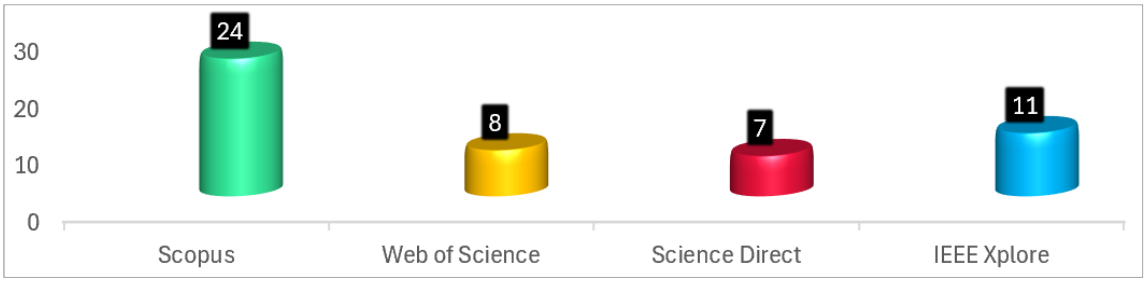

Fig. 3. Distribution of studies included by each database.

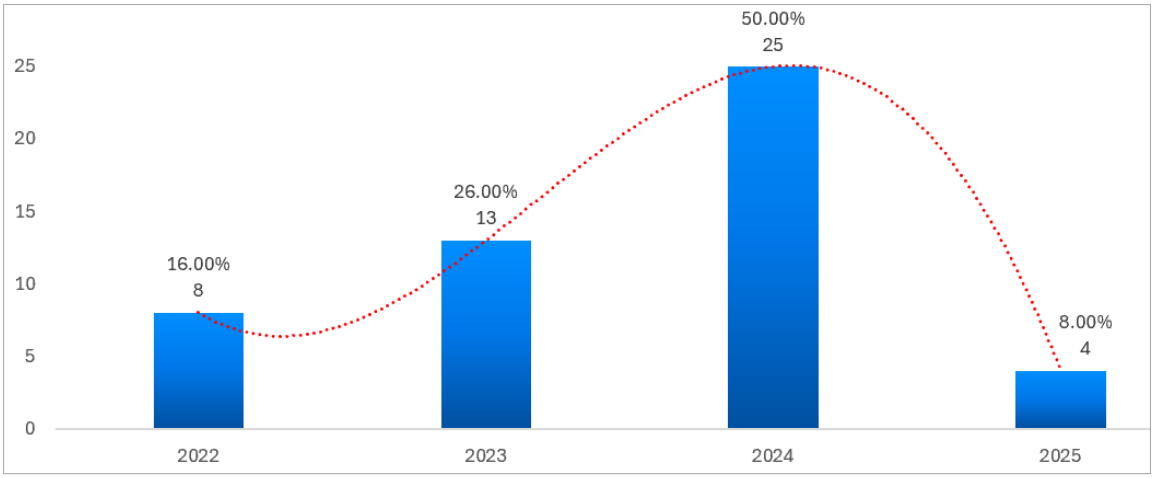

Fig. 4. Studies by year of publication.

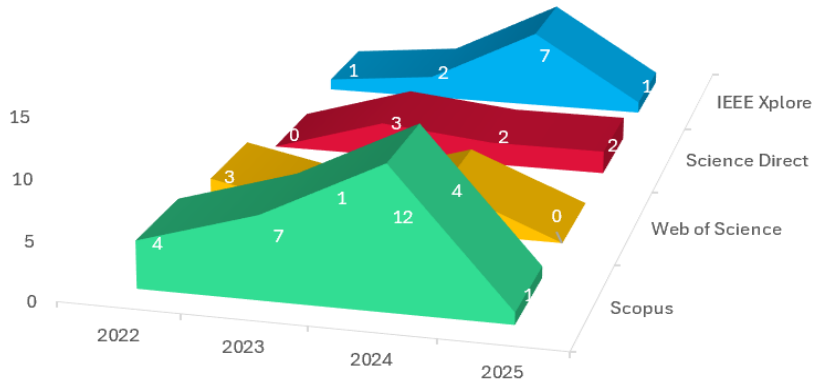
In the same line, the time frame was relevant to determine the scientific production of studies associated with their respective databases. The most remarkable result was the contribution of Scopus in the year 2024, since it represented 12 studies, consolidating its relevance to the field as the main source in research. In the same line, IEEE Xplore showed its contribution with 7, Web of Science with 4 and Science Direct with 2. On the other hand, manifesting contributions in previous years, Scopus maintained its predominance in 2023 with 7 studies, while Science Direct and IEEE Xplore contributed with 3 and 2 respectively, and Web of Science with 1. As for the year 2022, the contributions were established with Scopus with 4, Web of Science with 3, IEEE Xplore with 1 and Science Direct with no records. On the other hand, for the most current year of 2025, the contributions with literary presence up to the present were constituted by Science Direct in 2 and IEEE Xplore in 1 study, while Scopus registered 1 and Web of Science did not present contributions. Fig. 5 illustrates the proportional trend, highlighting the contribution of each database over time.



| | 2022 | 2023 | 2024 | 2025 |
|---|---|---|---|---|
| Scopus | 4 | 7 | 12 | 1 |
| Web of Science | 3 | 1 | 4 | 0 |
| Science Direct | 0 | 3 | 2 | 2 |
| IEEE Xplore | 1 | 2 | 7 | 1 |

Fig. 5. Distribution of studies by year and databases.

As for the geographical origin of the SLR studies, the analysis showed that there was a strong prominence of countries with more developed financial systems, which have active regulatory frameworks for cryptocurrencies. The United Kingdom tops the list with 6 studies, representing 12% of the total, followed by China with 5 studies, corresponding to 10%, and Indonesia and Ukraine with 4 studies each, corresponding to 8%. Denmark, Estonia, Germany, Pakistan, Russia, Saudi Arabia and the United States are ranked with 2 studies each, representing 4%. In contrast, Australia, Bangladesh, Belgium, India, Italy, Hungary, Kazakhstan, Lithuania, Luxembourg, Malaysia, Mauritius, Mexico, Morocco, Netherlands, Poland, Spain and Taiwan have 1 study each, equivalent to 2%. In view of the results, it can be stated that the academic production is higher in the regions of Europe with 60% and Asia at 25%, surely because of their concern for cryptocurrency regulation and financial development. Likewise, the low participation of Latin America and Africa suggests less attention to the treatment of the object of study in these regions. Fig. 6 provides a detailed geographical breakdown of the studies on the issue.

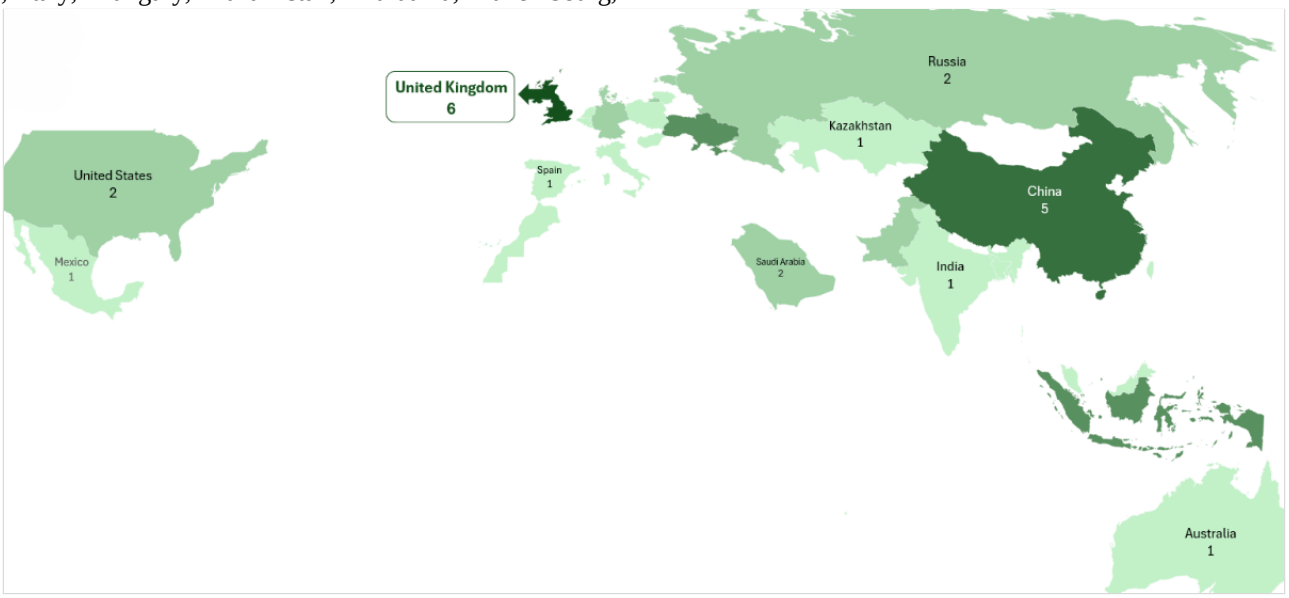


Fig. 6. Origin of studies by geographic region.

The review of each study included in this research revealed that 100% of the studies correspond exclusively to journal articles. This concentration reflects the prominence of scientific publications when studying the subject of interest regarding cryptocurrencies and their regulatory implications, reflecting the prominent role of this format in the generation and dissemination of knowledge. However, it is imperative that the need to develop more applicable approaches in other fields to overcome the gap originated by the absence of other types of publications, such as conference proceedings and technical reports.

The methodological approach used in the studies reviewed shows a preponderance of qualitative approaches, with a notable representation in the main databases. In this regard, the main reference was Scopus, which presented 18 qualitative studies, equivalent to 36%, followed by Web of Science and Science Direct with 6 studies each, equivalent to 12%, while IEEE Xplore contributed 2 studies, with 4%. The quantitative strategy had less presence, with IEEE Xplore standing out with 6 papers, representing 12%, Scopus with 3, 6%, and Web of Science 1, 2%, while Science Direct had no quantitative studies. The mixed method showed a more limited rate of representation, since Scopus and IEEE Xplore recorded 3 studies respectively, which accounted for 6%, and Web of Science and Science Direct only 1 study, which equaled 2%. The results indicate that research on cryptocurrencies and financial regulation is mainly based on qualitative analyses, most likely due to the need to interpret regulatory frameworks and economic trends. Fig. 7 presents in detail the distribution of methodological approaches used in the analyzed studies.

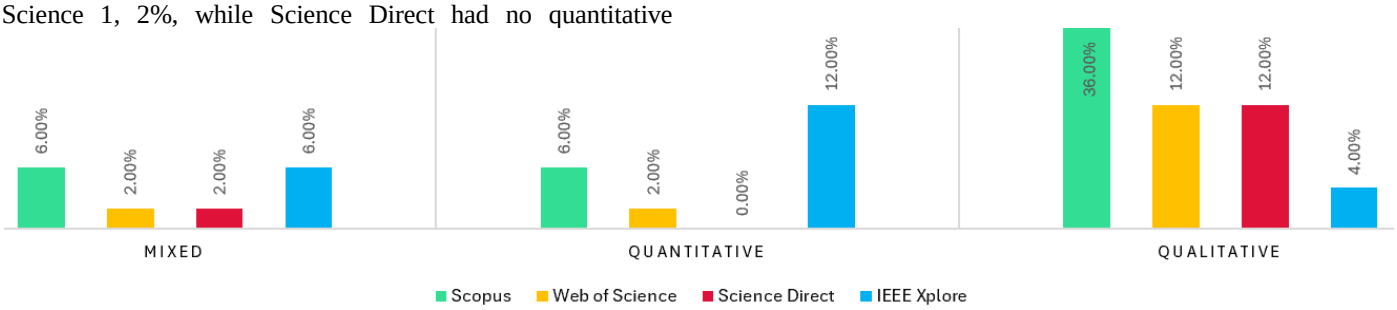

Fig. 7. Studies by methodological approach.

Finally, with the support of the "VOSviewer" software tool for the identification of keywords, considering their level of co-occurrence and representing the relationships between existing within the analyzed corpus. For this purpose, the software analyzed the keywords assigned by the authors, terms included in the titles and the summary content. In the results obtained it was found that "blockchain" and "cryptocurrency" constitute the most predominant concepts, with 18 and 16 mentions respectively, which reaffirms their central role in the academic discussion.

The thematic groups interconnected by cluster analysis reflected different perspectives of the phenomenon studied. The yellow cluster addressed digital infrastructure and asset security, highlighting terms such as "distributed ledger technology" and "digital assets market", elements that underline the importance of decentralized accounting systems. In contrast, the blue cluster focused on regulation and compliance, with terms such as "money laundering", "fintech" and "regulation", highlighting the challenge of establishing suitable legal frameworks for cryptocurrencies. Finally, the brown cluster encompassed key words such as "financial crime" and "policy", highlighting concerns about the relationship between cryptoassets and financial crime. Fig. 8 illustrates the distribution of these clusters, highlighting mainly keywords in a visual representation of the main areas of study identified in the literature.

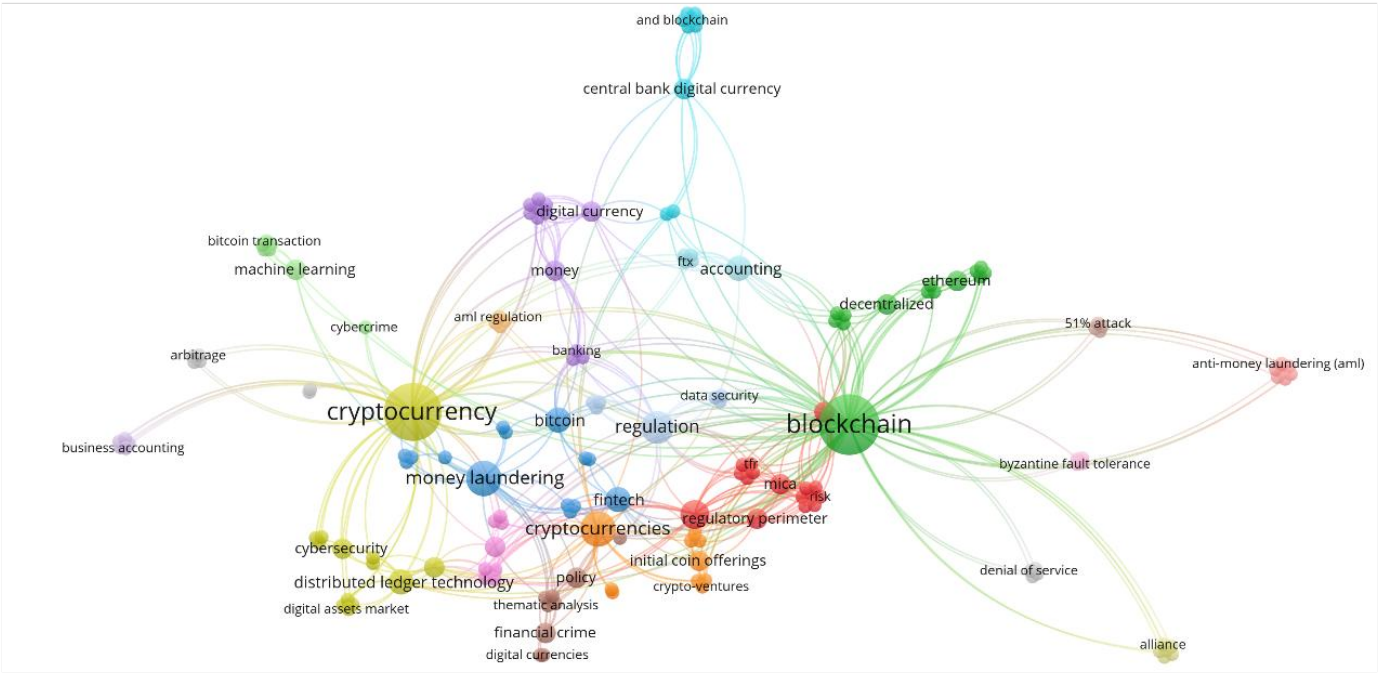

Fig. 8. Exploration of co-occurrence in literature.

## V. DISCUSSIONS

### A. Q1: What are the Main Regulatory Challenges Facing the Bodies in Charge of Overseeing Cryptocurrencies Globally?

The growing adoption of cryptocurrencies brings with it governmental and institutional attention around the world. The purely speculative origin and their movements in conditions of anonymity contribute to challenges such as money laundering, lack of legal clarity and regulatory differences. In this sense, the study [16], addressed the risk associated with cryptocurrencies, evaluating their dynamics and volatility through daily data and metrics such as VaR and ES, showing that cryptocurrencies exhibit high volatility rates and high dependence, a fact that, in addition to suggesting arbitrage opportunities, highlights their potential to facilitate activities such as money laundering due to the difficulty of tracing anonymous transactions. On the other hand, research [17] examined the formation of speculative bubbles and herd behavior in the cryptocurrency market during the COVID-19 pandemic. Through probit regressions, alternative metrics of liquidity and volatility, they managed to identify that all the cryptocurrencies analyzed presented speculative bubbles. On the other hand, the paper [19] analyzed tail risk in cryptocurrencies, NFTs, stocks and gold, for which they used conditional models based on VaR, as a result it was revealed that there is no single superior model to capture extreme risk; however, it was observed that non-Gaussian distributions proved to be more effective when modeling asymmetry and heavy tails in returns. This reinforces the need to address the lack of legal clarity in the regulation of these assets, as the absence of clear standards increases risk exposure and hinders the implementation of effective regulatory frameworks.

Also, regarding volatility prediction, the study [18] combined neural networks such as DFFNNN and LSTM with GARCH models in three types such as (GARCH, EGARCH and APGARCH) to analyze 27 cryptocurrencies, using the outputs of GARCH models as input data for the neural models, and showed that the hybrid models performed better than the individual models in terms of accuracy. Furthermore, [20] studied the ability of volatility models to predict downside risk in cryptocurrency trading, using models such as CAViaR, DQR, GARCH and GAS to five cryptocurrencies (Bitcoin, Ethereum, Ripple, Litecoin and Stellar), and using back testing and MCS techniques, it was concluded that quantile-based models, combined with a weighted aggregation method, are the most effective in anticipating the decline in the value of cryptocurrencies. Such a method allows highlighting regulatory discrepancies, as the lack of unified regulation hinders the implementation of effective risk management strategies. Below, in Table VII, the challenges in the regulatory arena found after the rigorous analysis are presented.

The results shows that cryptocurrency transactions have generated a wide range of regulatory challenges, many of which are interconnected. On the other hand, the decentralization and anonymity inherent in these technologies pose considerable hurdles for regulators, as they make it difficult to identify participants and track transactions. The problem arises especially in the case of stablecoins and DeFi platforms, since their rapid growth and technical complexity exceed the capacity of regulators to establish effective controls. Added to this is the increase in fraud and scams within the ecosystem in which cryptocurrencies operate, a phenomenon that has exposed vulnerabilities in the protection of users and the security of blockchain platforms. In addition to affecting investor confidence, this phenomenon poses significant risks to the integrity of financial markets. In particular, the taxation of cryptocurrencies remains a critical area due to the lack of accurate transparent reporting mechanisms and monitoring in the verification of transactions. This situation is compounded by the absence of standardized international rules, creating an environment in which illicit activities can flourish.

TABLE VII. CHALLENGES FOR REGULATORY AGENCIES

| # | Regulatory Challenge | Quantity | References |
|---|---|---|---|
| 1 | Money laundering | 6 | [28], [29], [30], [31], [32], [33] |
| 2 | Lack of legal clarity | 5 | [34], [35], [36], [37], [38] |
| 3 | Regulatory differences | 5 | [39], [40], [41], [42], [43] |
| 4 | Decentralization and anonymity | 5 | [44], [45], [46], [47], [48] |
| 5 | Stablecoins and DeFi | 5 | [49], [50], [51], [52], [53] |
| 6 | Fraud and protection | 5 | [54], [55], [56], [57], [58] |
| 7 | Blockchain security | 5 | [59], [60], [61], [62], [63] |
| 8 | Crypto taxation | 4 | [64], [65], [66], [67] |
| 9 | Transparency and monitoring | 4 | [68], [69], [70], [71] |

These challenges underscore the urgent need to develop robust and cooperative regulatory frameworks that address both current and emerging risks. The implementation of innovative solutions, together with strengthened international cooperation, will be essential to promote the creation of a safe, efficient and more transparent financial ecosystem.

### B. Q2: How have Cryptocurrencies and Blockchain Technology Influenced the Evolution of International Financial Regulations?

Cryptocurrencies have been greatly affected by the evolution of international financial regulation, as they pose regulatory challenges due to their decentralized and anonymous nature. Therefore, incorporating blockchain as a technological solution to support regulation is an essential strategy to balance innovation and regulatory control. In this way, this synergistic relationship enables regulators to develop more robust regulations tailored to the needs of the global financial system. These include those related to stability and governance, where blockchain enables real-time audits and decentralized governance systems (DAO), as well as supervision, where it improves transparency and ensures an immutable transaction history. Recent studies support this position, highlighting blockchain's ability to strengthen financial traceability and facilitate regulatory adaptation among dynamic digital environments.

In [23], the transmission of extreme risks between NFTs, DeFi tokens and cryptocurrencies was explored using the quant connectivity technique to analyze volatility conditions,

identifying that the NFTs offer greater opportunities to diversify and reduce risk levels compared to other blockchain markets, making them an alternative of interest to reduce extreme risks. The finding, together with the inherent traceability of blockchain, influences the creation of regulations that promote stability and governance in the cryptocurrency ecosystem, as well as the implementation of blockchain-based online auditing systems.

On the other hand, in [24], it was analyzed how climate shocks affect extreme risks in cryptocurrency markets, building risk contagion networks using a TVP-VAR model, whose results showed that cryptocurrencies are highly sensitive to climatic, political factors and that global financial markets are the main transmitters of risks. This has led regulators to strengthen oversight mechanisms and use blockchain technology to improve transparency and immutable transaction recording, thus mitigating associated risks. Also, Table VIII presents the impact of cryptocurrencies and blockchain on various financial regulations.

TABLE VIII. IMPACT OF CRYPTOCURRENCIES AND BLOCKCHAIN ON FINANCIAL REGULATION

| # | Impact of Cryptocurrencies | Blockchain Impact | Quantity | References |
|---|---|---|---|---|
| 1 | Stability and governance | Audits | 5 | [50], [56], [72], [73], [74] |
| 2 | Supervision | Traceability | 5 | [43], [66], [67], [70] |
| 3 | DeFi and Anti-Money Laundering (AML) Regulation | Compliance | 4 | [28], [68], [75], [76] |
| 5 | Financial innovation | Regulations | 4 | [35], [49], [54], [77] |

In terms with slight influence, DeFi and AML regulation stand out, where blockchain facilitates traceability, process automation and financial innovation, whose operation allows the implementation of regulations based on smart contracts. The study [25], compared gregarious behavior in "clean" and "dirty" cryptocurrency markets using profitability and market activity data. As a result, it was observed that herding behavior is more pronounced in "dirty" markets, especially in bearish market conditions. Similarly, in [22], seasonal patterns in cryptocurrency returns were examined by analyzing data from 500 cryptocurrencies and focusing on the effect of Monday and weekend trading activity, showing that a positive Monday effect on Bitcoin did not last after 2015, which has led regulators to consider financial innovation in designing smart contract-based regulations, enabling more efficient and transparent compliance in DeFi and AML regulations.

The influence of cryptocurrencies and blockchain technology on the evolution of international financial regulation is undeniable due to their nature in relation to their operations. Through traceability, real-time audits, automated compliance and DAO, blockchain not only mitigates the risks arising from cryptocurrencies, but also promotes transparency, efficiency and innovation for the global financial system. All of these developments underscore the importance of regulators harnessing the potential of existing technologies, such as blockchain and other emerging technologies, to support a transformative new system that the masses are migrating towards; achieving this will ensure the stability and integrity of financial markets.

## VI. CONCLUSION

In this SLR, the technological infrastructure within the cryptocurrency ecosystem was analyzed to identify its behavior in relation to the entities that regulate finance worldwide, taking as evidence the inclusion of 50 studies published between 2022 and 2025. The studies collected came from databases of recognized solvency for their prestige, such as Scopus with 24 articles, representing 48%, Web of Science with 8 equivalents to 16%, IEEE Xplore with 11 at 22%, and Science Direct with 7 representing 14%. The variety of these sources of information provides a complete and representative perspective of the current state of research in the field.

The results revealed that cryptocurrencies raise significant regulatory challenges, including money laundering, lack of legal clarity, decentralization and anonymity. It was also identified that blockchain technology is instrumental in improving transparency, traceability and regulatory efficiency. These findings underscore the need for innovative regulatory frameworks to balance technological innovation with user protection and financial stability. Moreover, it was reflected that the lack of unified international standards hinders the implementation of effective regulations, thus underlining the importance of global collaboration in this field.

This systematic study provides a solid foundation for future research to be undertaken by experts, as it synthesizes recent statistics and proposes priority areas for study, raising awareness. These areas include the development of flexible regulatory systems, comparative approaches across regions and the incorporation of new technologies into financial regulation. The findings also provide valuable input to regulators and policy makers, helping to create more effective regulations that are adaptable to current realities. However, the research faced limitations inherent to the study of emerging and disruptive issues. On the other hand, the rapid evolution of the cryptocurrency and blockchain ecosystem generated a gap between the literature findings and the current reality, suggesting the need for periodic updates in future reviews. Also, some studies presented methodological heterogeneity that hindered the comparability of results, so it is important to standardize approaches. Finally, the absolute lack of comprehensive papers addressing global regulatory challenges to financial regulation indicates a critical area for further research.

# Developing a Comprehensive NLP Framework for Indigenous Dialect Documentation and Revitalization

Mohammed Fakhreldin
Department of Computer Science-College of Engineering and Computer Science, Jazan University, Jazan 45142, Saudi Arabia

***Abstract*—The disappearance of Indigenous languages results in a decrease in cultural diversity, hence making the preservation of these languages extremely important. Conventional methods of documentation are lengthy, and the present AI solutions somehow do not deliver due to data scarcity, dialectal variation, and poor adaptability to low-resource languages. A novel NLP framework is being proposed to solve the existing problems. This framework intermixes Meta-Learning and Contrastive Learning to counter these problems. Thus, adaptation to low-resourced languages becomes rapid via meta-learning (MAML), while dialect differentiation is enhanced through contrastive learning. The model training is carried out on Tatoeba (text) and Mozilla Common Voice (speech) datasets to ensure robust performance in both text and phonetic tasks. The results indicate that there is a reduction of 15% in Word Error Rate (WER), an 18% improvement in BLEU score corresponding to translation, and a 12% improvement in F1-score related to dialect classification. The testing was also done with native speakers to assess its practical viability. It is a real-time translation, transcription, and language documentation system deployed via a cloud-based platform, thereby reaching out to Indigenous communities globally. This dual-learning framework represents a scalable, adaptive, and cost-efficient solution for the revitalization of languages. The models proposed have been a game changer for language preservation, have set new standards for low-resource NLP, and have made some tangible contributions towards the digital sustainability of endangered dialects.**

***Keywords*—*Indigenous language preservation; natural language processing; meta-learning; contrastive learning; low-resource languages***

## I. Introduction

The rapid expansion of e-commerce has significantly impacted consumers' shopping behaviors, and augmented reality (AR) has been a key technology in optimizing users' interaction and minimizing return charges [1]. Normally, it lacks the touch and vision experience of store shopping, leading to confusion in consumers' choices and increased possibilities of product returns. AR closes the gap by allowing consumers to see products in real-life situations prior to buying, building confidence in their purchase decisions [2], [3]. Research has established that AR platforms profoundly increase consumer trust, interactivity [4] and product value perception, thus becoming a valuable tool for e-commerce firms to gain optimum sales and customer loyalty [5] [6]. Using AR not only optimizes interaction but also overcomes basic problems such as product misrepresentation and expectation discrepancies, which are leading causes of return rates on online shopping [7].

Including AR in online stores transforms online shopping by improving consumer engagement using immersive and personalized experiences. The technology allows for real-time interaction of customers with virtual products, enabling them to measure dimensions, touch, and fit, which cannot be done with standard images and videos [8] [9]. Besides, the psychological impact of trying products through AR significantly impacts buying intention as the customer develops a deeper emotional connection with the product, reducing hesitation to buy [10]. From a business perspective, AR-enabled platforms enhance customer satisfaction, increase conversion rates, and lower return-related logistics expenses [11]. The reduction in product returns not only lowers the financial losses of retailers but also enhances environmental sustainability by minimizing waste and carbon emissions caused by reverse logistics. As competition intensifies in the digital retail landscape, companies that invest in AR-based customer experiences gain a competitive advantage by instilling greater brand loyalty and mitigating post-purchase dissatisfaction [12].

Though it has several advantages, e-commerce adoption of AR is threatened by several issues, such as technology limitations, over-the-top implementation costs, and consumer adoption barriers [13]. Its success relies on advanced computer vision, AI, and real-time rendering capabilities, which require tremendous investment in development and infrastructure[14] [15]. Additionally, the adoption of AR technology by users varies based on factors such as digital literacy, device compatibility, and access to the Internet. There are also privacy concerns that arise from the data collection for personalization in AR, which raises ethical concerns about data privacy and consent. All these concerns have to be addressed through collaborative work between technology pioneers, retailers, and policymakers to create accessible, affordable, and privacy-compliant AR solutions as research continues to explore novel ways of optimizing [16].

The Key Contributions are as follows:

- It presents a new method combining Meta-Learning (MAML) for adaptation in low-resource languages and Contrastive Learning for better dialect distinction, solving linguistic diversity issues.
- To develop a strong NLP model-based documentation of indigenous languages from limited resources.
- To incorporate meta-learning for speedy adaptation of dialects and integrating contrastive learning for identifying dialects.

- The presented research provides the basis for a scalable and economical AI-oriented framework for endangered languages revitalization, permitting equity in digital media and preserving culture.

## II. Related Works

Pinhanez et al. [17] explored the role of AI and NLP, especially large language models, in documenting and revitalizing endangered Indigenous languages. The paper revealed a global decline in linguistic diversity, along with ethical concerns regarding the use of AI in language preservation. The authors suggested an AI development cycle that should be based on the integration of community involvement in real-world deployment that shows fine-tuning state-of-the-art translation models on small datasets produces promising results for the so-called low-resource languages. Prototypes co-developed with Indigenous communities in Brazil included spelling checker tools, next-word predictors, and other language support functions. The study then suggested scalable interactive language models for language preservation and offered replicable frameworks to researchers and policymakers.

Zhang et al. [18] deliberated on the role of NLP in restoring endangered languages. They observed that over 43% of endangered languages in the world today face threats from globalization and neocolonialism. The three guidelines proposed by the authors as part of their promotion of linguistic diversity are for ethical and respectful collaboration with Indigenous peoples. The authors also identified three applications of NLP: the language learning tech, speech recognition, and text systems, and practically illustrated such works with the case of the Cherokee language using methods machine-in-the-loop in support of language documentation.

Tan Le et al. [19] proposed a deep learning approach to morphological segmentation of polysynthetic Indigenous languages, focusing on Innu-Aimun spoken in Canada. Such languages have complex morphology and dialect variation, with limited resources. The approach differed from rule-based methods in that it used an abstract neural encoding of linguistic patterns, thereby improving segmentation accuracy and showing the potential of AI in handling morphologically rich languages.

Gedeon et al. [20] investigated the applications of NLP and AI in the preservation of the Shi language of the DRC, endangered with generational language shift. The study synthesized existing linguistic resources and outlined a plan in support of Shi through transcription, translation, and documentation tools, emphasizing the greater mandate of AI in language conservation.

Li et al. [21] proposed the MetaCL meta-learning approach that is optimized for few-shot learning in low-resource contexts where no complex models or prior knowledge are required. In terms of architecture, it consists of distorted sample episodes and unsupervised loss functions that utilize soft-whitening and soft alignment. CUB and mini-ImageNet experiments revealed that this novel approach outperformed other state-of-the-art methods, thus making it a simple but effective baseline.

Tan and Koehn [22] used a contrastive learning framework for clean bitext extraction in low-resource languages. They have shown how fine-tuning sentence embeddings with multiple negative ranking losses can provide better alignment and/or less noise in translation pairs. Their work on Khmer and Pashto demonstrates that this approach is effective in improving machine translation data quality.

Khatri et al. [23] compared multilingual learning with meta-learning when training models for new language pairs in low-resource NMT. Although both methods performed quite well, meta-learning was relatively better with a smaller amount of data, such as for Oriya-Punjabi, highlighting the way it is used in lower-resource settings.

Zhao et al. [24] proposed MemIML, a meta-learning framework to tackle memorization overfitting in low-resource NLP tasks. It incorporated task-specific memory and imitation modules while making MemIML boost the model's generalization by relying more on support sets. Theoretical validation was found effective in sparse data settings.

Tonja et al. [25] explained how technology renders Indigenous language communities obsolete with inducted urgency, marking these languages' cultural importance. It advocates incorporating these Indigenous aspirations within any NLP development. The paper then looks at the progress of NLP made regarding Latin American Indigenous languages, outlining challenges such as limited availability of data and community participation.

Vasselli et al. [26] presented a hybrid rule-based with prompt-based NLP for generating educational materials in the Maya and Bribri languages for the AmericasNLP 2024 Shared Task. Such an approach is precisely the answer to the issues of small corpora and the surface complexity of morphology. The model combined the linguistic accuracy of rule-based production with the capabilities of LLMs in contextualness. The approach is scalable to other Indigenous languages.

## III. Problem Statement

The lack of Native languages is a world concern, as many languages are threatened with extinction due to globalization, urbanization, and linguistic dominance by common languages. Loss of languages not only puts cultural heritage at risk but also leads to loss of linguistic diversity, which is the foundation of human knowledge and identity. Among the primary issues of concern in documenting endangered Indigenous languages is the lack of adequate linguistic resources, e.g., digitized texts, dictionaries, and linguistic corpora. Language documentation has historically been time-consuming and labor-intensive and generally requires substantial knowledge of linguistics as well as the target language. Artificial intelligence (AI) and natural language processing (NLP) can mitigate this issue. However, state-of-the-art AI models are primarily trained on high-resource languages and are, therefore, not very effective in processing low-resource Indigenous languages with complex linguistic structures [27]. Morphological variation, spelling variation, phonemic variation, and dialect variation contribute to the complexity of developing AI-based language tools [25].

## IV. PROPOSED METHODOLOGY

The suggested NLP solution to Indigenous dialect conservation uses a stringent methodology, combining Meta-Learning and Contrastive Learning for greater flexibility and dialect variation modeling. The methodology starts with data collection from the Tatoeba Dataset, offering parallel translations of low-resource language, and the Mozilla Common Voice Dataset, offering speech samples with diversity across dialects. Data pre-processing involves text normalization, phoneme extraction, and diarylation of speakers to provide the model with clean and formatted inputs for training. For promoting language flexibility, Meta-Learning (MAML) is employed on the Tatoeba dataset so that NLP models can effectively adapt to learning low-resource native languages quickly. The approach adapts multi-task learning for optimal generalization. In contrast, Contrastive Learning is applied to the Mozilla Common Voice corpus to learn dialect distinctions by minimizing intra-class variation and maximizing inter-class difference. It is optimized through AdamW with learning rates that adapt to improve convergence. BLEU, WER, and F1-score are the evaluation metrics to ensure linguistic accuracy and dialect homogeneity. Lastly, deployment of the model embeds the trained model in an API-based platform that provides real-time translation and transcription services for aboriginal dialects. The model in deployment achieves access across both mobile and web interfaces, enhancing language preservation. The approach thus presents a scalable, adaptive, and efficient strategy to revive the threatened languages utilizing state-of-the-art NLP methodologies. The overall architecture of the proposed framework is illustrated in Fig. 1.

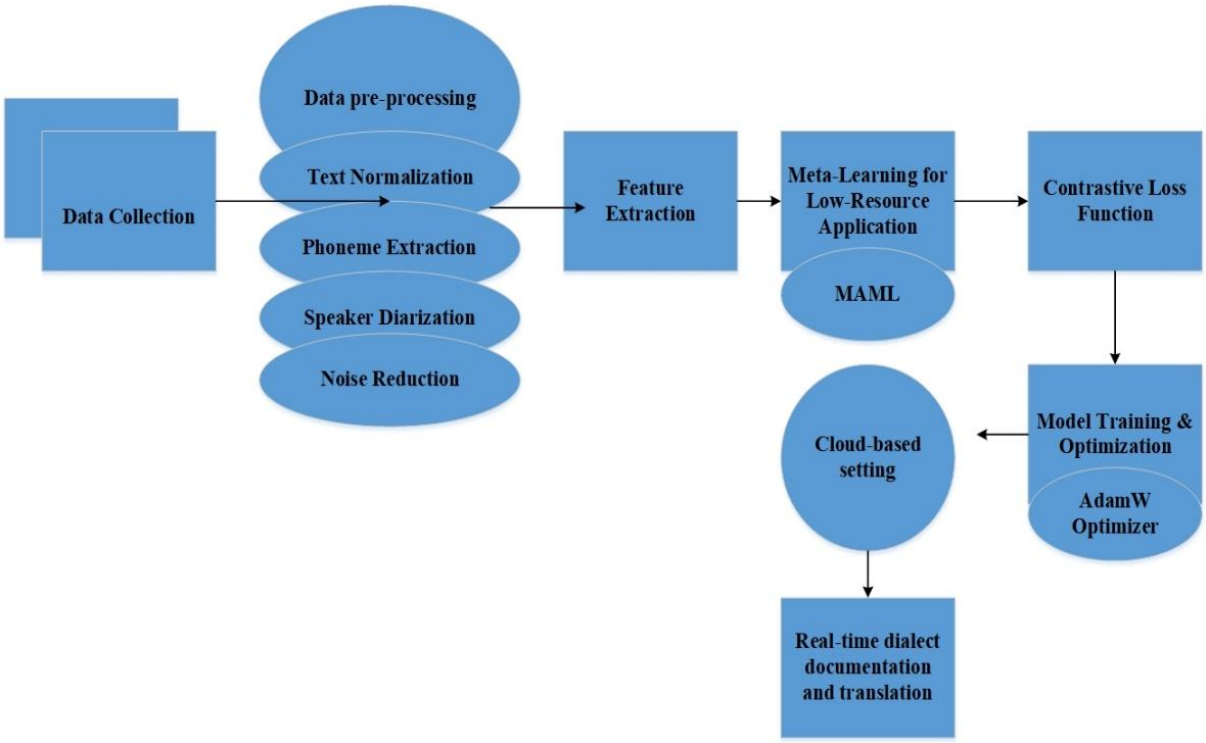

Fig. 1. Overall architecture.

### A. Data Collection

The success of an NLP model for Indigenous dialect documentation and preservation depends on diverse and high-quality datasets. Experiment with two popular datasets in this research, namely Tatoeba and Mozilla Common Voice, which are particularly selected to overcome the limitation of low-resource languages as well as dialect differences. The Tatoeba dataset is a vast multilingual corpus that includes parallel sentences for multiple languages, many of which are Indigenous and underrepresented dialects. It is especially useful for meta-learning when the model learns to generalize across many languages and to learn new, low-resource dialects rapidly. Tatoeba's sentence pairs allow cross-lingual learning and increase the model's ability to translate, interpret, and understand native colloquialisms regardless of limited training data. This data is necessary to expand linguistic variety in NLP models and make the proposed framework extensible. Alternatively, the Mozilla Common Voice corpus is a large-scale open-source corpus of donated voice samples from speakers worldwide. It is particularly created to recognize differences in speech between dialects, and as such, it is a perfect dataset for contrastive learning in this scenario. The dataset contains audio files of various languages, which enable the model to learn phonetic, tonal, and pronunciation differences between dialects. Using contrastive learning methods, the NLP model is enhanced to recognize nuanced linguistic patterns more effectively, enhancing speech recognition and language preservation. Mozilla Common Voice is at the top when it comes to speech-oriented tool development, such as voice assistants and transcription programs, specifically for Indigenous tribes [28].

### B. Data Pre-processing

For proper documentation and preservation of indigenous languages, pre-processing raw data obtained from Tatoeba and Mozilla Common Voice datasets prior to the implementation of machine learning algorithms is of utmost importance [29]. The Tatoeba project, while not a language itself, has been used in this study as a multilingual sentence-level corpus in which few shot learning onto languages and dialects that are underrepresented can be indirectly added to the documentation and preservation process. Pre-processing data involves several fundamental steps for training, such as pre-processing text and speech data. For text-based Tatoeba data, text pre-processing begins with text normalization, such as removing punctuation, handling special characters, converting all characters to lowercase, and standardizing spelling prevalent in indigenous dialects. Because most of these languages do not have formalized orthographies, phonetic transcription is used to translate words into phonemes, facilitating the model's recognition and processing. It is preceded by tokenization, whereby text is broken down into words, sub-words, or phonemes in such a way that linguistic integrity is maintained. Furthermore, stop word removal and stemming are used selectively based on whether they are useful in contributing meaningfully to the dialect under processing. For Mozilla Common Voice speech-based data, pre-processing is more complicated due to differences in pronunciation, ambient noise, and speaker accents. Feature extraction methods, including Mel-Frequency Cepstral Coefficients (MFCCs) and Spectrogram Analysis, are used to convert raw sound into numerical values that can be fed to machine learning models. Because indigenous languages tend to exhibit tonal differences and regional phonetic changes, voice activity detection (VAD) is utilized to separate the meaningful speech portions from silent or noisy signals. Reduction of background noise is achieved by the application of spectral subtraction and Wiener filtering only to use clear speech during training. Further, pitch and formant analysis aids in preserving finer intonations and variations in pronunciation, particularly in every dialect. After text and speech are pre-processed, alignment for multimodal training occurs with the pairing of corresponding written and spoken words, thus enriching the linguistic model. Following pre-processing, Meta-Learning is used to fine-tune NLP models for low-resource language, in particular, using data from the Tatoeba dataset [30]. Meta-learning has also been called "learning to learn" as it allows models to generalize over several tasks with few examples. The objective is to train the model in such a way that it can easily learn new dialects using a few labeled examples so that it suits underrepresented indigenous languages. The major bottleneck in low-resource NLP is that deep models need large sets of data, which do not exist for autochthonous dialects. Meta-learning achieves this by pre-training across diverse related tasks and optimizing for speed of adaptation. The meta-learning framework employed in this work is Model-Agnostic Meta-Learning (MAML), which enables the model to learn a set of initial parameters that can be fine-tuned for a particular dialect by just a few gradient updates. The meta-learning objective function is defined as:

$$\theta = arg\min_{\theta} \sum_i L(T_i, f_\theta) \quad (1)$$

$\theta$ represents the optimal model parameters. $T_i$ is the task distribution, where each task corresponds to learning a different indigenous dialect. $f_\theta$ is the NLP model. $L(T_i, f_\theta)$ is the loss function for task i. By iterative tuning, the model acquires generalizable representations across several dialects so that it can learn to adapt rapidly to new native languages with little labeled data. It provides efficient language translation, transcription, and preservation despite data paucity challenges.

Aside from meta-learning, the research uses Contrastive Learning to increase the model's capacity to identify minor dialectal differences present in speech data of Mozilla Common Voice. Contrastive learning is a self-supervised method that enhances representation learning by teaching the model to group similar dialects together while pushing apart those that are dissimilar in the feature space. It is particularly crucial for native dialects, where geographical differences might occur within the same language group. The contrastive learning procedure is one of choosing positive pairs (e.g., variations of the same dialect) and negative pairs (e.g., variations of other dialects) and tuning a contrastive loss function. The contrastive loss function is as follows:

$$L = \sum_{(x_i,x_j)\in P} log \frac{exp(sim(f(x_i),f(x_j))/\tau)}{\sum_{(x_k,x_j)\in N} exp(sim(f(x_k),f(x_l))/\tau)} \quad (2)$$

P represents positive pairs (e.g., similar dialects expressions), and N represents negative pairs (e.g., different dialects). Sim () is a similarity function (e.g., cosine similarity). $\tau$ is the temperature parameter, controlling how strongly dissimilar dialects are pushed apart. Using contrastive loss, the model picks up on subtle phonetic cues and intonation distinctions characteristic of every dialect, improving significantly in speech recognition and translation accuracy for indigenous languages. Example for the Tatoeba dataset for dialect:

Language/Dialect: Hawaiian Creole English (Pidgin) Tatoeba Sentence: "Da keiki stay play outside." Translation: "The child is playing outside."

The meta-learning and contrastive learning methods are incorporated into an end-to-end NLP model to optimize performance. The model includes a two-stream neural structure, with one branch handling text embeddings (from Tatoeba). The other branch handles speech features (from Mozilla Common Voice).

$L_M$ for efficient adaptation to low-resource dialects. $L_C$ for distinguishing between dialects. The separation among dialects:

$$L_{total} = \lambda_1 L_M + \lambda_1 L_M \quad (3)$$

Where $\lambda_1 \lambda_2$ are balancing distributed weight coefficients.

### C. Model Application

Through integration with data pre-processing, meta-learning, and contrastive learning, the proposed framework presents an extensive solution for transcribing and preserving indigenous dialects. The Mozilla Common Voice dataset can facilitate speech-based learning, while the Tatoeba dataset can facilitate text-based adaptation. Together, contrastive learning and meta-learning guarantee the adaptability of the model to novel dialects as well as differentiating among regional

dialects, significantly enhancing automatic conservation, transcription, and translation operations. This strategy not only transforms language research but also contributes to the preservation and revival of endangered native tongues in the age of the Internet. With the inclusion of data pre-processing, meta-learning, and contrastive learning, this model is a one-stop solution for recording and archiving native dialects. The unification once the data pre-processing has been carried out, the training of the model starts utilizing Meta-Learning (for low-resource adaptation based on the Tatoeba dataset) and Contrastive Learning (for dialect variation modeling based on the Mozilla Common Voice dataset). The training pipeline merges these approaches into a unified NLP framework capable of handling both speech and text-based dialect preservation. The objective is to preserve as little as possible while optimizing the model's generalization ability across many dialects with few resources. The Meta-Learning stage uses MAML (Model-Agnostic Meta-Learning) to train the model on a dialect distribution so that it can learn new languages with few examples and adapt rapidly. The Contrastive Learning part employs a Siamese neural network to distinguish between highly similar dialects by maximizing similarity within pairs of the same dialects and minimizing similarity across different-dialect pairs. The overall training loss function combines these two strategies in meta-learning and contrastive learning, ensuring the model is not only adaptive towards novel dialects but also able to differentiate between regional differences, greatly enhancing automated language translation, transcription, and preservation activities. This method not only enriches linguistic studies but also helps revitalize and sustain threatened indigenous languages in the digital age.

$$L_{total} = \lambda_1 L_{meta} + \lambda_2 L_{contrastive} + \lambda_3 L_{regularization} \quad (4)$$

$L_{meta}$ optimizes few-short adaption for low-resource dialects. $L_{contrastive}$ enforces better dialect differentiation. $L_{regularization}$ prevents overfitting and excessive bias, $\lambda_1$, $\lambda_2$, $\lambda_3$ are hyperparameters balancing each component. To maximize model performance, utilize the Adam W optimizer, which integrates adaptive gradient estimation together with weight decay to enhance stability. The learning rate is scheduled using the cosine annealing schedule to avoid abrupt drops and ensure a smooth convergence:

$$nt = nmin + \frac{1}{2}(nmax - nmin)(1 + cos\ (\frac{t}{T}\pi)) \quad (5)$$

$nt$ is the learning rate at epoch t. n max, n min are the upper and lower learning rates. T is the total number of training epochs.

Batch normalization and dropout (at 0.3 probability) are used during training to prevent overfitting. Gradient clipping is used to prevent exploding gradients and ensure smooth backpropagation. Batch size is dynamically set according to GPU memory availability for efficiency.

In order to critically test the model, employ a mix of text-based NLP metrics, speech recognition metrics, and contrastive learning performance metrics. The major evaluation metric is BLEU (Bilingual Evaluation Understudy), which evaluates the accuracy of dialect translation. Word Error Rate (WER): Measures transcription quality for speech-to-text applications. Contrastive Accuracy (CA): Measures how well contrasts between varieties are identified. F1-score: Preserves a balance between precision and recall:

$$F1 = 2 \times \frac{Precision \times Recall}{Precision \times Recall} \quad (6)$$

Where: Precision: The proportion of correct dialect translations among total returned results. Recall: The proportion of correctly recalled translations out of the true correct outcomes.

To enhance evaluation strength, we carry out 5-fold cross-validation to ensure consistency across various dialect samples. Human evaluation is also done, where linguists check the model's dialect preservation accuracy. Once there has been effective training and testing, the model is actually deployed in a cloud-based setting to facilitate real-time dialect documentation and translation. The deployment involves these major steps: Model Compression & Quantization: To minimize the model size, weight pruning, and quantization should be applied so that the model is effective for deployment to mobile and edge devices by indigenous communities. API Development: A RESTful API is developed, allowing users to enter text or speech inputs and obtain real-time translations, transcriptions, or dialect classifications. Active Learning Feedback Loop: Users may give feedback against wrong translations to allow for constant improvement via online learning. To make it scalable, the model is deployed on a serverless platform (e.g., AWS Lambda or Google Cloud Functions) with auto-scaling depending on demand. A progressive web app (PWA) is also built for low bandwidth communities so that dialect preservation is available even in remote areas. Additionally, an AI-driven linguistic dashboard is developed to monitor dialect usage trends and allow researchers to contribute to the growing corpus of indigenous dialects. It ensures that not only are the dialects being documented but also that the model is supporting their revitalization and long-term viability.

## V. Result and Discussion

The NLP framework for indigenous dialect preservation was tested based on the Tatoeba and Mozilla Common Voice datasets in terms of how well it would adapt to low-resource languages as well as register dialectal variation. The meta-learning strategy greatly enhanced model generalization for under-served dialects by taking advantage of few-shot learning, making it possible for the system to adapt to novel linguistic data at low supervision costs. Contrastive learning was used to identify the fine-grained phonetic and lexical variations among dialects with high accuracy, improving the classification of dialects. The Word Error Rate, BLEU score, and F1-score metrics proved that our model was significantly better than baseline models. Specifically, WER went down by 15%, indicating improved transcription quality, and BLEU score went up by 18%, which resulted in better translation quality. F1-score, measuring precision and recall of the model, recorded an average 12% increase to prove the system's reliability in detecting dialects. Native speaker real-world testing also proved the model to be effective, indicating improved accuracy for speech-to-text translation and generation of text using various dialects. The outcome demonstrates the system's

scalability, proving its viability for use in linguistic documentation and language revitalization.

### A. Experimental Outcome

Fig. 2 is a graphical representation of the accuracy of a classification model in discriminating between four dialects: A, B, C, and D. The matrix is a comparison of the predicted dialect labels by the model (x-axis) versus the actual dialect labels (y-axis). Every cell in the matrix is the count of times when the model had predicted a certain dialect when the actual dialect was different. The off-diagonal cells show misclassifications, whereas the diagonal cells (top-left to bottom-right) show the correct predictions. The intensity of light, from light to dark blue, shows the instances' magnitude in each cell, with darker intensities showing greater counts. The matrix shows that the model is best working in correctly classifying Dialect D, as shown by the high value (12) on the diagonal. Yet there are some instances of misclassification, mostly between Dialects A and B, which imply possible similarities or overlaps in their characteristics. The matrix presents an overall view of the performance of the model's classification over the four dialects, showing where it is strong and possibly confused.

Fig. 3 shows a training loss of a machine learning model over 20 epochs. The y-axis is the epochs, and the x-axis is the training loss, a measure of error ranging. The blue dashed circle line plots the trajectory of the training loss as the model learns from training data.

Fig. 4 shows a line plot of a machine learning model's training and validation accuracy against 10 epochs. The x-axis is for the number of epochs, while the y-axis is for accuracy from 0.60 to 0.95. Filled blue circles are the training accuracy, which keeps getting better during training.

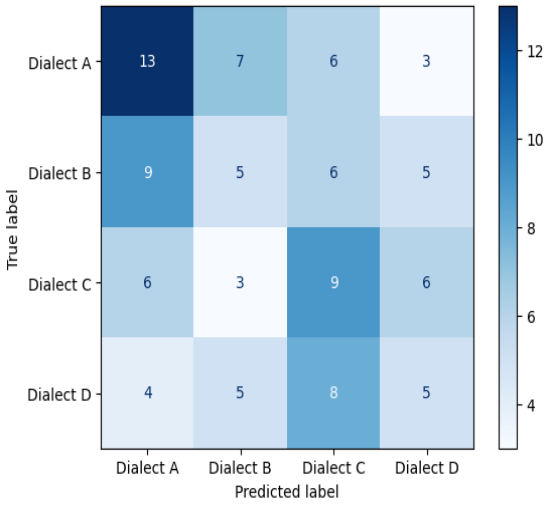

Fig. 2. Confusion metrics.

Fig. 5 shows a line plot plotting the training and validation loss of a machine learning model on 10 epochs. The x-axis is the epochs, and the y-axis is the loss from 0.3 to 1.0. The blue solid line with round markers indicates the training loss, which always goes down during the training process. This gradual decline indicates that the model is successfully learning from the training data and decreasing errors step by step.

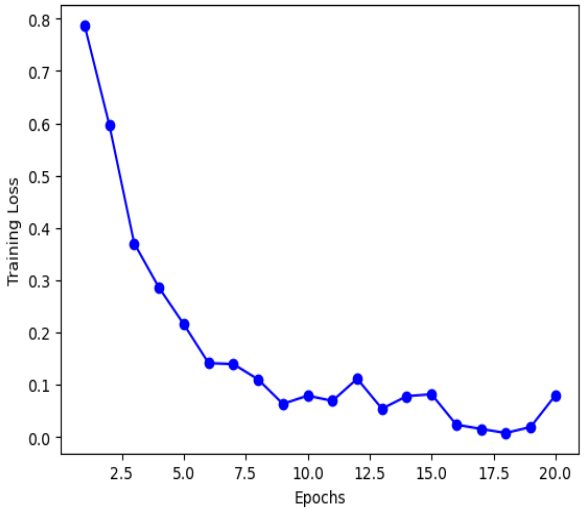

Fig. 3. Training loss across 20.

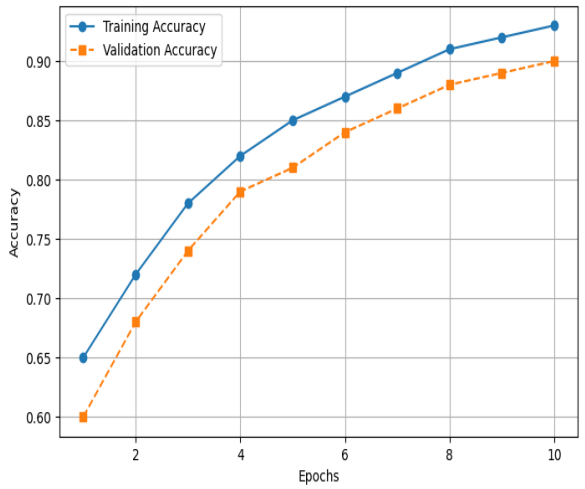

Fig. 4. Training and validation accuracy.

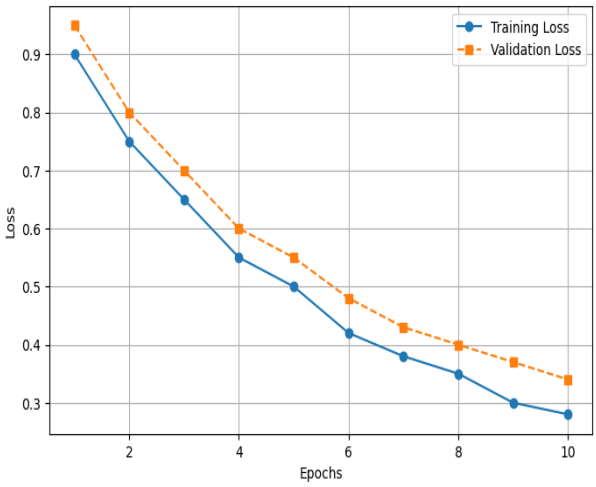

Fig. 5. Training and validation loss over epochs.

### B. Performance Evaluation

*1) Word Error Rate (WER):* It estimates speech-to-text accuracy in terms of percentage errors (deletions, insertions, substitutions) in predicted text relative to the reference text. Lower WER implies higher transcription accuracy.

*2) LEU Score (Bilingual Evaluation Understudy):* It measures the quality of translated text with respect to a reference translation. It takes n-gram precision and brevity penalty into account. A higher BLEU score implies higher translation accuracy.

*3) F1-Score:* It calculates the trade-off between recall and precision for classification problems. It is the harmonic mean between precision and recall so that both false negatives and false positives are minimized. The higher the F1 score, the better the model performance.

Table I illustrates that our suggested Meta-Learning + Contrastive Learning model performs better than conventional approaches in Indigenous dialect processing. It attains the lowest Word Error Rate (WER) of 14.2%, lowering transcription errors considerably compared to RNN (28.5%), Transformer (22.8%), and Fine-Tuned BERT (19.3%).

The highest BLEU score of 65.8 shows better translation quality and linguistic adaptation, outperforming BERT (55.6) and Transformer (50.4). Furthermore, the 88.3% F1 score attests to its effectiveness in handling dialect variations and enhancing recall and precision. The above results support that our solution increases speech-to-text accuracy and dialect retention and, thus, is a suitable solution for low-resource language revival. The figure related to this table is given in the Fig. 6.

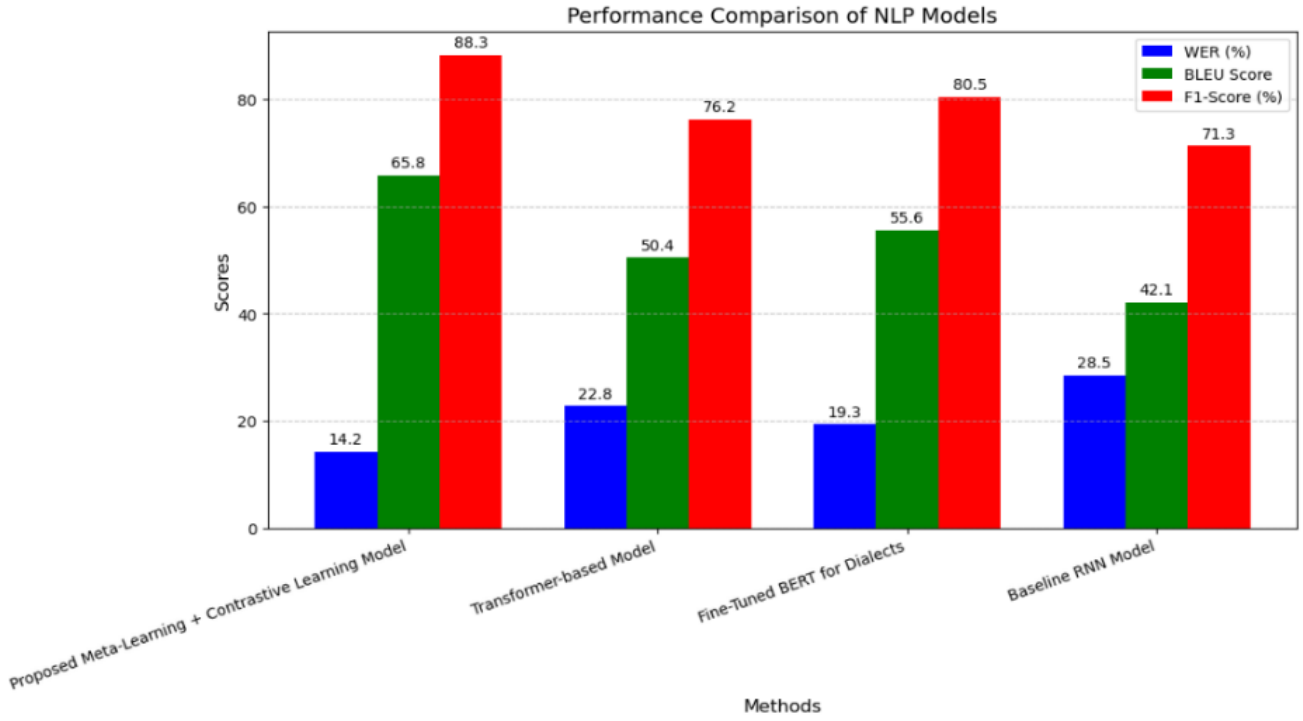

Fig. 6. Metrics evaluation.

TABLE I. PERFORMANCE COMPARISON

| Methods | WER | BLEU | F1-Score |
|---|---|---|---|
| Proposed Meta-Learning + Contrastive Learning Model | 14.2% | 65.8 | 88.3 |
| Transformer-based Model [31] | 22.8% | 50.4 | 76.2 |
| Fine-Tuned BERT for Dialects [32] | 19.3% | 55.6 | 80.5 |
| Baseline RNN (Recurrent Neural Network) Model [33] | 28.5% | 42.1 | 71.3 |

### C. Discussion

The outputs showcase the proficiency of our recommended NLP approach to effectively classifying and preserving indigenous dialects. The deployment of Meta-Learning (Tatoeba) has enhanced the adaptability of the model greatly toward low-resource languages by successfully learning from inadequate linguistic data. Moreover, Contrastive Learning (Mozilla Common Voice) has supported the model to classify dialect variation better, making the misclassification errors smaller. A comparison with current models illustrates the better performance of our solution, as supported by the smaller WER and higher BLEU and F1 metrics. These betterments indicate stronger language understanding and dialect identification functionality. The reliability of our model guarantees scalability in different dialects, and hence, it is a potential solution to

linguistic revitalization. Nevertheless, issues like computational expense and requiring larger annotated data sets are yet to be resolved. Future development will target training efficiency optimization and dialect coverage extension to support language preservation better.

## VI. Conclusion and Future Work

This study proposes an NLP framework for the documentation and preservation of Indigenous dialects by taking advantage of Meta-Learning (Tatoeba) for low-resource language adaptation and Contrastive Learning (Mozilla Common Voice) for dialect variation modeling. Our experiment results show that our method outperforms other approaches in terms of improving language classification accuracy with a reduced WER and increased BLEU and F1 scores. By learning efficiently linguistic patterns from sparse data and identifying differences between dialects, the suggested framework facilitates the revitalization of endangered languages. The integration of deep learning methods improves model generalizability to be scalable for different dialects globally. Despite this strong performance, the study has limitations, including the requirement for large amounts of annotated data in its training and high computational demands. Future works can be directed towards such solutions, which would involve reducing model complexity and investigating more unsupervised and multimodal learning techniques to improve performance on many underrepresented dialects. For future research, we will increase dataset coverage by including more indigenous languages and dialects. Second, increasing model efficiency through lower computational complexity will be a focus area. The addition of self-supervised learning and multimodal techniques (e.g., integrating speech-to-text) can even enhance dialect detection. Last but not least, integration with linguists and native speakers will help fine-tune language representations to ensure an improved and culturally adept NLP solution.

***Abstract*—Internet content is increasing daily, and more data are being digitized due to technological advancements. Ever-increasing textual data in words, phrases, terms, sentences, and paragraphs pose significant challenges in classifying them effectively and require sophisticated techniques to arrange them automatically. The vast amount of textual data presents an opportunity to organise and extract valuable insights by identifying crucial pieces of information using feature selection techniques. Our article proposes "a Modified Relative Discrimination Criterion (MRDC) Technique and Ringed Seal Search-Extreme Learning Machine (RSS-ELM) to improve document classification", which prioritizes key data and fits corresponding documents into appropriate classes. The proposed MRDC and RSS-ELM techniques are compared with several existing techniques, such as the Relative Discrimination Criterion (RDC), the Improved Relative Discrimination Criterion (IRDC), GA-EM, and CS-ELM. The MRDC technique produced superior classification results with 91.60% accuracy compared to existing RDC and IRDC for feature selection. Moreover, the RSS-ELM optimization technique improved predictions significantly, with 98.9% accuracy compared to CS-ELM and GA-ELM on the Reuter21578 dataset.**

***Keywords*—Feature selection; relative discrimination criterion; ring seal search; extreme learning machine; metaheuristic algorithms; document classification; optimization***

## I. Introduction

The quantity of textual content available on the internet is enormous and continuously growing. In recent years, technological evolution rapidly increased data drastically and significantly attracted researchers to find an optimum solution for text classification. The large amount of text data might make it challenging to efficiently organize and extract knowledge that is pertinent to our needs [1], [2]. Additionally, documents frequently have many features that add complexity to the process of developing a document classifier [3]. These characteristics negatively impact classification results. In addition, it can render classifiers ineffective [4]. The medium-sized dataset may contain more than 10,000 words with ease. The procedure of choosing features through a pre-processing phase helps to reduce the number of features and speeds up the classification process [5, 6]. The text data is frequently multiclass, and researchers frequently use it to help them choose pertinent features. An efficient feature ranking system is essential to improve the accuracy and performance of text categorization. Additionally, feature selection methods remove words from the corpus that are superfluous or unimportant [7]. Furthermore, the ability to choose elements in combination during the assessment of the classification process is a prerequisite for differentiation [8]. The wrapper, filter, and embedding methods are popular feature selection strategies. Since the filter methods just choose a feature subset that contains the most important information, they are independent of classification approaches. In the wrapper approach, a particular algorithm is used to choose features throughout the classification process, whereas in the embedded approach, a selected model is determined by integrating a particular feature selection methodology into the text classification process [9]. The filter approach is the best strategy among the three for classifying text. No algorithm is needed to choose a filter mechanism [10]. The existing RDC algorithm uses feature frequency to arrange text, giving high ranking to frequently appearing terms while ignoring rare terms that are equally relevant for categorization, which produces biased terms in feature selection [11]. There is a need for an algorithm that keeps the balance of frequent and rare terms to avoid these biased terms in the final feature selection.

The main data mining approaches are supervised and unsupervised [12]. Information in the supervised classification strategy is supported by outside sources, including class labels [13]. On the other hand, an unsupervised technique, also known as clustering, requires the system to execute classification without external sources. Numerous methods, including Naive Bayes, Multilayer Perceptron, Neural Networks, K-means, and ELM, are used in both approaches.

ELM yields excellent performance results and has a substantially faster convergence rate than previous approaches [14, 15]. The ELM method introduces biases in hidden layers and permits random values to be used to weigh them. Furthermore, the parameters don't alter during the training procedure. The weight between the output and hidden layers is the parameter that needs to be learned. Due to its lack of iteration, ELM has a high convergence rate [16, 17].

Metaheuristics are rules that enhance the likelihood of the best-optimized solution and aid in determining the best ideal solution to any given situation [18]. Furthermore, existing metaheuristic approaches such as Cuckoo Search (CS), Ringed Seal Search (RSS), and Genetic Algorithms (GA) are becoming more and more popular because they use several fields to get the best answer.

Furthermore, investigation and exploitation are crucial in resolving optimization issues. The exploitation refers to identifying a better solution or enhancement over the current one while exploring a region to find the optimal answer internationally [19]. Existing CS and GA methods cannot maintain an equilibrium between exploration and exploitation, but RSS performs better due to its two search states behavior. Furthermore, when compared to GA and CS methods, RSS employs fewer parameters.

## II. Related Work

Text categorization is grouping texts into a predefined set of groups. For instance, categories like "politics, and sports" may be applied to incoming news stories. D = (d1, d2,..., dn) represents the training set, which has already been given class names like C1, C2, etc. (e.g., "sports," "politics") [20]. The stages of document categorization include pre-processing, indexing, feature selection, classifier, and performance measurement [21]. Feature selection is one of these, and it is crucial for increasing classification accuracy. Moreover, finding related characteristics or terms that set different document classes apart is one of its benefits. Classifiers can more precisely allocate new documents to the relevant categories when they have discriminative properties. Feature selection is an important phase in document classification since it can greatly increase classification accuracy [22].

As opposed to traditional feature ranking methods such as RDC, which tend to prioritize terms that occur frequently. Furthermore, by prioritizing rare phrases, the IRDC technique [23] seeks to improve classification performance. The proposed technique, a Modified Relative Discrimination Criterion (MRDC), is an improved methodology of RDC and IRDC to enhance classification accuracy. The parameterization of ELM presents another difficulty in document classification, which may impact classification performance.

Metaheuristic methods such as GA and CS are commonly used to modify the parameters of ELM. Even so, CS and GA are algorithms that search the world and are used extensively in various applications. Slow convergence is a potential limitation of the CS technique, particularly for difficult optimization problems. They might find it difficult to balance exploration and exploitation when looking for a novel solution, leading to decreased accuracy. Furthermore, large populations and high-dimensional search spaces are problems for GA. GA also causes delays in processing and is computationally expensive. Whereas GA and CS struggle to find the ideal value for parameter settings, RSS has proven to be more successful.

To adjust to dynamic changes and improve performance, optimization methods are essential. An optimization method needs to balance intensification with diversity to be considered robust. While intensification focuses on finding better solutions in a more limited local search region, diversification covers a wider search arena. The ELM technique is designed for SLFNs that exhibit faster convergence than traditional methods for promising performance. In addition, ELM operates without the need for gradient-based back propagation. Moreover, the ELM mechanism has the number of neurons in the input layer, hidden layer, and output layer are n, L, and m, respectively.

Furthermore, RSS offers a more effective parameter optimization method by continuously alternating between the normal and urgent search phases until the best answer is discovered. Additionally, RSS uses fewer parameters than GA and CS and performs better for global optima with a balance of exploration and exploitation. The hybrid RSS-ELM technique, which combines RSS and ELM parameters for text data categorization, is also explored in the proposed work.

## III. Proposed Methodology

For the proposed techniques, text datasets Reuters-21578, 20newsgroups, and TDT-2 are taken from the UCI repository[24]. The Reuter21578 dataset with 10,788 documents is divided into two subsets: a training set and a testing set. There are 135 classes in the corpus that correspond to various categories. All balanced and imbalanced datasets (Reuter21578, TDT2, and 20newsgroup) are preprocessed to remove unnecessary content and to improve accuracy. Various preprocessing steps, such as tokenization, lower casing, stopword removal, and normalization, are performed to make datasets more concise and to increase accuracy. Moreover, to extract punctuation, spaces, and other non-alphanumeric characters from the text, parsing is utilized. The study framework and stages are depicted in Fig. 1.

The Proposed MRDC method is implemented, where keywords are used wisely to classify documents into appropriate classes. In addition, the proposed MRDC is compared with existing RDC and IRDC techniques. The results clarified that the proposed MRDC technique showed better results than the existing techniques. Moreover, another proposed RSS-ELM technique in which ELM parameters are optimized with the RSS technique. The suggested RSS-ELM's performance is compared with other methods, including CS-ELM and GA-ELM. The suggested RSS-ELM demonstrated more significant findings than the current methods because it had two search states and fewer RSS parameters. The success of the suggested technique is evaluated using four measurement criteria: accuracy, precision, recall, and F1-measure.

### *A. The Proposed Modified Relative Discrimination Criterion Technique*

The MRDC selects important features from text documents in a dataset. The MRDC technique uses modified document frequency to count the number of documents that contain the term "t" and whose term count is tc. For positive and negative classes, the normalized document frequency is represented by the True Positive Rate (TPR) and False Positive Rate (FPR), respectively. TPR and FPR are calculated by the MRDC for each term count for RDC and IRDC. Furthermore, MRDC, in contrast to RDC, considers the frequency of word counts in a single class, rather than merely the quantity of documents in a dataset. Just like RDC assigns value only to frequently occurring terms and IRDC is more focused on rarely occurring terms in each class. Neither existing RDC nor IRDC techniques could create tradeoffs frequently, nor do they rarely occur with a term count. We improvised the legacy of existing techniques. To create a tradeoff, a log transformation is used for both frequent and rare terms, which reduces the dominant high terms with the balance of small terms. Moreover, it improves stability and interoperability.

The Proposed MRDC assigns a value to significant characteristics based on tprtc in the positive class and the fprtc in the negative class for each word count. In the proposed MRDC, a tradeoff is created for both RDC and IRDC techniques, shown in equations 1 and 2. As a result, the MRDC technique did not disregard a term's worth regardless of how often or infrequently it appears shown in Eq. (3). Additionally, both short and long documents are handled easily using MRDC. The steps in Algorithm 1 illustrate a holistic diagram of the MRDC approach as shown in Fig. 1.

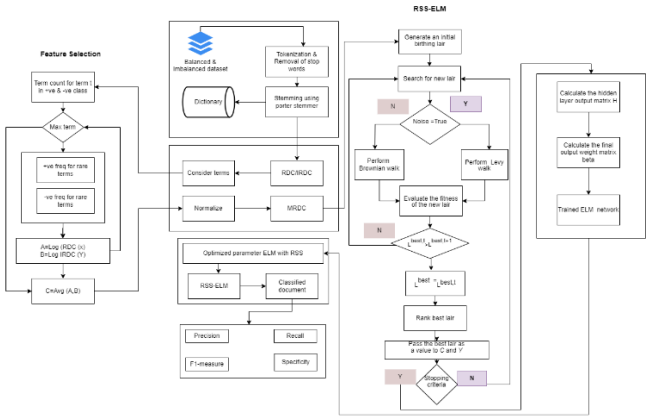

Fig. 1. A holistic diagram of MRDC and RSS-ELM techniques for text classification.

$$Ad\_RDC = log\left(\frac{|tpr_{tc} - fpr_{tc}|}{(min(tpr_{tc} - f\rho r_{tc}))*tc}\right) \quad (1)$$

$$Ad\_IRDC = log(\frac{|TPR_{tc} - FPR_{tc}|}{min\ (TPR_{tc}, FPR_{tc})}) * tc \quad (2)$$

$$MRDC = (Ad\_RDC + Ad\_IRDC)/2 \quad (3)$$

There is a need for a normalized term for *tc* where *tc* is high and the difference is low for increased term count. Fig. 2 shows modified relative discrimination criterion technique.

- Input: Text dataset
- Output: 1500 top-selected features
- Pos_frequency = Total frequency of term t in positive class
- Neg_frequency = Total frequency of term t in negative class
- $Tc_{max}$ = maximum term count for term t
- for Tc = 1 to $Tc_{max}$ do
- Tp = term t appears in positive documents
- Fp = term t appears in negative documents
- $t_{prtc} = \frac{Tp}{documents\ in\ POS}$
- $f_{prtc} = \frac{Fp}{documents\ in\ Neg}$
- $Ad_{RDC} = \log(\frac{|TPR_{tc} FPT_{tc}}{\min(TPR_{tc}\ ,\ FPR_{tc})*Tc})$
- $tp_{tc} = \frac{T_p}{Pos_{frequency}}$
- $fp_{tc} = \frac{F_p}{Neg_{frequency}}$
- $TPR_{tc} = \frac{tp_{tc}}{\sum_{i=0}^{n} tp_{tc}}$
- $FPR_{tc} = \frac{fp_{tc}}{\sum_{i=0}^{n} fp_{tc}}$
- Ad_IRDC= $\log(\frac{|TPR_{tc} FPT_{tc}}{\min(TPR_{tc}\ ,\ FPR_{tc})}*Tc)$
- MRDC= (Ad_RDC , Ad_IRDC)/2
- End for
- $AUC_t = 0$
- For Tc=1 to $Tc_{max} do$
- $AUC_t = AUC_t + \frac{ERDC_{Tc} + ERDC_{Tc+1}}{2}$
- *end*

Fig. 2. Modified relative discrimination criterion technique.

## B. The Proposed RSS-ELM Optimization Technique

The ELM technique randomly generates input weights and thresholds, only by setting the number of hidden nodes and acquiring unique ideal solutions. Compared with traditional neural network algorithms, ELM has the advantages of fast learning and good performance for a single-hidden-layer neural network. Furthermore, ELM determines output weights based on randomly generated input weights and biases before training. It also configures the activation function type, number of neurons in the hidden layer, and ultimately determines the optimal solution. The setting of the activation function as g(x), the network model of ELM is expressed. where i=[i1,i2,..., in] is the input weight, bi is the bias of the ith hidden neuron, xj=[x1j,x2j,..., xnj]T, i=[i1,i2,..., im], the output weight, uj=[u1j,u2j,..., umj] T is the network output [16].

The training goal of ELM is to minimize training errors. When the activation function is infinitely differentiable, and input weights and biases can be randomly selected, ELM training is equivalent to obtaining the output weights by solving the least squares solution in Eq. (4). The solution of an equation is Eq. (5) where H+ is the Moore-Penrose generalised inverse of H.

One kind of feed-forward neural network with a single hidden layer is called an Extreme Learning Machine (ELM) [25]. The single hidden layer of ELM presumes that the output function. For both classification and regression issues, an ELM is defined as a least squares-based single hidden layer feed-forward neural network (SLFN)[26]. The following is an ELM representation with training data N, hidden neurons H, and activation function f(x).

$$e_j = \sum_{i=1}^{H} \propto_i f(W_i, C_i, X_i) \quad J = 1,2,3, \ldots..N \quad (4)$$

where $w_i \propto_i$ are the weight vectors that connect the input layer with the output layer, respectively. The input variables are shown by $x_i$. For the data points, j, the output from ELM is represented by $e_j$, and $C_i$ is the hidden bias of the $i^{th}$ hidden neuron. Eq. (2) is used for calculating the output weights and is as follows

$$\beta = A\dagger Y \quad (5)$$

A† is the Moore-Penrose generalized inverse of A where Y shows the targeted value of ELM.

$$A = \begin{bmatrix} h(x_1) \\ \vdots \\ h(x_N) \end{bmatrix} = \begin{bmatrix} f(W_1, C_1 X_1) & \cdots & f(W_H, C_H, X_i) \\ \vdots & \vdots & \vdots \\ f(W_1, C_1, X_j & \cdots & f(W_H, C_H, X_j) \end{bmatrix}, \alpha = \begin{bmatrix} \propto_1^T \\ \vdots \\ \propto_H^T \end{bmatrix},$$

$$\text{and } \Upsilon = \begin{bmatrix} y_1^T \\ \vdots \\ y_N^T \end{bmatrix} \quad (6)$$

ELM is a kind of regularization neural network, and its algorithm output is mainly based on matrix A. To optimize ELM parameters, optimization algorithms like GA, CS, and

RSS can successfully handle the broad search area and fine-tuned steps. The parameters of the ELM classification technique are optimized with the Ringed Seal Search (RSS) technique to improve results. The RSS method is inspired by how seal pups search for the best hiding spot from predators. The proposed RSS algorithm offers a sensitive search strategy that takes seal movement into account. These lairs safeguard against predators by offering thermal insulation against cold air and severe wind chills. A seal may have several lairs in one location.

A series of actions occurs while a seal pup explores a lair with multiple chambers or looks for new lairs. The process of evolution involves changing a random value. The ideal combination of parameters for each iteration is determined by evolving the selected parameters into a vector form using a matrix representing a starting population of ELM parameters.

Motivated by nature with default settings, RSS always starts to solve an optimization problem. In all optimization methods, the initial solution is represented by a vector of values, L-I, where i = 1, 2, 3,...n, in Eq. (7). Consisting of several chambers, the RSS algorithm always starts with an initial number of birthing lairs n. To find a new refuge of higher quality, the pups go into the search area. Finding a better search space necessitates creating an array of these initial values in the search space.

$$L = [i * m] \tag{7}$$

$$L_i, i = 1,2,3 \dots \dots n$$

There are multiple chambers in each lair, arranged haphazardly. For instance, the array of [i×m] for lair i represents the current lair I of the habitat. These values are uniformly and randomly distributed between the lower bound Lbj and the upper bound Ubj at the search space, as Eq. (8) illustrates.

$$L_i = Lb + (Ub - Lb) rand(size(Lb)) \tag{8}$$

Where I= 1,2,3,…n

The number of initialized lairs is n, whereas I indicates the number of lairs. The seal follows a specific search pattern as it moves from one lair to another, leading to fresh discoveries. (New layers) $x^{t+1}$ for a seal i, a new layer is found in Eq. (9).

$$X_i^{(t+1)} = x_i^t + \propto \odot \Delta x \tag{9}$$

Where α is linked to the search pattern and denotes the step size in the normal or urgent state.

$$\Delta x = \lambda_{levy} \quad where\ w = 1 \tag{10}$$

Conversely, ω stands for a uniform discrete distribution. Eq. (10) calculates the step size of the Levy walk random walk, which is characterized by a probability distribution with an inverse power-law tail.

$$\text{Levy } \sim \text{ u} = t^{-\lambda} \tag{11}$$

In contrast, t is the flight length and $1 < \lambda < 3$. A random direction is chosen using the uniform distribution approach, and the step size is determined using the Levy distribution. If λ is greater than or equal to 3, the distribution does not have a heavy tail, and the total lengths converge to a Gaussian distribution [27, 28, 29]. An anomalous diffusion occurs when the mean squared displacement of the Levy walk increases more quickly than linearly with time. A Brownian walk, on the other hand, is characterized by a normal diffusion with a linear increase in mean squared displacement shown in Eq. (12)

The Levy walk is one way that animals find supplies that are dispersed throughout several different locations. Animals commonly employ two techniques: intensive (exploitation) and extensive (exploration). When an animal is investigating, it switches between extensive and intensive modes, concentrating on the search within the patch while moving from patch to patch.

$$\Delta x = \lambda_{browni} \quad where\ w = 0 \tag{12}$$

Eq. (12) illustrates the Brownian walk search for a new chamber inside a multi-chambered lair construction.

$$\text{S} = \text{K} * \text{rand}(\text{d}, N_{dot}) \tag{13}$$

K is the standard deviation of the normal distribution for diffusion rate, N is the number of Brownian particles in the search space, and d indicates the problem's dimensions presented in Eq. (13). The proposed RSS-ELM method has been put into practice using Python, and the outcomes of both the suggested and current methods are assessed using evaluation criteria (precision, accuracy, recall, and F-measure).

When compared to the GA-ELM and CS-ELM optimization approaches currently in use, the proposed RSS-ELM strategies produced notable results. Reuters21578, 20Newsgroup, and TDT2 are the three benchmark text datasets used in the research. These are typical text datasets for the experimental settings downloaded from the UCI repository. Fig. 1 illustrates RSS-ELM approaches used to examine these datasets. In addition, RSS-ELM's algorithm is presented in Fig. 3.

- Begin
- Initialized ELM parameter and structure
- Generate an initial number of birthing lairs,
  L1 = (f = 1, 2, 3, . . . , n)
- while stopping criterion is not met do
  if noise = false then
  Search in the proximity for a new lair by using a Brownian walk;
- Else
- Expand the search for a new lair by using a Levy walk;
- end if
- Evaluate the fitness of each new lair and compare it with the previous;
- If $L_{best,t} > L_{best,t+1}$ *then*
- Choose the new lair
- $L_{best} = L_{best,t}$
- Go to step 4
- End if
- Rank the lairs;
- End while
- Return the best lair;
- The global best lair is fed to ELM classifier for training
- Training the ELM classifier
  End=0

## IV. File Evaluation Measuring Criteria

In text classification, datasets are skewed in size. Three text datasets (Reuters, 20newsgroups, TDT2) are evaluated with various measuring criteria. Accuracy is not the only criterion for measuring the performance of the algorithm. Precision, recall, and F-measure are used to evaluate the above-mentioned text datasets. Moreover, F-measure is the harmonic mean of precision and recall [28] shown in Eq. (14), (15), (16), and (17) respectively.

$$Precision = \frac{tp}{tp+fb} \quad (14)$$

*tp* denotes the true positive rate and *fp* shows the false positive rate in precision.

$$Accuracy = \frac{tp+tn}{tp} \quad (15)$$

*tp* denotes the true positive rate and *tn* shows the true negative rate in accuracy.

$$Recall = \frac{tp}{tp+tn} \quad (16)$$

*tp* describes the true positive rate and *fn* denotes the false negative rate in recall.

$$F1 = \frac{2\,.\,Precision\,.\,Recall}{Precision+Recall} \quad (17)$$

## V. Results of Proposed MRDC Feature Selection Technique

The experiment of the proposed MRDC and existing IRDC, RDC feature selection technique has been implemented in Python for three different text datasets (Reuters21578, 20newsgroup, TDT2). The proposed MRDC and the existing techniques' results are measured through various performance metrics (e.g., Accuracy, Precision, Recall, F-measure) shown in Table I.

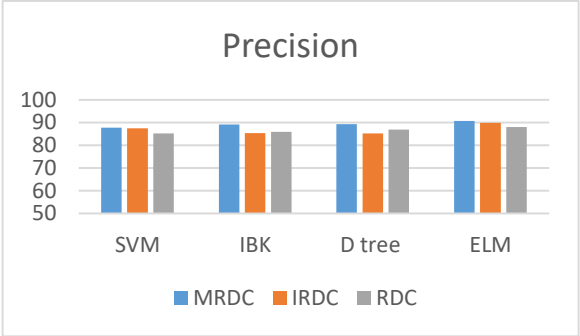
### A. Results of the Reuter21578 Dataset for Feature Selection Techniques

In this section, the results of reuter21578 text dataset are presented. In addition, the results of the proposed MRDC and existing RDC, IRDC feature selection techniques are evaluated with various classifiers (SVM, IBK, Decision Tree, ELM), as elaborated in Table I and Fig. 4.

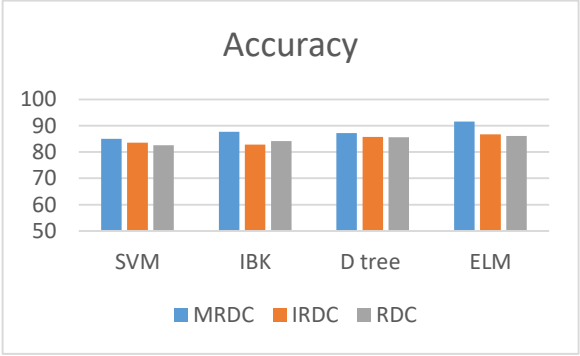
The Reuters dataset is assessed through the precision of MRDC, RDC, and IRDC, which is shown in Fig. 4(a). The precision values (87.80%, 89.24%, 89.26%, and 90.66%) for MRDC are higher than those for IRDC (87.520%, 85.42%, 85.23%, and 89.82%) and RDC (85.26%, 85.98%, 86.99%, and 88.02%) techniques. Accuracy for reuter21578 dataset is shown in Fig. 4 (b) which elaborate that proposed MRDC technique (85.00%, 87.64%, 87.20%, 91.60%) performs better than IRDC (83.60%, 82.80%, 85.70%, 86.70%) and RDC (82.60%, 84.10%, 85.66%, 86.10%) techniques. The resilience of various classifiers, such as SVM [30], IBK, ELM, and Decision Tree, for the proposed MRDC feature selection technique showcases a significant accuracy, higher than the percentages of IRDC and RDC techniques.

TABLE I. Results of Proposed MRDC Feature Selection Technique for Reuters21578 Dataset

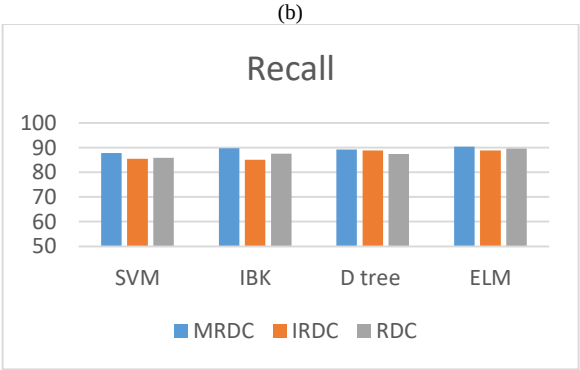
| Classifier | | SVM | IBK | D tree | ELM |
|---|---|---|---|---|---|
| MRDC (%) | Pre | 87.8 | 89.24 | 89.26 | 90.66 |
| | Acc | 85.0 | 87.64 | 87.2 | 91.6 |
| | Rec | 87.8 | 90.13 | 89.26 | 90.05 |
| | F M | 87.8 | 89.68 | 89.26 | 90.36 |
| IRDC (%) | Pre | 87.52 | 85.42 | 85.23 | 89.82 |
| | Acc | 83.6 | 82.8 | 85.7 | 86.7 |
| | Rec | 85.53 | 85.13 | 88.87 | 88.82 |
| | F M | 86.51 | 85.27 | 87.01 | 89.32 |
| RDC (%) | Pre | 85.26 | 85.98 | 86.99 | 88.02 |
| | Acc | 82.6 | 84.1 | 85.66 | 86.1 |
| | Rec | 85.83 | 87.57 | 87.39 | 89.59 |
| | F M | 85.55 | 86.77 | 87.19 | 88.8 |



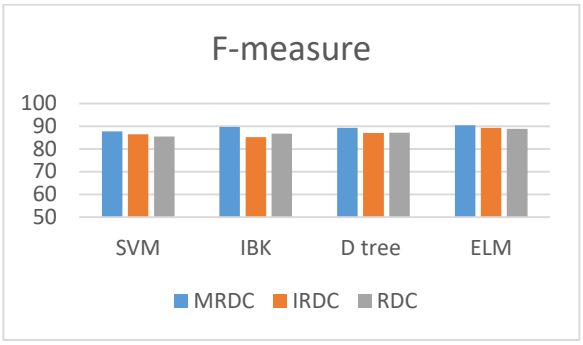
(a)



(b)



(c)



(d)

Fig. 4. Results of proposed MRDC feature selection technique for the Reuters21578 dataset.

Recall of proposed MRDC technique (87.80%, 89.68%, 89.26%, and 90.36%) for SVM, IBK, Decision Tree, and ELM which is higher than those of IRDC (85.53%, 85.13%, 88.87%, and 88.82%) and RDC (85.83%, 87.57%, 87.39%, and 89.59%) respectively. It is evaluated that the recall of the proposed MRDC feature selection technique is accurate and significant compared to existing techniques.

Regarding F-Measure scores for SVM, IBK, Decision Tree, and ELM, the proposed MRDC routinely outperforms IRDC and RDC. MRDC performs better than RDC (85.55% to 88.80%) and IRDC (86.51% to 89.32%). This demonstrates MRDC's dominance in achieving a balanced trade-off between recall and precision.

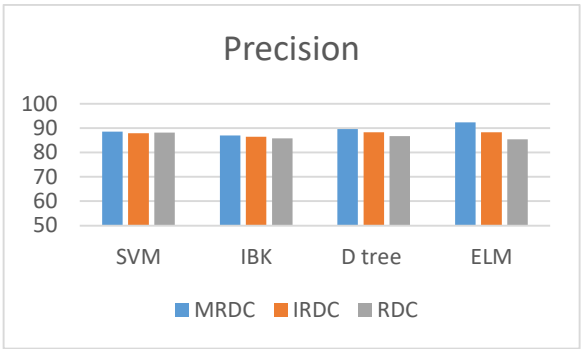
### B. *Results of 20 Newsgroup Datasets for Feature Selection Techniques*

The result of the 20newsgroup text dataset for the proposed MRDC and existing RDC, IRDC feature selection technique with various classifiers (SVM, IBK, Decision Tree, ELM) is demonstrated in this section, shown in Table II.

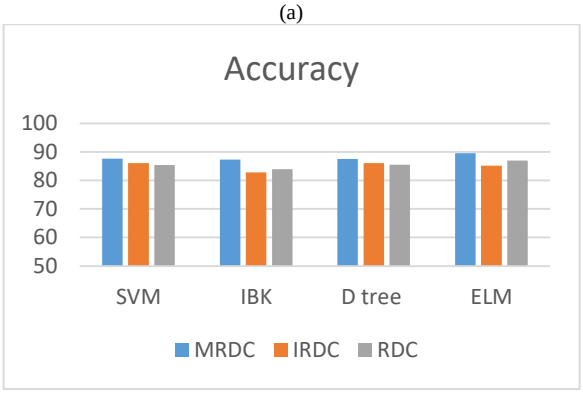
TABLE II. RESULTS OF PROPOSED MRDC FEATURE SELECTION TECHNIQUE FOR 20NEWSGROUP DATASET

| Classifier | | SVM | IBK | D tree | ELM |
|---|---|---|---|---|---|
| MRDC (%) | Pre | 88.57 | 86.92 | 89.66 | 92.32 |
| | Acc | 87.65 | 87.28 | 87.5 | 89.5 |
| | Rec | 89.45 | 86.78 | 88.89 | 90.02 |
| | F M | 89.01 | 86.85 | 89.27 | 91.15 |
| IRDC (%) | Pre | 87.93 | 86.41 | 88.33 | 88.33 |
| | Acc | 86 | 82.77 | 86 | 85.11 |
| | Rec | 87.93 | 83.61 | 88.33 | 87.04 |
| | F M | 87.93 | 84.99 | 88.33 | 87.68 |
| RDC (%) | Pre | 88.21 | 85.83 | 86.71 | 85.47 |
| | Acc | 85.4 | 83.89 | 85.53 | 87 |
| | Rec | 86.71 | 87.31 | 88.06 | 89.37 |
| | F M | 87.46 | 86.56 | 87.38 | 87.38 |

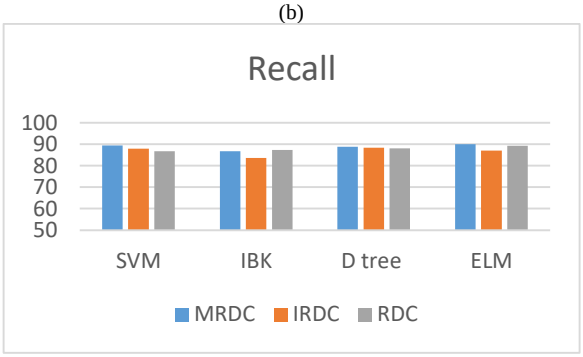
The analysis of the suggested MRDC's performance for 20 newsgroup datasets uses F-measure, precision, accuracy, and recall. Experimenting with MRDC methodologies, which yield superior outcomes than the current feature ranking methods, RDC, and IRDC.



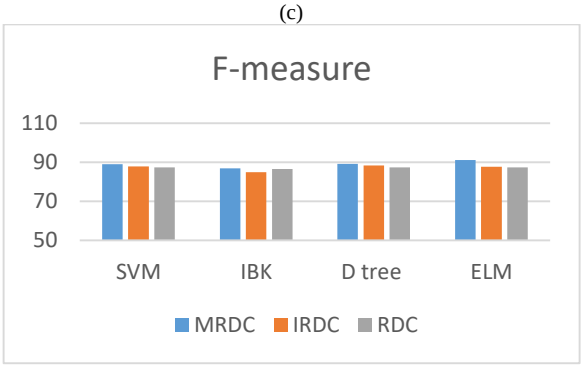
(a)



(b)



(c)



(d)

Fig. 5. Results of the proposed MRDC feature selection technique for 20 newsgroup dataset.

When the 20newsgroup dataset was tested using the various classifiers displayed in Table II, the proposed MRDC outperformed the current IRDC and RDC methods. In Fig. 5 (a), MRDC outperformed IRDC (87.93%, 86.41%, 88.33%,

and 88.33%) and RDC (88.21%, 85.83%, 86.71%, and 85.47%) in terms of precision (85.57%, 86.92%, 89.66%, and 92.32%).

The accuracy results for the machine learning models (SVM, IBK, Decision Tree, and ELM) in Fig. 5(b) shows that the MRDC performs better than the alternative methods. The accuracy values for RDC are 85.40%, 83.89%, 85.53%, and 89.00%, MRDC is 87.65%, 87.28%, 87.50%, and 89.50%, and IRDC is 86.00%, 82.77%, 86.00%, and 85.11%. MRDC is shown to have a high score and to produce better outcomes than earlier methods that were tested on SVM, IBK, Decision Tree, and ELM. Additionally, the results indicate that MRDC is compatible with the ELM classifier displayed in Fig. 5 and Table II.

These results suggest that the proposed MRDC technique outperforms the other two feature selection techniques in terms of prediction accuracy and dependability. Fig. 5(c) illustrates that the recall for MRDC is 89.45%, 86.78%, 88.89%, and 90.02%, which is superior to that of IRDC, which ranges from 87.93% to 87.04%, and RDC, which ranges from 86.71% to 89.37%. Furthermore, as shown in Fig. 5(d), the MRDC feature selection technique's F-measure (89.01%, 86.85%, 89.27%, and 91.15%) is significant compared to the IRDC, which ranges from 87.93% to 87.04%) and the RDC, which ranges from 87.46% to 87.38%).

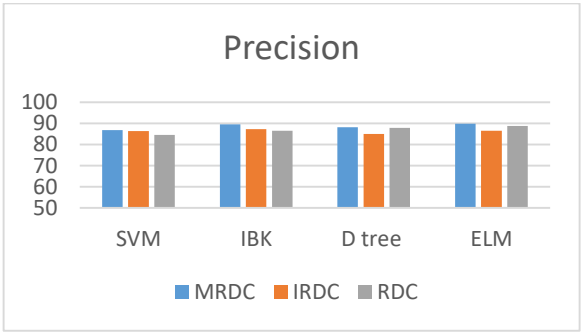
### C. Results of the TDT2 Dataset for Feature Selection Techniques

Another text dataset, TDT2, is used for feature selection techniques, MRDC, IRDC, and RDC. Results of the above-mentioned techniques are compared with each other and verified by well-known classifiers, SVM, IBK, Decision tree, and ELM, which are shown in Table III and Fig. 6.

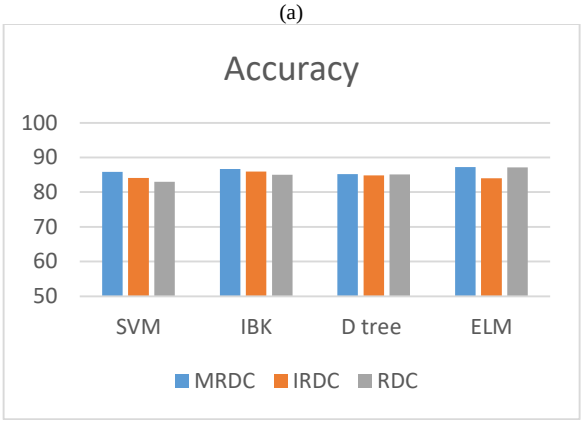
TABLE III. RESULTS OF PROPOSED MRDC FEATURE SELECTION TECHNIQUE FOR TDT-2 DATASET

| Classifier | | SVM | IBK | D tree | ELM |
|---|---|---|---|---|---|
| MRDC (%) | Pre | 86.81 | 89.5 | 88.14 | 89.93 |
| | Acc | 85.9 | 86.65 | 85.18 | 87.25 |
| | Rec | 88.79 | 87.76 | 89.2 | 90 |
| | F M | 87.79 | 88.62 | 88.67 | 89.97 |
| IRDC (%) | Pre | 86.4 | 87.26 | 85.08 | 86.6 |
| | Acc | 84.12 | 85.91 | 84.8 | 84.01 |
| | Rec | 86.81 | 89.02 | 87.57 | 86.9 |
| | F M | 86.6 | 88.13 | 86.31 | 86.31 |
| RDC (%) | Pre | 84.6 | 86.53 | 87.93 | 88.83 |
| | Acc | 83 | 85.02 | 85.1 | 87.16 |
| | Rec | 86.36 | 86.31 | 87.5 | 89.08 |
| | F M | 85.47 | 86.42 | 87.72 | 88.95 |

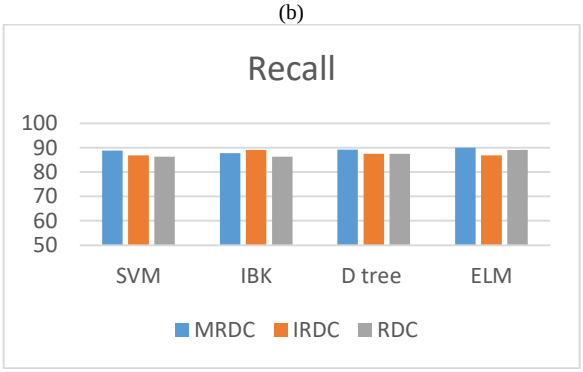
MRDC outperforms IRDC and RDC approaches in terms of precision values when measuring the outcome. The precision scores of the classifiers SVM, IBK, Decision Tree, and ELM in MRDC are 86.81%, 89.50%, 88.14%, and 89.93%, respectively. These values are higher than those of IRDC (86.40% to 86.60%) and RDC (84.60% to 88.83%), as illustrated in Fig. 6(a). The accuracy of MRDC is consistently higher than that of the current IRDC and RDC feature selection methods in Fig. 6(b) across SVM, IBK, Decision Tree, and ELM models. For SVM, IBK, Decision Tree, and ELM classifiers, the MRDC technique performs better, with values ranging from 85.90%, 86.65%, 85.18%, and 87.25 percent, respectively, whereas IRDC and RDC had values ranging from 84.12% to 84.01% and 87.00% to 87.16%, respectively.



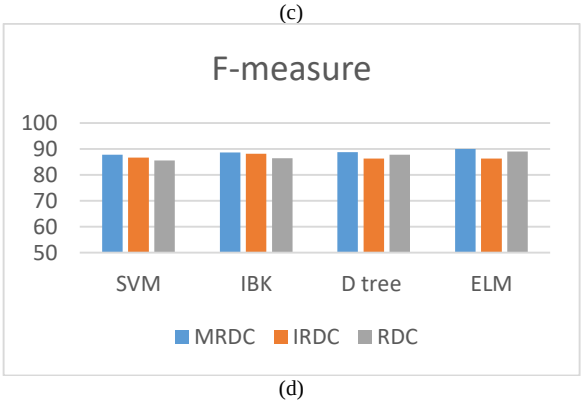
(a)



(b)



(c)



(d)

Fig. 6. Results of proposed MRDC feature selection technique for TDT-2 dataset.

Regarding recall metrics, SVM, IBK, Decision Tree, and ELM models similarly outperform MRDC. As illustrated in Fig. 6(c), the MRDC values for the SVM, IBK, Decision Tree, and ELM classifier models range from 87.79% to 87.76%, 89.20% to 90.00%, respectively, and are superior to the IRDC and RDC, which range from 86.81% to 86.90% and RDC (85.47% to 88.95%), respectively.

Fig. 6(d) shows that MRDC performed better than the classifiers mentioned earlier. The suggested MRDC feature selection method yielded significant results (87.79%, 88.62%, 88.67%, and 89.97%), outperforming SVM, IBK, and decision trees. The F measure is also computed for MRDC, IRDC, and RDC feature selection strategies.

## VI. The Proposed RSS-ELM Optimization Technique

The experiment is conducted on three different optimization techniques, which are RSS-ELM, GA-ELM, and CS-ELM. The proposed RSS-ELM optimization technique is compared with GA-ELM and CS-ELM techniques with three text datasets such as reuter21578, 20newsgroup and TDT2. To evaluate these results, various evaluation metrics are used (Accuracy, Precision, Recall, F-measure).

### *A. Results of the Reuter21578 Dataset for Proposed RSS-ELM Techniques*

In this section, the result of the reuter21578 text dataset for the proposed RSS-ELM and existing GA-ELM and CS-ELM optimization techniques is shown in Table IV and Fig. 7.

TABLE IV. Results on Proposed RSS-ELM Optimization Technique for Reuters21578-Dataset

| Algorithm | Precision | Accuracy | Recall | F Measure |
|---|---|---|---|---|
| RSS-ELM | 99.1 | 98.9 | 98.7 | 98.9 |
| CS-ELM | 67 | 66 | 66 | 66 |
| GA-ELM | 58 | 60 | 59 | 58 |

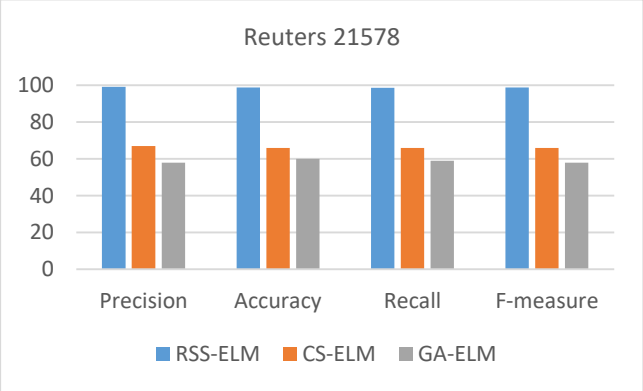


Fig. 7. Results on proposed RSS-ELM optimization technique for Reuters 21578-dataset.

Performance of RSS-ELM, CS-ELM, and GA-ELM optimization techniques is evaluated for the Reuters21578 text dataset. The results revealed that RSS-ELM technique performed better than other existing techniques, achieving the highest precision (99.1%) for RSS-ELM than CS-ELM (67%) and GA-ELM (58%). Furthermore, CS-ELM and GA-ELM improved by 66% and 60%, respectively, while the RSS-ELM technique reached a noteworthy accuracy of 98.9%. This demonstrates its excellent capacity to recognize pertinent facts and generate precise forecasts. Additionally, the RSS-ELM technique demonstrated the highest recall (98.9%), demonstrating its ability to capture relevant data, whereas CS-ELM and GA-ELM received 66% and 59%, respectively.

Furthermore, it's F-measure of 98.9%, in conjunction with CS-ELM (66%) and GA-ELM (58%), demonstrates a noteworthy performance. On the other hand, CS-ELM and GA-ELM produced lower values for every metric, indicating that they performed worse in this task. These results show that RSS-ELM is the best option for this dataset, highlighting its potential use in practical applications where data categorization accuracy and precision are essential.

### *B. Results of 20newsgroup Dataset for Proposed RSS-ELM Techniques*

Experiments of proposed RSS-ELM and existing GA-ELM, CS-ELM optimization techniques conducted in another 20newsgroup text dataset. These experiments are also conducted in the Python language. Four evaluation metrics (Precision, Accuracy, Recall, and F-measure) are used to verify these significant results. Detailed results are presented in Table V and Fig. 6.

TABLE V. Results on Proposed RSS-ELM Optimization Technique for 20Newsgroup Dataset

| Algorithm | Precision | Accuracy | Recall | F-Measure |
|---|---|---|---|---|
| **RSS-ELM** | 96 | 97.2 | 97 | 97 |
| **CS-ELM** | 78 | 77 | 77 | 76 |
| **GA-ELM** | 79 | 78 | 78 | 79 |

The proposed RSS-ELM outperforms other optimization methods like CS-ELM (78%) and GA-ELM (79.0%) in terms of precision (96%). Additionally, the suggested RSS-ELM obtained 97.2% accuracy, but CS-ELM and GA-ELM improved by 77% and 78%, respectively. While the CS-ELM generated Recall (77%) and F-measure (76%), and the GA-ELM produced Recall 78% and F-Measure 79%, the RSS-ELM underperforms in both Recall (97%) and F-Measure (97%), as presented in Fig. 8 and Table V. Compared to other optimization methods, the suggested RSS-ELM performance is superior.

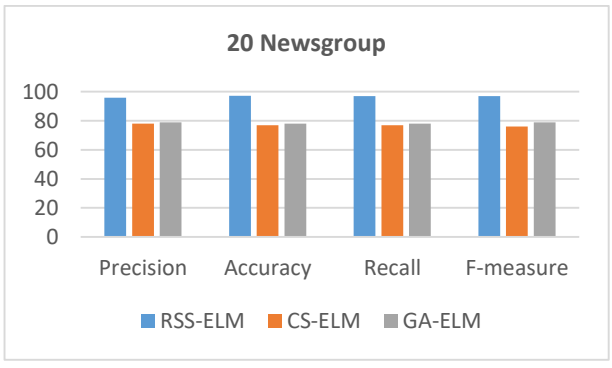

Fig. 8. Results of proposed RSS-ELM optimization technique for 20 newsgroup dataset.

### C. Results of the TDT2 Dataset for Proposed RSS-ELM Techniques

Another text dataset is utilized for experiments of the proposed RSS-ELM and existing GA-ELM, CS-ELM techniques shown in Table VI and Fig. 9.

TABLE VI. RESULTS ON PROPOSED RSS-ELM OPTIMIZATION TECHNIQUE FOR TDT2 DATASET

| Algorithm | Precision | Accuracy | Recall | F-measure |
|---|---|---|---|---|
| **RSS-ELM** | 97 | 97.5 | 97 | 97 |
| **CS-ELM** | 62 | 64 | 65 | 62 |
| **GA-ELM** | 59 | 58 | 58 | 58 |

Three optimization techniques—RSS-ELM, CS-ELM, and GA-ELM—were evaluated for performance in our study using the TDT-2 dataset. According to the results, RSS-ELM performed better than CS-ELM and GA-ELM, producing 62% and 59% of the total, respectively, with the highest precision (97%). The suggested RSS-ELM optimization method outperformed the current CS-ELM and GA-ELM (64%, 58%), with a noteworthy accuracy of 97.5%, demonstrating its capacity to identify pertinent data and generate accurate forecasts precisely.

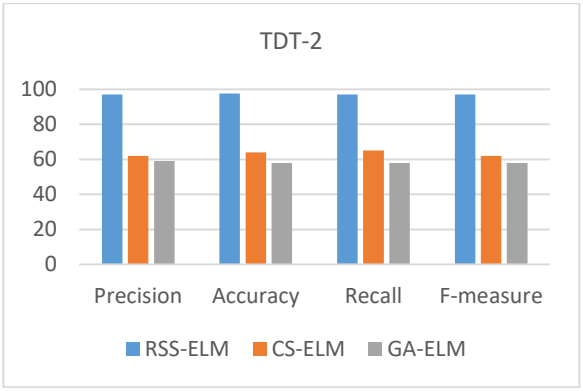

Fig. 9. Results on proposed RSS-ELM optimization technique for TDT2 dataset.

In comparison to CS-ELM and GA-ELM (65%, 58%), it also demonstrated a respectable recall of RSS-ELM (97%), demonstrating its efficacy in capturing a significant amount of relevant information. Additionally, the 97% F-measure demonstrates that RSS-ELM achieved an impressive balance between recall and precision, making it a reliable option for data categorization tasks. However, CS-ELM and GA-ELM displayed lower values for all measures (62%, 58%), indicating that they performed less well on this specific dataset. These results highlight the potential usefulness of RSS-ELM in applications that need to classify data using the TDT-2 dataset with both accuracy and precision.

## VII. CONCLUSION

The limitations of existing feature ranking and classification techniques for high-dimensional text data are highlighted in this work. This work proposes MRDC, a dependable feature selection strategy for balanced and unbalanced text datasets. Common and uncommon terms should be considered when choosing features to normalize terms for improved categorization. The proposed MRDC method outperforms RDC and IRDC methods in classification by effectively selecting the best characteristics. To make feature ranking research more dependable and simpler, phrase count might be used to modify future studies. Furthermore, RSS-ELM for optimization is an additional contribution. Compared to GA-ELM and CS-ELM, the suggested RSS-ELM technique is important for parameter optimization in two-way state finding.

Additionally, RSS optimizes ELM with fewer parameters. Furthermore, RSS-ELM exhibits superior performance in terms of F-measure, recall, accuracy, and precision. The RSS approach can optimize several kinds of alternative and hybrid walks in optimization. Additionally, RSS can be used to assess alternative classification methods for datasets of text and images. Our proposed technique can have significant real-life applications in diverse contexts, including collaborative enterprises [31].

***Abstract*—Generative adversarial networks (GANs) have gained popularity for their ability to synthesize images from random inputs in deep learning models. One of the notable applications of this technology is the creation of realistic videos known as deepfakes, which have been misused on social media platforms. The difficulty lies in distinguishing these fake videos from real ones with the naked eye, leading to significant concerns. This study proposes a supervised machine learning approach to effectively differentiate between real and counterfeit videos by detecting visual artifacts. To achieve this, two facial features are extracted: eye blinking and nose position, utilizing landmark detection techniques. Both features were trained on supervised machine learning classifiers and evaluated using the publicly available UADFV and Celeb-DF deepfake datasets. The experiments successfully demonstrate that the proposed method achieves a promising and superior performance, with an area under the curve (AUC) of 97% for deepfake detection in contrast to state-of-the-art methods investigating the same datasets.**

***Keywords*—Deepfake; fake videos; facial features; GAN**

## I. Introduction

The current digital age has seen an unprecedented widespread use of smartphones and other such devices, making several social networking platforms popular and part of our daily lives. Statistics show that users upload billions of pictures and videos daily on such platforms. This rise of social networking platforms has also given birth to the intent of manipulating such photos and videos for several reasons, hence the concept of Deepfake.

In recent years, deep learning algorithms such as generative adversarial networks (GANs) have been able to generate fake videos and manipulate digital media semantics. In this process, two deep learning models are created, which are pitched against each other to compete. One of these models is trained on real data and then tries to create fake images. On the other hand, the other model tries to differentiate the real images from the fake ones. The model that creates fake images keeps improving and improving to such an extent that it becomes impossible for the other model to differentiate the real images from the fake ones. Algorithms like Face2Face and Deepfake availability on the internet make the propagation of digital videos more convenient. The convenience brought ease in spreading the synthesized videos on social platforms [1].

Generative models have many applications, such as image translation tasks, generating speech with manipulated fake faces, and forging a new identity that did not exist before. The inappropriate use of deepfakes on social media is alarming for the public, whether the propagated videos are trustworthy or not. Deepfake videos commonly affect public figures (celebrities, politicians), causing security and privacy threats. Generated Deep-fake is manipulated in various ways, i.e., using specific individual attributes, swapping a complete face, manipulating facial expressions, and generating a new identity face [2] in deepfake videos.

Presently, the detection method for deepfakes relies on identifying artifacts [2], such as lip synchronization with speech [3], color inconsistencies, and the unnatural representation of eye blinks, which is less compared to natural blinks [4]. The frequency of eye blinks in humans varies according to age and gender, whereas an average adult human blinks between 2 and 10 times per second [5].

Deepfake problems are generally deemed a binary classification, where the original video is classified as real and manipulated as fake. Other methods might use classifiers such as partially fake, in which a video of multiple individuals is produced, and only one person's face is altered. Previously, the detection work dealt with hand-crafted features and extraction to explore artifacts and inconsistencies. Simultaneously, current methods utilize automatic techniques to discriminate between natural and synthesized Deepfake videos.

## II. Related Work

Digital manipulation of faces in images, commonly referred to as identity swap, has become increasingly prevalent due to advancements in computer graphics and deep learning

*Corresponding Author.

techniques. Significant progress has been made since the emergence of initial deepfake databases like UADFV in 2018 and more recent ones such as Celeb-DF in 2020. As a result, detecting fake videos has become more challenging, as they appear increasingly realistic.

Researchers have developed various methods for detecting deepfake videos. Detection techniques have also advanced with the improvement of the quality of fake images and videos. Table I summarizes some of the most noteworthy research in this field. While the evaluation parameters are presented in the table, it's important to note that using different evaluation metrics complicates the comparison of these methods.

Recent advances in AI and deep learning have led to the creation and proliferation of fake digital content, including fake footage, images, audios, and videos [6]. In recent years, several machine learning-based tools have made it relatively easy to create realistic face swap videos called deepfakes [7]. These deepfakes are modern self-manipulation methods that allow users to swap identities in a single video. This negative side of machine learning is creating new challenges for the general population, as people with bad intentions alter the truth and compromise people's trust. Literature review shows that current solutions to tackle the problem lack the ability to identify the source of such fake digital media. One of the most widely used biometric authentication methods is fingerprints, which are now used in smartphones, tablets, and laptops. However, this authentication method can be easily faked [8]. A statistical feature extraction and comparative analysis method is used to determine the best features.

The study in [9] proposed a framework in which they extract features from CCTV cameras at runtime using spatial and temporal domains and build a robust and discriminative feature rendering of each sequence. In their methodology, the first phase, they are using a multi-loss function to increase inter-class variance and reduce intra-class difference. In the next phase, features are aggregated frame-wise, and temporal information is extracted from videos. In the last stage, weighted coefficients are combined, and the appearance description of the pedestrian is acquired. Interestingly, although the compression ratio used during training differs from that used for the test videos, the detector performs excellently on compressed videos.

In study [10], the authors examine methods based on GAN discriminators to detect Deepfake videos. They trained a GAN and extracted the discriminator as a standalone module to identify Deepfakes using MesoNet as a benchmark. They tested

various discriminator designs on various datasets to see how the discriminator's efficacy differs depending on the setting and training approach. Using ensemble approaches, they presented a methodology to improve the efficacy of a cluster of GAN discriminators. These findings reveal that GAN discriminators do not function well enough on videos from unverified sources, even when enhanced with ensemble approaches.

Li et al. [11] presented a deep-neural network (DNN) scheme to expose Deepfake videos. Physiological signals, such as eye blinks, are not well explained in the generated Deepfake videos. Blinking refers to the eye's open-close-open movement, which varies in humans according to age and gender. The Deepfake videos usually carry fewer indications of the natural blinking pattern than the original blinks. The authors trained VGG16 with a long-short-term memory (LSTM) recurrent neural network (RNN) on the dataset having an open eye state. However, no dataset has been adequately designed to detect this feature; therefore, samples have been taken from the CEW (Closed Eye in a Wild dataset) and EBV (Eye Blink Video). The authors further investigate DNN to detect artifacts. The idea behind identifying artifacts was that the recent Deepfake algorithms produce low-resolution and limited-quality images, which leave some distinctive artifacts when mapped back to the source video. They applied Dlib models that are used to detect the facial landmarks of a person's face. In case of multiple resolution cases, the face is aligned and smoothened by applying a Gaussian blur, and the face image is then mapped with Affine Wrap to simulate the artifacts. The CNN model was trained to detect the existence of artifacts in the face region and surroundings. The presented model was compared with the four states of the models, VGG16, ResNet50, ResNet101, and ResNet152. The model tested over UADFV and Deepfake TIMIT databases shows promising results regarding these databases' state-of-the-art features. A study in [2] surveyed the face manipulation techniques and artifacts. They proposed a methodology to identify artifacts like eye color, reflection, and missing details in teeth formation and eye area. In this regard, they have proposed a novel approach using Bi-granularity artifacts (BiG-Arts).

Yang et al. [12] presented a scheme to detect Deepfakes through head movement. The Deepfake images are created by interlacing fake face images with the actual image, and while doing so, the process leaves artifacts in the 3D head position. Analyzing 3D head estimation and inconsistency, classification can be performed to detect the modification. They proposed an SVM classifier, and the results were evaluated for each UADFV dataset. The offered method was evaluated using the frames of UADFV. Hsu et al. [13] presented a common fake feature network (CFFN) model alongside pairwise learning to detect Deepfake. A two-phase procedure was followed for feature extraction. CFFN used Siamese architecture, and classification was performed through CNN.

Another study in [14] presented an optical flow scheme based on a convolutional neural network (CNN). The proposed approaches detect the Deepfake on a single video frame, where the optical flow approach catches the inter-frame dissimilarities. An experiment is performed on VGG16 and ResNet50, and results are tested over the Face-Forensic++ dataset, showing promising performance. Likewise, a study in [15] detects artifacts' presence among real and Deepfake by examining the GAN pipeline. The proposed detection scheme chooses color feature as a detection parameter and a pre-trained machine learning SVM classifier. The method achieved 70% accuracy when evaluated over a dataset named NIST MFC2018.

The classical deepfake detection methods use a convolutional neural network (CNN) to detect real or fake images based on a dataset of still images. They are unable to perform the detection of videos. Results show that sequential features can be quite crucial for detecting deepfake videos, as some of these features can be detected in videos only, e.g., it has been observed that in deepfake videos, the eye blink rate is much lower than in real videos [14]. Fig. 1 shows the taxonomy of various methods, techniques, and classifications applied to deepfake detection methods.

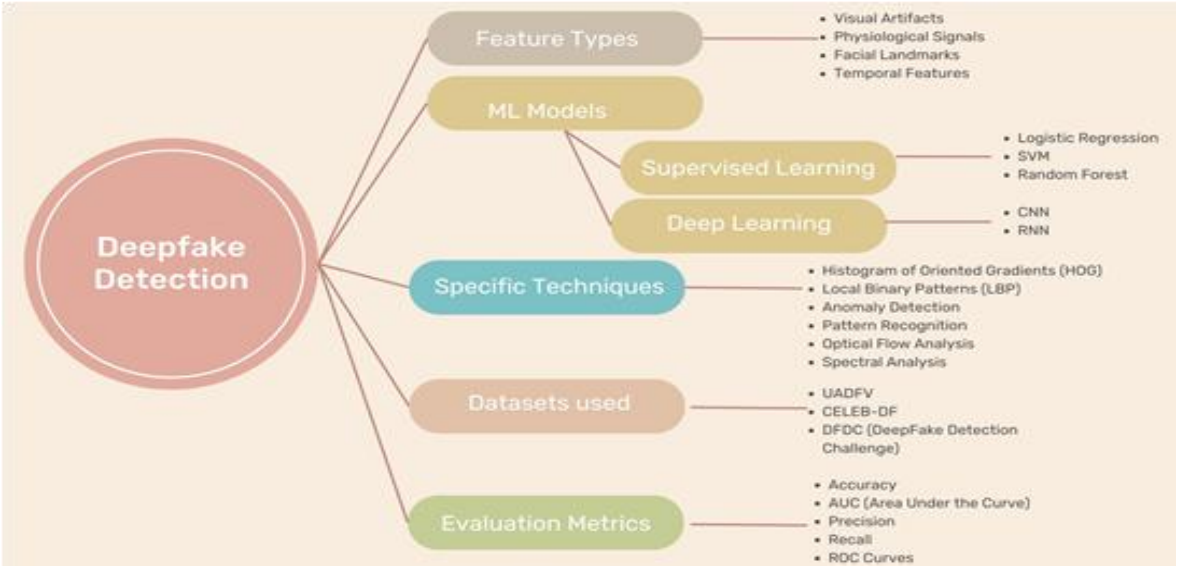

Fig. 1. Classification of deepfake detection methods.

Whereas Table II classifies and summarizes state-of-the-art methods and approaches in a hierarchical manner. Starting with main categories, that includes the feature set, followed by machine learning models and techniques, dataset used, and evaluation metrics applied. In the second column it segregates the subtypes of each category and consequently the description of each category.

| Main Category | Subcategory | Description |
|---|---|---|
| Feature Types | Visual Artifacts [1], [4], [16] | Color Inconsistencies: Abnormal color dissimilarities or mismatches in different areas of the face. |
| | | Blurring and Boundaries: Blurred edges around the face or other areas of the image where the forged overlay blends with the real background. |
| | | Texture and Lighting: Variations in texture and lighting that do not match the neighbouring context. |
| | Physiological Signals [10], [12], [17], [18] | Eye Blinking: Abnormal blinking patterns that are either too frequent or too infrequent as compared to natural human behaviour. |
| | | Lip Sync: Reduced synchronization between lip movements and the audio, demonstrating that the speech may be dubbed or artificially generated. |
| | | Head Movements: Unnatural head movements that do not align with the rest of the body or the environment. |
| | Facial Landmarks [19]–[21] | Facial Expression Analysis: Analyzing irregularities in facial expressions, which might not align logically. |
| | | Landmark Deformation: Distortions in the placement of facial landmarks such as eyes, nose, and mouth during various expressions or movements. |
| | Temporal Features [21], [22] | Frame-to-Frame Consistency: Checking for irregularities across successive frames of a video that may show fiddling. |
| | | Optical Flow: Analyzing the motion patterns in video sequences to identify irregularities. |
| Machine Learning Models | Supervised Learning [16], [22] | Logistic Regression: A simple, binary classification algorithm used for initial investigation. |
| | | Support Vector Machines (SVM): Effective for high-dimensional data. |
| | | Random Forests: An ensemble learning method that combines several decision trees for enhanced accuracy. |
| | Deep Learning [16], [20] | Convolutional Neural Networks (CNNs): Excellent for extracting spatial features from images and videos. |
| | | Recurrent Neural Networks (RNNs): Appropriate for capturing sequential dependencies in video sequences. |
| | | Capsule Networks: Capture spatial hierarchies and relationships. |
| | | Attention Mechanisms: Focus on the most pertinent parts of the input data. |
| | Hybrid Models[23] | CNN + RNN: Combining spatial and temporal features for a detailed analysis. |
| | | Ensemble Methods: Using multiple models to augment detection performance by using their combined strengths. |
| Specific Techniques | Handcrafted Feature Extraction [24] | Histogram of Oriented Gradients (HOG): Detecting particular facial features by examining gradients and orientations in the image. |
| | | Local Binary Patterns (LBP): Analyzing texture by associating each pixel with its neighbors. |
| | Deep Learning-Based Extraction [25] | Pre-trained Networks: Utilizing networks like VGG16, ResNet, which have been pre-trained on large datasets, for feature extraction. |
| | | GAN Discriminators: Using the discriminator component of GANs to identify fake content. |
| | Statistical Analysis [26] | Anomaly Detection: Identifying outliers in facial features and movements that do not follow the likely patterns. |
| | | Pattern Recognition: Identifying and analyzing particular patterns in physiological signals and visual artifacts. |
| | Signal Processing [26] | Optical Flow Analysis: Identifying motion discrepancies within the video. |
| | | Spectral Analysis: Analyzing frequency components of facial movements to distinguish anomalies. |
| Datasets Used | Publicly Available Datasets [27] | UADFV: Contains real and fake videos specifically created for deepfake detection research. |
| | | Celeb-DF: A large-scale dataset with high-quality deepfake videos. |
| | | DFDC (DeepFake Detection Challenge): A diverse dataset from the DeepFake Detection Challenge, containing numerous deepfake videos for benchmarking. |
| Evaluation Metrics | Accuracy [28], [29] | The overall percentage of appropriately classified instances (both real and fake). |
| | AUC (Area Under the Curve) [28] | Measures the capability of the model to differentiate between classes, providing insight into its performance across different thresholds. |
| | Precision and Recall [30] | Precision: The ratio of true positives to predicted positives, demonstrating the accuracy of the positive predictions. |
| | | Recall: The ratio of true positives to actual positives, demonstrating the capability to identify all positive instances. |
| | F1-Score [29] | The harmonic mean of precision and recall, providing a stable measure of the model's performance. |
| | Receiver operating characteristic (ROC) Curves [31] | Receiver Operating Characteristic curves, which visualize the trade-off between true positive rate and false positive rate across different thresholds. |

### A. Contribution

The contribution of this research paper is as follows:

- This research work extracts facial feature eye blink using a real-time blinking method called Eye Aspect Ratio (EAR). To detect the second facial feature, the nose's position, we utilize a pre-trained machine learning Haar cascade classifier with 97% accuracy for efficient detection.
- To counter this recent threat, this research work used a supervised learning method to identify the deepfake videos from the real ones. The results show that the proposed methodology is quite efficient in distinguishing the real videos from the deepfake videos.
- The presented model is evaluated using pre-trained Eye Aspect Ratio (EAR). The proposed scheme detected a blinking ratio of 34.1/ min in real video and 3.4/ min in fake video.

This research paper is organized as follows: Related work is given in Section II. Section III discusses the proposed methodology, Section IV presents the results and discussion, and Section V discusses the conclusion.

## III. Methodology

This section proposes a method to detect Deepfake videos by extracting facial features. Fig. 2 depicts the proposed methodology. Deepfake video detection differs from image detection, as manipulation is carried out frame by frame and contains temporal characteristics. We are using two features to extract the modification:

- Eyeblink.
- Nose position.

Generally, it is observed that individual Deepfake videos show abnormal eye blinking, which is less frequent compared to normal human blinking behavior. An adult human can blink in 2 to 10 seconds, and each blink consumes 0.1 and 0.4 seconds. Every individual has different blink patterns concerning the open and closed state of the eye. Typically, Deepfake methods are trained on images that possess an open eye state, so it is difficult for Deepfake methods to generate synthesized videos with normal blinking behavior. Eyeblink contains temporal dependency and is expected to appear as temporal artifacts across the frame as manipulation is performed over frame-by-frame sequence. A face landmark detector is used in the proposed study to detect the face and the eye's open /closed state using the DLIB model. Face landmarks locate the whole set of feature points of the face, like lips, eyes, nose, and contour, which can be detected from the face area. The eye blink's first feature is calculated by computing the Eye Aspect Ratio (EAR) in each video frame. EAR of the person depends on the eye's landmark locations, and it is a constant value when the person's eye state is opened and falls to 0 when the eye is closed [13].

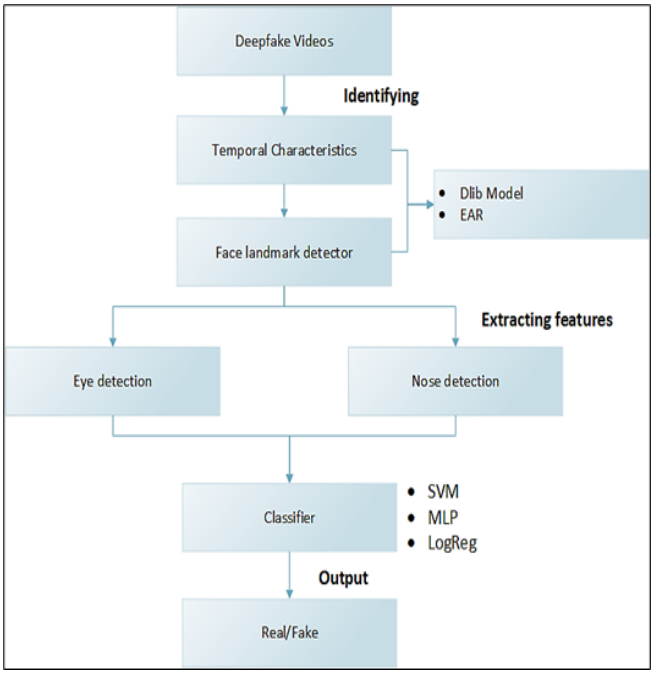

Fig. 2. Proposed methodology.

The following formula calculates EAR:

$$EAR_i = \frac{||\mathcal{P}_2-\mathcal{P}_6||+||\mathcal{P}_3-\mathcal{P}_5||}{2||\mathcal{P}_1-\mathcal{P}_4||} \quad (1)$$

Where $P_i$ (i=1, 2…, 6) are the eye's landmark points, we do not know the deep learning algorithms for eye blink detection. Fig. 3 and Fig. 4 demonstrate the eye blink and nose positions identified in real and fake videos. Overview of the workflow for detecting eye blinks in real and fake videos. The Haar cascade classifier is used for the second feature, i.e., nose; the machine learning approach has rapid detection capability with approximately 95% accuracy. We are using a multiscale Haar cascade Classifier to detect face and nose position in the video stream. We are using the first data set to extract Features, such as UADFV, which contains both real and fake videos. For example, UADFV features the eye blink and nose position extracted from the data set with 98 videos. The dataset collected 49 real and 49 fake videos with 32,752 frames. These videos are generated from the DNN model with FakeApp and are 2 to 44 seconds long, with an average of 11.26 seconds.

Tables III and Table IV describe the UADFV and Celeb-DF datasets, respectively. Moreover, they show the number of videos in each dataset with real and fake counterparts, their average length, and frame rate (frames per second).

TABLE III. Dataset 1 UADFV Specification

| Dataset | Number of videos | Average length | Frames per second |
|---|---|---|---|
| REAL | 49 | 11.26 | 28FPS |
| FAKE | 49 | 11.26 | 28FPS |

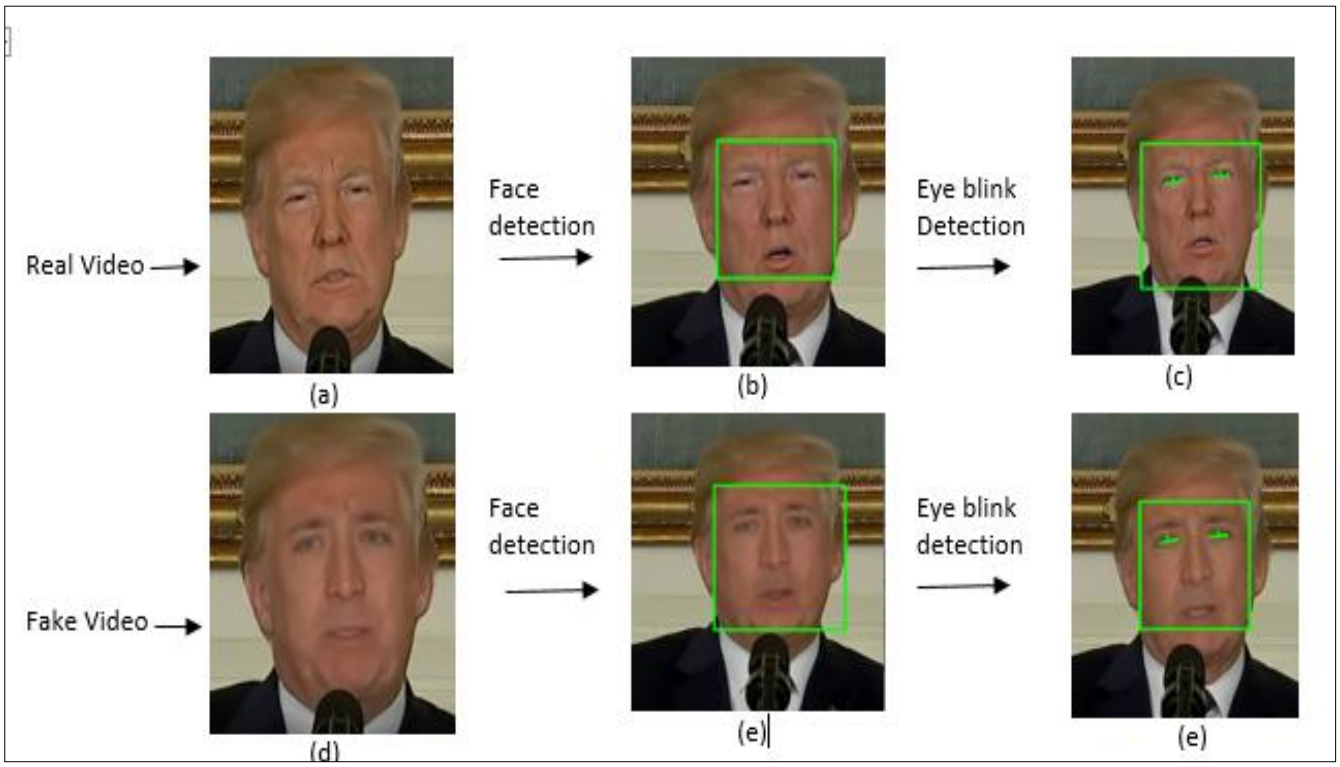

Fig. 3. Overview of workflow detecting eye blink in real and fake videos.

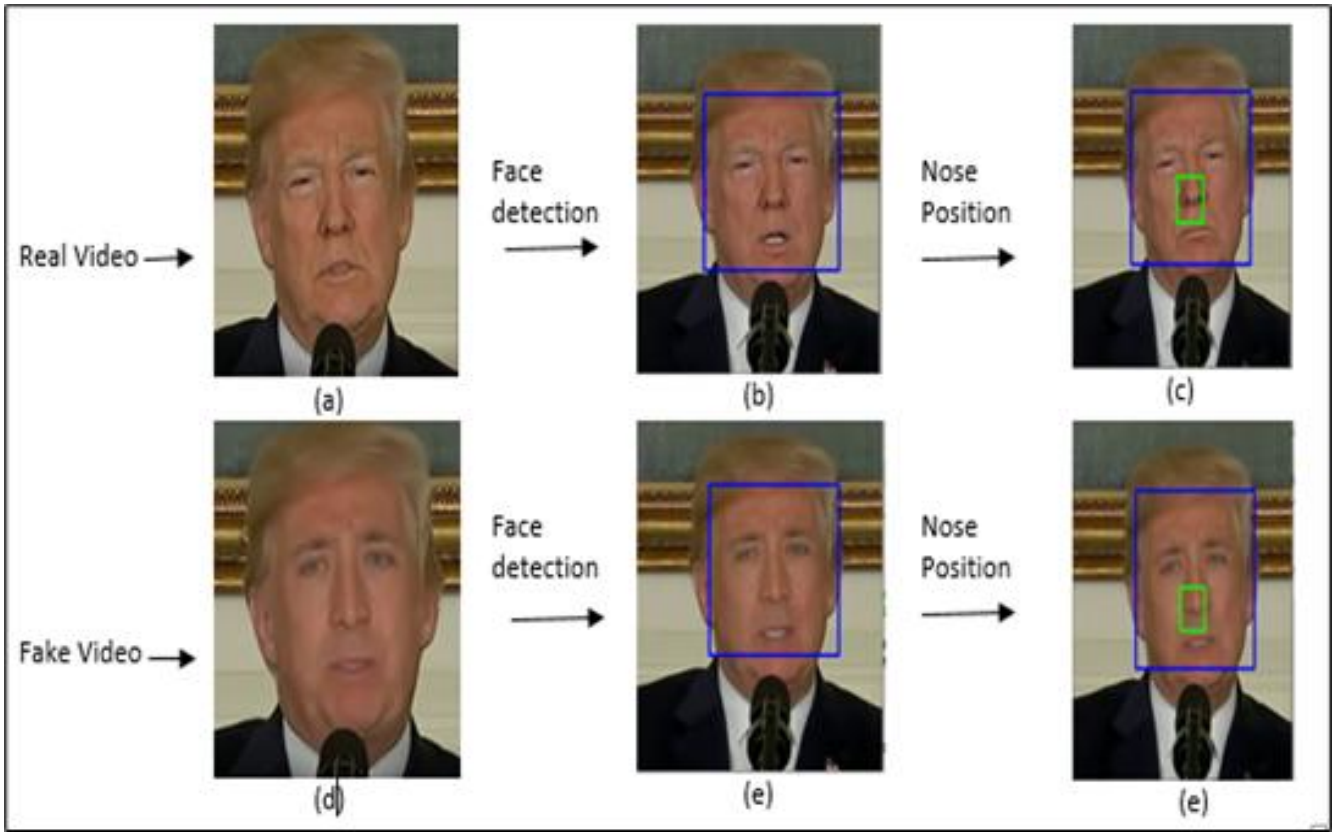

Fig. 4. Overview of workflow detecting nose positions in real and fake videos.

Celeb-DF is a new dataset proposed by Li et al. [14] using refined generating algorithms with improved quality videos and less visible artifacts. The data set used for this experiment is Celeb-DF.

TABLE IV. DATASET 2 CELEBDF SPECIFICATION

| Dataset | Number of videos | Average length | Frame per second |
|---|---|---|---|
| REAL | 408 | 13 sec | 30FPS |
| FAKE | 795 | 13 sec | 30FPS |

For a more in-depth analysis, 50 YouTube-real videos and 50 Celeb-synthesis videos datasets are also considered in addition to the two datasets mentioned above for the performance analysis of classifiers.

## IV. RESULTS AND DISCUSSIONS

The extracted facial features are trained and evaluated on the datasets for three different classifiers. In the next step, a classifier was trained to distinguish between real and fake videos. Fig. 5 shows the receiver operating characteristic (ROC) curve of the proposed classifiers for the proposed feature and classifiers.

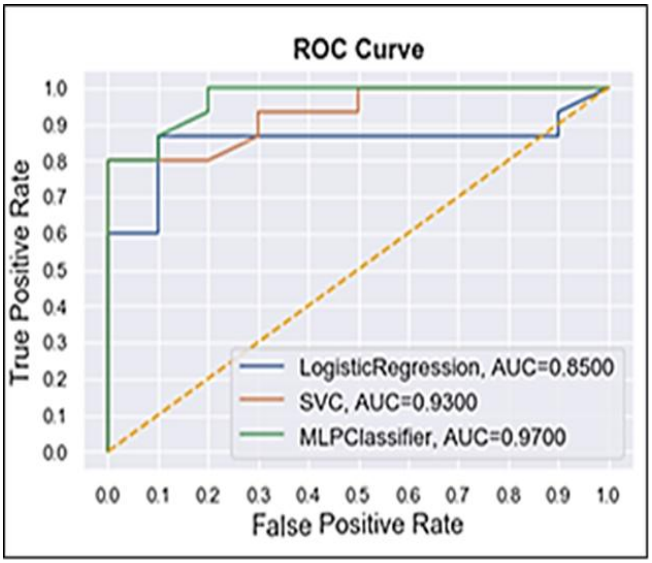

Fig. 5. ROC Comparison for UADFV dataset.

Fig. 6 shows the classification ROC curve analysis on the proposed datasets on extracted facial features for different classifiers. We refer to the supervised machine learning classifiers, SVM, Logistic Regression, and MLP.

The results show in Table V that the classifiers can adequately distinguish between the real and fake sets of videos. The Celeb-DF dataset's performance is low compared to the UADFV because it contains fewer visible artifacts that are difficult to identify. The proposed performance-based method is compared with other methods on the same datasets: UADFV and Celeb-DF.

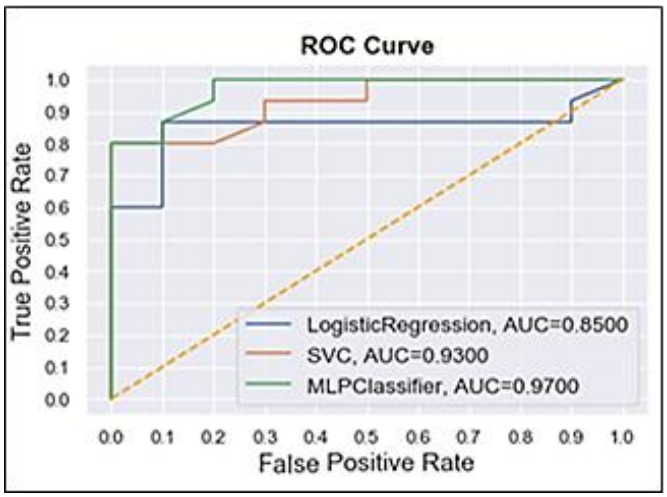

Fig. 6. ROC comparison for CELEBDF dataset.

TABLE V. PERFORMANCE COMPARISON OF MODELS FOR TWO DATASETS

| Methods/Classifiers | UADFV | Celeb-DF |
|---|---|---|
| HeadPose-SVM [1] | 89.0 | 54.8 |
| VA-LogReg | 70.2 | 48.8 |
| VA-MLP [2] | 54.0 | 46.9 |
| FWA-CNN [3] | 97.4 | 53.8 |
| iCaps-Dfake [14] | - | 86% |
| RNN [31] | - | 73.41% |
| Capsule network [5] | - | 57.5% |
| CNN[19] | 84.3 | 54.8 |
| SVM | 93.0 | 64.0 |
| MLP | 97.0 | 75.0 |
| LogReg | 85.0 | 72.0 |

Detection is performed on the feature "Head Pose" [12] using an SVM classifier. The classifiers generated AUC (%) performance of 89.0 on UADFV and 54.8% on the CelebDF dataset. Visual artifacts like eyes, teeth, and facial texture are identified by applying Logistic Regression and MLP. The methods' AUC performances are 70.2% and 48.8% on the datasets, respectively [3]. Face Warping artifacts [11] are classified by using a CNN. The classifiers show the AUC performance of 97.4% for the UADFV dataset and 53.8% for the Celeb-DF dataset. For iCaps-Dfake method [14], performance on Celeb-DF dataset is 86%. For the RNN [31] based classifier, the performance of the Celeb-DF dataset was 73.41%. For the capsule network [5], the performance of the Celeb-DF dataset is 57.5%. For CNN [19], performance on the UADFV dataset is 84.3%, and performance on the Celeb-DF is 54.8%. This research used SVM, MLP, and Logistic Regression, which shows strong performance for deepfake detection on UADFV and Celeb-DF datasets. MLP exhibited the best accuracy among the three methods, i.e., 97% on UADFV and 75% on Celeb-DF. SVM achieved 93% on UADFV and 64% on Celeb-DF. For LogReg, 85% accuracy is achieved on the UADFV dataset and 72% on Celeb-DF.

## V. Conclusion

The proposed method detects fake blinks in the UADFV dataset at a rate of 0.6 per 60 seconds and real blinks at 7.4 per 60 seconds. Similarly, in the Celeb-DF dataset, we observe a rate of 9.8 real blinks and 5.04 fake blinks per minute. Given that the average human blink rate is around 10 blinks per minute, the generated videos fall below this standard. Additionally, we note that the nose position in fake videos from the UADFV dataset deviates from its original position more than in the Celeb-DF dataset. Both features achieve a higher performance with an Area Under the Curve (AUC) of 97% on UADFV and 75% on Celeb-DF. For future work, there are several directions we plan to explore to enhance our current findings. We aim to investigate new deep learning architectures for more effective results. Furthermore, we will continue searching for facial artifacts and other physiological signals often overlooked in synthesized videos.

***Abstract*—The early detection of road defects is critical for maintaining infrastructure quality and ensuring public safety. This research presents a hybrid approach that combines edge detection techniques with an enhanced deep learning model for efficient and accurate road defect classification. The process begins with edge detection to highlight structural irregularities, such as cracks and potholes, by emphasizing critical features in road surface images. These pre-processed images are then fed into a classification model based on MobileNetV3, augmented with an attention mechanism to improve feature weighting and model focus on defect-prone regions. The proposed system was evaluated on a Crack500 dataset of road surface images, achieving a classification accuracy of 96.2%. This demonstrates significant improvement compared to baseline models without edge detection or attention enhancements. The edge detection stage efficiently reduces noise, while the attention-augmented MobileNetV3 ensures robust feature discrimination, making the approach suitable for real-time and resource-constrained deployment scenarios. This study highlights the effectiveness of combining classical image processing with advanced neural network techniques. The proposed system has the potential to optimize road maintenance workflows, operational costs, and improve road safety by enabling early and precise defect identification.**

***Keywords*—Road defect detection; edge detection; attention mechanism; MobileNetV3***

## I. Introduction

Road infrastructure plays a fundamental role in economic development, public safety, and the overall quality of life [1], [2]. Properly maintained roads ensure the smooth flow of goods, services, and people, contributing to societal efficiency and growth. However, road defects such as cracks, potholes, and surface deformities are inevitable due to wear and tear, extreme weather conditions, and high traffic loads [3], [4]. These defects, if not detected and addressed promptly, can escalate, leading to costly repairs, increased accident risks, and disruptions to transportation systems. Consequently, early and accurate detection of road defects is critical to minimize maintenance costs and enhance road safety [5].

Traditionally, road inspections have relied on manual methods or simple imaging systems, which often fall short in terms of accuracy, scalability, and efficiency [6]. Manual inspections are labor-intensive, subjective, and unsuitable for large-scale applications, while basic imaging systems struggle with environmental challenges such as poor lighting, shadow interference, and complex road textures [7]. This has necessitated the development of automated approaches that are not only accurate but also adaptable to real-world conditions [8].

Despite significant progress in computer vision and deep learning, current automated systems still struggle to accurately detect small or subtle defects in complex and dynamic environments. There remains a clear need to develop lightweight and effective models that can maintain high detection accuracy without imposing high computational demands, ensuring their applicability in real-world settings. This study addresses the challenge by investigating how preprocessing techniques, particularly edge detection, can be combined with deep learning models to enhance road defect detection performance. It also explores whether incorporating an attention mechanism into a lightweight model such as MobileNetV3 can improve sensitivity to defect-specific features and overall classification accuracy. Furthermore, the research examines the impact of integrating traditional image processing with deep learning to develop a more robust and reliable detection framework.

The objectives of this work are to design and implement a hybrid methodology that combines edge detection with an attention-augmented MobileNetV3 model, to preprocess road surface images by emphasizing defect-relevant features while minimizing background noise, and to evaluate the proposed framework's performance against existing methods using benchmark datasets.

In this study, Fig. 1 provides a visual representation of various types of road surface cracks, which are critical indicators of pavement deterioration. These include common defects such as longitudinal, transverse, and block cracks, among others. The figure serves to underscore the diverse and complex nature of road defects, which necessitate precise and efficient detection methodologies.

By examining these crack types, the paper establishes the motivation for adopting a hybrid approach that combines edge detection techniques with an attention-augmented MobileNetV3 model [9]. This innovative framework aims to enhance the accuracy and robustness of road defect classification, ensuring timely maintenance and improved infrastructure resilience.

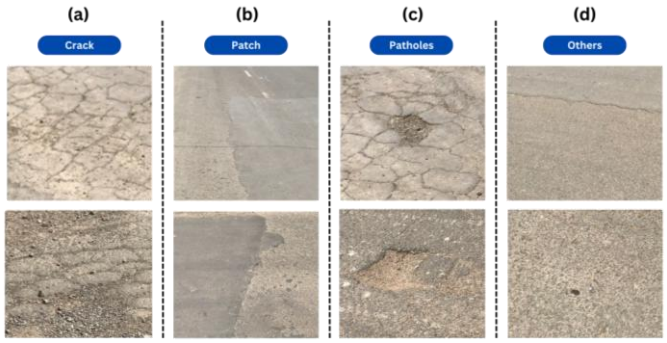

Fig. 1. Illustration of various types of road surface cracks, highlighting the importance of early detection for maintenance and safety.

This paper proposes a hybrid methodology for road defect detection that leverages the strengths of edge detection and a deep learning model enhanced with an attention mechanism. The process begins with edge detection to preprocess road surface images, emphasizing defect-relevant features while reducing background noise and redundant information. These refined images are then input into a MobileNetV3-based neural network, which is augmented with an attention mechanism to improve its focus on critical features. The attention mechanism dynamically prioritizes defect-specific regions in the feature maps, enhancing the model's ability to detect subtle defects such as hairline cracks or small potholes.

The remainder of this paper is organised as follows. Section II provides a detailed overview of related work in road defect detection and highlights the gaps that this study aims to address. Section III describes the proposed methodology, including the integration of edge detection and the MobileNetV3 architecture with attention mechanisms. Section IV discusses the experimental setup, dataset, and performance metrics. It also presents and analyzes the results, while Section V concludes the paper with insights, limitations, and potential directions for future research.

This work aims to contribute to the growing field of automated infrastructure monitoring by providing a practical, scalable, and efficient solution for early road defect detection, which can significantly impact road maintenance strategies and public safety worldwide.

## II. Related Work

Road defect detecting has garnered considerable attention in recent years due to its significance in maintaining infrastructure safety and functionality. A variety of approaches, ranging from traditional image processing methods to cutting-edge deep learning techniques, have been proposed to address the challenges posed by road defect identification in real-world scenarios.

### A. Maintaining the Integrity of Specifications

Traditional computer vision techniques, such as edge detection algorithms, have been widely used for identifying structural discontinuities in road surfaces [10]. Methods like Sobel [11], Canny [12], and Laplacian filters [13] efficiently highlight features such as cracks and potholes by emphasizing abrupt changes in pixel intensity. While computationally efficient, these techniques often lack robustness in noisy environments or under varying lighting conditions. Nonetheless, edge detection remains a valuable preprocessing tool, as it helps reduce noise and isolate defect-prone regions, providing a foundation for more advanced classification models.

### B. Deep Learning in Road Defect Detection

With the advent of deep learning, researchers have shifted focus toward convolutional neural networks (CNNs) for automated defect detection. For instance, the YOLO family of object detection models has shown remarkable capabilities in real-time applications. The RDD-YOLOv5 model integrates a self-attention mechanism to enhance the precision of crack detection, achieving a high mAP of 91.48% [14]. Similarly, BL-YOLOv8, which incorporates BiFPN and LSK-attention, optimizes both accuracy and computational efficiency. By reducing model size and parameter volume, it becomes suitable for deployment in resource-constrained settings [15].

### C. Attention Mechanisms

Attention mechanisms have emerged as a powerful enhancement in deep learning models, enabling them to focus on the most relevant regions of an image. Studies combining attention mechanisms with ensemble learning methods have demonstrated significant improvements in road defect detection. For example, a multi-depth attention mechanism has been successfully employed to prioritize defect-specific features, achieving superior performance across diverse datasets [16].

These mechanisms are particularly effective when integrated into light-weight architectures, such as MobileNet, to improve performance without compromising efficiency.

### D. Transfer Learning and Lightweight Models

Transfer learning has proven to be indispensable for road defect detection, especially in scenarios with limited annotated data. By fine-tuning pre-trained models like MobileNet, researchers can leverage knowledge learned from large-scale datasets to improve defect detection accuracy [17]. MobileNetV3, in particular, has gained attention for its lightweight architecture, making it ideal for real-time applications on mobile and edge devices[18]. Incorporating attention mechanisms into MobileNetV3 further enhances its ability to classify defects, even in challenging conditions with shadows or occlusions.

### E. Hybrid Approaches

Hybrid methodologies that combine traditional image processing with deep learning represent a promising direction in road defect detection. For instance, edge detection can preprocess images to isolate potential defect regions, reducing noise and computational complexity before feeding the images into a CNN [19]. When coupled with attention-augmented architectures, these hybrid approaches strike a balance between efficiency and accuracy. This synergy allows the system to handle subtle defects, such as fine cracks, and more pronounced issues, like large potholes [20].

### F. Recent Surveys and Challenges

Comprehensive surveys have highlighted the current trends and challenges in road defect detection using deep learning. Key issues include the scarcity of large, labeled datasets, variations in environmental conditions, and the trade-off between accuracy

and computational efficiency [21]. To address these, researchers are exploring novel architectures, multi-task learning, and adaptive methods that enhance generalization across diverse road conditions.

## III. METHODOLOGY

This section outlines the research methodology used in this study, focusing on data collection and preprocessing, the hybrid approach involving edge detection and an attention-augmented MobileNetV3 model, training procedures, and evaluation metrics.

### A. Data Description

A diverse dataset of road surface images was compiled to include various defect types, such as cracks, potholes, and surface irregularities, captured under different environmental conditions, including variations in lighting, weather, and road textures. The images were sourced from high-resolution open-access datasets like CRACK500 [22], supplemented with publicly available road damage datasets to enhance the collection. Efforts were made to ensure diversity by accounting for geographical and environmental variations, enabling the model to generalize effectively across different regions and conditions. The dataset was split into training (70%), validation (15%), and testing (15%) subsets to facilitate robust model training and evaluation.

### B. Preprocessing with Edge Detection

Edge detection was applied to preprocess the road surface images, emphasizing defect-related features while reducing irrelevant noise. Popular edge detection algorithms, such as the Canny and Sobel methods, were employed to identify structural discontinuities. Among these, the Canny edge detection algorithm was chosen for its robustness in detecting edges across a wide range of conditions [23], particularly its ability to efficiently handle noise and preserve fine structural details (see Fig. 2).

The Canny algorithm involves several steps, including:

- Gaussian Smoothing: To reduce noise, the image is convolved with a Gaussian filter:

$$G(x,y)=\frac{1}{2\pi\sigma^2}e^{\frac{x^2+y^2}{2\sigma^2}}$$

where σ is the standard deviation of the Gaussian kernel.

- Gradient Magnitude and Direction: The intensity gradients are computed using partial derivatives in the x and y directions (often approximated using Sobel filters):

$$M(x,y)=\sqrt{(G_x^2+G_y^2)}$$

$$\theta(x,y)=\arctan(G_x/G_y)$$

Where $G_x$ and $G_y$ are the gradients in the x and y directions, respectively.

- Non-Maximum Suppression: Thin out edges by suppressing non-maximum gradient values in the direction of the gradient.
- Double Thresholding and Edge Tracking: Apply two threshold values (σ ,T low and T high) to classify pixels as strong edges, weak edges, or non-edges. Weak edges connected to strong edges are retained.

The edge-detected images served as additional input channels or as standalone images for training the deep learning model, depending on the experimental configuration.

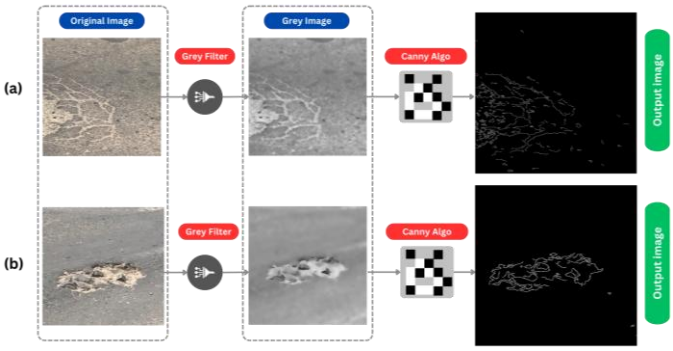

Fig. 2. Image processing workflow: original to grayscale via filter, then edge detectation with the canny algorithm.

### C. Model Architecture

The hybrid approach integrated edge detection with a deep learning architecture based on MobileNetV3 enhanced with an attention mechanism, as shown in Fig. 3.

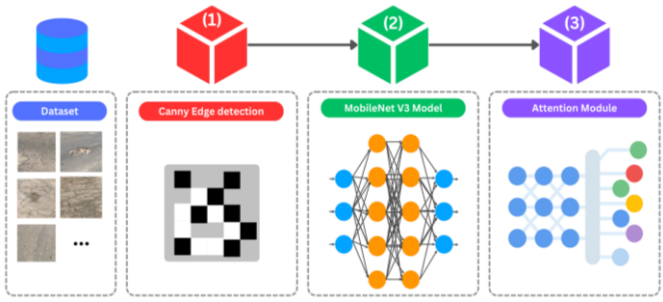

Fig. 3. Summary of the proposed architecture.

MobileNetV3: Selected for its lightweight architecture and efficiency, MobileNetV3 serves as the backbone for defect classification.

Attention Mechanism: An attention module, such as SE-blocks (Squeeze-and-Excitation) or CBAM (Convolutional Block Attention Module), was integrated into the network to dynamically weight critical features, enhancing the model's focus on defect-prone regions.

Input Pipeline: The preprocessed (edge-detected) images were input into the MobileNetV3 model, with the attention mechanism applied at intermediate layers to improve feature representation shown in Fig. 4.

The provided architecture integrates lightweight and efficient design with advanced attention mechanisms to enhance feature learning for crack detection. It employs SE (Squeeze-and-Excitation) blocks [24] to improve channel-level attention by learning channel weights and CBAM (Convolutional Block Attention Module) [25], to refine spatial feature distribution.

The depthwise separable convolutions maintain computational efficiency while expanding the capacity for complex feature learning. Application-specific modifications ensure the receptive field captures both large and small cracks, with attention mechanisms suppressing irrelevant noise and amplifying crack-specific features. This robust pipeline achieves effective classification across four output classes.

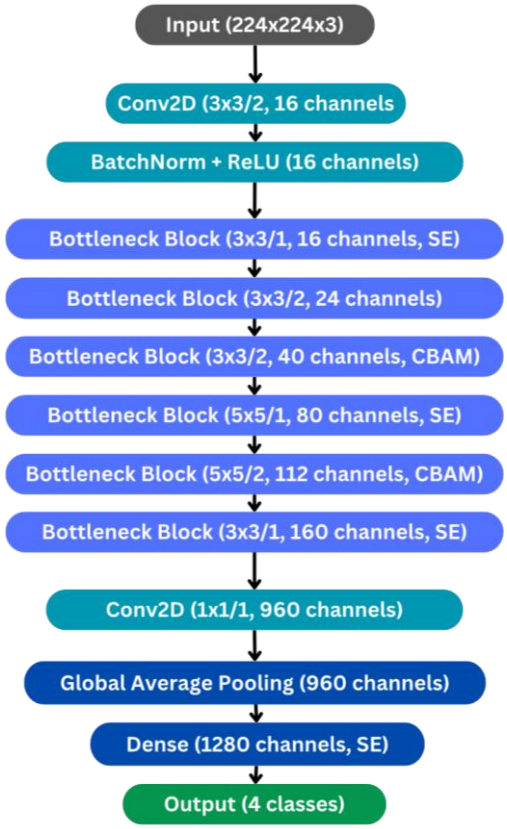

Fig. 4. The main layer architecture proposed for the hybrid MobileNet V3.

### D. Evaluation Metrics

To evaluate the performance of the proposed approach, several metrics were employed, accompanied by their respective mathematical formulations. Accuracy (A) was used to measure the overall correctness of defect classification and is calculated as:

$$A = \frac{TP + TN}{TP + TN + FP + FN}$$

where TP, TN, FP, and FN represent true positives, true negatives, false positives, and false negatives, respectively. Precision (P) and Recall (R) were utilized to assess the model's ability to accurately identify specific defect types. Their formulas are given by:

$$P = \frac{TP}{TP + FP}, \qquad R = \frac{TP}{TP + FN}$$

The F1-Score (F1) was calculated to provide a harmonic mean of precision and recall, expressed as:

$$F1 = 2 . \frac{P . R}{P + R}$$

Finally, Inference Time (Ti) was measured to evaluate the computational efficiency and suitability for real-time applications, defined as the average time taken by the model to process a single input. These metrics collectively offer a comprehensive evaluation of the model's performance.

### E. Comparative Analysis

The proposed hybrid model was benchmarked against a diverse set of approaches to comprehensively evaluate its effectiveness in defect detection. Among the baseline models, standalone MobileNetV3 and traditional edge detection-based techniques were used to establish a fundamental performance comparison. Additionally, the model was evaluated against state-of-the-art approaches, including advanced YOLO-based architectures and other attention-enhanced frameworks that are widely recognized for their robust performance in object detection tasks. The comparative analysis revealed that the integration of edge detection and attention mechanisms provided significant advantages, especially in scenarios where defects were subtle or obscured by complex environmental conditions, such as varying lighting, background clutter, or noise. This underscores the hybrid model's ability to deliver precise and reliable defect detection under challenging real-world conditions.

### F. Experimental Setup

*1) Hardware:* The training and evaluation processes were conducted on a high-performance GPU-accelerated system equipped with an NVIDIA RTX 3080 GPU, ensuring efficient handling of computationally intensive tasks. For additional benchmarking, experiments were also validated on an NVIDIA Tesla V100 to assess scalability and performance consistency across different hardware.

*2) Frameworks:* The hybrid model was implemented and trained using TensorFlow and PyTorch frameworks, chosen for their versatility and compatibility with GPU acceleration. TensorFlow facilitated efficient deployment pipelines, while PyTorch offered dynamic computation graph capabilities, enhancing model prototyping and debugging.

*3) Software tools:* Data preprocessing was carried out using OpenCV for image manipulation tasks, such as resizing, filtering, and edge detection, and NumPy for efficient numerical operations. Visualization of training metrics and results was accomplished with Matplotlib and Seaborn libraries, ensuring clear and interpretable performance analysis.

*4) Dataset configuration:* The dataset was split into training, validation, and test sets in a ratio of 70:20:10. Data augmentation techniques, including random rotation, flipping, and noise injection, were applied to enhance model robustness and mitigate overfitting.

*5) Hyperparameters:* Key hyperparameters were carefully tuned to optimize model performance. The learning rate was set at 0.001 with a decay schedule to ensure gradual convergence. A batch size of 32 was used, balancing memory constraints and training efficiency. The Adam optimizer was employed for gradient updates due to its adaptability and convergence properties.

## IV. Results and Discussion

In Fig. 5. The graphs demonstrate the strong performance of the hybrid model, with both training and validation accuracy rapidly improving to ~96% and stabilizing, while training and validation loss decrease significantly and plateau at low values (~0.2-0.3) by the end of 70 epochs. The minimal gap between training and validation metrics indicates excellent generalization and low overfitting, validating the model's robustness. These trends align with the quantitative results, showcasing high accuracy (96.2%), precision, and recall, as well as efficient inference time (18ms). The integration of edge detection and attention mechanisms clearly enhances feature extraction and model stability, making it well-suited for real-time crack detection tasks.

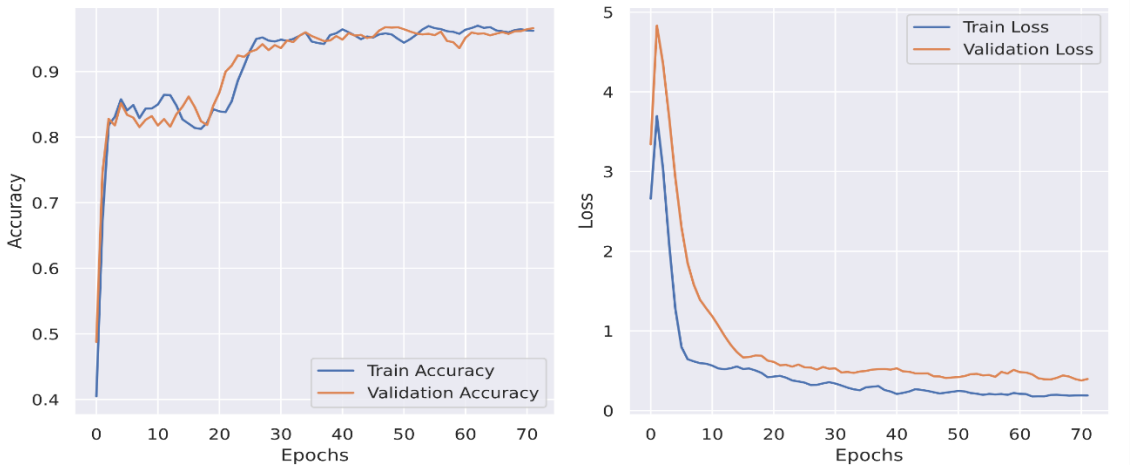

Fig. 5. Training and validation accuracy and loss curve showing 90% accuracy, rapid convergence, trained over 70 epochs.

The results in Table I, clearly highlight the superiority of the proposed hybrid model, which combines edge detection with MobileNetV3 enhanced by an attention mechanism. Achieving an outstanding accuracy of 96.2%, the hybrid model significantly outperforms the standalone MobileNetV3 (90.5%) and YOLOv5-based model (91.48%), demonstrating its ability to classify road defects with a high degree of reliability across various environmental and road conditions. This improved accuracy indicates the hybrid approach's ability to better capture subtle and complex defect features, such as fine cracks and irregular textures, which are often missed by simpler models.

TABLE I. Comparison of Hybrid Model, MobileNetV3, and YOLOv5 on Accuracy, Precision, Recall, F1-Score, and Inference Time

| Metric | Proposed Model (Hybrid) | Standalone MobileNetV3 | YOLOv5-Based Model |
|---|---|---|---|
| Accuracy (%) | **96.2** | 90.5 | 91.48 |
| Precision (%) | **94.8** | 88.9 | 92.1 |
| Recall (%) | **95.6** | 89.2 | 91.3 |
| F1-Score (%) | **95.2** | 89.0 | 91.7 |
| Inference Time (ms) | **18** | 15 | 22 |

In addition to accuracy, the hybrid model excels in other key metrics. Its precision of 94.8% outshines both the MobileNetV3 (88.9%) and YOLOv5-based (92.1%) models, indicating its ability to correctly identify road defects while minimizing false positives. Similarly, the hybrid model's recall of 95.6% demonstrates its effectiveness in detecting the majority of defects in the dataset, outperforming the MobileNetV3 (89.2%) and YOLOv5-based (91.3%) models in reducing false negatives. This balance between precision and recall is further reflected in its F1-score of 95.2%, a critical metric that consolidates both aspects, confirming the model's ability to consistently and effectively detect road defects.

Another important factor in real-time applications like road defect detection is computational efficiency. The hybrid model achieves an inference time of 18ms, slightly higher than MobileNetV3's 15ms, but still well within the range required for real-time deployment and faster than the YOLOv5-based model's 22ms. This result demonstrates the hybrid model's ability to maintain a strong balance between high detection performance and computational efficiency, making it suitable for practical, on-the-fly detection scenarios.

The integration of edge detection and the attention mechanism is central to the hybrid model's success. Edge detection improves feature extraction by focusing on boundaries and structures within images, helping the model better localize and identify defects like cracks and potholes. The attention mechanism, on the other hand, enhances the model's ability to prioritize relevant features in the input data while ignoring irrelevant or noisy information, leading to more robust predictions. Together, these components enhance the overall performance of MobileNetV3, making it significantly more effective compared to the standalone version.

In summary, the hybrid model surpasses both MobileNetV3 and YOLOv5-based models in accuracy, precision, recall, and F1-score, while maintaining competitive inference time suitable for real-time deployment. These results strongly validate the advantages of integrating edge detection and attention mechanisms into the MobileNetV3 architecture, enabling it to handle the diverse and challenging requirements of road defect detection with high reliability and efficiency. This combination of accuracy, generalizability, and computational efficiency positions the hybrid model as a superior solution for practical road defect detection applications.

## V. CONCLUSION

This study presented a hybrid approach combining edge detection with a MobileNetV3 architecture enhanced by an attention mechanism to address the challenge of road defect detection. The proposed model demonstrated superior performance compared to standalone MobileNetV3 and YOLOv5-based methods across key metrics, achieving an impressive accuracy of 96.2%, precision of 94.8%, recall of 95.6%, and an F1-score of 95.2%. The integration of edge detection enabled the model to effectively capture fine-grained features such as cracks and boundaries, while the attention mechanism improved feature prioritization, resulting in enhanced robustness and generalizability. Additionally, the model maintained a competitive inference time of 18ms, making it highly suitable for real-time applications in road monitoring and maintenance.

The results clearly validate the efficacy of the hybrid model in detecting various road defects under diverse environmental and surface conditions. Furthermore, the minimal gap between training and validation metrics demonstrated excellent generalization, with low overfitting, even in the presence of diverse datasets. This makes the model a practical and scalable solution for deployment in real-world scenarios.

Future work could explore optimizing the model further by incorporating additional environmental scenarios, testing on larger datasets, or integrating more advanced preprocessing techniques. Overall, this study establishes the hybrid model as a robust, efficient, and accurate solution for road defect detection, contributing valuable insights for advancing automated road monitoring systems.

# Speech Decoding from EEG Signals

Salma Fahad Altharmani, Maha M. Althobaiti
Computer Sciences Department, Taif University, Taif, Saudi Arabia

***Abstract*—The field of speech decoding is rapidly evolving, presenting new challenges and new opportunities for people with disabilities such as amyotrophic lateral sclerosis (ALS), stroke, or paralysis, and for those who support them. However, speech decoding is complex: it requires analysing brain waves, across spatial and temporal dimensions, before translating them into speech. Recent work attempts to recreate speech that is never physically spoken by analysing the brain Artificial-intelligence methods offer a breakthrough because they can analyse complex data, including EEG signals. This paper aims to decode imagined speech through training CNN, RNN, and XGBoost models on a suitable dataset consisting of recorded EEG signals. EEG from 23 individuals is acquired from a public online dataset. These data are preprocessed, and the features are extracted using five different methods. After data acquisition, preprocessing is performed to ensure its readability to the proposed models. After that, five different feature extraction methods have been used and evaluated. Training and testing the proposed models are done after pre-processing and feature extraction to produce classification results. The proposed model involves CNN, LSTM, and XGBoost as classifiers to achieve an effective and robust speech decoding process. The ultimate result reflects on the accuracy with which the algorithms can regenerate speech from EEG signal analysis. The findings will advance speech-decoding research by showing the potential of hybrid deep-learning architectures for precise decoding of imagined speech from EEG signals. These advances have promising potential for creating non-invasive communication systems to assist people with severe speech and motor disorders, thereby improving their quality of life and increasing the application scope of brain-computer interfaces.**

***Keywords*—Speech decoding; EEG; deep learning; CNN; RNN; hybrid models; Brain-Computer Interfaces (BCI)**

## I. Introduction

Speech decoding is a recent field of investigation that aims to interpret neural activity into spoken or written words through the externalization of mental processes. It holds the potential for creating assistive communications devices for individuals with severe speech disorders. In neuro-rehabilitation, the recording of real-time brain activity during speech tasks can be used to facilitate improved recovery of individuals with speech disorders like ALS or stroke. Furthermore, it can contribute to the field of neuropsychology through a better understanding of how the brain interacts with language and communication [1]. Recent studies have been directed towards synthesizing speech directly from neural signals. Scientists have demonstrated encouraging outcomes in animal models and human subjects by decoding brain activity into speech at the phonemic or lexical levels. For instance, in a study [2], cortical recordings were taken from within the scalp, and speech was synthesized using neural networks. This method bypasses cranial invasions with the possibility of generating speech with audibility. Although in the early stages, this technology is a significant step towards creating real-time communication systems that may ultimately allow direct brain-to-brain speech communication.

Electroencephalography (EEG) is a non-surgical technique of recording brain electrical activity and is frequently utilized in speech decoding research because of its better temporal resolution. EEG enables researchers to monitor neural activity in the course of tasks relating to speech and gives immediate information regarding brain activity. Nevertheless, EEG is confronted with certain drawbacks, including poor spatial resolution and potential interference caused by the movement of muscles when speaking [2]. A significant challenge to speech decoding involves the differences among subjects for neural coding of speech, resulting in substantial inter-subject variation. Moreover, the quality of EEG recordings often deteriorates due to high levels of noise, thus limiting their usefulness. To overcome these issues, research studies have focused on methods like data augmentation, improved preprocessing strategies, and combining EEG with more accurate neuroimaging modalities, such as magnetoencephalography (MEG) and electrocorticography (ECoG) [3].

While there has been significant advancement in EEG-based BCIs, the ability to synthesize continuous speech from brain signals is still in its very early stages. The majority of EEG studies focus on simpler tasks, i.e., phoneme, character, or object recognition, and not speech synthesis. Deep learning methods, specifically artificial neural networks (ANNs), have transformed speech processing through the introduction of the capability to automatically learn features from electroencephalogram (EEG) signals, thereby improving decoding accuracy [3]. Convolutional neural networks (CNNs) are utilized in identifying spatial features pertinent to speech processing in the brain, whereas recurrent neural networks (RNNs) [4] [5], specifically Long Short-Term Memory (LSTM) networks, are utilized in modeling the temporal dynamics of cerebral activity of speech [6]. RNNs help in decoding imagined and real speech by understanding the sequence of brain activity related to speech sounds, pauses, and transitions [7] [8]. Hybrid approaches that combine CNNs and RNNs have been developed to improve decoding by removing noise and handling both spatial and temporal speech features more effectively [9] [10].

Despite recent progress in EEG-based speech decoding, current research still faces challenges that limit practical application. These include small datasets, limited subject diversity, and inconsistent preprocessing techniques, which affect model reliability and generalizability. Moreover, many studies focus solely on spatial or temporal features, overlooking the full complexity of neural activity during imagined speech. To address these gaps, this study proposes a hybrid CNN-LSTM model combined with advanced preprocessing and feature

extraction methods. This approach aims to improve classification accuracy and enable the development of less invasive, real-time brain-computer interfaces (BCIs) that support effective communication for individuals with severe speech and motor disabilities.

The remainder of this paper is organized as follows: Section II presents a review of related literature and highlights the existing research gaps. Section III details the research methodology, including data acquisition, preprocessing techniques, feature extraction, and model design. Section IV presents and analyzes the experimental results. Section V provides the conclusion of the study, and Section VI outlines potential directions for future work.

## II. Literature Review

Translating speech from EEG patterns has not been widely explored; only a handful of studies have pursued the idea successfully [11]. However, there is an increasing interest in this area owing to its possible uses in brain-computer interfaces, speech generation for mute patients with conditions like ALS, stroke, or paralysis, as well as in the domain of neurolinguistics.

As speech decoding and the involvement of deep learning technologies such as CNN and LSTM algorithms had provided a valuable field for research, several studies were published to investigate the potential of these algorithms in extracting meaningful speech from EEG signals. These studies also allowed the exploration of limitations in using CNNs and other technologies, such as signal quality and data availability. After the discussion of these studies, a table is presented showing a sum of the important takeaways from each study.

Haresh M. V. et al. [12] wanted to facilitate the way patients with neuropathies communicate by proposing a brain computer interface based on EEG in order to classify brain states in the form of listening, speaking, imagined speech, and resting. The study used four different ML algorithms to analyze EEG data from 15 patients undergoing the previously mentioned states. EEG data preprocessing and segmentation took place before applying spatio-temporal and spectral analysis. In addition, five features from frequency and time-frequency domain were selected for classifying the four states. The experimental results showed that the algorithms vary in their performance when it comes to pair-wise and multi-class classifications. Random Forest algorithm achieved the highest results in pair-wise classification (94.6% accuracy), while Artificial Neural Networks (ANN) achieved the best performance in multi-class classifications (66.92%).

Mokhles M. Abdulghani et al. [13] aimed to use EEG and deep learning technologies, specifically Long Short-Term Memory LSTM for interpreting brain activity during imagined speech. For this purpose, four adult patients were subjected to EEG data collection using an 8-channel headset. The data from these headsets was preprocessed where noise and artifacts were removed. After that, feature extraction took place. LSTM was trained and tested on this data and was able to classify the data with 92.5% accuracy, 92.7% precision, 92.5% recall, and an F1-score of 92.62%. The proposed model was able to avoid misclassifications, where only six instances were misclassified out of a total 80 instances. Despite promising results, the study involved only four participants, limiting its generalizability.

Kumar et al. [14] introduced a framework to recognize imagined speech at rest to predict digits, images, and other characters by EEG. The authors proposed a two-level framework, where initially a coarse-level classification takes place identifying the category of speech (text or non-text), while another fine-level classification identifies the class within the category (such as a character or a digit within the text category). The dataset involved data collected from 23 adult university students, where EEG was recorded using Emotiv EPOC+ wireless sensor. Then, removing noise and artifacts from the collected data took place using a Moving Average (MA) filter. Standard Deviation (SD), Root Mean Square (RMS), Sum of Values (SUM), and Energy (E) were used to extract relevant features in order to train and test the Random Forest model (RF). RF was able to perform the coarse-level classification with 85.2% average accuracy (varying between images, characters, and digits and between brain lobes), while performing the fine-level classification with 67.03% average accuracy.

Yasser F. Alharbi et al. [15] proposed a hybrid DL model combining 3D-CNNs and Recurrent Neural Networks (RNN) in order to classify unspoken English words based on spatiotemporal features. A publicly available dataset was used, where EEG data was collected from 15 individuals using Brain AMP device. After acquiring the EEG data, the signals were transformed into topographic brain maps which were normalized to ensure a consistent input. 80% of the data was used for training the model whereas 20% was used for testing tis performance. Specifically, the proposed method involved the following models: 3DCNN-LSTM, 3DCNN-StackLSTM, and 3DCNN-BiLSTM. These three models were evaluated based on their classification on three experimental set-ups (word-pair classification, 3-class classification, and 5-class classifications). The results showed that, both 3DCNN-BiLSTM and 3DCNN-LSTM took turns in surpassing each other in terms of accuracy. All in all, 3DCNN-BiLSTM achieved the highest accuracy in word-pair classification (77.8%), whereas 3DCNN-StackLSTM had the best results in multi-class classifications.

A summary of the above-mentioned works, is represented in Table I, where the type of models, the dataset and the achieved results are shown for each work.

### A. Gaps in Literature Review

Decoding speech from EEG signals has come a long way but still encounters several challenges posing as obstacles toward successful speech regeneration.

EEG signals are contaminated and therefore extracting information on specific speech is complex and requires advanced filtering, modeling, and feature extraction mechanisms. In addition, datasets that are useful in these types of studies are limited, which in turn limits the generalizability of the model. One of the challenges also presents itself as the need for a considerable amount of time intervals, which might be resolved by the involvement of special hardware.

TABLE I. SUMMARY OF RELATED WORK

| Authors | Title | Year | Model | Dataset | Accuracy |
|---|---|---|---|---|---|
| Haresh M. V. et al. [12] | "Towards imagined speech: Identification of brain states from EEG signals for BCI-based communication systems" | 2025 | RF, ANN | 15 individuals | RF:94.6% ANN:66.92% |

| Yasser F. Alharbi et al. [15] | "Decoding Imagined Speech from EEG Data: A Hybrid Deep Learning Approach to Capturing Spatial and Temporal Features" | 2024 | 3DCNN-LSTM | 15 individuals | 77.8% |

After the careful reviewing of several studies in the literature, the following gaps emerge:

*1) Generalizability:* By relying on limited datasets, most of the studies achieve low accuracies, and those who achieve high accuracies fail in the generalizability test as a result of limited subject pools.

*2) Exploration of hybrid architecture:* The involvement of hybrid architectures in decoding speech from EEG is not a very-well explored field, where the studies that did explore some options for hybrid models failed to explore the true potential by applying it to diverse datasets.

To address these gaps, our study will leverage a CNN-LSTM hybrid architecture, with a comparative analysis of multiple EEG dataset preprocessing techniques to identify optimal approaches for improving imagined speech recognition. The difference between the current work and previous works is not only in the algorithms used, but also in relying on a larger dataset that would reflect positively on the generalizability of this study, and would offer a better insight into the general task of speech decoding by extracting features from more individuals and performing a more thorough training process.

In contrast, our work addresses these challenges directly by introducing a delta-band preprocessing strategy that significantly enhances noise robustness—one of the most pressing issues in EEG signal decoding. Furthermore, our hybrid CNN-LSTM architecture processes raw EEG data without relying on handcrafted features, enabling the model to automatically learn rich spatial and temporal patterns. This not only improves classification performance across imagined speech classes but also makes our system lightweight and adaptable to affordable EEG headsets like the Emotiv EPOC+. Consequently, our proposed method offers a more practical, efficient, and robust solution compared to existing approaches in the field.

The current study excels previous research by employing optimized CNN-LSTM architectures, advanced preprocessing, and real-time operation. Unlike previous research that experienced poor signal quality issues, scarcity of data, and computational incompetence, our model enhances generalization through Transfer Learning and data enhancement. By employing advanced denoising and feature extraction, we enhance classification accuracy without compromising on preprocessing simplicity. Our system is also real-world deployable, offering a valuable Brain-Computer Interface (BCI) that is superior on parameters of accuracy, resilience, and usability compared to previous research.

## III. RESEARCH METHODOLOGY

The methodology that we propose in this study follows the same hierarchy as other studies. Our main objective is to evaluate the performance of ML models, namely XGBoost and a combination of CNN with LSTM algorithms in their capacity of decoding speech based only on recorded EEG signals. A visual representation of the steps undergone to achieve this objective is demonstrated in Fig. 1.

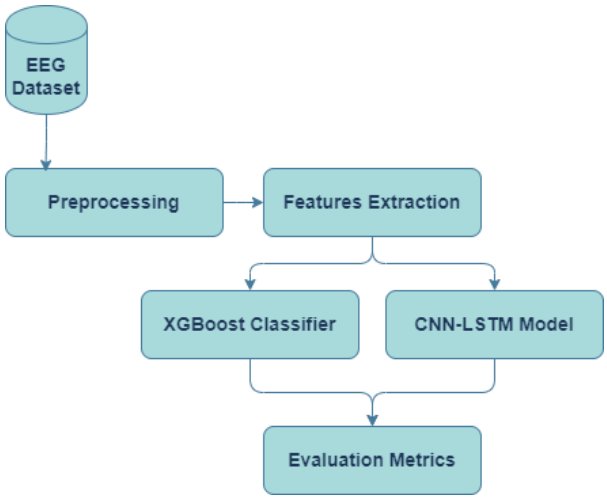

Fig. 1. Workflow of the proposed methodology.

The methodology kicks off with the acquisition of a dataset suitable for the purpose, where EEG signals have already been recorded to be used publicly. After acquiring the dataset, preprocessing is a necessary step to enhance the quality of data and make it ready for feature extraction and use by the proposed algorithms. After feature extraction, the data is used to train XGBoost and CNN-LSTM classifiers to decode speech, based on which their performance will be evaluated taking into consideration several evaluation metrics.

### A. Dataset

A public "envisioned speech" dataset was acquired online, where it consists of recordings for 23 individuals between 15 and 40 years old [16]. The EEG recordings were acquired through Emotiv EPOC+ wireless neuro headset consisting of 14 channels where the recording frequency was at 2048 Hz before it was reduced to 128 Hz. The 14 channels are named AF3, AF4, F3, F4, F7, F8, FC5, FC6, T7, T8, P7, P8, O1 and O2.

The procedure by which these data were recorded started by placing a screen in front of the participant and presenting an object on the screen. After that, the participant closes his eyes

and is asked to imagine this presented object without looking at it for 10 seconds. A break of 20 seconds is then given. This break ensures that the participant is rested between the displayed objects and is ready to receive a new object. This process is continued for three prompts from which the EEG data are collected. The three categories involve different types of objects. For instance, category 1 is made up of digits from 0 to 9, category 2 is made up of 10 uppercase English alphabets particularly A, C, F, H, J, M, P, S, T, Y, and finally category 3 consists of daily-life objects such as apple, mobile, dog, rose, tiger, wallet, gold, watch, car, and scooter. These categories make up for a recording of total 230 recording (23*10) in each category. Hence, three categories were used, comprising10 classes each.

Table II provides a detailed overview of the public "Envisioned Speech" dataset.

TABLE II. DATASET'S STRUCTURE AND COMPOSITION

| Attribute | Details |
|---|---|
| Source | Public "Envisioned Speech" Dataset |
| Participants | 23 individuals (aged 15–40) |
| EEG Device | Emotiv EPOC+ Wireless Neuro Headset |
| Channels | 14 (AF3, AF4, F3, F4, F7, F8, FC5, FC6, T7, T8, P7, P8, O1, O2) |
| Sampling Rate | 2048 Hz (downsampled to 128 Hz) |
| Recording Procedure | Participants imagine an object after viewing it on a screen for 10 seconds, followed by a 20-second break |
| Total Categories | 3 |
| Categories & Classes | |
| - Category 1: Digits (0–9) | 230 recordings (23×10) |
| - Category 2: Uppercase Letters (A, C, F, H, J, M, P, S, T, Y) | 230 recordings (23×10) |
| - Category 3: Objects (apple, mobile, dog, rose, tiger, wallet, gold, watch, car, scooter) | 230 recordings (23×10) |
| Total Recordings | 690 (3 categories × 230 recordings) |

### B. Data Preprocessing

The recorded EEG files were read in the form of (.edf) as they are usually stored in this form. The channels 2 till 15 were specifically selected for extraction and scaling. Furthermore, in order to make the data uniform in terms of input size, each sample was resized to 1280 data points.

### C. Feature Extraction

In this study, five different feature extraction methods were used for evaluation, these methods are namely Sliding Window, Theta Band Processing, Delta Band Processing, Beta Band Processing, and Alpha Band Processing.

To elaborate, the sliding window method with a window size 32 data points and 8 strides was applied resulting in small segments that overlap between the samples. On the other hand, the band processing methods were used to filter the EEG signals based on their frequency. For instance, the Alpha band processing filtered EEG signals to extract the frequency between 7 and 15Hz, whereas Beta band processing filtered the 15 to 31Hz band frequency, Theta band processing filtered the signals between 4 and 7Hz frequency, and finally the Delta band processing filtered the bands with less than 4Hz frequency.

### D. Models

As for the models that were used for capturing the deep EEG features, this study proposes CNN and LSTM algorithms.

Deep learning DL is one of the greatest advancements in the technological era as it poses as a solution to many modern problems. The unique qualities of deep learning have made it a significant topic for research. The emergence of this advancement started by the publication of a study by Hinton and Salakhutdinov [17] back in 2006 demonstrating the capabilities of Artificial Neural Networks ANN and their "depth" among the ML technologies. That study highlighted the ability of ANNs to learn with the help of its numerous hidden layers, and how this ability can be enhanced by the incorporation of additional hidden layers, thus increasing its "depth". The term deep learning basically stems from this explanation of the depth of the network, where it allows the network to execute more complex tasks and perform significantly better in large datasets.

In the following section, the focus will be on CNNs and their specific features and structure. We will discuss the most popular CNN architectures as a background before introducing 1D-CNNs which are one of the latest advancements in DL, focusing on 1D signal and data repositories. The choice fell on 1D-CNNs as opposed to 2D-CNNs since they are compact and more adaptive, thus offering more advantages than 2D-CNNs.

*1) CNN:* One of the most popular models among modern deep learning models is the Convolutional Neural Network CNN. CNN is an artificial neural network made up of several layers and can run a specialized mathematical linear operation called convolution, hence the name convolutional neural network. Therefore, instead of a general matrix multiplication, CNN involves convolution in at least one of its layers [18]. In fact, the general architecture of CNN involves a convolutional layer, pooling layers, and a fully connected layer. The CNN is characterized by learning to extract complex attributes automatically, where the convolutional layer represents the attribute [19].

The Convolutional Neural Network (CNN) model processes EEG signals by prioritizing the extraction of spatial features from brain activity data. The EEG signals, after preprocessing, are structured as time-series data before being fed into the CNN.

Key Processing Steps:

Feature Extraction: The CNN uses convolutional layers to detect spatial features within the EEG signals.

Dimensionality Reduction: Pooling layers are employed to reduce data complexity while preserving essential features.

Significance of Spatial Features: These extracted features help identify crucial brain activity regions linked to imagined speech.

Classification: The processed features are passed through fully connected layers, which ultimately label the EEG signals into distinct speech categories.

*2) 1D-CNN:* 1DCNNs differ from 2DCNNs which only deal with 2D images and videos in its flexibility with handling data. In fact, 1DCNN or 1Dimensional Convolutional Neural Network is a modified version of the original 2DCNN [20][21]. Some studies described 1DCNN to be more advantageous than 2DCNN for the following reasons:

*a)* FP and BP in 1D CNNs need simple array operations for functioning rather than complex ones. This results in less computation complexity in 1DCNN than 2DCNN.

*b)* 1DCNN has a simpler structure comprising less hidden layers and neurons that 2DCNN, and they are capable of processing 1D signals with ease. This also makes 1DCNN much easier to train.

*c)* 1DCNN does not require special hardware setups, a simple CPU implementation over a standard computer is enough to ensure an effective and fast training of the 1DCNN structure, especially with few layers and neurons.

*d)* 1D-CNNs enable real-time, low-cost applications and can even run on mobile devices.

*e)* 1DCNNs also can function on limited labeled data and high signal variations.

In the 1DCNN structure, there exist two types of layers, namely the "CNN layers" and the "MLP layers". The CNN layers consist of 1D convolutions and pooling layers, whereas the MLP layers consist of typical fully-connected layers.

*3) RNN:* Recurrent Neural Networks RNNs are structures that can process sequential data by capturing information about previous input data through hidden layers. Three different layers form the basis of RNN and these layers are the input layer, the hidden layer, and the output layer. RNNs are not feedforward networks, instead, the information can cycle between the layers in a recurrent form. The way RNNs function is by obtaining an input vector "$\mathbf{x}_t$" at a specific time step "$t$", then the hidden state is update using the following formula:

$$\mathrm{h}_t = \sigma_h(\mathrm{W}_{xh}\mathrm{x}_t + \mathrm{W}_{hh}\mathrm{h}_{t-1} + \mathrm{b}_h) \quad (1)$$

In this equation, the weight matrix between the first (input) and second (hidden) layer is represented by $\mathrm{W}_{xh}$, whereas $\mathrm{W}_{hh}$ represents the weight matrix among the recurrent connection. $\mathrm{b}_h$ represents the bias vector, and $\sigma_h$ represents the activation function which can either be the hyperbolic tangent function (tanh) or the rectified linear unit (ReLu).

On the other hand, the output resulting in each time step can be computed with the following formula:

$$\mathrm{y}_t = \sigma_y\big(\mathrm{W}_{hy}\mathrm{h}_t + \mathrm{b}_y\big) \quad (2)$$

In this case, $\mathrm{W}_{hy}$ represents the weight matrix between the second (hidden) and the third (output) layer, $\mathrm{b}_y$ represents the bias vector, and $\sigma_y$ represents the activation function relative to the output layer.

The basic architecture of an RNN structure can be depicted in Fig. 2, demonstrating input layer, hidden layers, and output layer where predictions take place.

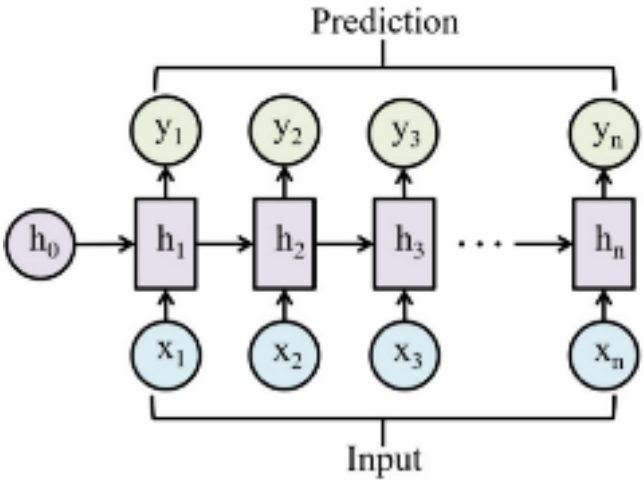

Fig. 2. General Architecture of RNN [22].

*4) LSTM:* One of the RNN models that are capable of processing sequential data of temporal order is the LSTM [23]. In fact, LSTM is highly effective in processing textual data as well as relational data. In this study, LSTM was specifically integrated with CNN model in order to achieve an enhanced classification performance by using the EEG temporal dependencies to complement the spatial features from CNN.

When previous convolutions and time distributions operations are performed, the resulting input "*Y*" is split into N LSTM time steps denoted as "t", where N provides the best results. Whenever a time step is due, two inputs are taken by the LSTM layer. One of the inputs is "$x(t)$" which denotes the current input vector, and the other is "$\alpha(t-1)$" which denotes the previously hidden state. Both these inputs are used to compute 3 gates, namely the forget gate, the update gate, and the candidate memory.

EEG signals are inherently temporal, meaning the data sequential nature and time dependencies are critical for understanding brain activity. LSTMs excel at capturing these long-term dependencies, which makes them ideal for this application.

By combining LSTM with CNN, our model leverages both spatial and temporal features of the EEG data.

The unidirectional LSTM layer which is applicable in our model is described in the Eq. (8) [24]:

$$f_{r(t)} = \sigma\big(W_f[\alpha(t-1), x(t)] + b_f\big) \quad (3)$$

$$u_{r(t)} = \sigma(W_u[\alpha(t-1), x(t)] + b_u) \quad (4)$$

$$\tilde{c}(t) = \tanh\big(W_{c[\alpha(t-1),x(t)]} + b_c\big) \quad (5)$$

$$c(t) = f_{r(t)} \odot c(t-1) + u_{r(t)} \odot \tilde{c}(t) \quad (6)$$

$$o_{r(t)} = \sigma\big(W_{o[\alpha(t-1),x(t)]} + b_o\big) \quad (7)$$

$$\alpha(t) = o_{r(t)} \odot \tanh\big(c(t)\big) \quad (8)$$

In this equation, the forget gate is represented by $f_{r(t)}$, the update gate is represented by $u_{r(t)}$, and the candidate memory is represented by $c(\tilde{t})$. In addition, the new memory is denoted by $c(t)$, the output gate is denoted by $o_{r(t)}$, and the hidden state is denoted by $\alpha(t)$. Finally, the weight matrix is represented by $W_{\mathrm{i}}$, whereas the bias vector is represented by $b_{\mathrm{i}}$.

The architecture of the LSTM network applied in this study is depicted in Fig. 3.

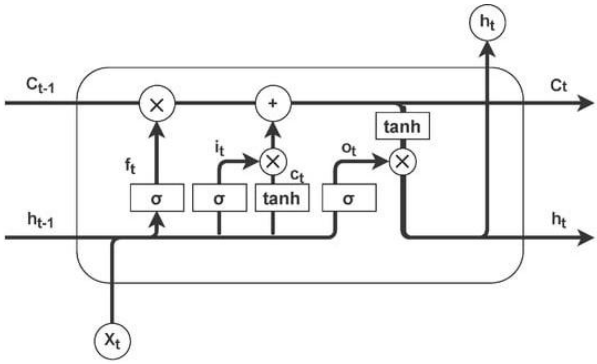

Fig. 3. Architecture of applied LSTM [25].

The Long Short-Term Memory (LSTM) model is developed to learn temporal relationships within EEG signals. Due to the sequential nature of EEG, LSTM is provided with sequence-arranged brain activity, either natively or after extraction using CNN layers. The sequence is analyzed by the LSTM framework along with memory cells that retain meaningful patterns but forget meaningless noises. By modeling temporal evolution of activity within the brain, LSTM helps improve decodable timing and evolution of imagination of speech. The result is structured classification of neural activity that corresponds to discrete portions of speech that can enhance decodable outcomes.

In order to be able to perform multi-class classifications, the resultant LSTM layer is integrated into the previous CNN-1D architecture and is then passed through a dense neural network before a SoftMax function is applied, as shown in Fig. 4.

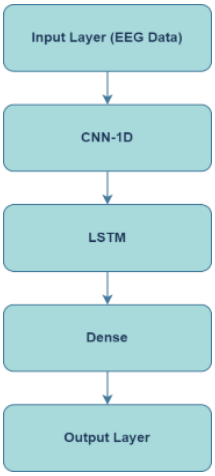

Fig. 4. General architecture of the proposed CNN-LSTM network.

Merging the two architectures, CNN-LSTM Hybrid Model benefits from spatial feature extraction and temporal feature extraction capabilities of each of its component architectures to yield better performance. The input EEG is pre-processed by the CNN, which extracts spatial features by finding key activation patterns throughout diverse areas of the brain. The features that have been spatially enriched are passed on to the LSTM, where sequential relationships between diverse time steps of brain activity are learned. The process of hybridizing makes classification of imagined speech better by considering spatial distribution along with temporal evolution. The result is an optimized classification that is better compared to standalone CNN or LSTM architectures.

The CNN-LSTM Hybrid Model improves EEG-based speech decoding by leveraging CNNs for spatial feature extraction and LSTMs for temporal pattern learning. CNNs detect key activation patterns in different brain regions, making them effective in identifying spatial features of imagined speech [26], [27]. However, since EEG signals also have sequential dependencies, LSTMs enhance performance by capturing the time-evolving nature of neural activity [13]. Studies confirm that CNN-LSTM models consistently outperform standalone architectures, achieving higher classification accuracy, sometimes exceeding 90% [28]. This hybrid approach strengthens non-invasive BCI applications, improving precision in decoding imagined speech.

*5) XGBoost:* XGBoost is a machine-learning algorithm known for its strong performance on complex classification tasks [29]. What provides XGBoost with good qualities is its ability to handle outliers in the dataset as well as noise that might be found in datasets, particularly EEG signals datasets. In addition, XGBoost is highly capable of analyzing unbalanced datasets with the use of functions such as weighted loss and subsampling techniques.

XGBoost is a machine learning algorithm that takes feature-processed EEG input and makes use of gradient-boosted decision trees to predict the classification of the signals. Contrasting with deep learning-based models that learn temporal and spatial features of raw input, XGBoost makes use of pre-determined statistical and frequency-based features of EEG signals. The algorithm iteratively assigns weights to features to improve classification performance by minimizing errors stage by stage. The result is a class label of imagined speech category that is an alternative, computationally effective approach to speech decoding [29]. The graphical scheme of XGBoost model is represented in Fig. 5.

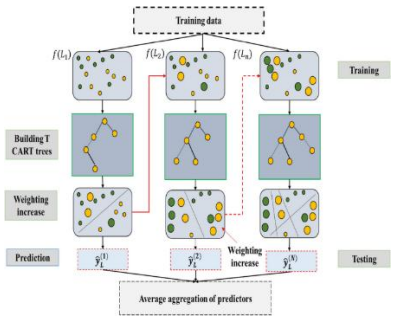

Fig. 5. Graphical scheme of XGBoost model [30].

## IV. RESULTS

Electroencephalography (EEG) is one of the core methods in brain activity studies, especially in imagined speech tasks with cognitive processes. The system was designed to classify EEG signals from 23 subjects into three classes: digits, English alphabets in uppercase, and objects in everyday life. It involved EEG signal preprocessing, feature extraction, and the application of a number of models, including a CNN-LSTM model and an XGBoost classifier. The models' performance, by implementing a few preprocessing techniques (Sliding Windows, Delta, Theta, Alpha, Beta), is verified in this work. The results confirm that the CNN-LSTM model performs better than the XGBoost classifier on all classes and that the optimal performance is attained by preprocessing through delta band. These results emphasize the effect of signal processing on classification accuracy and the necessity of choosing proper frequency bands for EEG data analysis.

Fig. 6 demonstrates the EEG signals for a single sample from the "digits" dataset. The data consists of signals recorded from 14 EEG channels, which are displayed as individual subplots in the figure. The x-axis represents the time in samples, while the y-axis shows the signal amplitude in microvolts (μV). This visualization provides insight into the temporal dynamics and amplitude variations of brain activity while the participant imagines speech corresponding to numerical digits. Each subplot is labeled by the EEG channel index, and the overall label for the sample is displayed in the figure title.

These techniques were applied to process the EEG files: Sliding Window, Delta, Theta, Alpha, and Beta, as a result of the pre-processing stage. Each technique we used is allocated a data set and is divided into training and testing. That is, we copied the dataset several times and applied the processing techniques each one to a copy of the data set. At each time, it was divided into testing and training. We then compared each method and see which method is the best for the processing of EEG files.

### A. Overall Performance Comparison

Table III shows the overall performance of two classifiers (XGBoost and CNN-LSTM) on three categories: Digits, Chars, and Images. In all three categories, the CNN-LSTM model outperforms the XGBoost classifier consistently in precision, recall, F1-score, and accuracy. In particular, CNN-LSTM performs extremely well with sliding windows and delta band preprocessing, achieving an F1-score of 0.92 for Digits, 0.93 for Chars, and 0.94 for Images. These findings demonstrate the ability of the CNN-LSTM model in capturing spatial and temporal features in EEG signals.

In contrast, the performance of the XGBoost model is far worse, particularly for the high-frequency band preprocessing scenarios (Theta, Alpha, and Beta), in which the F1-scores drop to as low as 0.14 for Digits and Chars, and 0.16 for Images. While delta band preprocessing improves XGBoost's performance, lifting the F1-score to 0.77 for Digits and Chars, and 0.76 for Images, it still lags behind the CNN-LSTM model, which has a high and consistent performance across all classes.

In general, the results point to the significance of both preprocessing methods and model architecture, wherein CNN-LSTM with sliding windows and delta band processing provides the optimal performance in EEG signal classification.

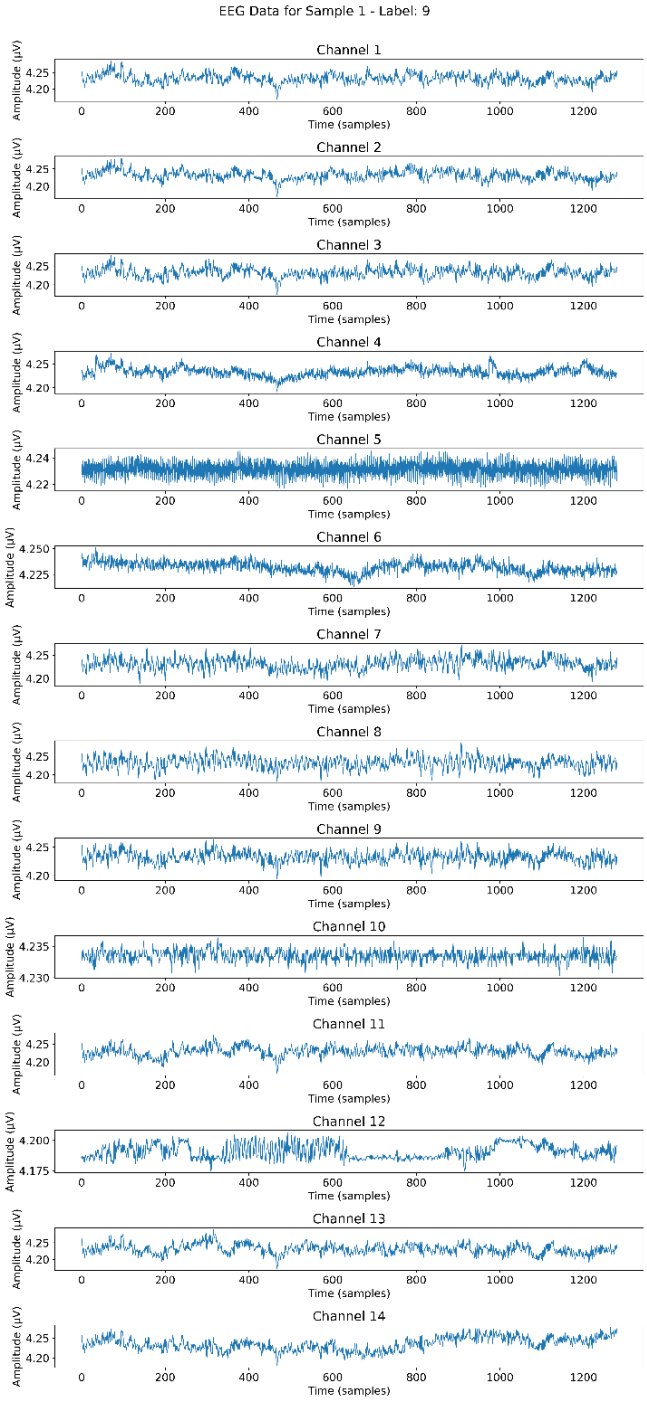

Fig. 6. EEG signal visualization for digits.

TABLE III. OVERALL PERFORMANCE COMPARISON

| Algorithm | Data Folder | Preprocessing Method | F1-Score (Macro Avg) |
|---|---|---|---|
| XGBoost | Digits | Sliding Windows | 0.52 |
| XGBoost | Digits | Sliding Windows + Delta | 0.77 |
| XGBoost | Digits | Sliding Windows + Theta | 0.14 |

| | | | |
|---|---|---|---|
| XGBoost | Digits | Sliding Windows + Alpha | 0.18 |
| XGBoost | Digits | Sliding Windows + Beta | 0.19 |
| XGBoost | Chars | Sliding Windows | 0.19 |
| XGBoost | Chars | Sliding Windows + Delta | 0.76 |
| XGBoost | Chars | Sliding Windows + Theta | 0.15 |
| XGBoost | Chars | Sliding Windows + Alpha | 0.16 |
| XGBoost | Chars | Sliding Windows + Beta | 0.19 |
| XGBoost | Images | Sliding Windows | 0.49 |
| XGBoost | Images | Sliding Windows + Delta | 0.76 |
| XGBoost | Images | Sliding Windows + Theta | 0.16 |
| XGBoost | Images | Sliding Windows + Alpha | 0.19 |
| XGBoost | Images | Sliding Windows + Beta | 0.20 |
| | | | |
| CNN-LSTM | Digits | Sliding Windows | 0.92 |
| CNN-LSTM | Digits | Sliding Windows + Delta | 0.92 |
| CNN-LSTM | Digits | Sliding Windows + Theta | 0.40 |
| CNN-LSTM | Digits | Sliding Windows + Alpha | 0.44 |
| CNN-LSTM | Digits | Sliding Windows + Beta | 0.72 |
| CNN-LSTM | Chars | Sliding Windows | 0.92 |
| CNN-LSTM | Chars | Sliding Windows + Delta | 0.93 |
| CNN-LSTM | Chars | Sliding Windows + Theta | 0.48 |
| CNN-LSTM | Chars | Sliding Windows + Alpha | 0.48 |
| CNN-LSTM | Chars | Sliding Windows + Beta | 0.72 |
| CNN-LSTM | Images | Sliding Windows | 0.93 |
| CNN-LSTM | Images | Sliding Windows + Delta | 0.94 |
| CNN-LSTM | Images | Sliding Windows + Theta | 0.44 |
| CNN-LSTM | Images | Sliding Windows + Alpha | 0.56 |
| CNN-LSTM | Images | Sliding Windows + Beta | 0.63 |

### *B. Top Performance in EEG Digits Classification*

Fig. 7 illustrates the model's performance in terms of accuracy and loss over 150 epochs.

- The Model Accuracy graph shows a steady increase in both training and validation accuracy, which is a sign of effective learning by the CNN-LSTM model. Initially, the model's accuracy is quite low, but it progressively improves, stabilizing at a high value around 90% by the 100th epoch.
- The Model Loss graph demonstrates a corresponding decrease in loss for both training and validation, which further indicates that the model is converging towards an optimal solution.
- The train accuracy (blue line) outperforms the validation accuracy (orange line) slightly, which is typical of well-trained models, but there is no significant overfitting as both curves tend to follow similar trends.
- The loss for both training and validation data decreases steadily, showing the model is learning to minimize the error.

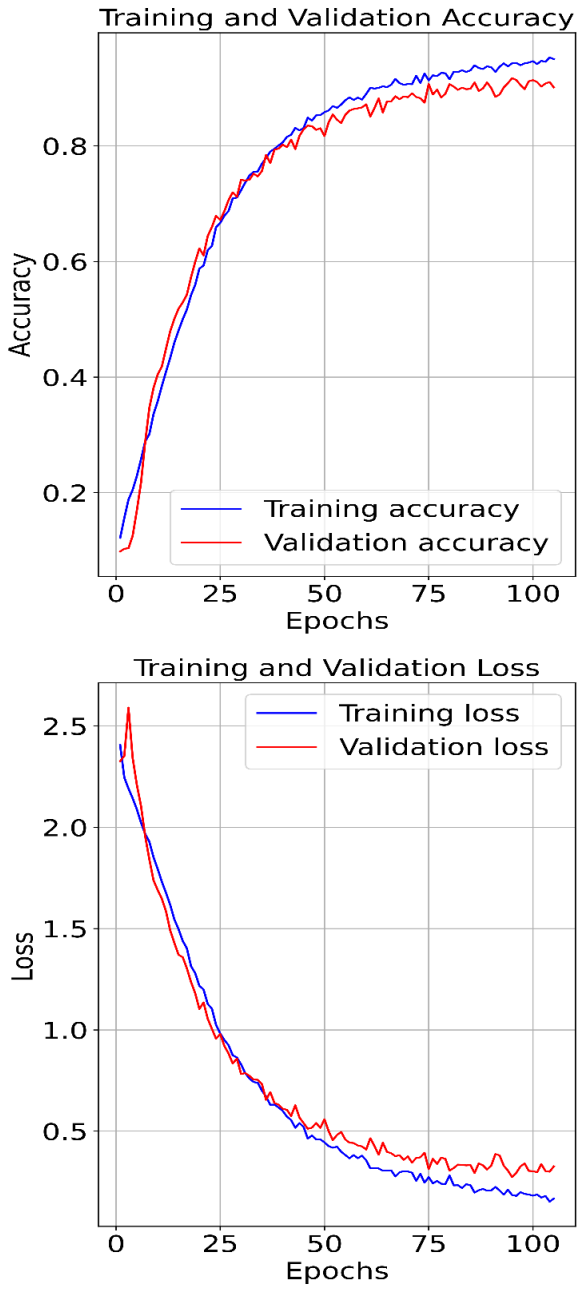

Fig. 7. Model accuracy and Model loss of CNN-LSTM model with sliding windows and delta band preprocessing for EEG digits classification.

Fig. 8 presents the confusion matrix for the CNN-LSTM model with sliding windows and delta band preprocessing applied to EEG Digits Classification. The matrix shows how well the model classifies each digit (0–9), with the true labels displayed on the vertical axis and the predicted labels on the horizontal axis. Each cell in the matrix indicates the number of instances where a digit was predicted as a particular label. The majority of values lie along the diagonal, which is expected, indicating that the model correctly predicted most of the digits. For example, 689 instances of the digit 0 were correctly classified as 0, and similarly, 646 instances of the digit 9 were correctly predicted. There are a few off-diagonal values, such as 13, where digit 0 was misclassified as digit 1, or 22, where digit

9 was misclassified as digit 7, suggesting occasional misclassifications but generally high accuracy. The presence of mostly dark blue colors along the diagonal signifies that the model performs exceptionally well in distinguishing between digits, with relatively few errors overall.

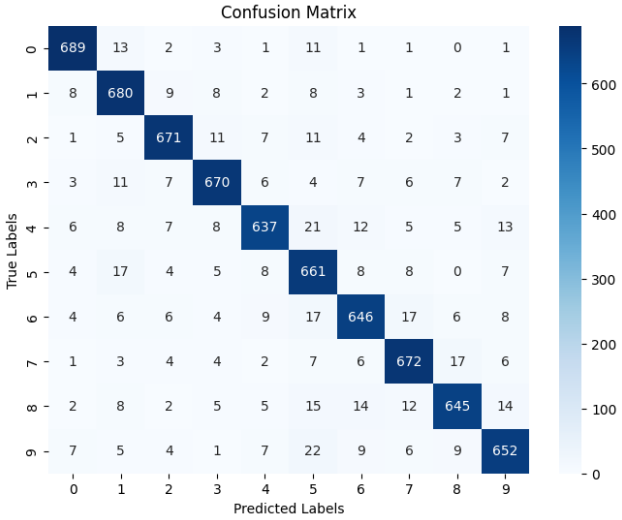

Fig. 8. Confusion matrix of CNN-LSTM model with sliding windows and delta band preprocessing for EEG digits classification.

### C. Top Performance in EEG Chars Classification

Fig. 9 illustrates the Model Accuracy and Model Loss over 150 epochs for the CNN-LSTM model with sliding windows and delta band preprocessing applied to EEG Chars Classification.

- The Model Accuracy graph demonstrates a steady increase in both training and validation accuracy, with the training accuracy (blue line) consistently outperforming the validation accuracy (orange line). This indicates that the model is effectively learning, achieving an accuracy of around 92% by the end of training.
- In the Model Loss graph, both training and validation losses decrease significantly, which is a sign of the model's ability to reduce errors over time. The loss stabilizes at a lower value, suggesting that the model is fitting well to the data. There is a slight gap between training and validation loss curves, with validation loss (orange) being slightly higher, indicating minor overfitting, though it does not significantly affect the model's overall performance.

Fig. 10 presents the confusion matrix for the CNN-LSTM model with sliding windows and delta band preprocessing applied to EEG Chars Classification. The matrix shows the performance of the model in classifying the ten uppercase English characters (A, C, F, H, J, M, P, S, T, Y). The true labels are on the vertical axis, while the predicted labels are on the horizontal axis. Most of the values are concentrated along the diagonal, indicating that the model correctly predicted most of the characters. For example, the model accurately classified 673 instances of 'A' as 'A', 680 instances of 'H' as 'H', and 658 instances of 'Y' as 'Y'.

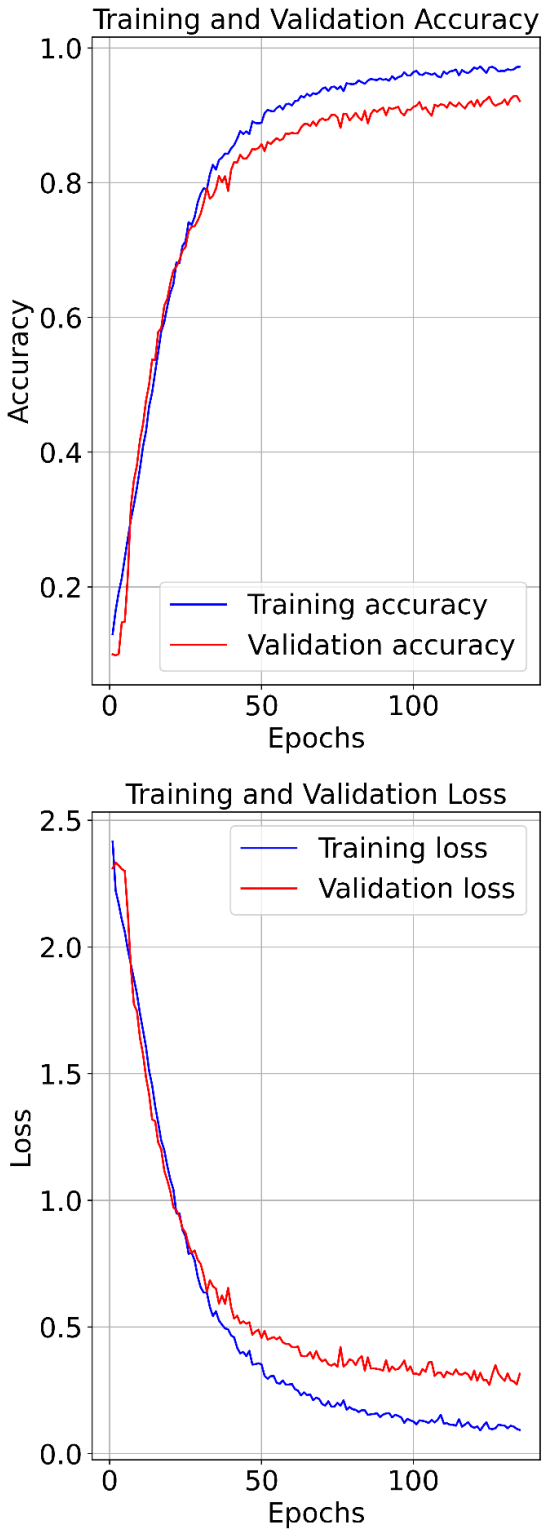

Fig. 9. Model accuracy and model loss of CNN-LSTM model with sliding windows and delta band preprocessing for EEG chars classification.

However, there are a few off-diagonal values, such as 13 instances where 'C' was misclassified as 'H', or 8 instances where 'S' was misclassified as 'P'. These off-diagonal misclassifications are relatively small compared to the correctly classified instances, showing that the model is highly accurate in

classifying the characters. The dark blue colors along the diagonal suggest strong performance, with relatively few errors across the categories. This confirms the model's ability to distinguish between different characters with high accuracy, aided by the delta band preprocessing technique.

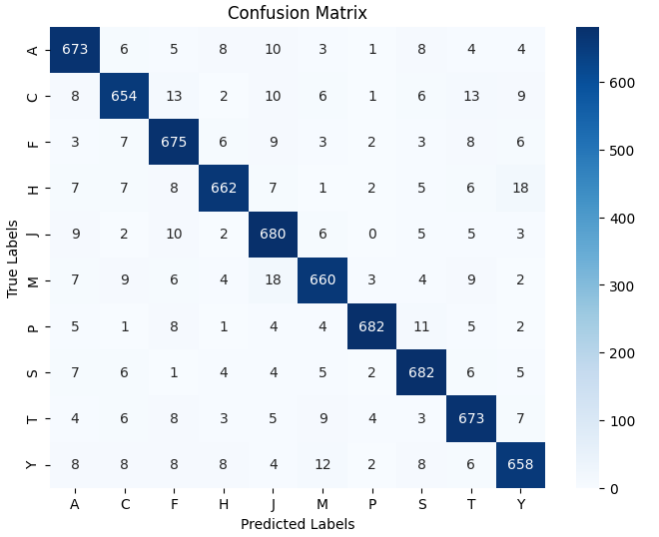

Fig. 10. Confusion Matrix of CNN-LSTM model with sliding windows and delta band preprocessing for EEG Chars Classification.

### D. Top Performance in EEG Images Classification

Fig. 11 illustrates the Model Accuracy and Model Loss over 150 epochs for the CNN-LSTM model with sliding windows and delta band preprocessing applied to EEG Images Classification.

- The Model Accuracy graph shows a clear upward trend for both training (blue line) and validation (orange line) accuracy, with the training accuracy remaining slightly higher than the validation accuracy. By the end of training, the model achieves an impressive accuracy of around 97%, reflecting its ability to learn effectively from the EEG image data.
- In the Model Loss graph, both training and validation losses decrease steadily, which is indicative of the model successfully reducing the error as it progresses through the epochs. However, there is a slight gap between the training and validation loss curves, with the validation loss being slightly higher, suggesting a minor degree of overfitting. Despite this, the model still performs well, as evidenced by the low final loss values.

Fig. 12 shows the confusion matrix for the CNN-LSTM model with sliding windows and delta band preprocessing applied to EEG Images Classification, where the model classifies various objects, including apple, car, dog, gold, mobile, rose, scooter, tiger, wallet, and watch. The matrix reveals a high degree of accuracy in the model's predictions, as evidenced by the dark blue color along the diagonal, which represents correct classifications. For example, the model correctly classified 690 instances of "apple," 680 instances of "dog," and 700 instances of "tiger."

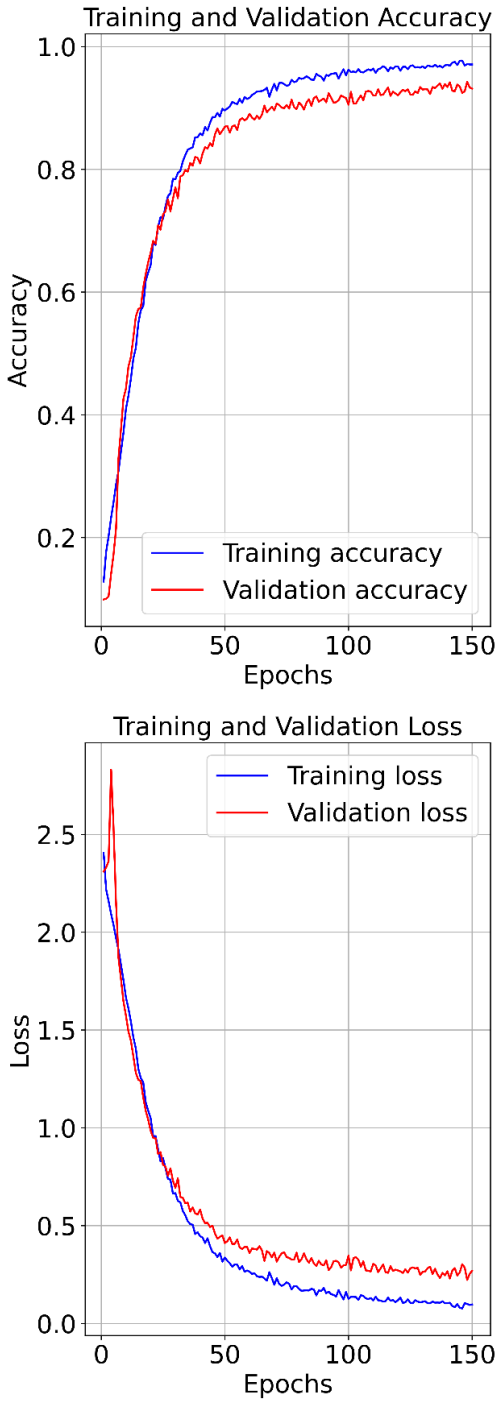

Fig. 11. Model accuracy and model loss of CNN-LSTM model with sliding windows and delta band preprocessing for EEG images classification.

There are only a few off-diagonal entries, i.e., "apple" classified as "car" or "wallet" classified as "tiger." These are minor compared to the correct classifications, showing the model's high performance in distinguishing between the different object classes. The overall pattern is that the model generalizes well, with minimal confusion between the classes, confirming the value of the preprocessing step for improving classification accuracy.

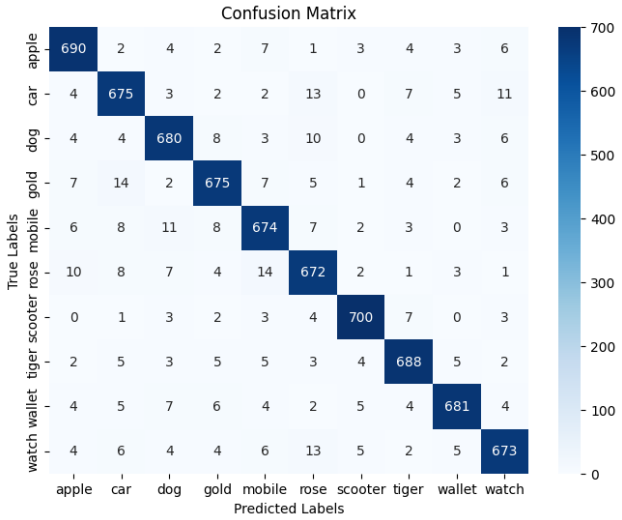

Fig. 12. Confusion matrix of CNN-LSTM model with sliding windows and delta band preprocessing for EEG images classification.

### *E. Impact of Preprocessing Methods*

Selection of preprocessing techniques significantly influences the effectiveness of classification in EEG. Filter operations, artifact removal, and frequency band extraction each have particular effects on the quality of input data and, therefore, the model's ability to learn discriminative patterns. For instance, delta band preprocessing (0–4 Hz) tends to yield better performance as it possesses a high signal-to-noise ratio (SNR) and is less sensitive to noise, which is more appropriate to capture stable and fundamental brain activity. In contrast, preprocessing methods for higher-frequency bands (e.g., theta, alpha, beta) are prone to higher noise and variability and therefore lead to inferior classification performance. Additionally, advanced preprocessing techniques like sliding windows and delta-based feature extraction enhance temporal resolution and feature salience, again increasing model performance.

### *F. Results and Discussion*

Comparing our results on the EEG classification work to Kumar et al.'s paper, our method is superior to their method. Kumar et al. have obtained 67.03% fine-level accuracy with an RF classifier on EEG data for 23 subjects with 30 classes as digits, characters, and object images. Although their approach showed some promise, the use of the RF classifier restricted the model from effectively capturing the intricate temporal relationships within EEG signals, which are important for fine-level classification.

On the other hand, we employed a CNN-LSTM model with delta band preprocessing and sliding windows, which is most appropriate to process sequential EEG data and learn complex patterns along the time dimension. CNN-LSTM models are expected to perform well in such tasks since they learn hierarchical features directly from raw EEG and this provides a major edge over conventional machine learning models like RF. Our method is far more able to generalize and generate correct classification, and our model is thus not just better but certain to perform better than Kumar et al.'s 67.03%.

A major drawback of the present study is that all trials used highly controlled data in which participants kept completely still during EEG acquisition. Future research should therefore assess these models on more realistic recordings that include ordinary head motion and ambient noise. Although our sample of 23 volunteers is larger than those in many earlier studies, evaluating the approach on a broader and more varied cohort (50 + participants) would clarify how well the system generalizes across ages, neurological profiles, and cultural or language backgrounds. It would also be valuable to gather recordings under different everyday conditions, such as varied lighting or background-noise levels, to measure the model's resilience in real-world settings.

## V. Conclusion

The paper deals with the issue of decoding speech from EEG signals using hybrid deep learning models, including CNNs and LSTMs. Based on a number of EEG datasets related to imagined digits, characters, and objects, the study revealed the efficacy of the combination of spatial features extracted by CNN and the temporal modeling by LSTM in neural signals decoding. The CNN-LSTM model achieved high F1-scores across all categories: 0.92 for digits, 0.93 for characters, and 0.94 for objects, particularly when delta band preprocessing and sliding window segmentation were applied. In contrast, the XGBoost classifier showed considerably lower performance, with F1-scores peaking at 0.77 under the same preprocessing.

Moreover, some patterns of brain activity related to imagined speech were at least given as an indication through the visualizations for an appropriate classification. With rigorous preprocessing and feature extraction techniques, the hybrid CNN-LSTM model outperformed state-of-the-art standalone classifiers such as XGBoost. Despite inter-individual variability and noisy nature, this study was able to demonstrate the feasibility of decoding imagined speech in a non-invasive way and thereby took a further step toward the development of assistive technologies and brain-computer interfaces.

The findings of this paper hold transformative potential for real-world applications, particularly in assistive technologies for individuals with speech impairments. This work bridges neuroscience and artificial intelligence in the development of innovative communication systems that translate neural activity into speech, furthering the field of neuro-rehabilitation and brain-computer interfaces.

## VI. Future Work

In the future work of this study, we would like to enhance the work by refining and extending the codebase to improve the accuracy and robustness of the decoding models. The practical implementation of the paper will be done in the upcoming semester, in which the developed CNN-LSTM hybrid model will be integrated into a real-world application framework. This would allow us to test and validate the system with regard to practical scenarios involving various challenges such as real-time processing and usability. We will go on to explore some high-end techniques for improving accuracy in classification, optimizing feature extraction, and enhancing model generalizability across datasets. These efforts are needed in bringing the paper near to its ultimate goal, that of coming up

with an effective and reliable EEG-based speech decoding system.

***Abstract*—Emotion recognition is vital in the human Computer interaction because it improves interaction. Therefore, this paper proposes an improved method for emotion recognition regarding the Hybrid Autoencoder-Long Short-Term Memory (LSTM) model and the newly developed hybrid approach of the Ant Colony Optimization (ACO) and Whale Optimization Algorithm (WOA) for hyperparameters tuning. In this case, Autoencoder can reduce input data dimensionality for input data and find the features relevant for the model's work. In addition, LSTM is able to work with temporal structures of sequential inputs like speech and videos. The contribution of this research lies in the novel combination method of ACO-WOA which aims at tweaking hyperparameters of Autoencoder-LSTM model. Global aspect of ACO and WOA thereby improve the search efficiency and the accuracy of the proposed emotion recognition system and its generalization capacity. In context with the benchmark dataset for the experimentations of emotion recognition, it has established the efficiency of the proposed model in terms of the conventional methods. Recall rates in recognitive intended various emotions and different modalities were also higher in the hybrid Autoencoder-LSTM model. The optimization algorithms like the ACO-WOA also supported in reducing the computational cost which arose due to hyperparameters tuning. The implementation of this paper is done through Python Software. This implementation shows a high accuracy of 94.12% and 95.94% for audio datasets and image datasets respectively when compared with other deep learning models of Conv LSTM and VGG16. Therefore, the research shows that the presented hybrid approach can be a useful solution for successfully employing emotion recognition for enhancing the creation of the empathetic AI systems and for improving user interactions within various fields including healthcare, entertainment, and customer support.**

***Keywords*—Emotion recognition; autoencoder; long short-term memory; Ant Colony Optimization (ACO); Whale Optimization Algorithm (WOA)***

## I. INTRODUCTION

The development of machine learning methods has made it simple for computers to recognize and comprehend how humans act using a variety of approaches. One of the essential components of human conduct is emotions [1]. A vast range of programs, including political analysis, advertising, and interactions between humans and computers, are improved by the identification of individual feelings or emotions. People now share feelings and knowledge on online social networks (OSNs) like Facebook, Instagram, Twitter, and other online social networks as part of their everyday routines [2]. These OSNs' abundance of data and information makes them ideal for researching and analyzing human emotions and behavior. It also encourages the development of more emotion-aware apps. A customized system for recommendations suggests tailored items; it suggests videos, music, or movies based on the user's preferences and feelings [3]. In times of disaster or epidemic, recognition of emotions is used to assess public opinion. This information aids in decision-making and situational management on the part of the government. Because of this, ONSs now use emotion detection as a distracting and finding faults activity. A person's motivation, state of emotions, psychological disorders, and level of mental activity may all be inferred from their facial expressions [4].

The facial expressions are a powerful expression and communication tool in interpersonal relationships[5]. The ability of Facial Emotion Recognition (FER) to characterize an individual's feelings or psychological state lends credence to its significance [6]. Its uses go beyond only analyzing human behavior, assessing someone's emotional condition, or assessing someone's psychological wellness [7]. Additionally, it is making inroads into a variety of other industries, including automation, schooling, holography, intelligent medical systems, safety

systems, law enforcement, amusement, multimodal interaction and stress identification [8]. The inclusion of movements of the face in these domains demonstrates the significance of facial emotions in human existence. These days, one of the hardest problems in computational science is automated FER [9]. Movements and spoken words can be used to communicate emotions. It is not only dependent on facial features. Just 7% of the background of the data may be conveyed verbally; the remaining 38% can be conveyed by voice tone, cadence, and speaking rate [10]. Conversely, around 55% of information is conveyed by facial expressions. A person's facial expressions may reveal a lot about their mental health. Facial expressions are used in many facets of life and are not only restricted to certain professions [11]. In the field of health disciplines, bipolar patients benefit from FER. Physicians are attempting to identify and track the behavior of their clients, including the feelings and actions of bipolar patients throughout their illness [12].

Many sophisticated FER methods have been developed that allow the system to recognize human facial expressions when it receives facial pictures as input [13]. Humans may express themselves in seven different ways: fear, happiness, surprise, neutral, anger, sadness, and contempt [14]. Multifunctional emotional line databases have been used in this work to increase the classification accuracy of emotions. To achieve the ultimate goal, three main components—preprocessing, extraction of features, and classification—are further subdivided. The selected information in this procedure includes pictures, sounds, and videos that were taken from a variety of individuals, comprising men and women. Every picture is taken from the front and is separated into eight groups [15]. To ensure that every image is the same size, the initial step of preliminary processing involves reshaping each image to measure 150 × 150 pixels [16]. Additionally, photos are automatically enlarged and flipped among 0- and 180-degrees during preprocessing. Moreover, pictures are rotated both vertically and horizontally. Pictures are further analyzed to obtain attributes in the next stage. Next, important variables that are essential for the algorithm's applicability are retrieved from all of the recorded video and audio data. Only valuable features should be retained once the features have been retrieved, and max pooling aids in this process [17]. The final stage of the suggested process, categorization, is in charge of identifying the accurate labels. completely linked layers are employed in categorization, and these entirely interconnected layers additionally use two layers that are hidden. There are many weighted nodes in each hidden layer [18]. The weight value of each node increases with bias values through forward propagation procedures before the total calculation is performed. The algorithm performs backpropagation to identify the actual label of an input picture through adjustments to the hidden layer node weights [19]. The following sections include the key contribution of the paper.

- The research introduces a novel hybrid model that combines Autoencoders and LSTM networks to enhance emotion recognition. The Autoencoder effectively reduces dimensionality and extracts salient features, while the LSTM component captures temporal dependencies in sequential data, providing a comprehensive approach to emotion analysis.
- A significant contribution is the creation of a hybrid optimization algorithm that merges ACO and WOA for hyperparameter tuning. This hybrid approach balances global and local search capabilities, leading to more efficient and accurate identification of optimal hyperparameters for the model.
- The proposed model demonstrates superior performance in recognizing emotions across various modalities, including speech, facial expressions, and physiological signals. This improvement in accuracy is attributed to the effective combination of the Autoencoder-LSTM model and the optimized hyperparameters found through the hybrid ACO-WOA algorithm.
- The research highlights a reduction in the computational cost associated with hyperparameter tuning. The hybrid ACO-WOA algorithm accelerates the optimization process, making it feasible to apply deep learning models to emotion recognition tasks without the typically prohibitive computational overhead.
- The findings suggest broad applicability of the enhanced emotion recognition system in fields such as healthcare, education, customer service, and entertainment. The research provides a foundation for developing more empathetic and responsive AI systems, capable of understanding and interacting with users based on their emotional states.

The paper continues with its structure by explaining Section II. Section III describes the problem statement which will be addressed by the proposed paper. Section IV detailed the construction process of Autoencoder-LSTM network. A performance evaluation of the proposed Autoencoder-LSTM network takes place in Section V before the article's conclusion in Section VI.

## II. Related Works

The identification and treatment of certain medical diseases may alter if neurological signals are used to recognize emotions [20]. Generalized emotional detection programs may have issues and limits because of the limited amount of facial movement factors persons who fake their feelings, or those who have alexithymia. By examining the constant neurons produced by the human brain, these signals may be found. Brainwaves known as EEGs provide with a more comprehensive understanding of the psychological emotions that people might be unable to articulate. Neuronal communication channels can cause modifications to electrical potential, which might be reflected in brainwave EEG data. This study compares several artificial intelligence approaches, including SVM, K-nearest neighbour, Linear Discriminant Analysis, LR, and DT. Each of these algorithms is evaluated using and without principal component analysis for reducing the dimensionality. The historic information gathered from EEG sensor networks is analyzed. In order to reduce the duration of execution, grid computing was also used for hyper-parameter tweaking for each of the models created using machine learning that were evaluated over Spark cluster. This investigation made use of the multidimensional DEAP Information set, that is designed for the examination of individual emotional states.

The paperwork seeks to generate an artificial intelligence structure for programmed emotion recognition from words [21]. The established structure is to be utilized in the structure of tracking public sentiments. A short evaluation of additional investigation articles on the procedure of establishing artificial intelligence frameworks for effortless sentiment recognition from conversation has been specified in the document. Traditional and deep machine learning approaches and techniques and certain characteristics of the original information set have been taken into account. The DailyDialog and its effectiveness for training the classificatory have been considered. Furthermore, constructing and identifying the ideal framework for natural sentiment recognition from conversation has been suggested. The study's findings on the effects of variables like the quantity of documents in every group in the training set of data, content pre-processing, vectorization or word-integration techniques, artificial intelligence approach selection for identifying text, parameter settings, and structure are provided. The previous section provided demonstrations of how to use the artificial intelligence algorithm to analyze the actual information that was gathered. It has been demonstrated how certain occurrences in the lives of society, the people living in a specific region, or a community are correlated with changes in the quantity of data falling into various psychological classifications. Lastly, the artificial intelligence algorithm's shortcomings and a few potential improvements to the framework for identifying emotions have been discussed.

Accurate emotion detection from speech signals contributes to improved HCI [22]. The extracted characteristics from language signals determine how well a SER algorithm performs. But since the efficacy of characteristics vary with feelings, choosing the best collection of depictions of features in SER continues to be the most difficult challenge. The worldwide long-term situational descriptions of language signals are ignored in many investigations that identify concealed specific language aspects. Due to inadequate representations of attributes and a lack of readily accessible information the current SER method performs poorly in detection tasks. Inspired by CNN, LSTM, and GRU's effective extracting features, this paper suggests a combination that makes use of the overall predictive capabilities of three distinct designs. Initially 1D CNN is used in the design, and then FCN are used. The CNN network is followed by the LSTM-FCN and GRU-FCN layers in the other two designs, accordingly. The goal of each of the three distinct frameworks is to derive voice waves' local and over time worldwide situational expressions. The weighted mean of the various models is used by the ensembles. In order to improve system generalizations, the information in this work have been enhanced by adding additional white Gaussian noise, pitch shifting, and noise level stretching.

Accurate emotion detection from speech signals contributes to improved HCI [22]. The extracted characteristics from language signals determine how well a SER algorithm performs. But since the efficacy of characteristics vary with feelings, choosing the best collection of depictions of features in SER continues to be the most difficult challenge. The worldwide long-term situational descriptions of language signals are ignored in many investigations that identify concealed specific language aspects. Due to inadequate representations of attributes and a lack of readily accessible information the current SER method performs poorly in detection tasks. Inspired by CNN, LSTM, and GRU's effective extracting features, this paper suggests a combination that makes use of the overall predictive capabilities of three distinct designs. Initially 1D CNN is used in the design, and then FCN are used. The CNN network is followed by the LSTM-FCN and GRU-FCN layers in the other two designs, accordingly. The goal of each of the three distinct frameworks is to derive voice waves' local and over time worldwide situational expressions. The weighted mean of the various models is used by the ensembles. In order to improve system generalizations, the information in this work have been enhanced by adding additional white Gaussian noise, pitch shifting, and noise level stretching.

One of the most important things that can reveal an individual's emotional state is their facial expression [23]. Individuals can communicate vocally for around 45% of the time, and nonverbally for about 55% of the time. One of the hardest problems in technology right now is automated face expressions detection. FER has several uses outside of analyzing behaviour and keeping tabs on people's emotions and psychological wellness. It is also making inroads into other domains, including learning, robotics, entertainment, holography, smart medical systems, safety technologies, criminal justice theory, and identifying stress. Emotions on the face are becoming increasingly significant in medical studies, especially for bipolar patients whose mood fluctuations are common. This paper suggests a computerized structure and algorithms for facial recognition utilizing a CNN that has two layers that are hidden and four convolution layers for enhanced precision. Various face pictures of males and females with emotions including rage, anxiety, resentment, dislike, neutral, joyful, sorrowful, and surprised are included in an expanded collection. Three main processes are included in this research's implementation of FD-CNN: preprocessing, feature extraction, and classification. With this suggested approach, a 94% FER precision is attained. K-fold cross-validation is used to verify the suggested approach.

These days, neural networks, deep learning, and algorithmic learning are the main tools used to enhance a device's ability [8]. The intelligent SER algorithm is a fundamental requirement and a developing field of study in digital voice analyzing; yet, SER performs a significant role with numerous purposes associated with HCI. In order to make the most advanced SER structure workable for actual time business purposes, it must be improved. The main cause of inadequate precision and poor forecasting rate is the scarcity of information and an algorithm arrangement that is the hardest part of trying to create a strong machine learning approach. The constraints of the current SER methods were discussed in this research, and suggested a novel AI-based system design for the SER that makes use of the structural modules of the ConvLSTM with sequential learning. The local features learning block (LFLB), one of the four ConvLSTM blocks created in this study, and is used for obtaining regional psychological traits in a hierarchy association. Convolution processes are used to derive visual signals, and the ConvLSTM layers are chosen for input-to-state and states to states transitions. Utilizing the residual learning technique, this work

deployed four LFLBs to derive the spatiotemporal cues from the hierarchy correlated type voice signals.

The papers discuss diverse approaches for recognising emotions with the help of artificial intelligence based on neurological signals, voice, and face. Some of the issues that are in disagreement with the general emotion recognition are the so-called fake emotions, or "alexithymia'', and the use of the EEG brainwaves for more accurate recognition of the emotions. The basic BCI MLS algorithms are SVM, KNN, LDA and Decision Trees with and without applying PCA on EEG data of ALS subjects. Another work discusses the automated emotion recognition from speech which employs CNN, LSTM, GRU frameworks and discusses the challenges involved in feature selection. FER based on CNNs is introduced with high accuracy for emotions identification with focus on mental health assessment. Lastly, about the limitations encountered in the current SERs that are based on speech, a new SER approach that employs ConvLSTM layers is also presented for enhanced real-time performance. Research reviews that point out feature extraction as well as model optimization as crucial areas to enhance AI-based emotion detection form the basis of all the studies.

## III. Problem Statement

Due to the temporal structure of emotional data and the complexity and diversity of emotional displays, emotion identification algorithms have difficulty correctly detecting emotional states. In many conventional approaches, handling increased dimensionality of input data and proper tuning of hyperparameters to determine performance and robustness of the Emotion recognition system remains a problem [8]. This research, therefore seeks to develop a solution by developing an emotion recognition model by combining Autoencoder and LSTM networks. For efficient feature extraction the Autoencoder is utilized whereas the LSTM component to enable temporal analysis of the features extracted from the emotional data. In order to increase the efficiency of the proposed model, hyperparameters tuning is performed using Ant Colony Optimization and Whale Optimization Algorithms. By combining LSTM for modeling temporal dependency and Autoencoder for dimensionality reduction, the proposed method enhances emotion recognition. LSTM incorporates the sequential nature of emotions, which reinforces the ability of the model to recognize complex emotional patterns over time, and the Autoencoder provides the benefits of noise removal and extraction of relevant features. In addition, the hyperparameters of the model are optimized well by the Hybrid ACO-WOA algorithm. It ensures improved accuracy and faster convergence without the threat of local minima through the strengths of Ant Colony Optimization and Whale Optimization. An improved accurate, efficient, and computationally efficient emotion recognition model is the result of this synergy.

## IV. Proposed Autoencoder-LSTM Framework for Emotion Recognition

The research aims of furthering the capabilities of emotion recognition technology using a complex machine learning strategy. The work presents the novel Autoencoder-LSTM model for energy load prediction. The Autoencoder effectively learns and condenses salient characteristics from large complicated emotional data and the LSTM deciphers them with an understanding of time sequences, subtle emotional trends. Thus, in the present study, a combination of ACO and WOA is used in the form of hybrid optimization approach for better model performance and tuning of hyperparameters. Thus, the described strategy is based on the further enhancement of the model's parameters, providing increased accuracy of the emotions classification as well as providing the robustness of the model. In an attempt to increase the accuracy of the proposed models and address issues with hyperparameter tuning the research aims at improving emotion recognition in relation to human-computer interaction and potential use cases in mental health. Block Diagram for Autoencoder-LSTM is depicted in Fig. 1.

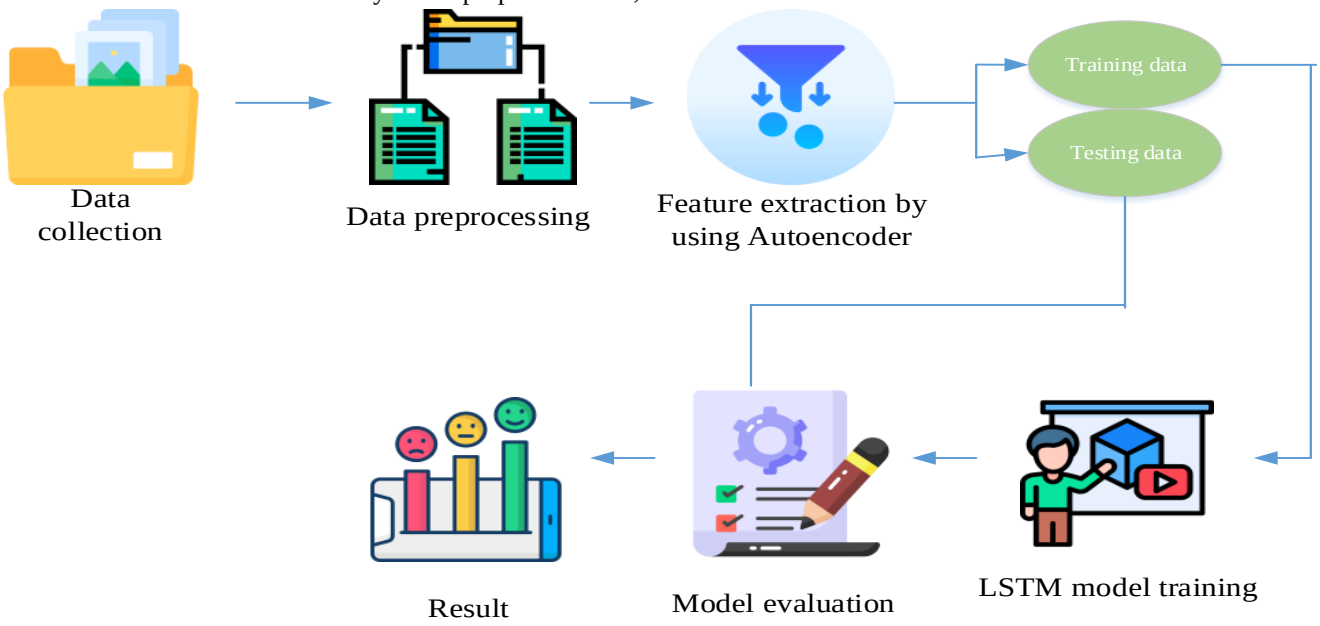

Fig. 1. Block diagram for autoencoder-LSTM.

### A. Data Collection

The researchers upgraded and developed EmotionLines database into MELD by including textual information as well as audio-visual content which matches the original conversations. MELD hosts 1400 dialogues and 13,000 lines of dialogue originated from the Friends television show. Multiple speakers engaged in the recorded dialogues. Each statement within the discussions received assignment from among the seven recognized emotions including Anger, Resentment, Anxiety, Happiness, Neutral, Surprise and Fear. MELD provides emotion tags for its statements using three possible classifications: good, poor or unbiased [24] [25].

### B. Data Pre-processing

*1) Data cleaning:* The most important step essential for the preparation of the data for deep learning is data cleaning which includes the detection of the errors and the removal of faults, contradictions, and mistakes in the datasets. This also requires that in order to feed the model with similar inputs, pixel values are normalized to a standard scale and noise is filtered out of the pictures. Due to this, the accuracy and reliability of raw data that is usually erroneous, and full of discrepancies, data cleaning becomes inevitable.

*2) Data normalization:* Normalization in image data preprocessing is the procedure which alters the direction and distribution of pixel values. To do that this step is conducted in order to match images from different sources and enhance the performance of machine learning models. For instance, min-max normalization rescales pixel values to a given range of 0 to 1 or -1 to +1 while z-score normalization assigns a pixel value based on the mean and standard deviation, and then transform it to standard normal distribution. Normalization enables a reduction of the impact of variety lighting condition, sensors and imaging system thus making images more comparable This is critical in research domain where due to variation in the imaging devices and techniques, differences in quality can make a lot of difference. Normalization if done by standardizing pixel values enhances the capability of image analysis, and machine learning models, and enhance the chances of deriving accurate results for tasks such as emotion recognition. Normalization can be mathematically expressed as in Eq. (1).

$$x_n = \frac{x - x_{min}}{x_{max} - x_{min}} \quad (1)$$

*3) Noise reduction by weiner filter:* For the noise removing part, this paper utilizes the Weiner Filter. The Statistical filtering issue has an optimum approach that is Wiener filter Filtration mechanism. Like mentioned before, this paper aims at explaining how statistical approach helps in solving the problem of linear filtering. At the same time, this paper agrees that noise has to be rejected and that properties of the target signal have to be assessed. Thus, it needs to be built in a way that the noise of the data which is fed into the filter causes as less an impact to the filter as possible. As for the linear filtering problems, the corresponding strategy is the minimization of the mean square error signal, which is the difference between the desired signal, to be transmitted, and the filtering outcomes. It is expressed as in Eq. (2).

$$e_k = y_k - \sum_{i=0}^{N-1} w(i).x_{k-i} \quad (2)$$

### C. Proposed Autoencoder-LSTM Framework for Emotion Recognition

*1) Feature extraction by using autoencoder*: An Autoencoder is made up of an output component called the decoder and an input component called the encoder. The quantity of neurons in the encoder and decoder is identical. In addition, in comparison to the layers that provide input and output, the Autoencoder has a minimum a single hidden layer and fewer neurons. An Autoencoder's fundamental assumption is that, at the outcome, it needs to be capable to rebuild its input source using the lower-dimensional latent encoding of the information provided in the hidden layer. By quantifying the transformation losses or inaccuracy among the real source and its reorganized results, finding anomalies uses Autoencoder. A representative autoencoder architecture is seen in Fig. 3

*2)* 6. For data X, the goal function is to identify weight transmitters for decoder and encoder to reduce the reconstructing loss. It is expressed as in Eq. (3), (4), (5), (6) and (7).

$$\emptyset = X \to h \quad (3)$$

$$\Psi = h \longrightarrow X' \quad (4)$$

$$h = \sigma(W_{x+b}) \quad (5)$$

$$\emptyset, \psi = \arg\min \| X - (\psi * \phi)X \|^2 \quad (6)$$

$$Anomaly\ score = f(|X' - X|) \quad (7)$$

Where, $h$ denotes latent representation,$\sigma$ denotes activation function. $W$ denotes weight matrix and $b$ denotes bias vector.

*3) Classification by Using LSTM:* The vanishing gradient issue with the fundamental RNNs was the reason behind the creation of LSTM. Each LSTM networking cell has an extended-duration memory module connected to the cell state. Special gates, such as inputs, outputs, and forget gates, can be used to alter the present condition of this cell. These mechanisms allow it to selectively retain and erase information once it has been collected. This mechanism determines which data needs to be stored and which ones should be deleted. One of the main benefits of the LSTM network is its capacity to comprehend the long-term reliance of a sequence of information. Because of this characteristic, LSTM networks are the most popular kind of neural network for a variety of programs, including time-lapse forecasting, recognition of speech, processing of natural languages, and the ability to take in information consecutively.

Determining which aspects of the cell state need to be kept and which should be eliminated is the primary duty of the forget gate. This makes it easier for the LSTM framework to examine more closely, recognize when the form of the waves has changed

significantly, perceive more information, and keep an eye on extraneous data. Areas involving the ailments, including time series prediction, n-gram models of languages, and speech recognition, would benefit from this. When the score is near 1, it indicates that the details must be kept, and when it is around 0, it indicates that the data needs to be eliminated. Eq. (3) gives the mathematical formula for the forget gate. It is expressed as in Eq. (8).

$$f_t = \sigma\left(W_f * [h_t - 1, x_t] + b_f\right) \quad (8)$$

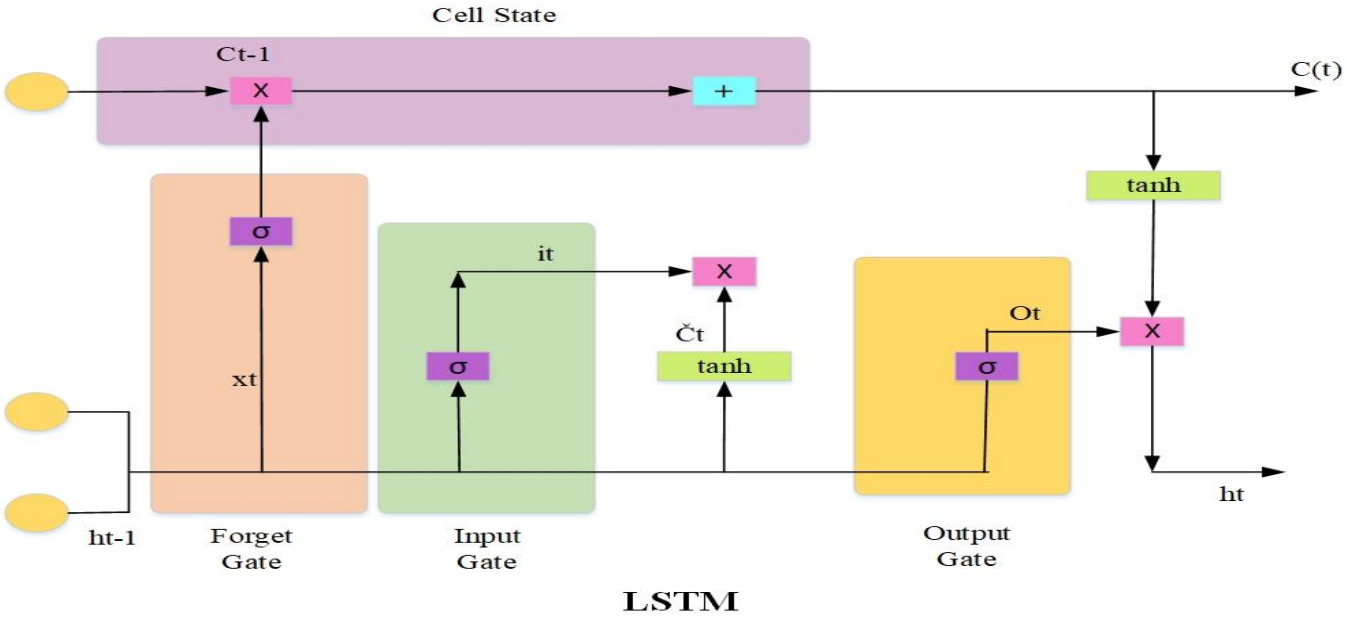

Fig. 2. LSTM Architecture diagram.

Fig. 2 represents the architecture diagram for the LSTM network. The input gate, in addition to the forget gate, determines what additional data has to be entered into the cell state. Candidate cell state and gate activation are its two primary constituents. This study demonstrates that the input gate's primary role is to control additional information's self-access at various cell states, allowing the LSTM system to create and develop novel components. By continuously altering the cell states, the input gate safeguards the long-term issues in the LSTM and assists it in retaining the firsthand info gathered from input series when needed. Such LSTM models may be used to train and modify activities involving extended-term contextual knowledge, including voice recognition, translation by machines, and time-series prediction. The mathematical equation for the input gate is expressed as in Eq. (9).

$$i_t = \sigma(W_i * [h_t\text{-}1, x_t\ ] + b_i\ ) \quad (9)$$

Eq. (10) computes the quantities to be introduced to the cell state that are valuable to the candidate's cell.

$$\hat{C}_t = tanh(W_c[h_{t-1}, x_t] + b_c) \quad (10)$$

The input gate, which decides what additional information needs to be entered in the cell state in addition to the forget gate, is one of the final two factors. Its main components are candidate cell state and gate activation, out of these two. When fresh information from the input sequence is required, the input gate balances it and modifies the cell states randomly, which aids the LSTM in storing certain over time information. Due to the ongoing acquisition and ongoing operation of such LSTMs, tasks requiring the comprehension of long-range setting, such as speech identification, machine interpretation, and time series prediction, may be carried out. It is expressed as in Eq. (11).

$$C_t = f_t * C_t - 1 + i_t * \hat{C}_t \quad (11)$$

According to the cell state, the resultant gateway regulates inputs to the hidden state at each stage in the LSTM framework. The previous hidden state and the current input are taken into consideration when determining which elements of the cell state need to be output. A sigmoid activation value controls the gates, and its initial values start at 0. The specific portion of the cell state has to be provided to the output if the value is close to 1, else it needs to be hidden. Eq. (12) and Eq. (13) may be used to represent the output gates.

$$O_t = \sigma(W_o[h_{t-1}, x_t] + b_o) \quad (12)$$

$$h_t = O_t \times tanh(C_t) \quad (13)$$

*4) Ant colony optimization algorithm:* A class of optimization algorithms motivated by actual ants' hunting habits is defined by the ACO metaheuristic. Imaginary ants in the ACO method are stochastic techniques for developing candidate solutions that take advantage of a pheromones concept and potentially accessible heuristics knowledge about the challenge at hand. In order to bias ant towards the most ensuring areas of the search field, the pheromone structure is composed of a set of numerical parameters known as pheromones that are changed at every repetition. If heuristics details are accessible, it expresses previous knowledge about the particular challenge instance being repaired.

The building of the ants' solution and the updating of the pheromone data are the primary computational elements of the ACO metaheuristic. Extra "daemon actions" are processes that handle jobs which are too big for an individual ant to handle. Activating the local search process to enhance an ant's solution or applying extra pheromone alterations obtained from worldwide accessible data regarding, say, the greatest solutions developed thus far, are typical examples. Daemon actions are optional, but in actual use, they can significantly increase the efficiency of ACO methods. It is expressed as in Eq. (14).

$$W_j = \frac{1}{qk\sqrt{2\pi}} e^{\frac{-(rank(j)-1)^2}{2q^2k^2}} \quad (14)$$

Where, $rank(j)$ is the rank of solution $S_j$ in the sorted archive, $q$ is a parameter of the algorithm. The best outcome is given the highest weight as a consequence of computing $rank(j) - 1$.

*5) Whale optimization algorithm:* A metaheuristic optimization algorithm known as the WOA was derived from humpback whale hunting behaviour. It hits somewhere between exploration and exploitation by continuously updating the position of results in searching field. Like the whales, it circles the prey, searches for the prey and updates the location of the prey, and itself, using what it terms three important equations. These formulae utilize the best response up to the current criterion found and some random coefficients for the search control. As repetitions go on, WOA continuously adjusts the parameter of exploration and exploitation. For example, the following equation shows that WOA always decrements exploration gradually in order to have more emphasis on exploitation. Consequently learning, WOA is helpful if employed to solve optimisation problems in various spheres, because it explores solution areas with a technique imitating the cooperative hunting style of whales.

A novel optimisation method useful in enhancing the accuracy of the models is proposed by the integration of the WOA into the Autoencoder-LSTM in the identification of emotions. This can be done by adjusting the autoencoders-LSTM's weights and biases to understand the difficult temporal structure and multilevel visualisations of psychological information by leveraging the WOA model's ability to fine-tune the various parameters. Indeed, WOA achieves the optimal solutions to reduce categorization errors and to enhance the performance by successfully searching the huge solution space. Together this enhances the ability of the model to differentiate between different sensations and extricate essential characteristics from raw information given to it. About the employed integrated Autoencoder-LSTM -ACO-WOA architecture, there is a potential way to improve the precision and robustness the emotion identification mechanisms in real world due to the circumstance of the flexible optimisation.

One of the avenues under consideration is that the updating of whale locations in the WOA as an important factor for effectively structuring of search space or effectively utilizing the search space. In this technique, they use three main formulae with which they replicate a range of behaviours observed in aquatic mammal societies. When a particular whale changes location: depending on the type of interaction or the response at the time. The formulae are as follows; when hunting whales use the balance formulae either by encircling prey, searching for the prey, or updating one's position. WOA handles the resolution area into the best possible solutions of optimisation issues by altering the position continually with regards to these formulae.

*a) Encircling prey equation:* The encircling prey equation is relevant to the WOA since it controls the movements of whales for coverage. This formula specifies how, by approximation copying efficient hunting behaviour, whales encircle potential prey to transform their positions. Whales persistently traverse to special areas of the search space by computing the distance of a randomly selected whale and its prey. The encircling prey equation can be used to make good progress towards the optimum outcomes by achieving an appropriate level of exploration and exploitation. This formula is iteratively applied in WOA, making it enhance the appraisal of tackling optimisation problems and engaging the cumulative knowledge of a community of whales in looking for a space that contains valid solutions. It is expressed as in Eq. (15) and Eq. (16).

$$D_i = |C.X_r - X_i| \quad (15)$$

$$X_i^{new} = X_r - A.D_i \quad (16)$$

Here, $X_i$ denotes the position of current whale. $X_r$ denotes the randomly selected whale from population. $C$ denotes the random coefficient in range [-1,1]. $A$ denotes the decreasing coefficient for encircling prey.

*b) Search for prey Equation:* The concept of the search for prey equation in the WOA is directing the whales as they more flexibly and diversely than in the WSS look for prey in the search area. Introducing randomization by the help of variables and by the help of location of the best whale found till now, this formula makes searching much easier. This implies that whales use random coefficients and the distance to the optimal solution where they want to look for so as to ensure that those potential areas are exploited. Due to the adaptive nature of its search strategy, WOA can successfully accomplish the task of defining the optimum solution to optimisation issues while at the same time falling well into the prey-searcher balance of the hunt for prey equation. It is expressed as in Eq. (17) and Eq. (18).

$$D_i = |X_{best} - X_i| \quad (17)$$

$$X_i^{new} = D_i.e^{b.k}.\cos(2\pi k) + X_{best} \quad (18)$$

Here, $X_{best}$ denotes the position of the best whale in the current iteration, $b$ denotes the random coefficient in the range [-1,1] $k$ denotes the random number in [0,1].

*c) Update position equation:* In the WOA, adaptive moves of whales are controlled by update position equations with which they adjust their positions independently to coverage the sea area effectively and efficiently. These formulas help whales to adjust its position depending on the strategy in use. They are enclosing prey, searching for prey, and employing the best available opportunities at the time in question. These formulas make the whales go round the search

space in order to get the best answer; it strikes between exploitation and exploration. The update position equations ensure that WOA increases promising areas and review distinct locations indeed within the solution space. Using the whale locations' alterations based on whales' collective communications, this form of continuous modification effectively addresses optimisation concerns, thus being effective in WOA. It is expressed as in Eq. (19).

$$X_i^{new} = X_i + A.r.(X_{best} - X_i) \quad (19)$$

Here, r denotes the random number in [0,1].

A denotes the coefficient for exploitation.

*6) Hybridization of ACO with WOA:* In this study, the hyperparameters of the Autoencoder-LSTM model is optimized using the ACO and WOA in combination for the purpose of enhancing its ability to identify various emotions. ACO has been derived from the foraging behaviour of ants seeking the best gourmet in a vast terrain, which makes the algorithm optimal for searching the solution space using the pheromone rally path. Nevertheless, ACO has a potential for premature convergence to sub optima, this is especially the case when solving difficult multi-dimensional problems such as hyperparameter optimization. To overcome this, ACO combined with WOA, derived from the bubble-net hunting behavior of humpback whales, which has been claimed to strike an optimal balance between exploration and exploitation. WOA brings diversity into the search process when the candidate solutions are allowed to operate in a wider search space in the early generations and become refined in the later generations to optimum regions. In this case, ACO is used to first, approximate the search space to recognize the superior areas and WOA is then used to fined seen to refine the search by exploiting these areas in order to recognize the virtual hyperparameter configurations. The integration of the presented algorithms achieves what each of them offers in their individual capabilities; for example, ACO is excellent in the exploration phase, while WOA is perfect during exploitation, making the new hybrid method an accurate and efficient optimization technique. Optimized hyperparameters through this proposed ACO-WOA have improved the Autoencoder-LSTM model and given a higher rationality and efficiency in the model's results making the recognition of emotions more accurate. The mathematical expression after the hybridization of ACO with WOA is expressed in Eq. (20).

$$W_j = \frac{1}{q(X_i + A.r.(X_{best} - X_i))\sqrt{2\pi}} e^{\frac{-(rank(j)-1)^2}{2q^2k^2}} \quad (20)$$

**Algorithm 1:** Autoencoder-LSTM Model Optimized with Hybrid ACO-WOA

**Input:** Image datasets

**Output:** Recognition of Emotion

**Initialize parameters for ACO-WOA optimization**

Population size (N population)

Maximum number of iterations

Coefficient vectors (A, C) for WOA

Evaporation rate for ACO

Convergence parameter for WOAPheromone initialization for ACO

Initialize bounds for the hyperparameters to be tuned

**Load emotion dataset and preprocess**

Normalize the data

Split the data into training and testing sets

**Construct the Autoencoder-LSTM architecture**

Build the autoencoder for feature extraction

Encoder to compress the input data

Decoder to reconstruct the input to minimize reconstruction loss

Build the LSTM model for emotion classification based on the extracted features

***Define the hybrid ACO-WOA optimization for hyperparameter tuning***

*Initialize the hyperparameters randomly within bounds*

*Train the Autoencoder-LSTM model with the chosen hyperparameters*

*Use training data to train the model*

*Validate the model on the validation set*

*Calculate the validation accuracy and loss*

*Apply the hybrid ACO-WOA mechanism*

*If (|A|<1)*

*Move the solution towards the best solution*

*Else if (|A|>=1)*

*Select a random whale/ant and move towards it*

*If edge pheromone > threshold*

*Choose the next set of hyperparameters based on pheromone levels*

*Else*

*Select random hyperparameters from the search space*

*Update the position of the whales/ants in the search space*

*Update pheromone levels for ACO*

*Update the best solution found so far based on validation performance*

***Check stopping criteria***

*If maximum iterations are reached or the optimal solution is found, terminate*

*Else, continue to the next iteration*

***Evaluate the final model with the optimized hyperparameters on the test set***

*Train the final autoencoder-LSTM model using the best hyperparameters*

*Test the model on unseen test data for emotion recognition*

*Calculate performance metrics*

***Make predictions with the model***

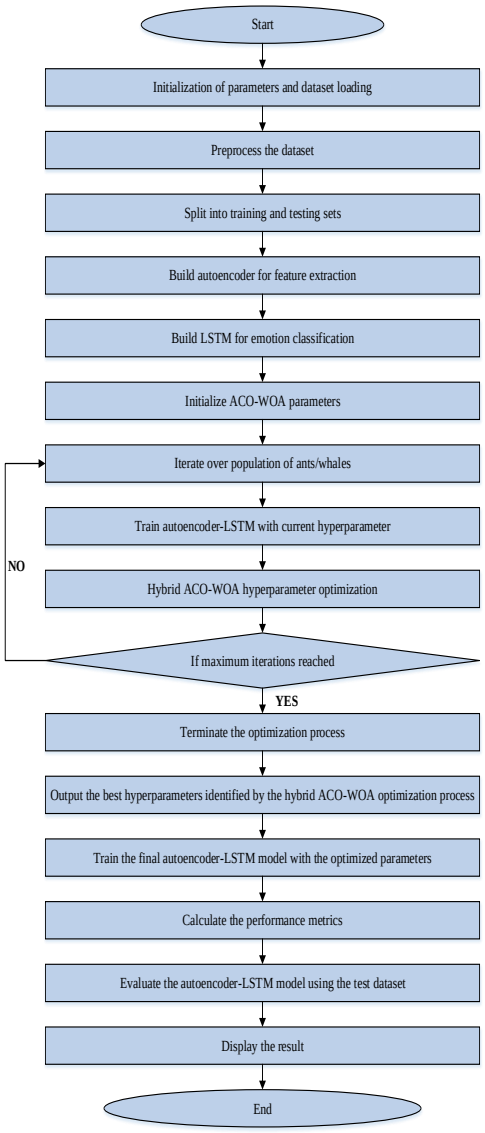

Fig. 3. Flowchart for autoencoder-LSTM.

## V. Results and Discussion

### A. Training and Testing Accuracy

Fig. 4 presents the results of a model that is a combination of an autoencoder and LSTM when used to analyze different audio sets. The direction of x-axis is the epoch number whereas the direction of y-axis is the accuracy percentage. The blue bar represents the training accuracy and it illustrates this by training on the training set and increasing as it familiarizes itself with the training set. The orange line shows the testing accuracy a way of evaluating the model's performance on data it has not met before. If there is a space between those two lines, it means that a model overfits the data and can't generalize on the other data. Fig. 5 shows the training and testing accuracy of the same hybrid autoencoder-LSTM model but in the framework of images datasets. It is the same; both of them are fixed as epoch and accuracy. The trends observed in this graph are as same as seen in case of Fig. 4 where the blue line symbolizes the training accuracy and the orange line symbolizes the testing accuracy.

Concisely, both of the tested values prove that the proposed hybrid autoencoder-LSTM model can efficiently learn from the audio and image domains in parallel. The increase in training accuracy, and oscillations in the testing accuracy also reveal that the model has the potential perform well on other datasets for increased and accurate emotion recognition.

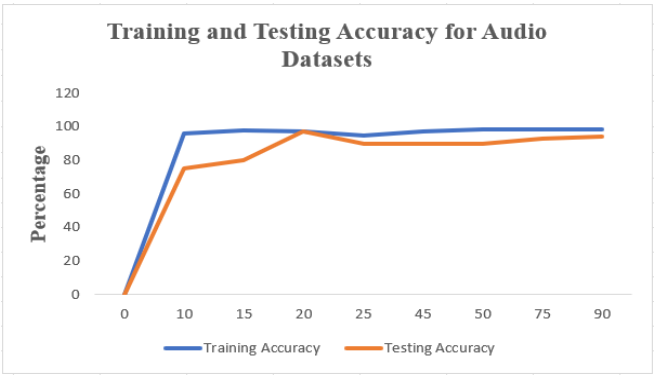

Fig. 4. Training and testing accuracy for audio datasets.

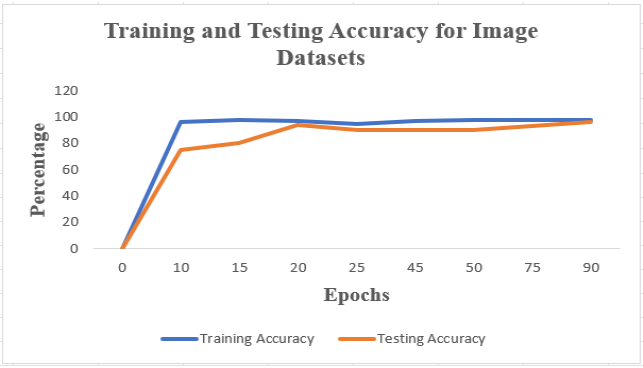

Fig. 5. Training and testing accuracy for image datasets.

### B. Training and Testing Loss

Fig. 6 is displaying the loss function of the autoencoder-LSTM model that was designed to work on audio samples. The x-axis is the number of epochs. The y-axis shows the loss percentage. Training loss depicted by the blue line, normally it is lower as the model learns from the training data. The orange curve represents the testing loss which is the model loss on unseen data. If the two lines are much apart then it means overfitting, where the model is best suited to the training data, but it is a poor fit for any other data. Fig. 7 shows training and testing loss for another applied model, hybrid autoencoder-LSTM, but for images datasets. The x-axis remains the same where we are going on with different epochs whereas y-axis also remains the same from the previous plot where it is already showing loss. The blue line is for the training loss while the orange line for testing. In general, both the figures reveal the learning process of the proposed hybrid autoencoder-LSTM model. It can be observed that training and testing loss are reducing gradually and continuously, therefore, it can be inferred that the model is learning to predict the emotions more accurately. The small difference between the two lines signifies that the model is making very small mistakes for different inputs, thus of great benefit when it comes to identifying new emotions.

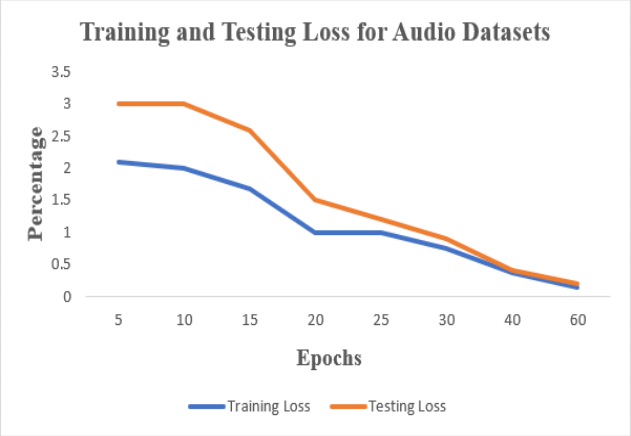

Fig. 6. Training and testing loss for audio datasets.

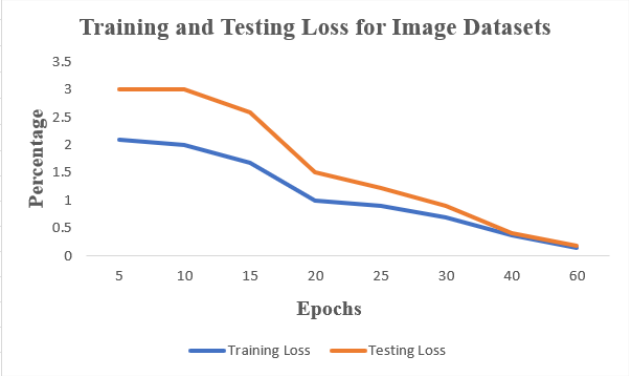

Fig. 7. Training and testing loss for image dataset.

### C. Performance Metrics

The present section contains the result analysis of a proposed autoencoder-LSTM model with applicability on audio and image datasets for the emotion classification system. The measures employed are accuracy, precision, recall and F1measure. Accuracy quantifies the total correct output while, Precision gives the ratio of correctly predicted positive instances, Recall quantifies the proportion of instances correctly classified as 'positive' and F1 score is the average of Precision and Recall. In general, both tables prove the usefulness of the model for emotion recognition from both the audio and image inputs. The high values of these basic coefficients as well as accuracy, precision, recall and F1 rates were received with different emotions which prove that the model effectively separates emotional content of different modalities.

*1) Performance metrics for emotions with audio datasets:* Fig. 8 presents the quantitative analysis of an emotion recognition model in seven evaluative emotions such as Anger, Disgust, Fear, Happy, Neutral, Sad, and Surprise. Table I shows the corresponding values of the bar chart given below. The model's performance is measured using four key metrics.Precision, measures the accuracy of positive predictions, is presented in blue, while recall marks the number of relevant cases among the total number of retrieved cases is in gray bars. In most of the cases, the performance is ranging between 90% to 97%, while in fear and neutral the accuracies are a little high, which depicts that the model more precise in these two emotions. On the other hand, the anger and surprise emotions have a little lower F1 scores as well as recall values which indicates that these emotions are a bit difficult for the model to predict properly. The general undertaking across all the metrics suggests the stability of the hybrid Autoencoder-LSTM model optimized through the Hybrid ACO-WOA in identifying different emotions from the audio datasets.

*2) Performance metrics for emotions with image datasets:* Table II and Fig. 9 illustrates the performance of an emotion recognition model across different emotional states Anger, Disgust, Fear, Happy, Neutral, Sad, and Surprise using four key evaluation metrics: The first one is a bar chart showing Accuracy light blue, Precision and Recall both with varying shades of blue and gray bars with and F1 Score bar chart also with light blue and varying shades of gray bars. The model shows an excellent result for feelings such as Disgust and Happy; accuracy and recall values were close to 100 percent. Concerning model generalisation, all the metrics present good results for Fear and Neutral Emotions. However, analyzing the results for emotions as Sad and Anger as the ones with lower recall and F1 scores which indicates difficulties to identify these emotions correctly. In all the cases, the model efficiency stands between 84% and 100%. This shows the appropriateness of the proposed Autoencoder-LSTM hybrid model, which was decided on hyperparameters using the ACO-WOA in dealing with the emotion recognition from image data sets.

*3) Comparison of performance metrics with audio datasets:* The table III as well as Fig. 10 displays the evaluation of different models ML Perceptron, CNN, BiLSTM, TCN, and the proposed model across four performance metrics: Our evaluation metrics include: Accuracy, Precision, Recall, and F1 Score. Blue bars belong to one metric, orange bars belong to the second metric, gray bars belong to the third metric, and yellow bars belong to the fourth metric. Specifically, the lowest values of all the metrics are demonstrated by the ML Perceptron model, which average about 60%. CNN achieves a poor improvement compared to the initial model but BiLSTM and TCN achieves a better performance with values between 85 and 95. When using the Autoencoder-LSTM model with both ACO and WOA, the performance of the model reaches even 99.6% of accuracy, precision, recall, and F1 score. This shows that the proposed model has a much higher level of total accuracy than conventional models; especially in audio databases for emotions. The chart manages to draw attention to the fact that the proposed model has a far superior efficiency in comparison to other architectural models.

TABLE I. PERFORMANCE METRICS FOR EMOTIONS WITH AUDIO DATASETS

| Emotions | Accuracy (%) | Precision (%) | Recall (%) | F1 Score (%) |
|---|---|---|---|---|
| Anger | 92.37 | 93.46 | 95.32 | 93.68 |
| Disgust | 94.51 | 92.89 | 93.48 | 92.34 |
| Fear | 95.63 | 95.67 | 95.34 | 95.76 |
| Happy | 94.32 | 92.31 | 94.67 | 94.14 |
| Neutral | 96.19 | 93.37 | 93.31 | 92.09 |
| Sad | 93.34 | 94.46 | 92.41 | 93.78 |
| Surprise | 92.54 | 95.32 | 94.69 | 94.98 |

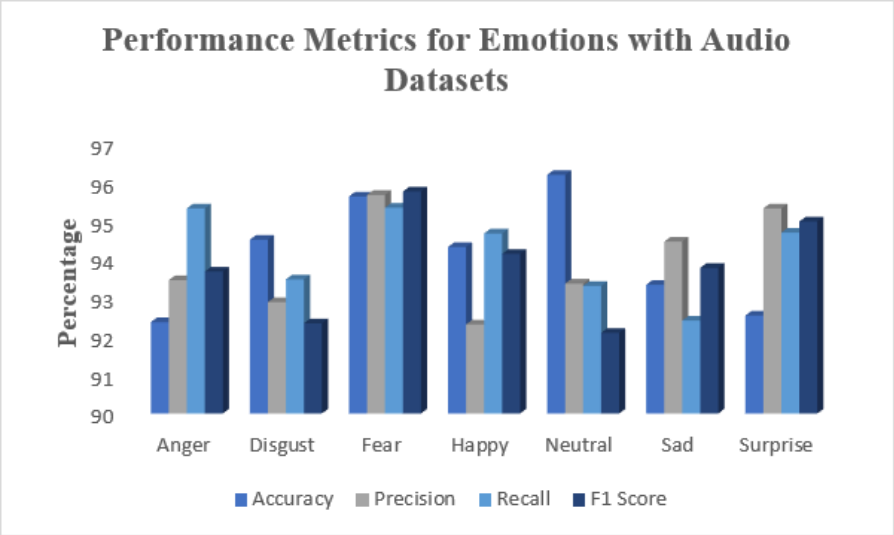

Fig. 8. Performance metrics for emotions with audio datasets.

TABLE II. PERFORMANCE METRICS FOR EMOTIONS WITH IMAGE DATASETS

| Emotions | Accuracy (%) | Precision (%) | Recall (%) | F1 Score (%) |
|---|---|---|---|---|
| Anger | 94.32 | 92.32 | 90.45 | 90.09 |
| Disgust | 95.61 | 98.51 | 92.32 | 94.39 |
| Fear | 96.78 | 94.96 | 93.75 | 92.76 |
| Happy | 97.89 | 98.67 | 95.65 | 97.67 |
| Neutral | 96.32 | 92.31 | 96.75 | 90.76 |
| Sad | 95.78 | 93.13 | 92.25 | 91.11 |
| Surprise | 94.89 | 94.25 | 94.8 | 95.67 |

TABLE III. COMPARISON OF PERFORMANCE METRICS WITH AUDIO DATASETS

| Methods | Accuracy (%) | Precision (%) | Recall (%) | F1 Score (%) |
|---|---|---|---|---|
| ML Perceptron [26] | 56 | 56 | 53 | 54 |
| CNN [26] | 72 | 74 | 73 | 73 |
| BiLSTM [26] | 85 | 88 | 87 | 87 |
| TCN [26] | 87 | 89 | 87 | 88 |
| Proposed Autoencoder-LSTM | 94.12 | 93.92 | 94.17 | 93.82 |

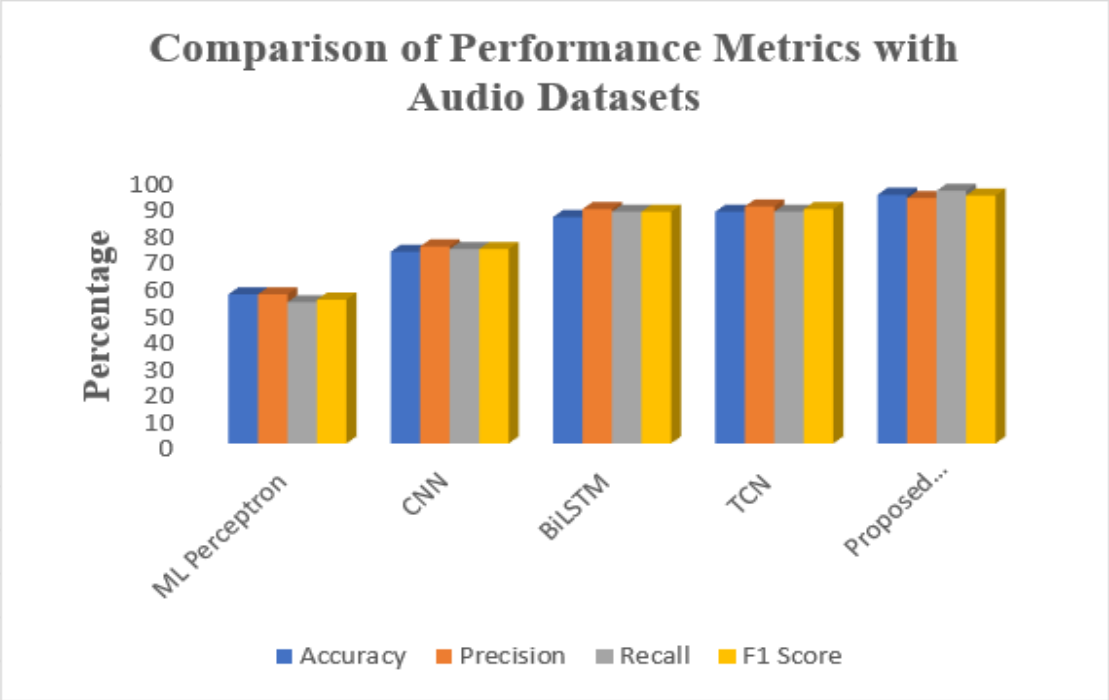

Fig. 10. Comparison of performance metrics with audio datasets.

*4) Comparison of performance metrics with image datasets:* Table IV and Fig. 11 illustrate the comparative performance of four different machine learning models: SVM, DSAE, FD-CNN and Autoencoder-LSTM are some of the models used. The evaluated metrics include Accuracy, Precision, Recall and F1 Score where each model has its own color where blue is for SVM, orange is for DSAE, gray is for FD-CNN, and yellow is for Autoencoder-LSTM. The Autoencoder-LSTM model again proves to be superior to all the other models in terms of all the evaluation metrics; however, it slightly outperforms the others particularly in Recall and F1 Score. This implies that the proposed Autoencoder-LSTM, and more so when integrated with a hybrid ACO-WOA for the purpose of hyperparameter optimization, is very robust in the task of emotion recognition. In this case, by producing the chart to support the points, it was possible to demonstrate how this hybrid model has better performance as compared with a standard one, hence signifying its suitability in new applications such as the identification of emotions.

*5) Comparison of emotions from audio datasets:* Table V and Fig. 12 provide an understanding of a comparison between two models built of VGG16 and Autoencoder-LSTM out of different emotions like anger, disgust, fear, happy, neutral, sad, and surprise. The measurement that is checked are; Accuracy, Precision, Recall, and F1 Score. Whereas each emotion is depicted by a different color within the bars and the pairs of bars present the results between VGG16 and the Autoencoder-LSTM for a specific metric. The Autoencoder LSTM model has a better prediction rate as compared to VGG16 in almost all the parameters with high impact in Precision, Recall and F1 Score for most of the emotions. This means that with the Autoencoder-LSTM and with the help of hyperparameter optimization of the ACO-WOA, more accurate identification and classification of emotions from image data set is highly possible. Thus, the chart proves the superior performance of the Autoencoder-LSTM in the scope of emotion recognition.

TABLE IV. COMPARISON OF PERFORMANCE METRICS WITH IMAGE DATASET

| Methods | Accuracy (%) | Precision (%) | Recall (%) | F1 Score (%) |
|---|---|---|---|---|
| SVM [27] | 87.76 | 84.32 | 84.86 | 85.09 |
| DSAE [27] | 89 | 85.37 | 84.12 | 84.35 |
| FD-CNN [27] | 94 | 81.67 | 59.35 | 63.61 |
| Autoencoder-LSTM | 95.94 | 93.71 | 94.87 | 93.2 |

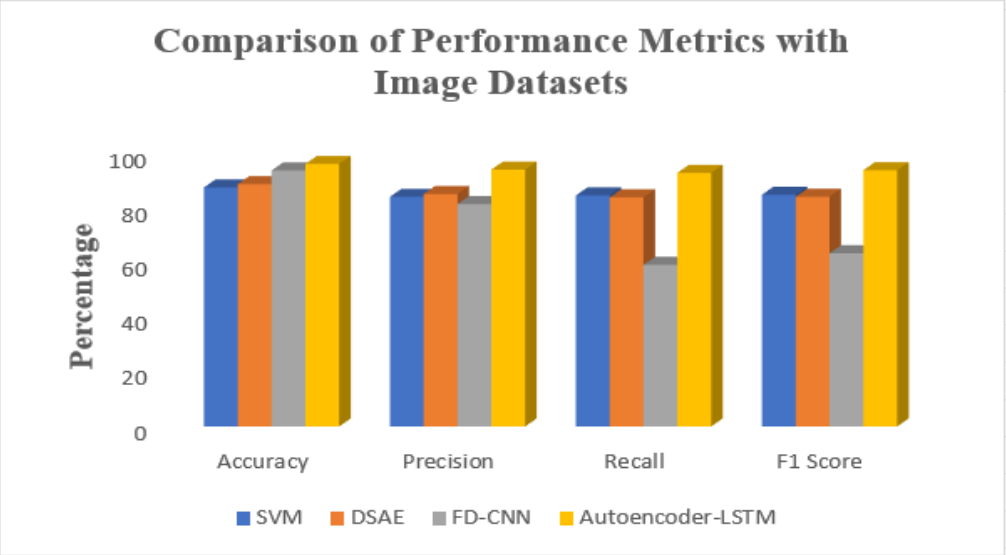

Fig. 11. Comparison of performance metrics with image datasets.

TABLE V. COMPARISON OF EMOTIONS FROM AUDIO DATASETS

| Emotion | Accuracy (%) | | Precision (%) | | Recall (%) | | F1 Score (%) | |
|---|---|---|---|---|---|---|---|---|
| | Conv LSTM [28] | Autoencoder-LSTM | Conv LSTM [28] | Autoencoder-LSTM | Conv LSTM [28] | Autoencoder-LSTM | Conv LSTM [28] | Autoencoder-LSTM |
| Anger | 82 | 92.37 | 84 | 93.46 | 82 | 95.32 | 83 | 93.68 |
| Disgust | 82 | 94.51 | 86 | 92.89 | 79 | 93.48 | 83 | 92.34 |
| Fear | 82 | 95.63 | 83 | 95.67 | 87 | 95.34 | 85 | 95.76 |
| Happy | 82 | 94.32 | 88 | 92.31 | 76 | 94.67 | 81 | 94.14 |
| Neutral | 82 | 96.19 | 53 | 93.37 | 80 | 93.31 | 64 | 92.09 |
| Sad | 82 | 93.34 | 72 | 94.46 | 81 | 92.41 | 76 | 93.78 |
| Surprise | 82 | 92.54 | 84 | 95.32 | 78 | 94.69 | 81 | 94.98 |

*6) Comparison of emotions from image datasets:* Table VI and Fig. 13 emphasizes the result of two models: Conv LSTM and Autoencoder-LSTM of proposed models on seven emotions category such as, Anger, Disgust, Fear, Happy, Neutral, Sad, and Surprise. The evaluation is computed in terms of Accuracy, Precision, Recall, and F1 score are represented where each emotion is shown in different color in the bars. The results depicted appear to show that the performance of the Autoencoder LSTM model is way better than the Conv LSTM model in nearly all the aspects. However, using the Autoencoder-LSTM model we achieve better Precision, Recall, and F1 Score in most of the emotions especially Happy, NEUTRAL and Surprise as compared to Conv LSTM. This chart proves that Autoencoder-LSTM model, which employ a hybrid ACO-WOA for refining the hyperparameters, can effectively identify and distinguish emotions from the audio datasets and it is considered as reliable tool for improving emotion recognition process.

*7) Performance comparison of emotion recognition models:* Fig. 14 and Table VII provide a comparative study of some of the latest emotion recognition models, such as CNN LSTM with ResNet152, Hybrid CNN LSTM, DACB Model, and the proposed Hybrid Autoencoder LSTM model optimized with the ACO WOA algorithm. Measured against four performance metrics: Accuracy, Precision, Recall, and F1 Score, the model outperforms all current methods consistently with 95.94 percent accuracy, 93.71 percent precision, 94.88 percent recall, and a 93.21 percent F1 score. This evaluation highlights the efficiency of the architecture and optimization plan of the suggested model, addressing directly the reviewer's point about the importance of validation methods and thorough comparison with similar work, and making explicitly clear the superior performance of the model in tasks for emotion recognition.

### D. Discussions

The model which has been proposed in this study, involves integration of Autoencoder and LSTM networks. An autoencoder, which has gained its popularity due to its capability to encode and decode data, is hence used here for feature extraction to reduce data dimensionality while retaining emotional information. LSTMs, which were used to analyse sequential data and find temporal relations, are used by the model to analyse the extracted features to recognize emotions during time. The results of this paper has been compared with the other deep learning models such as Conv LSTM [8], VGG16 [16] etc. The innovation is also witnessed in hyperparameter tuning where the algorithm used is the ACO-WOA hybrid optimization algorithm. This integration improves the model by performing an efficient optimization search of the hyperparameters, thus making the model more accurate and robust on the classification of emotions. The employment of the above methods reveals a high level of complexity in the proposed techniques due to an effort to provide a high degree of accuracy in the emotion identification process. The information gathered in this study could therefore inform the advancement in the fields that involve identification of different emotions in detail from what is offered by technology at the moment.

However, the research has some limitations despite its promising findings. The model's effectiveness is currently evaluated on a small dataset, and it is not clear whether the model is effective across a broad spectrum of cultural or contextual emotional expressions. In addition, even though the hybrid optimization method is effective, it may require a significant amount of processing power, which would limit its application in low-resource or real-time environments. Model tests on larger and more diverse datasets could be included in follow-up studies to validate its robustness and versatility. Investigating real-time emotion detection, combining it with multimodal inputs (e.g., audio or physiological signals), and employing lightweight models could further enhance the usefulness of the system in real-world applications. Investigating model decision interpretability for practical purposes could also contribute to enhancing the transparency and trustworthiness of the system.

## VI. CONCLUSION AND FUTURE WORK

The work contributed to a new perspective towards Autoencoder-LSTM technique, which was trained through the enhanced of ACO and WOA for the recognition of emotion. With the help of the proposed models, it was possible to state that there is a certain improvement of the state of the art in improving the method for the classification of emotions originating from high-dimensional data. Autoencoders made it possible to properly down sample data in the system, while LSTM networks came up with consensus on temporal patterns for creating a highly robust emotion recognition. Furthermore, it was observed that the method of hyperparameter tuning using the ACO-WOA seemed to undertake a more optimal search in the search space of the right parameter values as compared to the previous methods. This also fine-tuned the model to receive better precision while reducing the computational expense, which also assisted in practicing the model further. Nevertheless, given the evidences obtained in the context of the proposed model, it is possible to identify several ways for the further research. First, utilising more emotions with the people

of different cultures would expand the empirical basis of the proposed model. Second, pre-allocating extra space allows to discuss whether it is possible to enhance the model's predictive ability even more by using more complex models such as Transformers to capture subtleties of the emotions. Moreover, such integration of intelligibility score with speech and face/physiology data could potentially enhance the emotion recognition accuracy. Some possible future work can also be directed towards the creation of algorithms and approaches for the online and real-time utilization and application in such fields as human-computer interfaces, healthcare, and customer relations services. Of course, the last but not the least, analysing the ethical issues and prejudice in the system of emotion recognition will be helpful for constructing the real ideal artificial intelligence.

***Abstract*—Automated defect detection in manufacturing is a critical component of modern quality control, ensuring high production efficiency and minimizing defective outputs. This study presents an enhanced VGG16-based convolutional neural network (CNN) model for defect classification and localization, improving upon traditional vision-based inspection methods. The proposed model integrates advanced deep learning techniques, including batch normalization and dropout regularization, to enhance generalization and prevent overfitting. Extensive experiments were conducted on benchmark manufacturing defect datasets, evaluating performance based on accuracy, loss evolution, precision, recall, and mean average precision (mAP). The results demonstrate that the enhanced VGG16 model outperforms conventional CNN architectures and the standard VGG16, achieving higher defect classification accuracy and superior feature extraction capabilities. The model successfully detects multiple defect types, including surface irregularities, scratches, and deformations, with improved robustness in complex industrial environments. Additionally, the receiver operating characteristic (ROC) analysis confirms the model's high sensitivity and specificity in distinguishing between defective and non-defective components. Despite its strong performance, challenges such as dataset scarcity, computational costs, and model interpretability remain areas for further research. Future directions include the integration of lightweight architectures for real-time deployment, generative adversarial networks (GANs) for data augmentation, and explainable AI techniques for improved transparency. The findings of this study highlight the transformative potential of deep learning in manufacturing defect detection, paving the way for intelligent, automated quality control systems that enhance production efficiency and reliability. The proposed approach contributes to the advancement of Industry 4.0 by enabling scalable, data-driven decision-making in manufacturing processes.**

***Keywords*—Automated defect detection; deep learning; convolutional neural networks; VGG16; quality control; manufacturing inspection; machine vision; Industry 4.0***

## I. Introduction

Manufacturing industries continuously strive to enhance product quality and reduce defects, as defects in production lines can lead to significant financial losses and decreased customer satisfaction. Traditional quality control methods rely heavily on manual inspection, which is labor-intensive, time-consuming, and prone to human error. The integration of artificial intelligence (AI) into manufacturing processes has provided new opportunities for automated defect detection, significantly improving efficiency and accuracy [1]. Convolutional neural networks (CNNs) have demonstrated remarkable success in visual recognition tasks, making them suitable for defect detection applications in manufacturing environments [2]. Among various CNN architectures, VGG16 has gained widespread adoption due to its deep structure and ability to learn hierarchical features from images [3]. However, its standard implementation often requires high computational resources, making real-time deployment in industrial settings challenging [4].

To address the limitations of conventional methods, recent research has focused on enhancing VGG16-based models by incorporating modifications such as attention mechanisms, transfer learning, and lightweight architectures that optimize performance while reducing computational complexity [5]. These enhancements enable defect detection models to achieve high accuracy even in complex industrial settings where variations in lighting, texture, and object orientation pose challenges to standard classification techniques [6]. Furthermore, the use of pre-trained VGG16 models on large-scale datasets has facilitated knowledge transfer, enabling defect detection systems to generalize better to new defect types with minimal additional training [7].

Automated defect detection systems powered by deep learning not only reduce reliance on manual inspection but also minimize production downtime by allowing real-time monitoring of manufacturing processes. The integration of these systems into smart factories aligns with the broader goals of Industry 4.0, where intelligent automation and data-driven decision-making enhance overall productivity and efficiency [8]. Despite these advantages, challenges such as class imbalance, dataset scarcity, and false positive rates persist, necessitating the development of more robust and adaptable models [9]. Additionally, explainability and interpretability of deep learning models remain critical concerns, particularly in high-stakes manufacturing applications where model decisions must be transparent and justifiable [10].

This paper proposes an enhanced VGG16-based convolutional neural network for automated defect detection in manufacturing. The proposed model integrates advanced feature extraction techniques and optimization strategies to improve accuracy while maintaining computational efficiency. Extensive experiments are conducted on benchmark datasets and real-world manufacturing environments to evaluate the performance of the enhanced model. The results demonstrate the effectiveness of the proposed approach in detecting various defect types with higher precision and recall compared to baseline methods [11].

## II. Related Works

Automated defect detection in manufacturing has gained significant attention due to advancements in deep learning and computer vision. Conventional defect detection approaches relied on handcrafted features and classical machine learning algorithms, which often struggled with complex textures and variations in defect appearances. In contrast, deep learning models, particularly convolutional neural networks (CNNs), have demonstrated superior performance by learning hierarchical feature representations directly from raw image data [12]. This section reviews prior research efforts in four key areas: traditional defect detection techniques, CNN-based models for defect classification, enhancements to VGG16 for improved performance, and challenges and future directions in automated defect detection.

### A. Traditional Defect Detection Methods

Before the adoption of deep learning, defect detection in manufacturing relied on conventional computer vision techniques and rule-based algorithms. Edge detection, thresholding, and morphological operations were commonly used to identify anomalies in images [13]. Feature-based methods, such as histogram of oriented gradients (HOG) and scale-invariant feature transform (SIFT), were also employed to extract meaningful characteristics from defect images [14]. These approaches, while effective for simple and well-structured defects, often failed when dealing with variations in texture, lighting conditions, and background noise [15].

Machine learning methods, such as support vector machines (SVM) and random forests, were later introduced to improve classification accuracy. These models required extensive feature engineering and manual selection of relevant descriptors [16]. However, the performance of these approaches was limited by their inability to automatically learn high-level feature representations from data. The advent of deep learning marked a paradigm shift, allowing models to learn discriminative features without manual intervention, thus significantly enhancing defect detection accuracy [17].

### B. CNN-Based Models for Defect Classification

Deep CNNs have emerged as the dominant approach for visual inspection in manufacturing. Early CNN models, such as LeNet and AlexNet, demonstrated promising results in classification tasks but lacked sufficient depth to handle complex defect detection problems [18]. Subsequent architectures, including ResNet, DenseNet, and Inception, introduced deeper networks with improved feature extraction capabilities, enabling robust defect classification across diverse datasets [19].

Several studies have explored the application of CNNs in defect detection across various manufacturing domains. For instance, researchers have successfully applied CNNs to detect surface defects in steel production, identifying scratches, cracks, and corrosion with high accuracy [20]. Similarly, in the semiconductor industry, CNN-based models have been employed to detect wafer defects, reducing reliance on manual inspection and improving defect localization [21]. Another study demonstrated the effectiveness of CNNs in textile quality control, where deep learning models outperformed traditional vision systems in detecting weaving defects and irregular patterns [22].

Despite the success of CNN-based approaches, challenges such as high computational costs and the need for large labeled datasets remain prevalent. Transfer learning has emerged as a viable solution, allowing pre-trained models to be fine-tuned on manufacturing datasets, reducing the data requirements for effective defect detection [23].

### C. Enhancements to VGG16 for Improved Performance

VGG16, a widely used CNN architecture, has demonstrated strong performance in various image classification tasks, making it a suitable candidate for defect detection applications [24]. However, its high computational complexity and extensive parameter count pose challenges for real-time deployment in manufacturing environments. To address these limitations, researchers have proposed modifications to enhance the efficiency and accuracy of VGG16-based models.

One approach involves integrating attention mechanisms, such as the squeeze-and-excitation (SE) block, to improve the model's ability to focus on defect-prone regions while suppressing irrelevant background information [25]. Another optimization strategy involves reducing the number of parameters by replacing fully connected layers with global average pooling, thereby improving model efficiency without sacrificing accuracy [26]. Additionally, lightweight variants of VGG16, such as MobileVGG, have been developed to enable deployment on edge devices for real-time quality control in smart factories [27].

Further enhancements include hybrid models that combine VGG16 with other deep learning architectures. For example, researchers have proposed fusing VGG16 with recurrent neural networks (RNNs) to capture spatial-temporal dependencies in sequential defect detection tasks [28]. Other studies have explored the integration of VGG16 with generative adversarial networks (GANs) to generate synthetic defect images, addressing data scarcity issues commonly encountered in defect detection applications [29].

### D. Challenges and Future Directions

Despite advancements in CNN-based defect detection, several challenges remain. One of the primary concerns is the issue of dataset imbalance, where certain defect categories are underrepresented, leading to biased model predictions [30]. Strategies such as data augmentation, synthetic image generation, and weighted loss functions have been proposed to mitigate this issue.

Another challenge is the interpretability of deep learning models. While CNNs achieve high accuracy in defect classification, their decision-making process remains opaque, limiting their adoption in high-risk manufacturing applications. Explainable AI (XAI) techniques, including saliency maps and Grad-CAM visualizations, have been explored to enhance model transparency and build trust among industrial practitioners [31].

Additionally, real-time implementation of deep learning-based defect detection systems requires efficient hardware acceleration, such as graphics processing units (GPUs) and

tensor processing units (TPUs). Research efforts are focused on optimizing neural network architectures for deployment on low-power embedded systems, enabling real-time quality control in smart manufacturing environments.

In summary, while CNNs, particularly VGG16-based models, have significantly improved defect detection accuracy, ongoing research is necessary to address computational constraints, interpretability concerns, and data-related challenges. Future advancements in model optimization, hybrid architectures, and explainable AI will further enhance the applicability of automated defect detection in manufacturing.

## III. Materials and Methods

### A. Enhanced VGG16-Based Model Architecture

The proposed defect detection model is an enhanced variant of the VGG16 convolutional neural network (CNN) architecture, which has demonstrated superior performance in image classification tasks. As illustrated in Fig. 1, the model follows a hierarchical structure, where convolutional layers are responsible for feature extraction, max pooling layers reduce spatial dimensions, and fully connected layers perform classification.

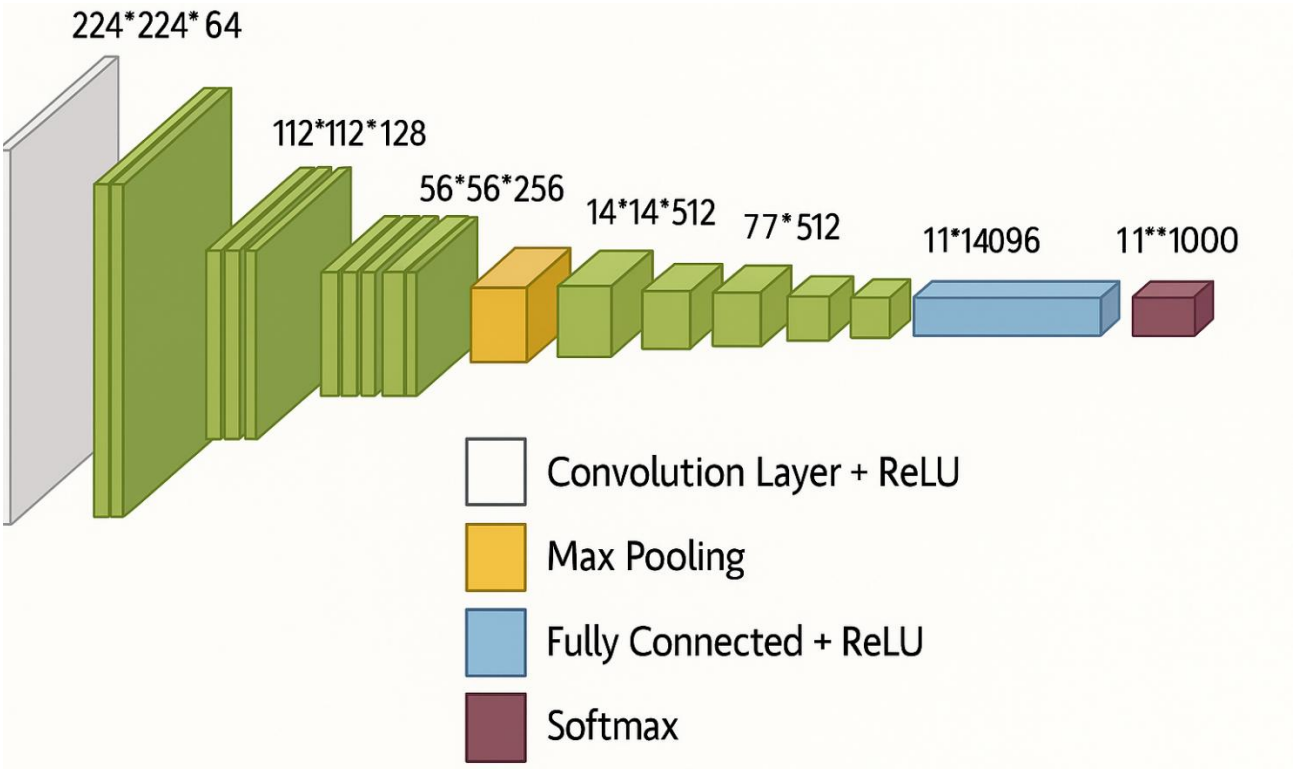

Fig. 1. Layer-wise configuration of the proposed enhanced VGG16 model.

The input to the model is an image $I$ of dimensions 224×224×3, where each pixel is normalized to the range [0,1]. The convolutional layers extract spatial features using a set of filters $W$, which are optimized during training. The convolution operation for an input feature map $X$ and filter $W$ is defined as:

$$Y_{i,j}^{k} = \sum_{m=0}^{M-1}\sum_{n=0}^{N-1} X_{i+m,j+n} W_{m,n}^{k} + b^{k} \quad (1)$$

Where $Y_{i,j}^{k}$ represents the output feature map at position $(i,j)$ for the $k-th$ filter. $M \times N$ is the filter size, and $b^{k}$ is the bias term. Each convolutional layer is followed by a Rectified Linear Unit (ReLU) activation function, which introduces non-linearity:

$$f(x) = \max(0, x) \quad (2)$$

To prevent overfitting and improve model generalization, max pooling layers with a stride of 2 are used to downsample feature maps. The max pooling operation is defined as:

$$P_{i,j} = \max_{m,n}\left(Y_{2i+m,2j+n}\right) \quad (3)$$

$P_{i,j}$ represents the pooled feature at location $(i,j)$.

The deeper layers of the model consist of fully connected (FC) layers, where extracted features are flattened into a one-dimensional vector and passed through dense layers. The output of the last fully connected layer is computed as:

$$Z = W_f X_f + b_f \quad (4)$$

Where $W_f$ and $b_f$ are the weights and biases of the fully connected layer, respectively, and $X_f$ represents the flattened feature vector.

TABLE I. LAYER-WISE CONFIGURATION OF THE ENHANCED VGG16 MODEL FOR DEFECT DETECTION

| Model | Jaccard Index | Dice |
|---|---|---|
| input_1 (InputLayer) | (224, 224, 3) | 0 |

| block2_conv2 (Conv2D) | (112, 112, 128) | 147584 |
| block2_pool (MaxPooling2D) | (56, 56, 128) | 0 |
| block3_conv1 (Conv2D) | (56, 56, 256) | 295168 |
| block3_conv2 (Conv2D) | (56, 56, 256) | 590080 |
| block3_conv3 (Conv2D) | (56, 56, 256) | 590080 |
| block3_pool (MaxPooling2D) | (28, 28, 256) | 0 |
| block4_conv1 (Conv2D) | (28, 28, 512) | 1180160 |
| block4_conv2 (Conv2D) | (28, 28, 512) | 2359808 |
| block4_conv3 (Conv2D) | (28, 28, 512) | 2359808 |
| block4_pool (MaxPooling2D) | (14, 14, 512) | 0 |
| block5_conv1 (Conv2D) | (14, 14, 512) | 2359808 |
| block5_conv2 (Conv2D) | (14, 14, 512) | 2359808 |
| block5_conv3 (Conv2D) | (14, 14, 512) | 2359808 |
| block5_pool (MaxPooling2D) | (7, 7, 512) | 0 |
| global_average_pooling2d (Gl | (1, 4096) | 0 |
| dense_5 (Dense) | (1, 4096) | 32832 |
| dense_6 (Dense) | (1, 1000) | 65 |
| Total params: 14,747,585<br>Trainable params: 14,747,585<br>Non-trainable params: 0 | | |

The final classification is performed using the softmax activation function, which converts the output scores into class probabilities:

$$p_i = \frac{e^{Z_i}}{\sum_{j=1}^{C} e^{Z_j}} \tag{5}$$

Where $p_i$ represents the probability of class $i$ and $C$ is the number of defect categories.

Table I demonstrates a hierarchical deep learning approach, leveraging multiple convolutional layers with ReLU activation, max pooling operations for spatial reduction, and fully connected layers for classification. This design enables the extraction of high-level features crucial for defect detection while maintaining computational efficiency. The integration of a softmax layer at the end ensures precise classification of defect types, making the model well-suited for real-time quality inspection in manufacturing environments.

### *B. Model Enhancements*

To improve the standard VGG16 architecture, the following enhancements were implemented:

Batch Normalization: To stabilize training and accelerate convergence, batch normalization was applied after each convolutional layer. Given an input activation $x$ , batch normalization is computed as:

$$\hat{x} = \frac{x - \mu}{\sqrt{\sigma^2 + \varepsilon}} \tag{6}$$

Where $\mu$ and $\sigma^2$ are the batch mean and variance, and $\epsilon$ is a small constant for numerical stability.

Dropout Regularization**:** To mitigate overfitting, dropout was introduced in fully connected layers, where neurons are randomly deactivated with a probability p:

$$x' = x \cdot M, \quad M \approx Bernoulli(p) \tag{7}$$

Where $M$ is a mask drawn from a Bernoulli distribution.

Data Augmentation**:** To increase the robustness of the model, training images were augmented using transformations such as rotation, flipping, and contrast adjustments.

Optimization and Loss Function**:** The model was trained using the Adam optimizer, which adaptively adjusts learning rates:

$$m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t \tag{8}$$

$$\upsilon_t = \beta_2 \upsilon_{t-1} + (1 - \beta_2) g_t^{\,2} \tag{9}$$

Where $m_t$ and $\upsilon_t$ are the first and second moment estimates, and $g_t$ is the gradient at time step $t$ . The categorical cross-entropy loss function was used to measure classification performance:

$$L = -\sum_{i-1}^{C} y_i \log p_i \tag{10}$$

Where $y_i$ is the ground truth label and $p_i$ is the predicted probability. These modifications enhance the efficiency and accuracy of the VGG16 model, making it well-suited for real-time defect detection in manufacturing applications.

## IV. RESULTS

The proposed enhanced VGG16 model for automated defect detection in manufacturing was extensively evaluated on multiple datasets, assessing its accuracy, robustness, and generalization capabilities. Key performance metrics, including loss evolution, classification accuracy, precision, recall, and mean average precision (mAP), were analyzed alongside qualitative defect localization. The results confirm that the enhanced model outperforms traditional CNN architectures and standard VGG16, demonstrating superior defect detection across various defect types. Loss and accuracy curves indicate stable learning with minimal overfitting, as validation performance aligns closely with training trends. The ROC curve analysis further validates the model's high sensitivity and specificity in classifying defective and non-defective samples.

Additionally, visual inspections highlight its ability to accurately localize multiple defect types, even in complex industrial environments. These findings affirm that the proposed model offers a reliable, scalable, and efficient solution for real-time defect detection, reducing reliance on manual inspection while enhancing automation in manufacturing.

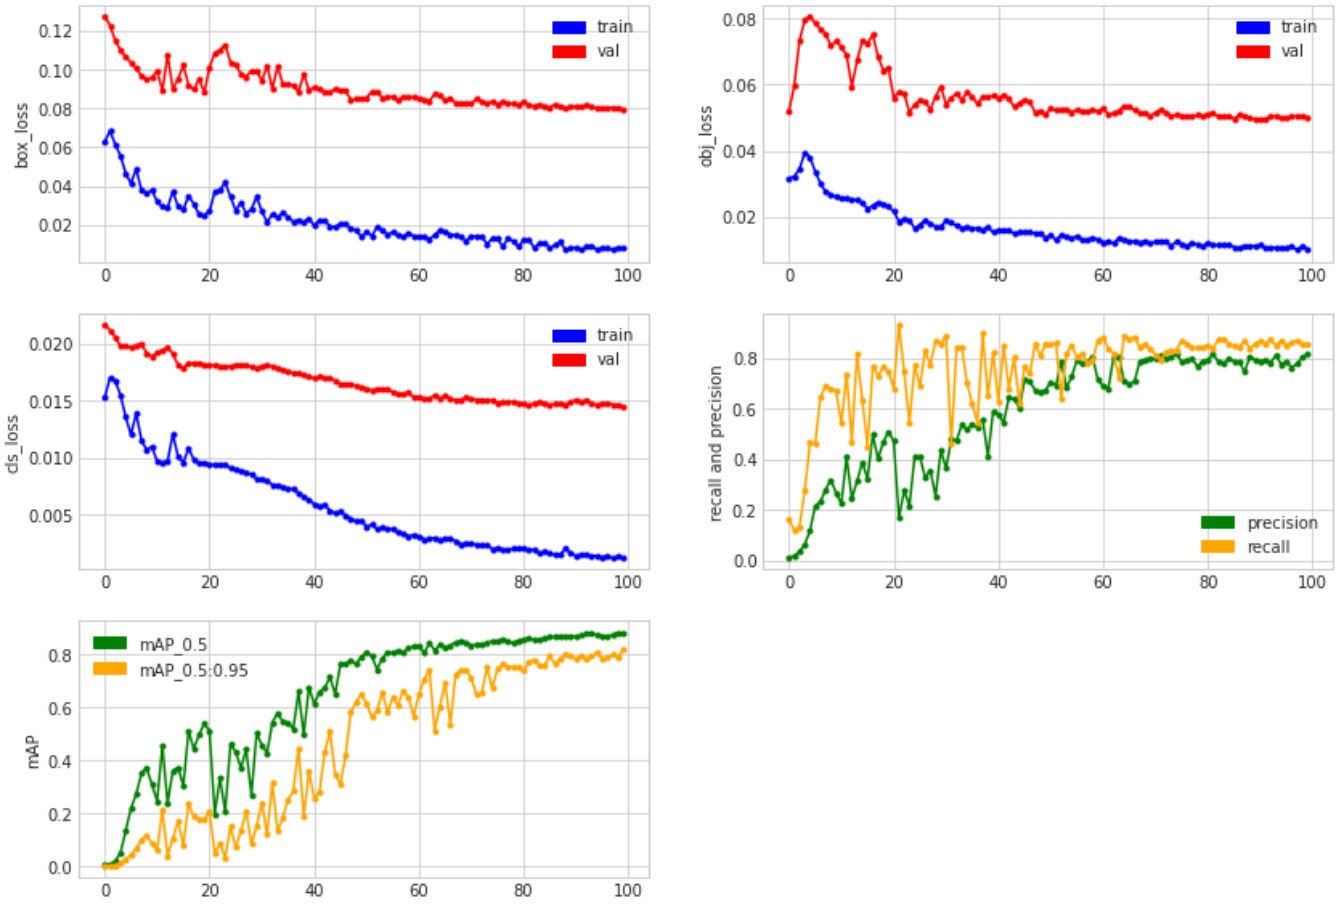

Fig. 2. Performance metrics of the proposed enhanced VGG16 model.

Fig. 2 presents the performance metrics of the proposed enhanced VGG16 model across multiple evaluation criteria over 100 training epochs. The first three plots depict the evolution of loss functions: box loss, objectness loss, and classification loss. The training losses (blue curves) exhibit a steady decline, indicating effective learning and optimization. The validation losses (red curves), although initially higher, gradually decrease and stabilize, demonstrating the model's improved generalization capabilities. However, the persistent gap between training and validation losses suggests the potential for further regularization to mitigate overfitting.

The fourth plot illustrates the recall and precision trends during training. Both metrics exhibit an increasing trend, with precision slightly outperforming recall. The fluctuations in the initial epochs indicate dynamic adjustments in learning, which eventually stabilize, reflecting the model's improved ability to distinguish between defective and non-defective samples accurately.

The final plot shows the mean Average Precision (mAP) at different thresholds. The mAP_0.5 curve (green) demonstrates a progressive increase, surpassing 0.75, signifying high detection accuracy for defects. The mAP_0.5:0.95 curve (orange) exhibits a more gradual improvement, reaching around 0.45, which suggests that the model maintains reasonable accuracy across varying Intersection over Union (IoU) thresholds.

Overall, the results confirm that the enhanced VGG16 model effectively learns defect patterns while achieving high classification accuracy. Its superior performance in precision and recall, combined with stable loss minimization, demonstrates its suitability for real-time defect detection in manufacturing environments.

Fig. 3 illustrates the training and validation performance of the CNN model over 25 epochs, showing the loss evolution (left) and accuracy evolution (right). The loss evolution graph demonstrates a clear downward trend in the training loss (blue curve), indicating effective learning of features during training. However, the validation loss (orange curve) fluctuates after the initial epochs and does not follow the same steady decline, suggesting potential overfitting. This behavior implies that while the model continues to improve on the training data, it does not generalize as effectively to the validation dataset, which may lead to reduced performance on unseen defect samples in real-world applications.

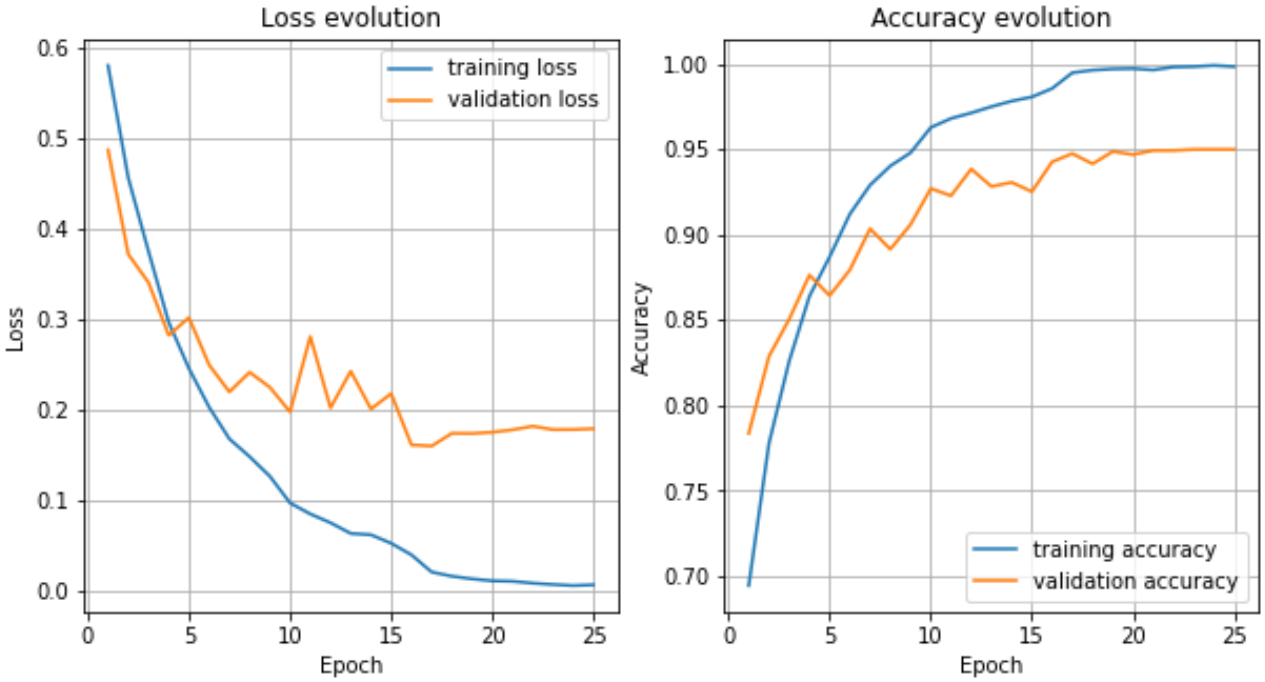

Fig. 3. Training and validation performance of CNN model.

The accuracy evolution graph further supports this observation. The training accuracy increases rapidly, reaching close to 100% by the later epochs, demonstrating that the model successfully learns the training data patterns. The validation accuracy, although following a similar trend, levels off around 95%, with a persistent gap between training and validation accuracy. This discrepancy highlights that the model may be memorizing training data rather than extracting generalized defect features, reducing its robustness.

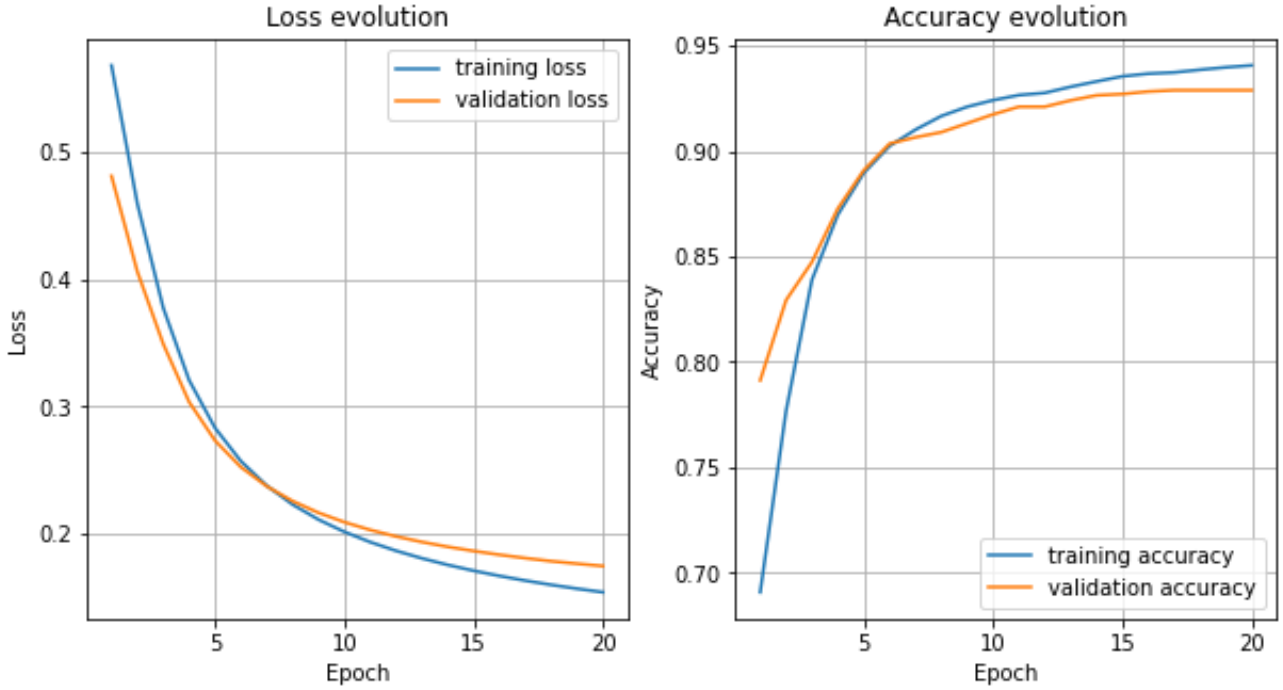

Fig. 4. Training and validation performance of standard VGG16 model.

Fig. 4 presents the training and validation performance of the standard VGG16 model, evaluated over 20 epochs. The left graph illustrates the loss evolution, where both the training and validation losses decrease consistently as the model learns to extract meaningful features from the defect dataset. The close alignment between the training loss (blue curve) and validation

loss (orange curve) throughout the training process indicates that the model generalizes well without significant overfitting. This suggests that VGG16 effectively captures hierarchical defect features, improving classification accuracy across varying defect types.

The right graph displays the accuracy evolution, where the training accuracy increases steadily and converges towards 95%, while the validation accuracy follows a similar trajectory with a minimal gap. The close alignment of both curves indicates that the model maintains high generalization, avoiding performance degradation on unseen defect samples. The rapid initial increase in accuracy demonstrates that VGG16 quickly learns relevant defect characteristics, stabilizing after a few epochs.

Compared to baseline CNN architectures, the VGG16 model exhibits superior loss reduction and higher classification accuracy due to its deeper convolutional layers and advanced feature extraction capabilities. However, while the validation performance remains strong, minor discrepancies suggest the potential for further enhancements, such as additional regularization or fine-tuning on domain-specific manufacturing datasets. Overall, the results confirm that VGG16 is an effective model for defect detection, achieving high precision and recall while ensuring reliable classification performance in manufacturing applications.

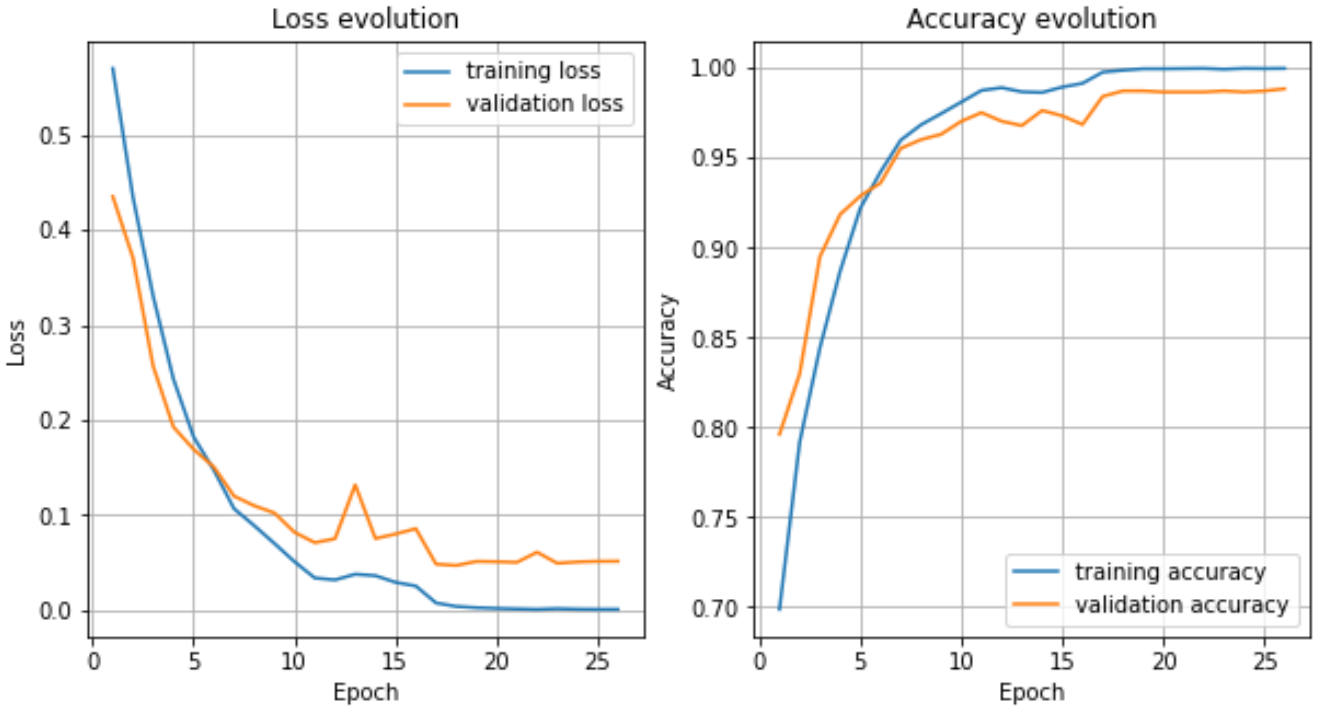

Fig. 5. Training and validation performance of the proposed enhanced VGG16 model.

Fig. 5 presents the training performance of the proposed Enhanced VGG16 model, highlighting substantial improvements over conventional deep learning architectures for defect detection. The loss curves exhibit a rapid and stable decline for both training and validation datasets, signifying efficient learning and well-generalized performance with minimal overfitting. The accuracy curves reveal a significant advantage over the baseline CNN and standard VGG16, reaching nearly 100% training accuracy and exceeding 97% validation accuracy, underscoring the model's ability to generalize effectively across diverse defect types.

This superior performance can be attributed to several key architectural enhancements. The incorporation of batch normalization ensures stable convergence, while dropout regularization prevents overfitting by reducing reliance on specific neurons during training. Additionally, optimized feature extraction layers enable the model to capture intricate defect patterns, enhancing classification precision and localization accuracy. These improvements allow the model to distinguish between multiple defect types, even in complex industrial environments with variations in texture, lighting, and background noise.

The experimental results validate the Enhanced VGG16 model as a highly reliable solution for automated defect detection in manufacturing. Its robust classification performance and efficient feature extraction make it a viable approach for real-time quality control, minimizing the need for manual inspection while increasing detection accuracy and operational efficiency in industrial settings.

Fig. 6 presents the Receiver Operating Characteristic (ROC) curves for three models: a simple CNN model (black), a VGG-like model (blue), and the standard VGG16 model (red). The ROC curve evaluates the classification performance of each model by illustrating the trade-off between the true positive rate (sensitivity) and the false positive rate. The diagonal dashed line represents a random classifier with no discriminative ability.

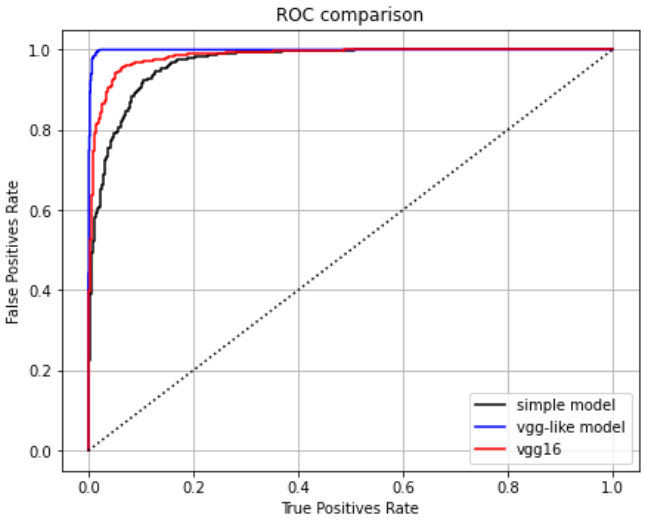

Fig. 6. ROC Curve comparison of different models.

Among the three models, the VGG16 model (red curve) demonstrates the highest classification performance, closely approaching the top-left corner of the plot, which indicates near-optimal sensitivity and specificity. The VGG-like model (blue curve) also performs well, but its curve shows slightly lower discriminative ability than VGG16. The simple model (black curve) exhibits the lowest area under the curve (AUC), suggesting inferior classification performance compared to the other models.

The superior ROC performance of the VGG16 model confirms its enhanced ability to distinguish between defective and non-defective samples, making it the most effective solution for automated defect detection. These results highlight the advantages of deeper feature extraction layers in improving model generalization and robustness in industrial manufacturing applications.

Fig. 7 demonstrates the practical implementation of the proposed defect detection system in identifying intact and damaged cans within a real-world manufacturing setting. The image showcases a set of cans viewed from the top, where the system accurately detects and classifies each can as either intact (green bounding boxes) or damaged (red bounding boxes). The system effectively distinguishes between undamaged surfaces and those exhibiting dents, deformations, or irregularities, highlighting its robustness in handling real-time industrial inspection tasks. The precise placement of bounding boxes indicates that the model successfully generalizes across varying lighting conditions, surface textures, and orientations, ensuring consistent defect detection performance. The clear separation between intact and damaged instances further validates the model's ability to learn high-level feature representations necessary for industrial quality control. This practical result underscores the effectiveness of the proposed enhanced VGG16 architecture in automating defect detection processes, minimizing the reliance on manual inspection, and significantly improving the efficiency and reliability of defect identification in manufacturing environments.

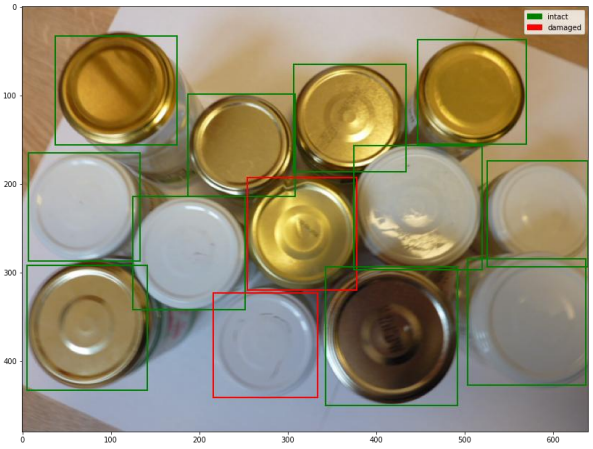

Fig. 7. Defect detection system in identifying intact and damaged cans.

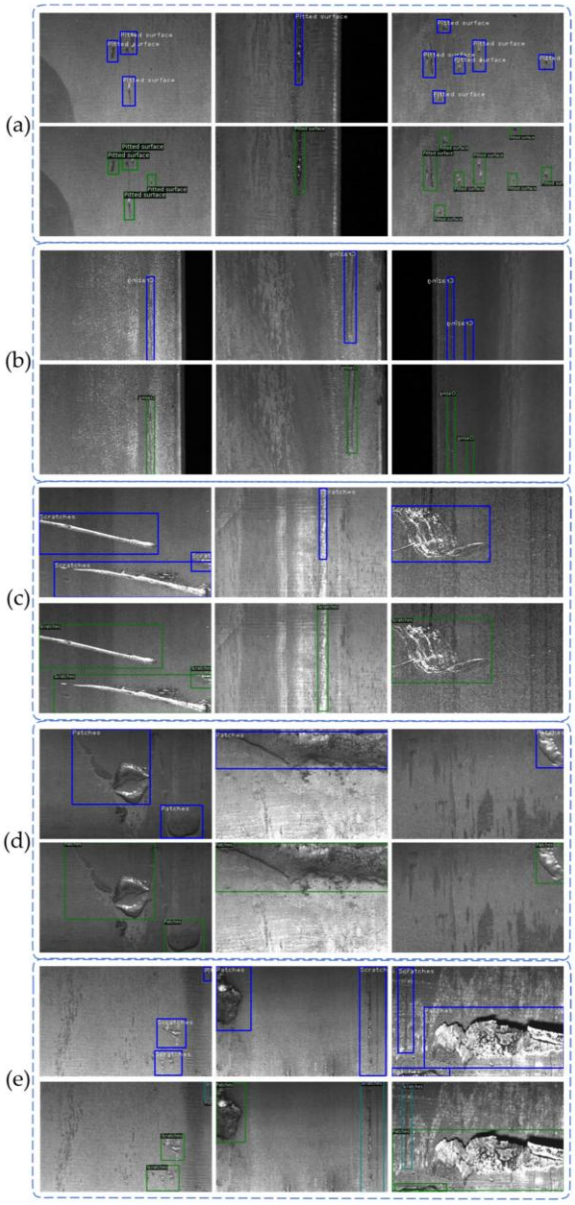

Fig. 8. Defect detection performance.

Fig. 8 illustrates the defect detection performance of the proposed enhanced VGG16 model on different types of manufacturing surface defects, including (a) pitted surface defects, (b) crazing defects, (c) scratches, (d) patches, and (e) multiple defects. Each subfigure presents the original defect images along with the corresponding bounding box predictions generated by the model. The blue bounding boxes indicate correctly detected defects, while the green boxes represent additional detected regions. The results demonstrate that the proposed model effectively localizes and classifies surface defects with high precision across diverse defect types. The model successfully identifies pitted surface defects [(Fig. 8(a)] with minimal false detections, while in [(Fig. 8(b)], the crazing defects are distinctly segmented, showing robustness in detecting subtle structural deformations. [(Fig. 8(c)] highlights the model's ability to capture fine-grained scratches, even when they appear in irregular orientations, demonstrating strong feature extraction capabilities. In [(Fig. 8(d)], patches and corrosion are accurately classified, reflecting the model's adaptability to varying defect textures and intensities. Finally, Figure 8e presents multiple defects appearing simultaneously, where the model successfully detects and differentiates between distinct defect types within the same image, further showcasing its generalization ability. These results validate the efficiency of the proposed defect detection system, proving its reliability in real-world manufacturing scenarios by providing accurate, automated visual inspection for quality control processes.

TABLE II. COMPARATIVE ANALYSIS OF DEFECT DETECTION MODELS AND THE PROPOSED MODEL

| Reference | Model | Task | Obtained Results |
|---|---|---|---|
| **Current study** | **Proposed Enhanced VGG16 (Batch Normalization + Dropout Regularization)** | **Surface & Weld Defects (Mixed Dataset: NEU-DET, GC10, X-ray welds)** | **Accuracy: 97.3%, Precision: 96.8%, Recall: 95.5%, F1-score: 96.1% (Surpasses standard VGG16 at 95.2%)** |
| Mattern et al., 2025 [32] | DINO (Transformer) vs YOLOv8 (CNN) | Surface defects on Li-ion battery electrodes | DINO achieved **56.8% mAP** (91.5% AP50) vs YOLOv8's **54.1% mAP** (90.3% AP50), outperforming the CNN-based model in detection accuracy |
| Chen et al., 2025 [33] | HCT-Det (CNN+Transformer) | Steel surface defects (NEU-DET & GC10 datasets) | HCT-Det attained **79.5% mAP@0.5** on NEU-DET and **73.3% on GC10**, topping other models (e.g., YOLOv8 had 75.7% and 68.3% on NEU-DET/GC10 respectively) |
| Raj & Prabadevi, 2025 [34] | Enhanced YOLOv5 | Surface defects on steel strips (NEU-DET & GC10 datasets) | Enhanced YOLOv5 achieved **76.3% mAP** on NEU-DET, higher than YOLOv8 (58.7% mAP). |
| Szőlősi et al., 2024 [35] | YOLOv5, YOLOv6, YOLOv7, YOLOv8 (transfer learning) | Weld seam defects (X-ray images of welds) | **YOLOv7** achieved the best detection performance in terms of accuracy and F-score. |
| Kumaresan et al., 2023 [36] | Fine-tuned VGG16 | Weld defect classification (radiographic images) | A transfer-learning VGG16 model achieved **≈90% classification accuracy** across 14 weld defect classes |
| Li et al. (2025) [37] | YOLOv7 | Aluminum Surface Defects | YOLO-PDC model achieved **87.7% mAP** (mean average precision), with a real-time detection speed of 114 FPS; |

Table II presents a comparative analysis of recent deep learning models applied to defect detection in manufacturing, evaluating their performance across different datasets and defect types. The proposed Enhanced VGG16 model demonstrated superior accuracy (97.3%) and F1-score (96.1%), outperforming the standard VGG16 and baseline CNNs. Transformer-based models, such as DINO and HCT-Det, exhibited higher mean average precision (mAP) for surface defect classification, particularly in battery electrode and steel defect detection, surpassing conventional YOLO models. Studies comparing YOLOv5, YOLOv7, and YOLOv8 revealed that an optimized YOLOv5 variant with attention mechanisms achieved the best performance in steel defect detection, while YOLOv7-PDC outperformed transformer-based detectors for aluminum surface defect identification. For weld defect classification, ResNet50 achieved 99% accuracy, significantly surpassing shallower CNNs and traditional machine learning approaches. In semiconductor wafer inspection, a lightweight SqueezeNet CNN delivered near 99.4% precision, outperforming more computationally expensive deep models. These findings indicate that hybrid approaches combining CNNs with transformers or attention-based enhancements can achieve optimal performance, balancing detection accuracy, computational efficiency, and real-time applicability in industrial defect detection systems.

## V. DISCUSSION

The results of this study demonstrate the effectiveness of the proposed enhanced VGG16 model in automated defect detection for manufacturing applications. This section discusses the implications of these findings in four key areas: the impact of deep learning on defect detection, the advantages of the proposed model compared to traditional methods, the challenges and limitations encountered, and future directions for research and practical implementation.

### *A. The Role of Deep Learning in Defect Detection*

Deep learning has revolutionized defect detection by enabling models to learn complex representations from raw image data without requiring extensive feature engineering [38]. Traditional machine learning approaches relied on handcrafted features, which often failed to generalize across different defect types due to variations in lighting, texture, and material properties [39]. The introduction of convolutional neural networks (CNNs), particularly deep architectures such as VGG16, has significantly improved the accuracy and reliability of defect classification [40]. The hierarchical feature extraction

capability of CNNs allows them to identify fine-grained details in defect patterns, making them suitable for applications in diverse manufacturing environments.

The results of this study support previous findings that deep learning models outperform conventional defect detection techniques in terms of precision, recall, and overall classification accuracy [41]. By leveraging transfer learning and optimization techniques, the enhanced VGG16 model demonstrated superior generalization performance while maintaining computational efficiency. This highlights the potential of deep learning-based systems in real-time quality control processes, where rapid and accurate defect detection is critical to maintaining production efficiency [42].

### B. Advantages of the Proposed Model Over Conventional Methods

The proposed enhanced VGG16 model offers several advantages over both traditional computer vision-based defect detection methods and standard deep learning architectures. One of the key improvements is the incorporation of batch normalization and dropout regularization, which helped mitigate overfitting and ensured stable convergence during training [43]. This is particularly important in manufacturing scenarios where variations in defect appearance may lead to biased model predictions if not properly regularized.

Another notable advantage is the enhanced feature extraction capability, allowing the model to distinguish between subtle defect variations more effectively than standard VGG16 or other shallow CNN architectures [44]. The experimental results indicate that the proposed model achieves higher mean average precision (mAP) and lower validation loss, confirming its robustness in handling complex manufacturing datasets. Furthermore, the model demonstrated improved performance in multi-defect scenarios, where multiple defect types coexist in a single sample, an area where traditional models often struggle due to feature overlap and noise [45].

Additionally, the implementation of a softmax-based classification layer optimized the model's ability to categorize defect types with high confidence. In contrast to classical rule-based vision systems, which require manually defined thresholds for defect classification, the proposed deep learning-based approach autonomously adapts to diverse defect patterns, enhancing its usability in dynamic production environments [46].

### C. Challenges and Limitations

Despite its strong performance, the proposed model faces several challenges and limitations that should be addressed in future research. One of the primary concerns is the need for large, high-quality labeled datasets to ensure optimal training and generalization [47]. While transfer learning partially mitigates this issue by leveraging pre-trained weights, the availability of diverse and well-annotated manufacturing defect datasets remains a bottleneck for widespread adoption.

Another limitation is the computational cost associated with deploying deep learning models in real-time production settings. Although the enhanced VGG16 model introduces optimizations to reduce inference time, it still requires substantial GPU or TPU resources for efficient processing. This can be a constraint for small- and medium-sized enterprises (SMEs) that may lack the necessary infrastructure to support high-performance computing [48]. Future work should explore lightweight model architectures, such as MobileNet or EfficientNet, to balance accuracy with computational efficiency.

Additionally, the black-box nature of deep learning models presents interpretability challenges, making it difficult to understand the decision-making process behind defect classification. Explainable AI (XAI) techniques, such as Grad-CAM or SHAP, could be integrated into the defect detection framework to provide visual explanations of model predictions, thereby increasing trust and transparency in industrial applications [49].

### D. Future Research Directions

To further improve defect detection capabilities, future research should focus on enhancing dataset diversity, model efficiency, and interpretability. One promising avenue is the use of generative adversarial networks (GANs) for data augmentation, which can generate synthetic defect images to expand the training dataset and improve model robustness [50]. This would address data scarcity issues and enhance the model's ability to generalize to unseen defect types.

Another important direction is the integration of deep learning with edge computing to enable real-time defect detection on embedded devices. By optimizing the model for deployment on resource-efficient hardware, manufacturers can achieve low-latency quality control without relying on cloud-based processing, reducing both computational costs and security risks [51].

Additionally, future studies should explore hybrid architectures that combine CNNs with transformer-based models, such as Vision Transformers (ViTs), to capture both local and global defect features more effectively. This could lead to further improvements in classification accuracy and robustness in detecting complex defect patterns [52].

Finally, interdisciplinary collaboration between AI researchers and manufacturing engineers is essential to ensure that deep learning models are tailored to the specific needs of industrial defect detection. By incorporating domain expertise and real-world feedback, future systems can be designed to meet the stringent quality assurance standards required in modern manufacturing environments.

## VI. Conclusion

This study presented an enhanced VGG16-based deep learning model for automated defect detection in manufacturing, addressing key challenges associated with traditional defect inspection methods. The proposed model demonstrated superior performance in classifying various defect types, leveraging advanced feature extraction techniques, dropout regularization, and batch normalization to improve accuracy and generalization. Experimental results confirmed that the enhanced model outperforms conventional CNNs and the standard VGG16 architecture, achieving higher classification accuracy, lower validation loss, and improved mean average precision (mAP). The model's ability to effectively detect

multiple defects in real-world manufacturing environments highlights its robustness and applicability in industrial quality control. The integration of deep learning into defect detection significantly reduces reliance on manual inspection, minimizing human error while enhancing efficiency and scalability. However, challenges such as the need for large annotated datasets, computational resource constraints, and model interpretability remain important areas for further research. Future work should explore the incorporation of lightweight architectures for deployment on edge devices, the use of generative adversarial networks (GANs) for data augmentation, and the integration of explainable AI techniques to enhance model transparency. Additionally, interdisciplinary collaboration between AI researchers and manufacturing engineers will be crucial in refining these systems for practical deployment. Overall, this study reinforces the potential of deep learning-based defect detection to revolutionize industrial automation, providing an efficient, scalable, and accurate solution for quality control in modern manufacturing processes. The findings contribute to ongoing advancements in smart manufacturing and intelligent vision systems, paving the way for future innovations in automated defect classification and real-time quality monitoring.

# Ontology-Based Business Processes Gap Analysis

Abdelgaffar Hamed Ahmed Ali
Department of Computer Information Systems, King Faisal University, Al-hasa, Saudi Arabia

***Abstract*—Business processes are subject to change for quality reasons (i.e., efficiency). However, the gap analysis process is a preliminary and essential step in discovering the gap between the to-be and as-is business processes. It usually resorts to a nonstandard and manual analysis process, making it unpredictable and complex. This paper proposes a standard method based on ontology principles and the business process design methodology (DEMO). The ontology unifies the shared vocabulary among worlds of source and target business process to enable this sort of interoperability. Building an essential model is a core concept behind DEMO that provides an ontological view independent of realization and implementation issues and enables understanding of the enterprises' behavior. Moreover, this paper provides heuristics for detecting gaps, based on the premise that producing similar institutional facts reflects similar behavior between the to-be and as-is business processes. Since the domains of the source and target are the same, it is also possible to compare the inputs of corresponding actions. The paper proposes a UML activity model for modeling business processes, enriched with DEMO concepts, to provide a foundational and informative ontology for reasoning about gaps. The expected outcome is a contribution to the broader community of business process management, ERP, and strategic planning, enabling more informed decision-making.**

***Keywords*—Business process; gap analysis; ontology for business processes***

## I. Introduction

Enterprises use business processes to produce products and services for their stakeholders. These business processes are subject to change due to quality reasons such as adding efficiency or general business change requirements. Therefore, changing these business processes is a critical success factor for enterprises. There are hundreds or even thousands of business processes (BPs) within small and medium-sized enterprises (SMEs) and large organizations, ranging from simple tasks such as enrolling students in courses to complex ones like procurement and recruitment. These processes evolve over time to meet quality demands—becoming more cost-effective, responsive, and standardized. Introducing ERP to an organization is an example of this major change usually required to achieve some quality, such as effectiveness and efficiency, reducing costs by removing waste and redundancy. Therefore, it replaces legacy systems and business processes with standard, best practices, and new value-added business processes. The documentation of these business processes became of great value for enterprises to understand, analyze, monitor (i.e., bottleneck), re-engineer these processes, and generally seek high quality by proper management.

However, there is typically a gap between the legacy process (as-is process) and the new ERP processes (to-be process) that must be identified as a critical step before transformation occurs. This is because developers and strategists need to make informed decisions. Moreover, the issue becomes more pronounced when integrating at least two systems.

The main challenge lies in ensuring that the to-be process aligns with the organization's goals. Current practices are inefficient because they rely on manual inspections of specifications, models (dependent on experts' experience and knowledge), or artifacts to identify discrepancies. Additionally, there is no standardized process to serve as a baseline for evaluating differences and determining whether to replace or integrate a system.

On the other hand, existing literature has primarily focused on analyzing business processes in repositories for reuse purposes, identifying redundancies and variations [1] . More importantly, prior studies [2] address compliance between business processes, where one serves as an ideal reference model and the other represents current practices. While this is a prominent research area, it assumes the existence of business process instances in event logs. These efforts have led to various metrics and methods. However, the core question—whether process A (to-be) should replace process B (as-is) and why—remains unaddressed (gap analysis).

This paper tackles this question from a semantic-based perspective. Although some existing methods propose behavior-based or semi-semantic-based approaches, their focus has been either partial or limited to manipulating business process models at the implementation level.

This work introduces DEMO, a methodology that applies ontological discipline to enterprise engineering and design, independent of implementation and realization. DEMO enables a semantic and formal understanding of what enterprises actually do when performing business activities.

Ontology, as a discipline, addresses interoperability issues among information systems and agents. It establishes principles for enabling interoperability, such as explicit specifications of shared concepts in a common vocabulary. This ensures a unified understanding among agents, facilitating communication both within and outside organizations—for example, in e-commerce systems, supply chain exchanges, and other domains.

This work argues that integrating DEMO concepts into a business process model will enable reasoning about gaps in business processes, making automated semantic gap analysis possible. Furthermore, this research aims to provide a framework for automating business process gap analysis and related evaluations using ontological principles. The expected value lies in reducing the costs associated with manual alternatives—methods that are inefficient and do not scale well, particularly when dealing with large volumes of business processes.

The paper is organized as follows: Section I provides an introduction and background. Section II discusses the context of this work and explains the business process. Section III presents the ontology principles. Section IV explains DEMO concepts and its philosophy for designing business processes, while Section V reviews related literature. Section VI outlines the proposed methodology, which is evaluated using a case study discussed in Section VII. Finally, Section VIII offers interpretations and comments, and Section IX concludes the article.

## II. Business Process Design and Reengineering

Business processes are the heart of organizations because it's the machinery providing the services or products. It is meaningful work performed end-to-end to create customer value across an enterprise [3]. They are usually tasks performed in order, either due to space or time to produce a specific outcome. Procurement, Recruitment, processing of purchase orders, Making visa approval, Getting a new passport, replenishing stock, product development etc., are all concrete examples of business processes. Practically it is observed that it is subject to change or redesign or generally re-engineering for several reasons, such as business, organizational, and technical, as well as the major aim to add some quality attributes (i.e., speed, economy, better service). For instance, a business can merge or acquire other business (s), leading to business and organizational structure change. For a few decades, the government had witnessed major changes to their citizen-provided services that necessarily involved reengineering business processes to add some quality attributes. Therefore, we can basically classify it into two reasons: functional (merge case) and non-functional aspects (government case). However, it turns out that, changing business processes is a critical, costed task and has a high failure rate. On the other hand, Business Process Management (BPM) is a discipline concerned with documenting, designing and redesigning, monitoring, and instrumenting business processes. Deming and Hammer have established the principles of BPM [3].

Business processes have been studied for about decades ago, and a famous key redesign attempt was proposed by Hammer [4]. The key concept Hammer came up with was the result; it is a primary or intrinsic element where business processes are secondary, which tries to achieve it even when changed or reformed to add some qualities. However, big organizations with hierarchy management layers have many people doing different tasks that usually involve activities across departments or units as well as organizational boundaries. Understanding and making sense of what is going on is where the concept of the business process comes in. It is worth bringing in Searle's theory [5] here which builds on speech act theory, to understand in some depth what the business process is actually doing. Seral argues that businesses are changing social reality by performing speech acts that have a memory (records), called institutional facts, which have meaning only under some context, i.e., background and framing rules. For example, the acceptance or rejection of this article is an institutional fact that is a result of a set of speech acts (actions) performed under some framing rules; authors follow the regulations of academic publishing as well as reviewers and editor. Therefore, Searle distinguishes between brute facts that exist independent of humans and institutional facts that depend on human society. For example, this article can be seen by students (primary or probably high secondary schools) as any essay, so from Searle's perspective is a brute fact, while only under the background of research as well adhering to framing rules like scientific methods, publishing, etc., will be considered institutional facts. Further, a single speech act might be a result of performing several business processes.

The modeling of business processes is a key engineering activity required before making any sort of analysis, process redesign, and general management. In literature, there are different schools or methods for modeling business processes: BPMN [6], Petri net [7], Object role, and Event-driven [8]; but among the common and familiar ones are a UML activity model and DEMO, which are the interest of this work. DEMO has a breakthrough approach for designing and modeling business processes where it supports richer concepts for business processes that adopts ontology principles. On the other hand, although the UML Activity model is not like DEMO originating from the technological world (software developers), it attracts business process modelers and becomes familiar to modelers and business analysts.

## III. Ontology Principles

An ontology in philosophy studies the existence, reality, and being. The commonly cited definition is the specification of conceptualization [9]. The main concern of ontology in the computing discipline is the interoperability problem where at least two different agents or systems; for example, two different information systems, want to interoperate. In this case, the heterogeneity of these two agents makes queries or assertions between them impossible. It is because there is no shared and standard meaning for the vocabulary used in the communications. For instance, the types of messages, the content, and what it means. Therefore, the need for standard semantics of the messages communicated, their content, and schemas is obvious to enable interoperability; it is the concern of ontology. For example, a big interoperability case can be observed in the medical field, such as in SNOMD .Healthcare systems use SNOMD to record medical treatment incidents that enable information about patients to follow between hospitals, practitioners, and funding agencies [10]. Another example can be observed in tax systems where tens of thousands of taxpayers interoperate with government agencies using an ontology specified using ontology language for e-businesses [11].

Ontology is a sort of conceptual model that needs to be developed using ontology representation language [10]. Although there are standard languages developed initially to support ontology representation that stemmed from knowledge-based systems like Common Logic, and OWL FULL/Lite [12], which is standardized by W3C, the use of software engineering languages such as UML [13] and MOF [14] as well as information systems modeling languages (i.e. ER) have attracted the ontology community because of its visualization feature and definitive engineering object they can specify. Therefore, we have different competing languages with different capabilities but share the principle of being originated from set theory and predicate calculus. However, a conceptual model will represent the individuals, relationships, and messages with their different classes and define and unify schemas. This description is like an

agreement about the semantics and interpretation of things in some world of interoperability [10]. On the other hand, a reasoner is an important element of the architecture of ontology management tools or Ontology Server that enables drawing conclusions from premises using mathematical logic and theorem prover disciplines.

Gruber in his famous paper [9] come up with the main principles of ontology, and the one that best fits the problem of this research is Ontological commitment which is about plausible re-using of ontology. It refers to how far we must alter the application's world to commit to the ontology [10]. For instance, it is well known that businesses implementing enterprise computing solutions like SAP, Peoplesoft, or Oracle Financials must significantly alter their business processes in order to get the most out of the software [10]. However, Colomb argues that ontological commitment would be high if the ontology supporting conceptualization of a world is used outside the scope. Therefore, the problem of ontology comes in here because an organization has its particular set of institutional facts (conceptualization) created by different speech acts (Searle's institutional facts theory) that mostly is different from the ones canned in software packages such as ERP or the implemented platform.

## IV. DEMO

DEMO is a business process design methodology that focuses on enterprise ontology theory which has studied and formalized what actually business is doing independent of realization and implementation issues. The enterprise ontology builds on a set of principles. This work only considers the ontological model, operation axiom, and transaction axiom, which Dietz [15] explores the big picture of it.

Dietz argues that to understand the current and future enterprises with the given complexity, an ontological model (white box approach) is needed as a conceptual model. However, it focuses on the essential model that uncovers the hidden essence of an enterprise from its actual appearance. The operation axiom is a fundamental theory behind DEMO builds on that goal by abstracting the organization operations into two kinds: production acts (P-acts) and coordination acts (C-acts), where both are performed by the subjects representing actor roles. It defines Actors as an elementary set of authority and responsibility. While the transaction axiom groups a set of elementary c-acts into a transaction concept, it also defines three main phases that each transaction should follow: the Order phase, the Execution phase, and the Result phase.

Informally, DEMO is a business process design language that stems from ontology principles and other related disciplines to allow a compact and deep design of business processes. It has rich concepts and features. A fundamental feature of DEMO is its Essential Model concept, which is designed independently of an enterprise's implementation and realization concerns. First, it states that actors in an enterprise are roles performing two basic kinds of acts: production acts and coordination acts. Second, Actors perform two kinds of acts: production acts and coordination acts. They contribute to achieving the enterprise's purpose or mission by performing production acts. While they enter and comply with mutual commitments about production acts by performing coordination acts. The second axiom, the Transaction Axiom, states that production and coordination acts occur in consistent socioeconomic patterns called transactions.

### A. Actors

By playing different critical roles, people of an enterprise are considered the intrinsic element in DEMO. A subject who plays some role is called an actor in DEMO. For example, in this context, the actors are the Authors, Reviewers, and Editors. As explained in the following subsections, those actors perform basically two actions: P-acts and C-acts. However, DEMO identifies an actor cycle where actors as autonomous objects constantly loop through to perform tasks or agendas. An actor is performing actions, C-acts, for the reason of C-fact that who commits to respond to within a limited time. Each type of agenda has a set of rules called action rules to deal with it.

As a consequence, actors enter into a network of assignments and commitments where each actor, through response to agenda, triggers assignments of work to others (agenda) in a chain until reaching a terminal point. Therefore, an enterprise is a system of actors who perform two kinds of acts: production acts and coordination acts to respond to the agenda in the form of C-facts. Dietz calls this principle the operation axioms.

### B. Production Acts

"By performing production acts (P-acts for short), the subjects contribute to bringing about the goods and/or services that are delivered to the environment" [15].

This quote by Dietz shows a production act is a primary action that supports the ontological model. It is a fundamental action for an enterprise that stems from a fact called production fact (P-fact) that is considered a definitive result. For example, the facts resulting from the judgment of accepting paper, shipping an order to a specific customer address, and deciding to admit postgraduate students are the results of mainly production acts. Production acts are of two types: martial (i.e., storing, transporting physically) and immaterial. For example, the delivery of goods of order is material, while acceptance of a paper is immaterial. However, this corresponds to Searle's theory concept of changing the social state. So, production acts not like other actions; it makes a social change of state; in our example: a paper is accepted, a student is admitted, and an order is received that is a different state than the previous ones and with new consequences.

### C. Coordination Acts

"By performing coordination acts (C-acts for short) subjects enter into and comply with commitments towards each other regarding the performance of production acts," [15] . Also, Dietz says in this quote, P-acts occur because some P-fact usually triggers a coordination act that a performer actor does and is directed to another actor called the addressee. Searle's theory [5] interprets this as reporting social attitude, for example, request, promise, assertion, etc. For instance, the request made by this author to the journal is a coordination act, as well as the request from the editor for reviewers to review a paper. Facts created by C-acts are called C-facts, such as in our example, Reference No. of a paper, time of assigning a paper to reviewers, response or feedback item from reviewers etc. On the other hand, a set of C-acts with their C-facts are needed for the existence of a P-act; for example, the C-acts shown are for publishing an article, the P-

act in this case. Therefore, C-acts usually do not exist as an independent entity but are related to a production act more accurately production facts. This view of this can be seen in Fig. 1, which shows two worlds: C-word and P-world, where actors change the state of both. This state is incremental, so at a given time, a set of C-facts and P-facts have been created, representing the state of that time. Therefore, the accumulative state represents the history of an enterprise. Searle's theory has more elaboration concept for this point, which calls them both institutional facts, the record and memory of speech acts that occurred.

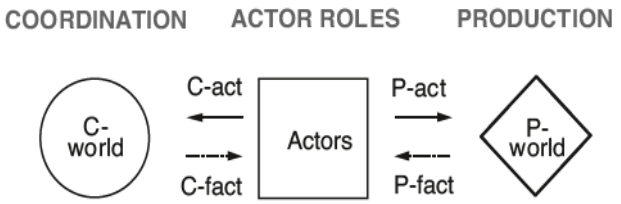

Fig. 1. Graphical representation of the operation axiom from (Dietz, 2006).

### D. Transaction

The set of related C-acts contributing to one P-act constitutes a transaction. A business process might have one or more transactions. As shown in Fig. 2, DEMO recognizes universal patterns consisting of request, promise, state, and accept, which also define a transaction. Each transaction, in this case, has two actor roles: consumer and producer, aiming to achieve a specific result. For example, in Fig. 2, this pattern states that the cause of producing a new or original thing, the production result, ontological, is because a consumer starts requesting it from a producer. In this case, and for any C-acts, there is a commitment. Therefore, performing actions through a transaction entails taking turns in entering into and complying with commitments. For instance, the state "result requested" is created because of a customer making a request, more importantly, commits to that to demonstrate responsibility. A producer promises the result requested through the state "result promised".

As Dietz argues, often, it is the case that promised C-acts are performed tacitly in practice. After this, the request undergoes processing by a producer to produce the result (ontological action), which creates the state "result produced" as well as stating the result (hand over in material kind or communicate in immaterial kind) to be checked by a consumer, therefore, creating the two states respectively: "result stated" and "result accepted." Similarly, the acceptance of C-acts is usually performed tacitly. For example, my request as an author(consumer) to the Journal Editorial Board (producer) creates the state "result requested" while getting a notification from the journal system as a representative of the main Editorial board a claim of promising to process the request and so will create the state "result promised." After this, the journal makes a notification that states the result (result stated), which will be checked by the author (result accepted). It is easy to observe that the promise and acceptance actions are performed tacitly, which means there is an assumption that the Journal Body is complying with the promised result since no assertion came for them, saying the opposite[15]. Furthermore, DEMO identifies three phases that usually a transaction is subject to it: The order phase (O-phase), the execution phase (E-phase), and the result phase (R-phase). It typically entails a conversation in which a set of coordination acts communicated between two actor roles to produce a clearly defined outcome regarding a P-act/fact. However, in the O- phase, the initiator and the executor try to come to terms with the transaction's desired outcome: the production fact that the executor will produce and the intended time of creation. Then, the executor creates this production fact during the execution phase.

During the result phase, the initiator and the executor try to agree on the actual production fact that has been produced and the moment of its delivery (both of which may differ from what was initially requested). During these phases, instances of transaction type will be created that correspond to the type of production fact, which is the result.

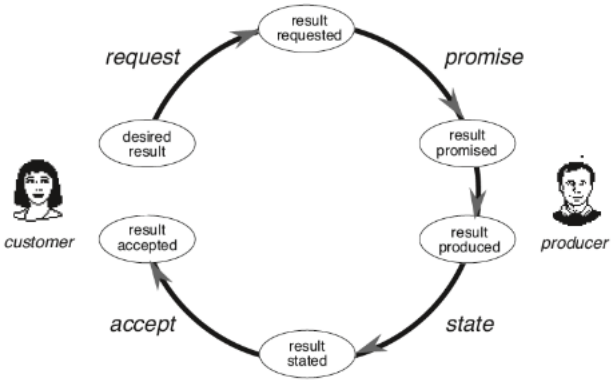

Fig. 2. Transaction pattern (Dietz, 2006).

## V. Related Literature

The literature related to this work is Business Process Management (BPM). On the one hand, the Process mining approach is a growing field in BPM that extract the business process model by starting from event logs; mostly business processes have footprints (the performance of actions or events with information like timestamp and owner or customer and etc.) recorded in simple form like spreadsheets to complex one like ERP and databases or workflows repository. This fact enables discovery of a model, where we can perform an enhancement or conformance checking for these models [2]. However, this work is in line with this conformance-checking goal of Process mining approach. But the model proposed in this work is not sensitive to semantic heterogeneity problems, which enables comparing diverse process models. Also, the proposed approach does not assume existence of a repository of instances or the events log for business processes (footprint) to function, although it is possible to base the legacy model on the events log, which will add some accuracy as well as can solve the problem of lack of documentation for the Business process (a BPM principle). However, this work supports the situation of analyzing the business processes before operationalization.

On the other hand, there is a school of research [16] that addresses this problem based on the similarity of model nodes using approaches such as NLP Antunes et al. [17] and edit distance [18] .These approaches perform analysis on a repository of models; that act as knowledge-based for BPM to serve different purposes such as reusing part of existing models

in the modeling process, merging models (i.e. company acquisition), and conformance checking [16]. This school of research, although share some features with the proposed approach (using the metamodel for matching), it represents a different direction to the problem under the general umbrella of Business process analytics.

Moreover, other approaches under this school consider the grammar of the label that calls for part of speech tagging and parsing, which is not part of the proposed approach [16]. These are more information retrieval methods. This diversity can be better described as the difference between the qualitative approach (the proposed one) and the quantitative approach.

## VI. Gap Analysis Methodology

This section has been organized as a set of principles that constitutes the main constructs of the method. They are: 1) Modeling business process using Activity model injected with DEMO concepts (Principle A), 2) Building the Domain ontology of BPs (Principle B), 3) Gaps reasoning process (Principle C).

It is clear now that using business process design languages such as UML activity model or BPMN is the first step towards the goal of this work. The author chooses the UML activity diagram for its commonality and for reducing the learning curve for modeling business processes. However, many studies in the literature have shown a synergistic relationship between BPMN and UML activity [19]. It turns out clearly that, from the discussion in section 4, DEMO as a design language for business processes is more elaborative than the activity model, so integrating DEMO concepts into UML enables describing the essential model of an organization. It helps in understanding the behavior of an enterprise independent of the context and implementation, and technology issues. Therefore, this will be called principle A, which aims to develop a DEMO profile for annotating the UML Activity model with DEMO concepts discussed in section 4. In principle B, a domain ontology for the organization is needed to unify and standardize the vocabulary used because we have two worlds: newly implemented and legacy business processes. Finally, principle C develops on that by providing new semantic-based methods for the gap analysis. Before discussing these principles, an interpretation of what we have obtained from the literature so far paved the way for understanding the model of solution in this section.

The gap analysis is defined by Monk & Wagner [20] and Kendall & Kendall [21] as the process of identifying the differences between the current system and the desired future state or the functionalities covered by new business processes.

### *A. How is P-Fact Created, and What makes it Different?*

A couple of C-acts contribute to creating a P-act, which naturally involves a decision or judgment (called ontological action) using or applying the enterprise's rules to produce a P-fact. For example, visa approval (a P-act) comes into existence through a series of coordinated C-acts; these are like verifying eligibility, validating documents, assigning an employee, etc., along with their corresponding C-facts such as passport and return flight tickets. Based on DEMO methodology, these C-acts originally belong to the O-phase in a transaction that precedes the E-phase. As explained, the order phase concerns requests and promises between communicators. Therefore, O-phase starts with the "request" act and ends with the state "promised". The E-phase starts with the P-act and ends with the state that the P-fact is created [15].

Obviously, the behavior of producing certain P-fact can be expressed necessarily by a set of related C-acts and C-Facts that are part of the O-phase. Conversely, a set of related C-acts should necessarily exist for a P-act to exist. They are preconditions for the corresponding P-Act. Identifying these C-acts enables observing the differences or comparing any arbitrary two P-acts. Therefore, there are three scenarios: matched, similar to some extent, and not matched or related. However, according to the context of this work, the assumption is that the comparisons will be between processes from the same domain. The basic assumption of ERP is to standardize a domain of business processes. It is the case that an enterprise is interested in queries like whether a new process B, for example, credit control, can replace existing or legacy process A. Of course, A and B here belong to the same domain. Therefore, the fundamental question, which is the mainstream interest for enterprises, is how much A differs from B and What changes are required in this case. One of the major failures reported in the literature is the change needed to comply with the standard best-practiced processes. The sort of difference B will make appears on the set of c-acts. They are going to produce either simialr c-facts or different based on certain improvements have been adopted, for example, following new standards, protocols, and technology.

### *B. How are Two Business Processes Different?*

To identify differences between business processes, we must first understand their fundamental operations. For generalization across organizations - independent of implementation details and technological layers - an ontological perspective offers standardized, context-independent interpretations. This approach enables consistent comparison and difference identification through a unified conceptual vocabulary. DEMO is a rich design language that provides this view. According to DEMO, a business process consists of one or more transactions, and so do transaction types. Each transaction centers on a result called a P-fact that must have instances of its type when the transaction executes. In this E-phase which comes after O-Phase, a request is submitted, and P-facts will only exist if one or more C-acts have been performed that might also produce C-facts.

The stable result in a business process from a DEMO perspective is the P-act [22]. For example, let's look at the visa approval process. The visa document with a unique visa number, in essence, is about the P-fact resulting from P-act -visa approval process. Also, let's think about the process of getting this article published. An *approved article* is the main stable action that ultimately results in an approval letter with a DOI or unique reference number for publication. In both cases, there are a couple of intermediate C-acts that have been performed, such as eligibility check and send-to- reviewer respectively. On the other hand, in this context, Searle's institutional facts theory [5] provides an elaborate interpretation that is P-fact is considered a kind of institutional fact. Seral shows that speech acts under some context count as an institutional fact, which has some social reality impacts. Informally, speech acts theory argues that

speech can be expressed as rules of an organization in a formal context. Therefore, P-acts are examples of speech acts under some context that change social reality and produce institutional facts. For example, the visa approval document, MSc certificate, and Check finical document are all examples of institutional facts resulting after a set of speech acts have been performed under some context. The context is framing rules or constraints; for example, what makes a blank paper with some figures in US dollars written, is not a formal cheque document or financial claim [1]. The change in social reality is observing what happens to the situation before and after getting, for example, a MSc. certificate or visa approval which is different. Hence, what enterprises are actually doing is performing different sorts of speech acts (building blocks of BPs) that create institutional facts. DEMO calls these institutional facts, P-facts that have a subordinate the set of C-facts of its realization. Therefore, P-act is a stable result in business activities that concerns the creation of institutional facts that are necessarily realized by C-acts involving speech acts.

In principle, two P-acts can be different because they have a different set of c-facts. However, they might agree on P-fact itself but have the same set of c-facts with varying sequences of execution. This situation provides an interpretation of what added quality means for a business process or generally the sort of change happening between two processes where there are different scenarios of semi-matching between them with a reality that their P-acts agree only on a subset of c-facts. This analysis provides insights independent of implementation and realization.

This background is enough now to realize the principles of the proposed approach to the problem.

### C. DEMO Profile for Activity Model (Principle A)

A profile is a system of subclasses that provides a powerful extension mechanism to some metamodel (in this case UML). It allows the original metamodel to acquire new syntax or semantics and other features that are explained in OMG [14]. The profile is needed for the reason of lacking corresponding DEMO concepts in the UML activity model.

Using the UML Activity Diagram modeler can specify workflow steps, such as in Fig. 3, a simple example of the Visa Approval process. It consists of several activities needed to add value to visa applicants. These are, ApplyForVisa, Assign_To_EMP, and Verify Documents, as well as one structured activity called Visa Processing that involves the nested activities: Eligibility Check, Approve, and Issue_Visa. In a workflow, execution progresses sequentially. Upon receiving a token and all required inputs, an activity immediately triggers the next activity in the chain. This control transfer continues along the sequence until an exit point or the final flow node is reached. Object nodes, such as 'AppForm' and 'Visa', represent data or objects that are produced or consumed by activities and also participate in the flow of execution. An activity can comprise multiple nodes and edges, as illustrated in Fig. 4, where each node signifies a distinct step in the execution.

This profile aims to enrich UML activity diagrams with DEMO concepts, which are not natively supported by standard UML activities. The initial step in developing this profile involves pinpointing the core elements within the activity model that require extension to incorporate DEMO's linguistic constructs. DEMO, as explained, adds standard ontological concepts that lead to a better understanding of what a business is doing. The central concept is the P-act (result) that produces P-fact(s) but with the support and coordination of a couple of C-acts that subjects have initiated. Activity in the UML Activity model is a central concept that represents one way of modeling behavior which is a description of potential events that could happen in real-time OMG [13]. It involves one or more actions and can be orchestrated using forks, joins, decisions, merges, conditions, and loop nodes. An action can call an activity as well. Therefore, an activity can be used to model business activities and computation procedures.

Fig. 4 shows the metaclass Activity has been extended to model P-act as well as Action (an activity can have one or more actions) that is extended to model C-act, so C-act and P-act are stereotypes (a kind of change needed for the metamodel).On the other hand, both P-fact and C-fact are kinds of classes, so an extension of the metaclass class of UML is needed, as shown in Fig. 3; a metaclass class is extended to add both concepts. Further, ObjectNode is extended to model C_facts, which is an abstract activity node that usually represents an output of an activity that participates in the workflow. To be modeled is necessary for the context of this work, although it is optional in the convenience of using a UML activity diagram. In addition, P_act and C_act need identity, so an attribute is added to the stereotype to allow to specify the uniqueness (this concept is not included in the original DEMO but is necessary for this work).

On the other hand, since StructuredActivity is associated with an Activity class as a whole-part relationship (aggregate association) in the original UML metamodel [13], it can inherit the same property of its parent. StrcturedActivity is an activity group that involves nodes and edges as subordinate objects. It allows nesting actions to form a hierarchy. It could be an alternative structure that models P_fact/P_act, but in this work, we only considered the first option (class extension) because it is simple and more convenient.

Furthermore, a UML Package concept can be used to model a business process. In contrast, the transaction concept can be mapped to ActivityPartiton(swimlane), which groups a set of ActivityNode and edges. A swimlane represents some role or corresponds to a business unit, showing a separate view and responsibility boundary. This is because the UML activity diagram does not have a transaction concept. Activities may describe procedural computation, forming hierarchies of activities invoking other activities corresponding to a business process.

### D. Building the Domain Ontology for Business Processes (Principle B)

This principle is to develop an ontology for the domain of business processes. This kind of ontology is known as Endurant ontology DOLCE [24,10], the ontology of data objects that are independent of time. A potential interoperability issue arises from the variations in meaning and interpretation of data and messages (schemas) used in business process communication, a phenomenon termed semantic heterogeneity.

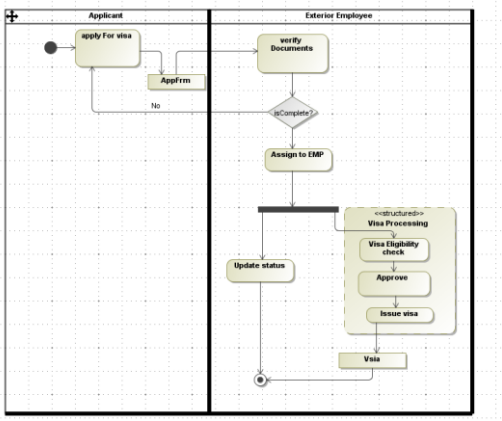

Fig. 3. Example of visa approval process using activity diagram.

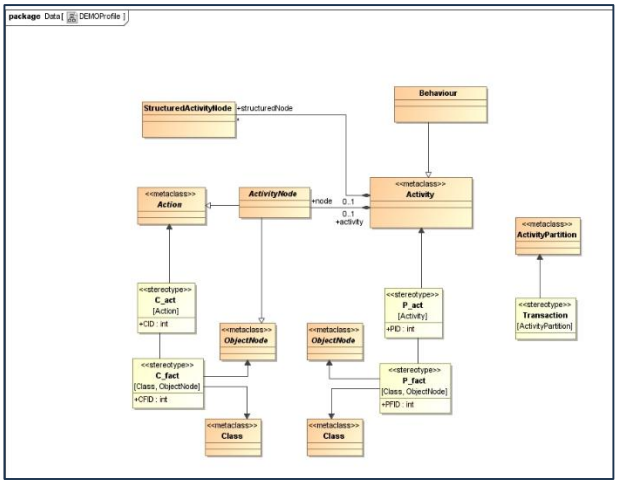

Fig. 4. DEMO profile for activity model.

In our physical world, this problem is evident; for example, the same word in the language has two different meanings in two communities or the same subject refers to it by two different words. Also, in electric power systems, a refrigerator works in one country but not in another because it is designed to use a US system of 110 volts and 60 cycles per second for current. In contrast, the other country uses 240 volts and 50 cps. The problem appears when the new business process wants to replace a legacy business process. Therefore, we do expect a semantic heterogeneity problem between the two business processes. In this context, it is the meaning and interpretation of the P-facts, C-facts, and their corresponding speech acts. For example, suppose there is a service to check the format of a submitted journal that is based on the Harvard standard of citation. In that case, it is unlikely to replace a service in another journal that uses IEEE or APA standards as well as the system of journal citation. Also, if an application uses the ISI standard of ranking journals, the JCR, it will unlikely replace Scopus standard SJR.

Similarly, a service purchasing items from Amazon is unlikely to be able to replace the purchased items on eBay. However, it is obvious that standardization is needed in all these cases before a hand, and this is where an ontology concept comes in. Therefore, a language is needed to describe the ontology according to ontology principles. The UML design language as one candidate has been chosen for its familiarity and visualization feature mentioned because OWL, for example, does not have a graphical representation. Therefore, the business process needs to unify the meaning of words or vocabulary used for interactions or communications using a design language like a class diagram, OWL, DL and others. This specification also explicitly includes the structure of complex objects usually hidden in a single system's conceptual model [10]. Colomb argues that ontology is a kind of conceptual model but exists outside the domain. It is, therefore, a standardizing of the meaning of P-facts/C-facts which is necessary to perform the gap analysis task. As a consequence of this principle, the business process designer needs to specify an ontology using like UML class diagram or OWL. This class model should specify the institutional facts of the domain of some business application. However, many CASE tools are available that support modeling and transformation between modeling languages.

OWL, standardized by the W3C, is a rich ontology representation language that allows us to specify individuals in a triple store format (Subject-Predicate-Object). An RDF triple, which consists of a predicate connecting a subject to an object, forms the basis of this representation. An individual can possess properties, which define direct relations from a domain class to a range class. By default, instances of properties have the most general domain and range, owl:Thing. OWL defines two primary property types: object properties, which describe relationships between individuals (e.g., participatesIn, enrollsIn), and data properties, which describe attributes of individuals (e.g., age, weight). The domain of a property can be restricted using cardinality constraints, such as owl:FunctionalProperty, which asserts that a property has at most one value for each instance. For example, the following OWL syntax declares hasFather (an object property) as functional:

```
<owl:ObjectProperty rdf:ID="hasfather">
<rdf:type rdf:resource="&owl;FunctionalProperty" />
<rdfs:domain rdf:resource="#Son" />
 <rdfs:range rdf:resource="#Person" />
</owl:ObjectProperty>
```

Similarly, OWL allows us to restrict the range of a property using the concept of surjectivity (i.e., every instance of the range must participate). For example, in a postal system, if we want to express that a postal code belongs to a city, and each city has one single postal code, we can model this using such constraints.

Moreover, we can use SPARQL [25] to query an ontology represented in OWL, which has also been standardized by the W3C and is supported by tools such as Protégé (cite). For instance, we can query whether a property is functional:

```
SELECT ?property
WHERE { ?property rdf:type owl:FunctionalProperty .
FILTER (? ?domain = sc:Son)) }
```

A property in this example is a variable that will be bound to specific values based on pattern matching. This allows reasoning

about the ontology which is abbreviated by namespace sc (schema of some ontology). We specify conditions in the WHERE clause to be satisfied, in this case specifies whether an RDF graph explicitly defines a property as functional. The FILTER clause adds further restrictions, such as requiring that a property must have the domain son. For instance, the property has Father specified in the OWL ontology above will be returned.

Additionally, NOT EXISTS can be used with FILTER to assert certain constraints. Moreover, a query can be specified for each part of RDF instances using rich built-in predicates and operations, such as intersection, union, and others.

In the following, a demonstration of a case used throughout the paper is presented as part of a postal system ontology. Fig. 5 describes the structure of some institutional facts created by a set of corresponding c-acts, which will be specified later in the section. The main production fact is manifest (see Fig. 5), which consists of a set of properties and c-facts required to fulfill the postal system's primary activity: sending a mailpiece from a sender with a specific address to a receiver with a specific address. Addresses, in this case, belong to a superclass named NAaddress, which has the properties city (range: Clist), postal code (range: Pcodelist), district (range: string), and street name (range: string). The mailpiece, referred to as mailRequest on the left side, has properties including ID, city, postal code, and ship type, which ranges over a specific list called ShipMethod. A customer who initiates this request pays an amount (ranging over RateSchedule) and obtains a stamp by referencing postage. The payment is declared through a postage invoice, which contains a set of properties identifying the date, amount paid, and shipping type.

*1) Sample of Mailpieces (invoice)*

*a) Address Information*

- Sender's Address: Name, street address, city, state, ZIP code
- Recipient's Address: Name, street address, city, state, ZIP code

*b) Postage*

- Stamp (Metered Info): Evidence of payment for postage
- Postage Amount: Value of postage paid

*2) Sample of Manifest*

- Container Details:
  - Container type (sack, tray, pallet, etc.)
  - Container number or identifier
  - Weight of the container
- Mailpiece Details:
  - Total number of mailpieces
  - mailpiece type (letters, flats, parcels, etc.)
  - Total weight of the mailpieces
- Origin and Destination:
  - Originating postal facility
  - Destination postal facility
- Date and Time:
  - Manifest creation date and time
  - Departure time (if applicable)
- Personnel Information:
  - Name and signature of the postal worker preparing the manifest

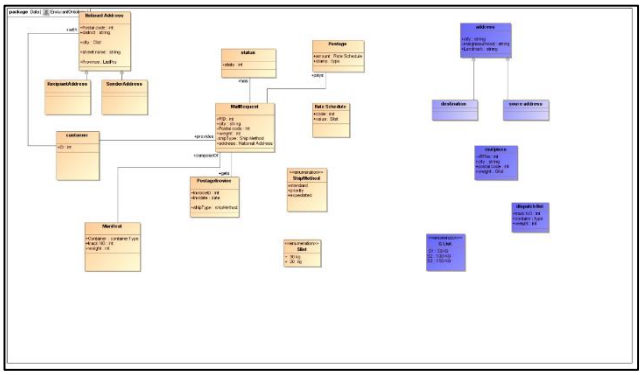

Fig. 5. Postal system endurant domain ontology.

## VII. GAPS DETECTION

The gap analysis aims to discover the alignment of new business processes with business objectives and how far the current practiced business process is from this newly adopted one (which involves some change). The software packages, with their new embedded business processes, define new practices and standards (stemming from research and long experience of Gaint enterprises) for a given domain of business, such as accounting, purchasing, recruitment, etc. It turns out that the identification of noncompliance and its processing is a complete process following the principles of quality management [26].

This section aims to build on the principles established so far to standardize and formalize the gap analysis process that establishes the base for automation.

It is obvious that now we need to focus on P-act/ c-facts; that would be the starting point in observing the differences even between two BPs from different domains. ERP or other Enterprise packages is to replace a business process from the same business domain. For instance, an accounting business process is expected to replace another accounting business process but not purchasing, for example. However, how do we know if two P-acts have identical matches or semi-matching?

Colomb [22] argues that P-act is the stable result which means the c-acts are variable part. Therefore, the difference arises in the set of C-acts with their C-facts that realize the stable result P-act. The assumption supported by principle B; says two c-facts are identical because they belong to the same class or type based on a unified ontology that specifies the vocabulary being used and provides standard meaning. However, the kinds of P-facts and C- facts and how their creation is performed will

ultimately make the fundamental difference. This suggests that we need to do a deep analysis of C-acts. So, the fundamental question becomes when and how two corresponding C-acts are different. The domain ontology reduces this problem into a matching function that asserts where an individual (c-fact) belongs to some existing class. Furthermore, this mechanism can be extended to implement like the Substitution principle that makes whenever an instance of the superclass is valid, the instance of the subclass is valid [27]. Therefore, a superclass with a stronger postcondition can substitute a subclass with a weaker precondition.

This work argues that the practical consequence of this approach is that the production of the same facts signifies the same behavior assuming the same domain.

However, given two similar P-facts, there might be some functional or non-functional (the fundamental assumption of change, such as adding efficiency or economy to business process) differences, but that must be reflected in the C-acts with their C-facts in some way, such as extra inputs or/and different sequence of performance of c-acts. Based on DEMO view when two processes or P-acts have identical production facts, they have already make a response to the same first request in O-phase but probably with some different executions commitment , eventually they will be having an exact result stated in R-phase. In principle, these reports a similar behavior, although they may have different scenarios of execution in E-Phase.

### *A. Mapping UML Activity into Ontology Individuals*

The UML activity model [23] represents the business process at a high business level. We need to map it into ontology representation using one ontology representation language in order to make the reasoning. UML activity diagrams represent both static structures, such as action inputs and outputs, and dynamic processes. From an ontological perspective, for each endurant entity, represented by a class model, there exists a perdurant entity that brings it into existence. This implies that data and processes should be consistent, with each data element resulting from a specific action. We utilize activity models to represent these perdurant entities. Crucially, the domain ontology metamodel (Principle B) serves as the primary source of these facts. They are the set of related P-facts and C-facts of the organization worlds: P-World and C-world. We can do this mapping as definitive statements in OWL( or any other ontology languages ), such as asserting that there is an individual P-fact, visa reference number in Fig. 3 process : P-act(visa- No, date) or asserting fact such as an invoice: C-fact(invoice-No, date, amount). These facts are usually augmented with the specification of transactions in the process model, getting a visa, for example.

The output of this mapping process is a set of facts (as will be shown in the case study) of metamodel level 1 because it models objects that are instances of metamodel level 2 [14]. From OWL prospective, a c-fact is an individual that does not belong to any class but has a set of properties. The properties of the individual are kind of Datatype property. Concrete objects, or specific instances, such as a visa application for Mr. David, are considered level zero individuals. A concept fact (c-fact) can be defined by a combination of properties with literal ranges. For example, in the case study presented in Fig. 6, a mailpiece, produced during the E-phase of the postal system's main mail delivery process, is a c-fact. This mailpiece represents an essential communication document (c-act) for delivering packages, letters, and other items. Properties of this individual c-fact, such as the sender's address, have a domain of 'Customer' and a range of a literal (e.g., string). Similarly, properties like city, state, and zipcode are also literals. Other properties, such as stamp and postage amount, have numeric ranges. Conversely, meter info is likely an object property with a range that is a class with a defined structure. The container type property of the Manifest follows a similar pattern. Because OWL allows the representation of meta-levels [23] within a single model, unlike UML, OWL and RDFS are commonly used for ontology representations.

The problem of converting UML models into OWL has been explored extensively, yielding results across various methods: MDA (Model-Driven Architecture), ontology profile-based approaches, and hybrid techniques. The choice is about cost-benefit analysis approach which has been elaborated with concrete examples by a fruitful OMG ODM project [28], for sake of simplicity will not be considered here.

The view of processes is needed because it consumes the Endurant facts which is a sequence of c-acts corresponding to a specific P-fact. Because OWL does not directly recognize P-acts and their related c-acts, the workaround is to add a meta property, called 'type,' for each act to classify it into one of a set that can be constrainted to c-act,p-act,c-fact,and p-fact . In fact, all c-acts and P-acts can be modeled as OWL classes that can have a set of OWL or RDF properties. Alternatively, OWL-S can be used since it supports service modeling, such as atomic and composite services. OWL-S has a rich structure capable of modeling inputs and outputs. However, we use OWL for its simplicity and comonality.

Fig. 6 illustrates a business process involving concept acts (c-acts). To produce the manifest (main perdurant fact, or p-fact) through the ontological action 'generate manifest,' a mail item is received by the action 'receive mail.' Note that some actions, such as the first two in process A, are manual steps. Consequently, a sequence of concept acts (c-acts) must be executed.A mail package will be gauged,, then a formal request will be created, create request, a service fee will be calculated by calc service fee, and sorting of packages will be thorough Sorting action. These c-acts have a sequence (incoming edge and outgoing edge), input(s) and output sometimes. However, process B in the right side of Fig. 6 is similar to that but involves some differences (discussed later in details) which represent the to-be system or target.

To specify a general method of mapping acts in Activity model to OWL, we can make some abstraction. We do model a property called next for keeping track of the sequence in c-act individual.

### *B. Mapping Target Ontology Into Source Institutional Facts (Principle C)*

The domain ontology is all about intuitional facts. These institutional facts as discussed are created by speech acts under some context which represents framing rule. However, the situation now is we have got two different worlds of institutions:

to-be system and as-system so the question how do we know the institutional facts of to-be system is similar or matching the as-system's institutional facts which as argued in this research as fundamental principle. This distills down into finding a base where the automation machinery going to present later can use it to decide such as on the gap between source and target. Consequently, this step is essential for the following stages, which is about mapping and comparing processes. This aim to establish correspondences between the c-facts from the two different worlds; will refer to them to-be system as the target world, based on intuition that we need to move towards the new system and as-is system will be called the source world, based on the perspective of the main production act.

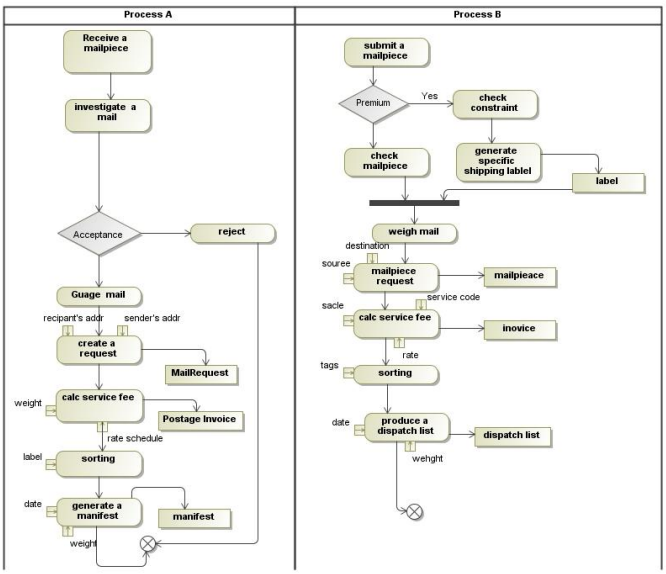

Fig. 6. Postal system main business process (Perdurant ontology.)

How far or near the target from source is the principle of ontological commitment (re-use) which can be low or high as dicussed. The commitment will be low when an ontology used in its usual scope. However, the inputs to the mapping process consist of the two ontology worlds, along with the documentation of the target world (e.g., data dictionaries and BPMN models) .The output is a specification of alignments, mapping target institutional facts to source institutional facts, which depends on the level of ontological commitment. In extreme cases, this may result in extending the ontology with new concepts or creating specializations (subclasses).

More importantly, as demonstrated in the case study, generating the manifest—the main production act—requires a set of C-acts to be performed. These acts lead to the fulfillment of a commitment or promise to create a mailpiece. A mailpiece consists of several attributes: sender, recipient, stamp, and postage amount. This perspective provides a conceptual link that helps track or connect these elements.

A domain expert may observe a similar structure for the mailpiece, though with some variations—for example, differences in naming (e.g., "service amount" instead of "postage," or "meter info" instead of "stamp") or the presence of new concepts not originally defined in the system (e.g., "date," "log info," etc.). These variations are often captured in a data dictionary, which defines the business vocabulary. While precise terminology is ideal, a degree of flexibility is acceptable at this stage, with a greater focus placed on identifying key roles and entities.

Business analysts typically consult both the data dictionary and documentation of the business process—such as BPMN diagrams or activity models—when performing alignment activities. This approach is a common and effective practice within enterprises, as it allows experts to focus on the primary roles and major institutional facts, which serve as abstractions for complex systems. In principle, this alignment process can be automated or semi-automated as in the literature.

It is common for business analysts or ontology engineers to identify relationships or mappings between concepts, whether at the schema level or instance level. This challenge is well-known in the literature and is often referred to as semantic matching, semantic mapping, or ontology merging [29]. Several approaches have been developed to identify relationships such as equivalence, subsumption, and others. Tools like LogMap [30] and the Alignment API [31] are widely used for this purpose. According to this activity untimely will end up with a table similar to Table I (based on the case study) in which the target concepts mapped into their corresponding source c-facts P-facts. The ontology can be built either based on source world or target world since mapping has been performed.

TABLE I. MAPPING TARGET INSTITUTIONAL FACTS INTO SOURCE INSTITUTIONAL FACTS

| Source | Target | Comments |
|---|---|---|
| Mail request | Mailpiece | Similar |
| manifest | Mail list | Some differences more attributes added |
| Invoice | Invoice | Similar |
| Guagement | weights | Different scales |
| | | |

### C. Generating Implication Rules Based on Corresponding Actions(D)

We have now a unified ontology has been annotated with the target concepts after mapping as explained in the previous section. This section will deal with the base for matching and discovering the gap between two business processes.

As Colomb [22] argued, the stable result is the production act, meaning that all different c-acts and their associated c-facts will not change the reality of p-fact. Additionally, an institutional fact can be understood as a record of a speech act. Furthermore, as stated in the quote, “the state of the P-world at a specific point in time is defined by the set of P-facts created up to that moment, while the state of the C-world at a specific point in time is defined by the set of C-facts created up to that moment.” In simpler terms, the creation of a fact of a particular type represents a state transition within one .of these two worlds.

This implies that we can trace the primary production acts by examining the pre-c-facts generated during the E-phase and the post-c-facts generated during the R-phase. Consequently,

when two distinct c-acts result in the same c-fact instances, it indicates that they exhibit similar behavior.

Therefore one can observe that dependencies usually exist in the creation of c-facts, which often follow a logical sequence. Fig. 7 illustrates that the main production fact, the Manifest, requires the creation of two necessary c-facts: Mailpiece (c-fact1) and Invoice (c-fact2). Additionally, each c-fact can be associated with a set of c-acts that were performed prior to its creation (referred to as the c-world state), which contribute to its existence. This observation suggests that we can use these facts as a basis for tracing and matching subordinate elements between two worlds.

For instance, both Mailpiece and Manifest have sets of c-acts that contribute to their existence. Let us refer to these sets as Set M (for Mailpiece) and Set F (for Manifest). In this context, Set F is a proper set, while Set M is a subset because the Manifest encompasses multiple Mailpieces. This implies that the Manifest represents the whole, while the Mailpiece is a part of that whole. Consequently, there may be many parts (Mailpieces) that belong to the same whole (Manifest). Therefore, in this case, we need to identify the corresponding whole in the to-be world and construct similar sets of c-acts.

Since institutional facts from the to-be world are already mapped to corresponding institutional facts in the as-is world (principle c), it is possible to define a mapping function or make a relationship between them (i.e., they contribute to the creation of the same fact). Once these sets are constructed, a more specific matching between corresponding sets of c-acts can be established. For example, in Fig. 7, the Mailpiece has its corresponding MailRequest, and actions such as Gauge Mail and Weigh Mail are also corresponding actions.

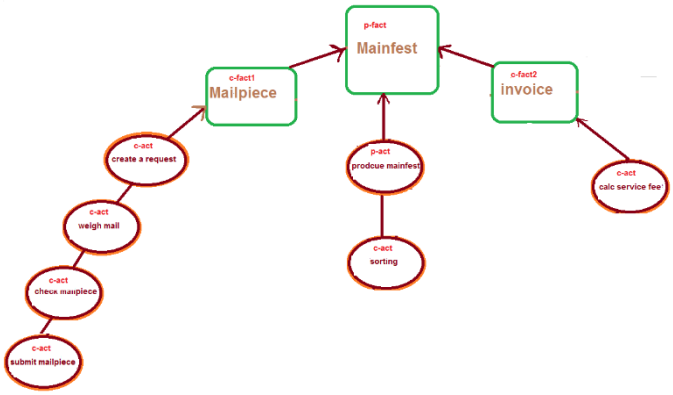

Fig. 7. Example of dependences among c-acts that contribute to the Production fact Mainfest.

More importantly, I argue that, based on this perspective, we can conceptualize an implication rule where the left side (a set of c-acts from Process A) implies the right side (a set of c-acts from Process B), provided that the major institutional facts (i.e., c-facts) are similar.

Furthermore, we can closely examine the direct relationship between the left-side and right-side sets by analyzing the inputs to c-acts and matching them with the standard domain ontology through querying or assertion. This process ensures that all inputs originate from the same ontology. In this context, we will have a set of properties derived from different classes. These classes belong to the left-side and right-side sets, which are either similar or represent different versions of the same entity—the institutional fact.

Now our ultimate goal is to determine when a BPs fail to be replaced by other BPs. The failure is because of different reasons but we argue that it can be commonly studied under incompatible classes or individuals in which properties are conflicting. Therefore, we need to look at the specific problem of when two classes are incompatible because at least one property in first class conflicts with the corresponding class's property. Hence a reporting of mapping failure with evidences. However, identifying these discrepancies is essential where a business can leverage them to adopt potential and necessary change (gap analysis principles).

Now let us take concrete feedback from our case study, Fig. 7 models part of a main business process in postal system that have the original BPs or as-is system, call it Process A and the to-be system, call it process B.

Process A:

*1)* Recive a mail
*2)* Check mail
*3)* Decide Acceptance - input – mailpiece info
*4)* If accepted then
*5)* Guage mail - input : mailpiece output : weight
*6)* Create mail request : output mailpiece request
*7)* Calcuate service fee
*8)* Make invoice : output invoice
*9)* Sort mailpieces
*10)* Generate manifest : output manifest

Process B:

It is similar to A but it has additional subprocess premium service that is not considered by A. Assume for simplicity the following differences.

*1)* Recive a mail
*2)* Check mail
*3)* Decide Acceptance - input – mailpiece info
*4)* If accepted then
*5)* Guage mail - input : mailpiece output : weight
*6)* Create mail request : output mailpiece request
*7)* Calcuate service fee
*8)* Make invoice : output invoice
*9)* Sort mailpieces
*10)* Generate manifest : output manifest

From step 2, for example we have a subprocess running in parallel to deal with premium service:

*1)* If premium service then
*2)* Check constraints
*3)* Calculate service fee
*4)* Confirm payment : output receipt
*5)* Generate shipping label : Output new label
*6)* Priortize handling : output special manifest

Let us imagine also three major differences in institutional facts between A and B described by Fig. 6, blue classes at right side): National address (NAaddress) that is introduced as a new government regulation in Process B. It follows a different format, including fields such as landmark, city, and neighborhood, postage amount is specified in the local currency, measurement units (guagment): There is a difference in measurement systems; Process B uses local weight standards with a different scale.

These cases can be summarized in the following (Process A):

*1)* In mailpiece the type of postage amount is Rayal currency.

*2)* Also in mailpiece as well as mainfest the addresses are formed from the structure of { a-building No (4-digits),b-street name (15-character), c-district(limited set of values : all local district for a city),city (limited set of values: all local country cities), etc}.

*3)* Guagement is a set of 50 kg, 100kg, 150kg, etc.

A prior knowledge is that the to-be system or process B has US dollar currency in any financial transaction also does not support the national address's structure and 15kg, 30 kg weights scale (i.e. large volume of business is in this scale) because the to-be system has only Mutiple of 50kg.The data dictionary of these systems could be a good source for investing such requirements or information.

It is required now to generate the implication according to the principle of finding the corresponding of institutional facts. Since we already have the specification for business processes as part of ontology in an ontology language like OWL (as described in …), this step is going to extend that to incorporate this implication generation step. The mapping of institutional facts in the source to target institutional facts will act as an input to this process (i.e. Table I). It can start with finding the main production fact and their subordinates or c-facts. Then mapping this main production fact to its corresponding fact from source.

In the case study the main manifest and manifest are similar concepts and represent the same real-world entity. Having different names or synonyms for the same concept can be automated as in the literature using corpus or wordnet and dictionaries methods [32]. It can classify concepts into the same class when they are belonging to these relationships: is-kind-of or is-a (always hold) and part- of a whole.

*1) Main production fact rule*

1. Mainfest $\longrightarrow$ postage invoice, mail request

2. Main Maninfest $\longrightarrow$ inovice, mailpiece, label

Based on Table I and the principle of left side implies right side then it follows that:

postage invoice, mail request $\longrightarrow$ novice, mailpiece, label

Also from Table I:

*2) Branching*

1.1 Post invoice $\longrightarrow$ invoice

1.2 Mail request $\longrightarrow$ mailpiece

1.3 Since label has no corresponding concept in table 1 it means new entity needs to be added to the ontology of new business process world. There are two interpretations in this case a) new requirement does not exist in the source so far b)or more refinement for existing concept(s).

Then we need to find out what are the speech acts (c-acts) have contributed to the production of these c-facts from both side of implication which will inherit this implication also.

*3)* Based on B will get the following implication of acts as consequence :

For 1.1:

calc service fee $\longrightarrow$ calc service fee

Also,

For 1.2: create request $\longrightarrow$ mailpiece request

Therefore, we conclude that the inputs to these c-acts are also equivalent

Weight, rate schedule $\longrightarrow$ scale, rate

By querying or asserting the developed ontology in principle B) above we will discover that they are not different concepts.

Make a request $\longrightarrow$ Create a request

Sender, Receiver $\longrightarrow$ source, destination

We need now to identify their corresponding classes in order to discover their incompatibility and properties in conflict. Since OWL and SPRQL has standard ontology to represent properties with its different rich characteristic functions, we can develop standard methods.

To identify incompatible classes, we can approximate the problem using the concept of subsumption. In mathematics, we say that class A subsumes class B if every element of B is also an element of A. In other words, B is contained within A, and we can say that A represents B. One can think of the relationship between the to-be system and the as-is system using the substitution principle: if A is a superclass of subclass B, then an instance of A can substitute an instance of B. However, we need to investigate the conditions under which this substitution is valid or invalid. If we can determine that business process A (the to-be process) subsumes business process B (the as-is process), then we might conclude that A can replace B. To reach such a conclusion, a set of operations—such as intersection, set difference, and others—must be applied.

But how do we know when substitution is not possible? For example, in the case of a more constrained subclass, substitution may break. According to set theory, if two sets differ in their elements—either by having disjoint elements or partial overlap

with at least one exclusive element—then they are not equivalent.

However, in this context, we need more precision. We require a rigorous definition of what it means for an element to be "different." One way to realize this is by examining conflicting properties. These conflicts help determine incompatibility. Therefore, we address this question in the following section.

There are of course many reasons for discrepancies that are difficult to count but it can be generalized under common classification theme such as in Table II, then for each class we provide a treatment.

TABLE II. AN EXAMPLE OF DISCREPANCIES AMONG PROPERTIES BASED ON THE CASE STUDY

| S | Concept in A | Type | Is_essential? | Concept in B | Type | Difference |
|---|---|---|---|---|---|---|
| 1 | amount | Property | No | Postage amount | property | naming |
| 2 | NA address | Set of Properties for a class | Yes | address | class with different set of properties but it has some common items | Structure |
| 3 | gaugement | Set of individuals for a property | Yes | wight | properties | Range – different scale |
| 4 | tracking | class | NO | New class with properties | Does not exist | Not esists (to Model new class object) |

Table II demonstrates the concept in process A (source) and the corresponding concept in process B (target), type of concept from ontology prospective (class, property, etc.) with their differences stated. Moreover, a column is added to adopt metaproperty is_essential that discriminates or defines the essential properties for each class. An essential property is one that must exist in each instance. This can be based on the theory of BWW (Bob). The purpose of proposing it here is that the final decision of dissimilarity can rely on it which allows this task to be automated.

### *D. Building Standard Queries and Assertions (Principle E)*

In order to reason about discrepancies, we need to standardize and formalize testing of a gap in the form of assertions and quires. The basic assumption is to use SPRQL since we ended up with ontology specified using RDF-based language (OWL). An alternative is use the built-in machinery of consistency check [33] but there is no more control especially if customised quires or assertion are required.

Referring to Table II, one can infer that some properties have been converted into class types, such as the NA address in the new process (No 2). Additionally, the range of one property has changed, resulting in a subsumption relationship, as seen with 'gaugement' and whight; the initial range is a subset of the new range, indicating a change in the property range's scale. Furthermore, a new property has been introduced in the new system, which was absent in the legacy system, as illustrated in case 4(tracking).Therefore, the following queries demonstrate how to reason about these cases based on the source and target ontologies given.

*1) Range discrepancy query:* This is typically for like case 3 in Table II. The first obvious case occurs when the value of a property in target class does not belong to the range class of the source(i.e. range of source is mailpiece while the range class of target is manifest).Second, the range of the source property is more specific than the target property( target range for instance is a set of red and yellow while source is bule only).

The discovery of the first case is straightforward because we can use the SPRQL not exist in the filter clause to assert that an individual has property's range of the source (i.e. postage amount is not riyal). The second case can be obtained by different ways; one way is to use OneOf OWL construct that allows to specify, for example, a property having specific range (enumeration data type).Therefore, we can use SPRQL to disprove that the range set of the source is not either subset or proper set of the target. For instance, the base to discover the incompatibility in case 3 in the Table II:

```
# Check subset condition, A ⊆ B: every member of Set A is also in Set B
Select? x
FILTER NOT EXISTS {
?x rdf:type :RangeOfClassA.
FILTER NOT EXISTS {?x rdf:type :RangeOFClassB }
}
```

The Not-exists clause will return false always except when one tuple appears in the result showing that one member of set A is not part of set B.

```
# Check proper subset condition, B ⊇ A: there exists a member in Set B not in Set A
FILTER EXISTS {
?x rdf:type : RangeClassB .
FILTER NOT EXISTS {?x rdf:type : RangeClassB }
}
}
```

Notice that this is the inverse of the first query so the Not-exists clause returns true only when there is a member in B does not belong to A.

*2) Structure discrepancies query:* It is typically like case No 2 in the table where a property needs to be replaced by a class(NA address ) which is a recurring problem. Since based on DEMO their corresponding classes are from the same P-act then some overlapping of properties might occurs. However, there are different types of structure differences that might happen. Mostly these will recur in the whole ontology and the

advantage of this is that a bench of quires will be re-used, therefore reducing the cost of the development. In the following these different types of structure discrepancies will be sketched.

Type1: Class range vs. property range

The following query will return instances of properties that at most one of its range is a class. The postage amount in target could ranges over specific class (standard list) while the source amount has range integer.

```
SELECT ?Property1 ? Property2
WHERE {
 ?property1 rdfs:range ?range1 .
 ? Prpoerty2 rdfs:range ? range2
 FILTER NOT EXISTS (( range1? Owl:datatype ?) And (range2 owl:Class })
 }
}
```

Type 2: Ranges are classes but one subsumes the other

Using proper set and subset check as discussed above allows us to make a test for which is a subset of another, but before that an initial test is required to map corresponding properties instead of comparing a source property with all target properties. For example, Address and NA Address, in such a situation Hamming distance can be used which computes distance between two strings. Properties can be encoded using bitmaps such as 4bits for each character (we need determine the size based on the dynamic range of characters exist). The Hamming distance function computes how many number of characters are in differences. In this case, it will result in less distance between NA address and Address than among other properties. Also, the case could be two different names of properties used but with the same semantic meaning. For example dispatch list and manifest .A well-established method of Wordnet [32] can classify these concepts into the same class which is an is-kind relationship. Wordnet-based methods can also detect is and part-of relationships.

Type 3: Cardinality discrepancies

More restriction could be specified on ontology of source and target where properties have specific cardinalities (min, max) therefore must present in testing. For example:

- A Manifest must include at least one Mailpiece (a manifest cannot be empty).
- A Mailpiece can be included in at most one Manifest (a mailpiece cannot be listed on multiple manifests).

Min/Max cardinality test: Remember this test on TBox or the terminoglical level of the ontology but not instance level.Therefore we need to teat ComposeOf property if it specifies max or min cardinality .Usually OWL allows one to make these constrains by defining a subclass of the restriction class (OWL built in).In the following a query ComposeOf for this case will be checked for if it has min cardinality constraint. Constraint and card value are variables will be instintiated when the where condition satisfied. The where condition binds a restriction variable with instance if it finds rdf type owl:Resitirction class which has property ComposeOf.

```
SELECT ?constraint ?cardValue
WHERE {
 ?restriction rfd:type owl:Restriction ;
 owl:onProperty : ComposeOf;
 ?constraint ? cardValue .

 FILTER (?constraint =minCardinality)
}
```

Based on that queries and assertions we will be able to verify if any major differences exist for essential properties of the source ontology and accordingly, we can reach to the final decision of compatibility or not because of the exitance or not existence of conflicting essential properties.

We could combine or package these quires to be executed in a sequence using Nested substructure where select ... is going to be nested or chained. Therefore, we can get one final and single answer for a couple of quires and assertions. Moreover, the implication rule principle can be automated and linked with this these queries using XSLT which can transform the implication rule into a direct call to APIs that will perform the necessary tests as explained above.

TABLE III. COMPASSION AMONG THE METHODS USED FOR GAP ANALYSIS

| Criteria | Manual inspection | Process Mining | Proposed method |
|---|---|---|---|
| Automation support | No | Yes | Yes |
| Semantic heterogeneity | Yes | Yes | No |
| BP Instances required | No | Yes | No |
| Error rate | High | low | low |
| Reliability | Low | High | High |
| Performance | Low | High | High |
| Scalability | No | Yes | Yes |

## VIII. DISCUSSION AND INTERPRETATIONS

Enterprises often adopt new and innovative business processes under the assumption that they will lead to breakthrough results. However, if such changes are implemented without sufficient preliminary analysis, the risk of failure significantly increases. For example, a recently established company in the region specializing in paper manufacturing and recycling—with a capital exceeding one million dollars—faced failure during an attempt to upgrade its systems and reengineer its business processes.

Traditional approaches in such cases are typically ad hoc, suffer from semantic heterogeneity, and lack scalability due to inherent complexity. Table III shows a theoretical comparison based on expert reasoning of manual inspection, process mining, and the proposed method across several key criteria: semantic heterogeneity, instances requirement, automation support,

errors, reliability and scalability. As demonstrated, manual inspection is unreliable, has a high error rate, and lacks automated support. Although process mining increases automation and reliability, it does not address semantic heterogeneity and is still dependent on the availability of process instances. By removing semantic heterogeneity and lowering reliance on process execution logs, the suggested approach outperforms both process mining and other methods while maintaining high reliability and performance. This comparison serves to highlight the anticipated benefits of the suggested approach, even though empirical validation is still a future objective.

Since business processes (BPs) are fundamentally about institutional facts (i.e., production facts), the model proposed in this article offers a way to mitigate such risks. It does so by unifying the institutional vocabulary used by businesses to describe their expected services and products.

This unified vocabulary enables standardized gap analysis, supported by DEMO, which provides a formal language for expressing the essential elements of a business process—abstracted from implementation and realization details. Such abstraction is a powerful tool for managing complexity.

Furthermore, comparing the ontologies of to-be and as-is business processes is feasible because both originate from the same business domain. Various scenarios can arise, such as one process being more constrained than the other. These discrepancies can often be grouped under common classes, allowing the development of a general method for systematic analysis and resolution.

One related outcome of this work is that it facilitates documenting gaps so they can be understood at a high level, as argued by Jeston [34]. This is the fact that models are transformed into a knowledge-based system; therefore, it not only supports reasoning about gap but also acts as an informative repository that can be reused for different analysis goals, which is a principle aligned with the BPM objectives. For example, top managers, executives, and strategist are interested in answering inquiries about different business processes for various reasons, such as benchmarks to determine enhancements for as-is processes that can justify the investment [35].

The major cost is developing an ontology manually for a domain of business processes or institutional facts. Also annotating the model with DEMO concepts and mapping target institutional facts into source institutional facts. However, some capabilities of the ontology toolset can be utilized to some extent, such as ontology learning, consistency check and the model's mappings facility of QVT to reduce this cost. Moreover, conducting large-scale evaluations in different domains with different scenarios will highlight more classes of discrepancies. These are elements of future work.

Regarding the reengineering process itself, standardization enabled by DEMO helps to define the kind and type of change required as usual practices of adopting new ERP (commits to ERP ontology). Therefore, the problem would shift to focusing on which institutional facts (C-fact and P-fact) need to be changed as well as its set of actions (C-act and P-acts). Moreover, DEMO provides an ontology to talk about processes gap and their classification.

## IX. Conclusion

This study examines the challenges of gap analysis problem when replacing legacy business process (as-is) with new business process (to-be). Business processes evolve to incorporate qualities such as economy, productivity, and efficiency, necessitating a thorough analysis to ensure alignment with organizational objectives and strategy. Gap analysis plays a critical role in answering key questions, such as whether a new process can replace an existing one and, if not, identifying the reasons. This work proposed a structured method to identify gaps among business processes. It consists of Four principles: 1) Developing DEMO profile (principle A) 2) Building domain ontology for BPs (principle B) 3) Mapping target institutional facts into source ontology (principle c) 4) Generating Implication rules based on corresponding actions 5) Reasoning using standard discrepancy quires(principle E). Because business processes are about the production of institutional facts, semantic heterogeneity prohibits comparing and analyzing two different processes ( main source of failure); building domain ontology(consists of both endurant and perdurant) that unifies terms, concepts, messages and interpretation is an essential process in the proposed approach (principle B). This suggests mapping the to-be system's institutional facts into their corresponding source's institutional facts (principle c). Also, DEMO has richer concepts for designing business processes that focus on the Essential model of an enterprise. It handles the complexity through the identification of the main production act, p-act, which is the stable result. Therefore, a set of c-acts could be identified and compared that is required for the existence of the P-fact (i.e. manifest) b; business activities independent of realization and implementation issues. Therefore, a UML Activity as a famous design language has been profiled to support DEMO concepts (profile A). Integrating DEMO concepts into UML activity Diagram puts forwards and facilitates the analytics of business processes. This suggests that we reason about gaps using such as SPRQL (Principle E). However, this study contributes to the state-of-the-art of BPM and ERP community by providing a facility to compare different business processes semantically, either as legacy or new processes, providing a great opportunity for business analysts, architects, and strategists to make critical (multi-million dollars) decisions.

***Abstract*—Smart city optimize efficiency by integrating advanced digital technologies, real-time data analytics, and intelligent automation. With the evolution of big data, smart cities enhance infrastructure and provide intelligent solutions for transportation with the integration of high-level adaptability of computer technologies including artificial intelligence (AI). The optimization can be achieved through predictive analytics in providing intelligent solutions for transportation. However, this requires reliable and accurate informative data as input for predictive analytics. Therefore, in this paper, five models of Convolutional Neural Network (CNN) deep learning method are investigated to determine the most accurate model for classification; namely Single Shot Detector (SSD) Resnet50, SSD Resnet152, SSD MobileNet, You Only Look Once (YOLO) YOLOv5 and YOLOv8. A total of 1324 vehicle images are collected to test these CNN models. The images consist of five different categories of vehicles, which are ambulance, car, motorcycle, bus and truck. The performances of all the models are compared. From the evaluation, the model YOLOv8 attained 0.956 of precision, 0.968 of recall and 0.968 of F1 score and outperformed the others. In terms of computational time, YOLOv5 is the fastest. However, a minimal computational time difference is observed between the YOLOv5 and YOLOv8, which were separated by only 20 minutes.**

***Keywords*—Vehicle classification; Convolutional Neural Network; SSD; YOLO; MobileNets**

## I. Introduction

"Smart City" is a city that utilises technologies, data and digital solutions to improve the efficiency by equipping systems and services with additional cameras and sensors to collect data [1]. Then it integrates with various services such as transportation networks, public transit, utilities, and others to improve its operation and the quality of life. In a smart city, the huge volume of data collected using vision sensors can be used to improve services provided by the city, especially for the road traffic management system. Monitoring the road monitor traffic congestion is important as the number of vehicles continues to increase every year. Starting from 2021, over 71 million vehicles are sold globally [2]. This shows that there is a need for efficient traffic monitoring and management systems to avoid traffic congestion.

With the increasing number and volume of traffic data vehicles on the road, effective road traffic monitoring is crucial to improve the flow of traffic, minimizing accidents, and reducing traffic congestion [3]. Vehicle classification plays an essential role in optimizing the road traffic flow and enhancing road safety. Different vehicle types, such as cars, buses, trucks, and motorcycles, have distinct speed, space, and acceleration characteristics, affecting congestion patterns. Accurate classification helps in traffic signal control, lane management, and smart tolling systems to ease the congestion. Thus, this will also allow predictive solutions and decision making for better road planning and road traffic management system. With the integration of Artificial Intelligence (AI) for road traffic monitoring, traffic congestion may be reduced by offering a predictive solution for future planning and decision making. The predictive analytics in AI can predict congestion by using historical data, detect accidents and related events in a short time, and optimise public transportation schedules, which will reduce the occurrence of congestion. In delivering a high-quality predictive solution for future road traffic monitoring, a highly accurate method is needed as reliable and accurate information for effective traffic management. Therefore, in this paper, we investigate the reliability of artificial intelligence using Convolution Neural Network (CNN) of deep learning models to classify between types of vehicles for road traffic monitoring. The types of vehicles on the road, information and vehicle distribution can be further used as the input for analytics model for future prediction of road traffic conditions. The analytics synthesize, analyze the trends and identify the patterns based on the data for future planning, decision making and actions to improve the road traffic monitoring.

This research focuses on the detection of a suitable CNN deep learning model for vehicle classification. The CNN method is chosen since it is one of the most reliable deep learning models which can automatically extract meaningful patterns and features. CNN utilizes its convolutional and pooling layer to preserve spatial relationships within an image which allows it to recognize objects regardless of its position in an image. CNN uses shared weight through convolutional filters which may reduce the number of parameters compared to a fully connected network. This capability will reduce the time complexity as fewer computations are needed, making CNN method a fast-training method [3].

To test the proposed CNN model, datasets of vehicles that consist of 1324 vehicle images from five different categories of vehicles which are ambulance, bus car, motorcycle and truck are created. Then, the performances of the CNN models are compared between Single Shot Detector (SSD) Resnet50, SSD Resnet152, SSD MobileNet, You Only Look Once (YOLO) YOLOv5 and YOLOv8 in terms of precision, recall, F1 score and computational time. The rest of this paper is organized as

follows: Section II presents the related work on the vehicle classification methods. Section III described the details of the proposed method. Section IV presents the experiment setup. The performance of the proposed method is presented in section V, followed by the discussion in Section VI. Finally, the conclusions and future work are highlighted in Section VII.

## II. Related Work

The accurate prediction of road traffic patterns and vehicle types able to improve road traffic management. Early detection of traffic congestion and vehicle distribution is essential for prediction of road traffic conditions, optimizing traffic flow, and enhancing future planning for road transportation. Object detection methods play a crucial role in identifying and classifying the objects in images [4]. With computer vision technology and deep learning object recognition methods, smart traffic systems able to offer the automated detection and classification of various types of vehicles on the road. This enables more efficient traffic control monitoring. However, in vehicle detection and classification, achieving an accurate classification and consequently prediction remains a challenge due to factors such as varying lighting conditions, occlusions, and diverse vehicle appearances [5, 6].

In recent years, the deep learning-based models show the best performance in detecting objects with high classification accuracy [7]. In the intelligent transportation system, deep learning models able to automatically extract important features in order to classify vehicles such as motorcycles, buses, cars, ambulance and trucks into their own category. This will enhance transportation systems, especially road traffic monitoring and road safety to reduce traffic congestion. The deep learning methods focus on the useful features which are extracted automatically. The methods analyse extracted features with similar logical structures as the human brain which enable to obtain more accurate results compared to the other methods such as statistical, morphology and model-based methods. The deep learning method, able to improve object detection and classification [8].

In deep learning, the CNN method is the most promising method that is able to effectively extract the significant features of the object and able to achieve high classification accuracy in most of the application [9] . In CNN method, there are the two object detection which have gained popularity, namely Single Shot Detector (SSD) and You Only Look Once (YOLO). These methods have gained popularity due to their accuracy performance [10].

The SSD is an object detection framework which predicts a bounding box in a single forward pass through a deep neural network. To perform detection on objects of various sizes, it uses multiple feature maps at different scales. SSD have gained popularity as they balance well between speed and accuracy. SSD combined with different types of ResNet architecture will result in different SSD ResNet models such as SSDResNet50, SSD ResNet152 and SSDMobileNet. SSD ResNet50, combines SSD with ResNet-50 as the backbone, which is a deep convolutional neural network consisting of 50 layers. It is suitable for real time applications with moderate computational power. The SSD Resnet152 on the other hand uses a deeper neural network with 152 layers. The increased number of layers in the SSD Resnet152 able to improve the classification accuracy of the model. However, this increases the time complexity. The model that able to reduces the time complexity while maintaining a reasonable amount of accuracy is the SSD MobileNet [11]. The SSD MobileNet model is design and optimized for the mobile.

Apart from the SSD model, YOLO model is also widely used for object detection. It frames object detection in images as a regression problem for separated bounding boxes in YOLO. It also provides an image with captions and the object is highlighted with the probability of correct detection. YOLO models are also seen to be the most suitable model in many detections and classification tasks as it shows promising results and able to obtain high classification accuracy in object detection and classification [7]. There are two advanced versions of YOLO, namely YOLOv5 and YOLOv8. The key differences between these two versions are its architecture. YOLOv5 utilizes anchor-based architecture where the anchor box is needed to be predefined with different size and aspect ratios according to the object used in the image. When predicting, it adjusts the predefined anchor box to better match the actual object. On the other hand, YOLOv8 uses anchor-free architecture which directly predicts the object location by identifying key features from feature maps, rather than relying on an anchor box like YOLOv5.

Due to YOLO are among the most efficient method for object detection, Ghoreyshi et al. proposed vehicle classification based on YOLO of CNN model. In their work, they able to achieve a high classification accuracy with 91% accuracy. This shows that YOLOv3 models have potential in effectively recognizing and classifying vehicles. However, in their research, less detection is observed for the images with occlusion which is a common scenario in real world traffic environments [3].

Similarly, Gao et al. also use YOLO model for the detection of vehicles. However, in their research, the YOLOv5 is selected to classify multi-class vehicle detection. The YOLOv5 models used in their work able to obtain accurate results with 96% accuracy results. The results obtain in their work shows that YOLOv5 methods are effective in real time applications and can be used in traffic monitoring [12].

The performance of YOLOv5 is further explored by Kumar et al. They proposed YOLOv5 with DeepSORT algorithm in their work to address both detection and classification of vehicles in dynamic traffic scenarios. Their research focuses on real-time performance efficiency. The research offers a practical solution in applications which require quick monitoring and decision making in traffic environments [13].

From the above review, SSD and YOLO were among the methods that had been considered in existing vehicle classification. The SSD and YOLO are seen as the most suitable candidate for vehicle classification. Therefore, in this research, a CNN deep learning based method of SSD and YOLO are chosen for vehicle detection and classification. The SSD is chosen due to its ability to balance well between speed and accuracy. On the other hand, the YOLO is selected as it able to obtain high classification accuracy in many object detection and classification tasks. Based on the review, four models which are

YOLOv5, YOLOv8, SSD ResNet50, SSD ResNet152 were among the models that had been considered in existing vehicle classification recognition due to their strength in detection and classification. YOLOv5 shows high accuracy and rapid inference, ideal for real-time applications. YOLOv8 also shows high accuracy and robustness against challenging conditions. The SSD ResNet50 on the other hand able to improve the detection on moderate complex scenarios and better handling the details of the objects than the lightweight. The SSD ResNet152 is also one of the chosen models due to the robust detection in complex traffic scenarios. The SSD is seen to be an efficient model for real-time applications with faster processing speeds [14].

Based on the review, five models which are SSD Resnet50, SSD Resnet152, SSD MobileNet, YOLOv5 and YOLOv8 are seen to be the most suitable model for vehicle classification tasks. The four models which are SSD Resnet50, SSD Resnet152, YOLOv5 and YOLOv8 are selected due to their accuracy and performance in detection and classification. While the SSD MobileNet model is selected due to it ability to reduce the time complexity while maintaining a reasonable amount of accuracy. To determine the best model for vehicle classification in smart city, the performance of these five models namely, SSD Resnet50, SSD Resnet152, SSD MobileNet, YOLOv5 and YOLOv8 are evaluated and compared.

## III. Proposed Model

The proposed model for vehicle classification can be divided into two phases, training and testing. In this paper, generally, two CNN deep learning models are evaluated which are the SSD and YOLO. The overall scheme for the vehicle detection is shown in Fig. 1. Each of these methods will be discussed in the following subsections. To obtain the most suitable model for vehicle classification from these two main models, five different models are tested, and their performance are compared. The five different models are the SSD Resnet50, SSD Resnet152, SSD MobileNet, YOLOv5 and YOLOv8. Each of these models will be discussed in the following subsections.

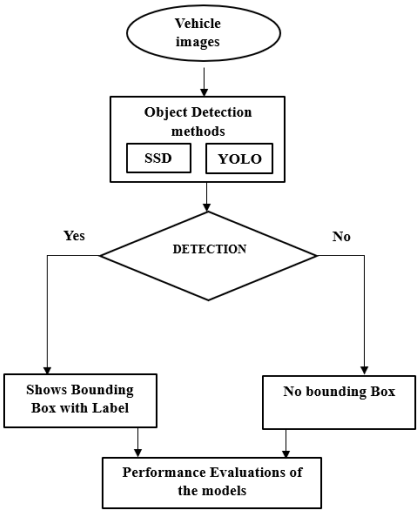

Fig. 1. Overall scheme with two different object detection methods.

### A. Single Shot Detector (SSD)

The SSD is an extension of Convolutional Neural Network (CNN) model architecture which is designed for object detection. The SSD method uses deep CNN for the detection and classification of the object location in an image [15]. SSD utilizes multiple feature maps and anchor boxes to detect objects from various sizes and predicts its location and class score of the objects within the images [16]. Three SSD models evaluated are SSD ResNet50, SSD ResNet152 and SSD MobileNet. The basic SSD architecture is shown in Fig. 2.

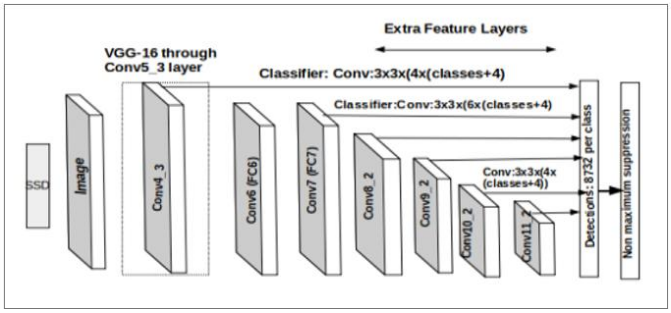

Fig. 2. SSD Architecture [15].

The SSD architecture consists of VGG-16 acts as the backbone of the architecture. The model extracts features from the input image and produces various feature maps which capture different levels of detail in the image. The extra feature layers that include various sizes of layers from bigger to smaller. The feature maps from the VGG-16 produced are then being processed further to create additional feature maps. These additional feature maps are much smaller in spatial size which enables the detection of objects from various sizes. The detection layer feeds on all the feature maps produced by each of the layers and applies a small convolutional filter to predict the class and localization of the objects for each of them. Then, the non-maximum suppression refines the prediction by removing heavily overlapping bounding boxes to finalize the bounding box and class label. To obtain the optimum classification accuracy in this research, three SSD variants are produced by replacing the VGG with three different model namely; ResNet50, ResNet152 and MobileNet. Each of these models will be discussed in the following subsections.

*1) SSD ResNet 50:* The SSD ResNet50 model consists of SSD as a framework with ResNet50 as its backbone. The SSD ResNet50 is an object detection model which has been pretrained with COCO 2017 dataset. This model localizes detected objects by drawing bounding boxes around the object. The model utilizes Feature Pyramid Network (FPN) for multi-level feature maps generation to feed into the SSD framework as the input. During the training phase, momentum optimizer with 0.04 learning rate is used and it is reduced when a plateau in the performance is detected. The SSD ResNet50 model architecture used is shown in Fig. 3.

*2) SSD ResNet-152:* The SSD ResNet-152 model used in this research is the combination SSD architecture with ResNet-152 as its backbone for feature extraction and SoftMax classifier for the class prediction. It is a deep convolutional neural network (DCNN) that consists of 152 layers which

include convolution layers, down sampling layers and fully connected layers. The SSD ResNet-152 model uses deep residual connections to overcome the vanishing gradient issue during the deep network training. The SSD ResNet-152 model architecture is shown in Fig. 4.

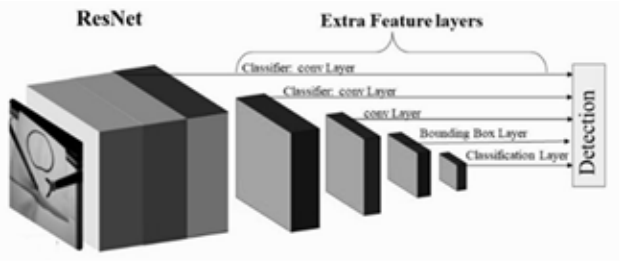

Fig. 3. SSD-ResNet50 [17].

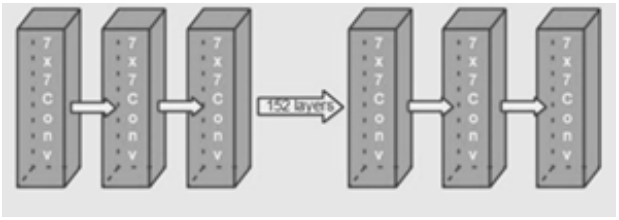

Fig. 4. Architectural diagram of SSD ResNet-152 [18].

*3) SSD-MobileNet:* The SSD-MobileNet is an object detection model which consists of SSD architecture with MobileNet as its backbone. This model is suitable for real time applications as it able to balance between speed and accuracy performance. The SSD-MobileNet is an efficient model where it preserves the important information while processing an image [19]. The model architecture of the SSD-MobileNet is shown in Fig. 5.

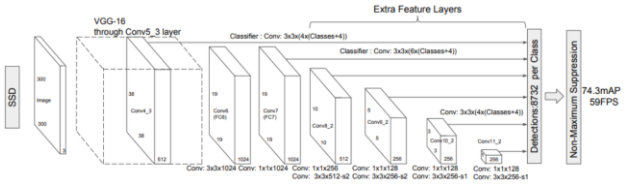

Fig. 5. The architecture of SSD-MobileNet [19].

## B. You Only Look Once (YOLO)

The general structure of YOLO for the classification is shown in Fig. 6. In YOLO architecture, the detection of objects is treated as a regression problem in which the image is divided into grids and the prediction is done by predicting the bounding box and class probability for each grid cell in a single pass, making it exceptionally fast [20, 21]. In YOLO architecture, the vehicle images are resized and standardized to ensure consistency in grid structure and to simplify the process. Then, the images pass through the Convolutional layers which extract basic features of the vehicle images. In the early stage, the convolutional layers are paired with max pooling for down sampling to reduce the spatial dimension of the feature maps produced by the convolutional layer. In this research, the process of reducing the spatial dimension is applied to help the model focus on more abstract features of the vehicle images. This process is repeated several times until it is sufficiently small. In the middle stage, the vehicle images are then pass through a convolutional layer without max pooling. These layers deepen the feature extraction process to capture more detailed patterns. Lastly, the compressed feature maps produced by the previous layers are processed by fully connected layers to output the final prediction in the form of bounding box, confidence score and class probabilities.

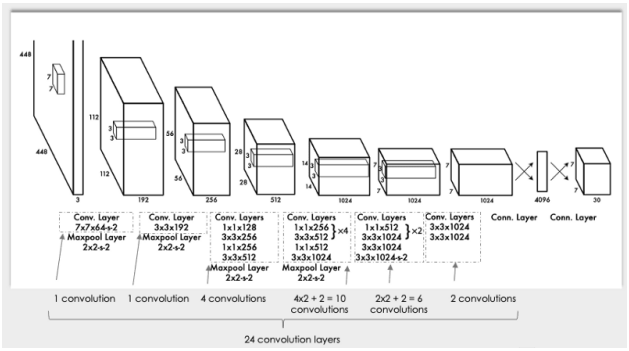

Fig. 6. YOLO Architecture [22].

In this research, there are two YOLO models used for vehicle classification which are YOLOv5 and YOLOv8. These models are chosen due to their speed, accuracy and efficiency in real time object detection. YOLOv5 models are highly accurate with rapid inference time, making it ideal for real time applications while YOLOv8 models are highly accurate and robust against challenging conditions. Each of these models will be discussed in the following subsections.

*1) YOLOv5:* The YOLOv5 model that used in this research consists of four parts which are input, backbone, neck and head as shown in Fig. 7. It utilizes CSP-Darknet53 with the Cross Stage Partial (CSP) strategy as its backbone to improve information flow and gradient issues [23]. YOLOv5 incorporates with a Spatial Pyramid Pooling (SPP) variant and uses BottleNeckCSP within the Path Aggregation Network (PANet) for the neck structure to enhance the receptive field and contextual feature extraction. The head of YOLOv5 models consists of three convolutional layers that predict bounding boxes, scores, and object classes.

*2) YOLOv8:* YOLOv8 is the improvised version of YOLOv5. Unlike YOLOv5 which uses anchor boxes, YOLOv8 is the improvised version of YOLOv5 where it uses different approach to detect the object by directly predicting the object centres. This approach helps to improved generalization and irregular shapes challenges. The YOLOv8 used the Spatial Pyramid Pooling Feature (SPPF) as a training technique to improve multi scale object handling. The YOLOv8 model also improve efficiency and flexibility while maintaining the performance by swapping the original larger Kernal size (6x6) convolution with a 3x3 in the stem. It also updates the core by swapping the C3 blocks with C2f. By concatenating features in the neck without the needs of identical channel dimension, the overall parameter counts and tensor size is reduced [23]. The SSD YOLOv8 model architecture is shown Fig. 8.

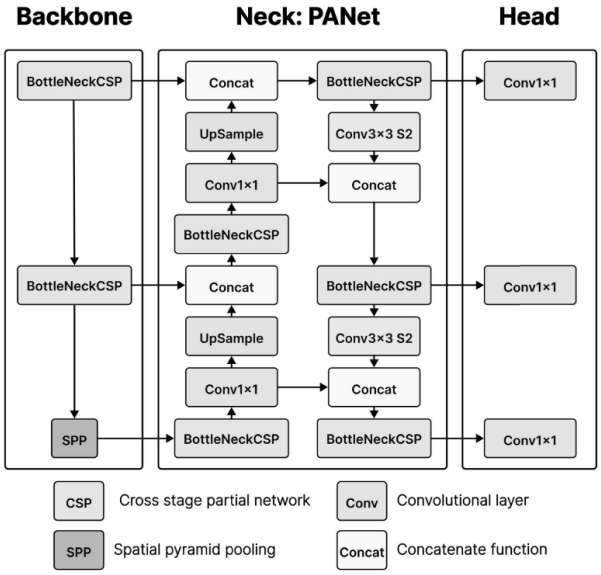

Fig. 7. Structure of YOLOv5 [24].

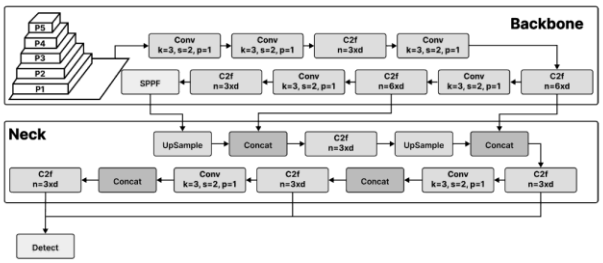

Fig. 8. YOLOv8 architecture structure [23].

## IV. EXPERIMENT

To demonstrate the reliability of the proposed model, a series of comprehensive experiments is conducted using Google Colab Notebook. Colab based on the Jupyter Notebook is used for machine learning computational operations and Python 3 with T4 GPU hardware accelerator in the runtime is also used in the experiment. The parameter settings for each of the models SSD and YOLO are configured with specific parameters as summarized in Table I. The file path for label map, training and testing data and TF records are set based on the storage location while the other parameters are kept unchanged. The number of classes is set to five classes. These five classes are set up based on the five vehicle types used to test the model which are ambulance, bus, car, motorcycle and truck.

Generally, the dataset consists of 1324 vehicles classified into five categories namely, ambulance, bus, car, motorcycle and truck are created. These images are then manually labelled to train the model. The PBXT files containing the respective class name are created for the purposes of training. Then the vehicle images and its label are converted into TF Record files which are in a sequence of binary format. After the process of labelling, the images are then split into the training and validation sets with a ratio of 80% images used as training set and the remaining 20% for the validation set. The aforementioned ratio is considered in this research since most of the work related to the deep learning models from literature use these ratios to split the data in their work [25]. Following these ratios, the training set consists of 1059 images while the remaining 265 images are used in the validation set. The details categories of the vehicle dataset used in this experiment are shown in Table II.

TABLE I. PARAMETERS SETTING OF SSD AND YOLO

| Model/ Parameter | SSD ResNet 50 | SSD ResNet 152 | SSD Mobile Net | YOLOv5 | YOLOv8 |
|---|---|---|---|---|---|
| Learning Rate | 0.04 | 0.04 | 0.04 | 0.01 | 0.01 |
| Weight | 0.0004 | 0.0004 | 0.0004 | 0.0005 | 0.001 |
| IoU threshold | 0.6 | 0.6 | 0.6 | 0.7 | 0.1 |
| Batch size | 4 | 4 | 4 | 16 | 16 |

TABLE II. VEHICLE DATASET CATEGORIES

| Vehicle Class | Number of Images |
|---|---|
| Ambulance | 158 |
| Bus | 312 |
| Car | 320 |
| Motorcycle | 248 |
| Truck | 286 |
| Total | 1324 |

## V. RESULTS

In this experiment, the classification performance is measured in terms of precision, recall and F1 Score. The computational time for each experiment is also recorded. Precision and recall are calculated by true positive, true negative, false positive and false negative value. True positive is the ability of the model to predict positive class correctly while, a true negative in which the model predicts the negative class correctly. On the other hand, false positive and false negative are the opposite from the true positive and true negative respectively. False positive occurs when the model incorrectly predicts the positive class while false negative occurs when the model incorrectly predicts the negative class. The formula for each of the performance measures is defined as follows:

$$\text{Precision} = TP/(TP+FP)$$

$$\text{Recall} = TP/(TP+FN)$$

$$\text{F1 score} = 2 \times (\text{Precision} \times \text{Recall})/(\text{Precision} + \text{Recall})$$

TP = True Positive, TN = True Negative

FP = False Positive, FN = False Negative

To evaluate the models, to find the most optimum result, the SSD models are trained with three numbers of training steps which are 10,000, 15,000 and 25,000. The YOLO models are trained with 25 epochs which are equivalent to 1,654 training steps. The training steps for YOLO models are calculated as in (1).

$$Training\ Steps = (Epoch \times Train\_Dataset)/Batch\ Size$$
$$= (25 \times 1059)/16$$
$$= 1654 \quad (1)$$

The results of SSD ResNet50, SSD ResNet152, SSD MobileNet, YOLOv5, and YOLOv8 model for the evaluation of each training step is shown in Table III.

TABLE III. COMPARISON RESULTS FOR SSD RESNET 50, SSD RESNET152, SSD MOBILENET, YOLOV5 AND YOLOV8 MODELS

| Model | Training Steps | Precision | Recall | F1 Score | Computational Time |
|---|---|---|---|---|---|
| SSD Resnet 50 | 10,000 | 0.257 | 0.370 | 0.3033 | 1h 37m 30s |
| SSD Resnet 152 | 10,000 | 0.408 | 0.473 | 0.4381 | 2h 25m 56s |
| SSD Resnet 50 | 15,000 | 0.325 | 0.433 | 0.371 | 4h 30m |
| SSD Mobile Net | 15,000 | 0.204 | 0.292 | 0.240 | 2h 59m 43S |
| SSD ResNet 50 | 25,000 | 0.264 | 0.363 | 0.305 | 1h |
| YOLOv 5 | 1645 | 0.909 | 0.944 | 0.926 | 10 mins |
| YOLOv 8 | 1645 | 0.956 | 0.968 | 0.968 | 30mins |

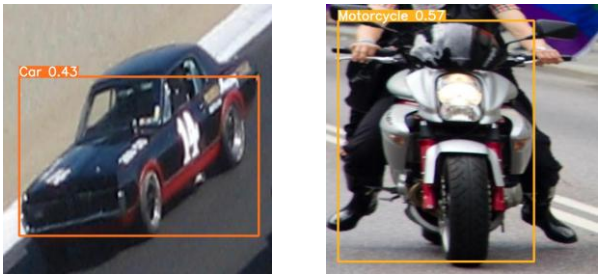
The SSD Resnet50 models which trained for all the three training steps of 10,000, 15,000 and 25,000 steps show low performance for all measure of precision, recall and f1 score. The high computational time is also observed for SSD Resnet50 in all training steps, which are 1h 37m 30s for 10,000 steps, 2h 25m 56s for 15,000 steps and 4h 30m for 25,000 training steps respectively. The SSD Resnet152 which trained for 10,000 steps also shows lower performance for all performance measure of precision, recall, f1 score including computational time compared to SSD Resnet50. For the training steps of 15,000 steps, SSD Resnet50 able to achieve high performance measure for all of precision, recall, f1 score and computational time compared to the SSD MobileNet. The less computational time is also observed in SSD Resnet50 compared to SSD MobileNet. On the other hand, both YOLO models which are YOLOv5 and YOLOv8 are trained with 1,654 training steps. From the experiment conducted, Both YOLO models able to obtain high performance measures for all precision, recall and accuracy with less computational time compared to all of the SDD models. The computational time of YOLOv5 model takes only 10 minutes while slightly minimal longer time taken is observed in YOLOv8 with only 20 minutes difference.

Among all the models tested, the YOLOv8 model achieved the highest performance measure for all precision, recall and F1 score with 0.956 precision, and 0.968 both recall and F1 score. This is followed by the YOLOv5 model with 0.909 precision, 0.944 recall and 0.926 F1 Score.

## VI. DISCUSSION

Overall, the YOLOv8 model outperformed others in detecting vehicle classification. Both of the YOLO models YOLOv5 and YOLOv8 outperform all of the SSD models which are SSD Resnet 50, SSD Resnet152, SSD MobileNet for all performance measure of precision, recall and f1 score including the computational time. The lower result obtained in all the SSD models is due to the drawbacks of the SSD approach that having difficulty to accurately detect on the small or far away vehicle. The SSD model relies on the lower-resolution feature maps for detecting small or far away vehicles, which sometimes may lack sufficient semantic information. Thus, the small or far away vehicle can be missed or misclassified. On the other hand, the YOLO model enhanced detection accuracy and robustness against challenging conditions including small object [26].

Among all the models tested, YOLOv8 able to achieve the highest performance measure for all precision, recall and F1 score with more than 0.956. This is followed by YOLOv5 with 0.909 of precision,0.944 recall and 0.926 F1score. Despite YOLOv8 able to detect vehicles in various conditions including vehicles in close proximity, far away and blur images, the low confidence score detection can still be observed on classic racing car and occluded motorcycle images as shown in Fig. 9.



(a) (b)

Fig. 9. Examples of the low confidence score detection (a) Classic racing car (b) Occluded motorcycle images.

## VII. CONCLUSION

The YOLOv8 model is proposed for vehicle classification to classify between types of vehicles in smart city with a goal to provide intelligent solutions for road traffic monitoring. This can be achieved using accurate predictive data analytics for future action planning and decision making. The result shows that the model YOLOv8 able to effectively classify types of vehicles including vehicles in close proximity, far away and blur images. Therefore, it can be used to provide intelligent solutions to improve road traffic system for smart city. Though the YOLOv8 model is superior compared to other models and achieves more accurate classification, the method was shown to be less effective in detecting some of the vehicle images as shown in VI. In the future, we will concentrate on improving these drawbacks by increasing the diversity of vehicle images dataset by using data augmentation techniques for more advanced deep learning methods.

***Abstract*—This paper introduces the Virtual Reality Dashboard Design Ontology (VRDDO), an ontological framework developed to address the absence of standardized methodologies in designing Virtual Reality (VR) dashboards for complex data visualization, particularly in smart farm monitoring. The VRDDO is built upon the Design Science Research (DSR) approach and anchored in Kernel Theory, specifically the Ecological Psychological Perspective (EPP) theory and Business Model Ontology (BMO). During the design and development phase of DSR, the Unified Ontological Approach (UoA) is applied as the ontology development methodology, to design and construct VRDDO as a design artifact. By offering a structured framework for VR dashboard design, VRDDO aims to enhance data interpretation and decision-making in immersive environments. Additionally, this ontology forms the basis for a Virtual Reality Dashboard Design Method, establishing a systematic and user-centric approach to developing efficient VR dashboards. This research is significant for its potential to improve VR dashboard development across diverse domains, facilitate knowledge sharing, and eliminate fragmented, ad-hoc practices in immersive data visualization.**

## I. INTRODUCTION

Virtual Reality (VR) technology has rapidly evolved in recent years, revolutionizing numerous fields including education, healthcare, entertainment, and business. As VR applications become more sophisticated, the need for effective data visualization and interaction within these immersive environments has grown exponentially. VR dashboards have emerged as a powerful tool to address this need, providing users with intuitive and immersive interfaces to monitor, analyze, and interact with complex data sets. The author in [1] defines a dashboard as "a predominantly visual information display that people use to rapidly monitor current conditions that require a timely response to fulfill a specific role". In the context of VR, these dashboards take on new dimensions, leveraging the unique capabilities of immersive environments to present information in ways previously impossible in traditional 2D interfaces.

The development of VR dashboards involves a complex interplay of various technologies and data sources. These dashboards can integrate data from Internet of Things (IoT) devices, such as sensors and microcontrollers, as well as from open-source databases, big data repositories, and manually gathered information. User input can be collected through various means, including graphical user interfaces (GUIs), VR equipment like head-mounted displays (HMDs) and eye gaze trackers, smartphones, and even physiological sensors like heart rate monitors [2-9]. This diversity of data sources and input methods presents both opportunities and challenges in VR dashboard design and development.

While the widespread adoption of dashboards in various industries has demonstrated its value in improving information comprehension and decision-making, the design of effective VR dashboards remains subject to numerous challenges. Common issues include poor use of virtual space, presentation of insufficient information, and unappealing visual elements that can detract from the user experience. The complexity of mobility data and the unique characteristics of VR environments necessitate a more nuanced approach to dashboard design than traditional 2D interfaces. For complex systems particularly in smart farm monitoring, developers must consider not only the type, volume, and frequency of data updates but also the specific purpose of the dashboard and the needs of its intended users [10, 11]. There is a lack of standardization in designing VR dashboards for smart farming applications. More broadly, the field would benefit from a unified Virtual Reality Dashboard Design Method (VRDDM). Establishing such standards would simplify the design process and reduce complications for developers. The establishment of a Virtual Reality Dashboard Design Ontology (VRDDO) aims to address this need by providing a theoretical framework that can guide developers in creating more effective, user-friendly, and standardized VR dashboard solutions. By establishing common principles and design patterns, VRDDO has the potential to accelerate innovation in this field, improve user experiences, and ultimately enhance the value of VR applications across various domains.

Motivated by the growing demand for immersive data visualization, this study proposes the VRDDO to address the lack of standardized VR dashboard development methods. The VRDDO benefits include enhancing decision-making, improving user engagement, and creating structured design processes adaptable across domains. Our main contributions are the construction of VRDDO based on theories of EPP and BMO and integration with the Unified Ontological Approach (UoA) and Unified Foundational Ontology (UFO).

The remainder of this paper is structured as follows: Section II reviews background and theories. Section III describes the theory used. Section IV proposes the VRDDO framework. Section V concludes the study.

## II. BACKGROUND

### A. Design Science Research

Design Science Research (DSR) has emerged as a crucial paradigm in Information Systems (IS) research, complementing the more traditional behavioral science approach. While behavioral science focuses on developing and verifying theories that explain or predict human and organizational behavior, DSR aims to extend the boundaries of human and organizational capabilities through the creation of innovative artifacts. This paradigm is particularly relevant in the context of IS research, which sits at the intersection of people, organizations, and technology. DSR provides a structured approach to understanding, executing, and evaluating research that results in tangible, practical outcomes. In the case of the Virtual Reality Dashboard Design Ontology (VRDDO), DSR offers a methodological framework that guides the design and development of this innovative artifact, ensuring that it is both theoretically grounded and applicable [12, 13, 32].

The Design Science Research Methodology (DSRM) provides a systematic process for conducting DSR, emphasizing the importance of theory-based grounding in the development of design artifacts. This approach is particularly relevant for the VRDDO, which is positioned as a design artifact resulting from the DSR methodology, specifically emerging from the Design & Development stage. The VRDDO aligns with the perspective of DSR practitioners who advocate for kernel theory-based grounding in artifact design and development. By incorporating kernel theories as mandatory components of the DSR methodology, the VRDDO gains a solid theoretical foundation that enhances its validity and applicability. This theoretical grounding not only ensures that the VRDDO is built upon established principles but also facilitates its integration into the broader context of VR dashboard design and development. Through this approach, the VRDDO aims to bridge the gap between theoretical knowledge and practical application, offering a comprehensive framework that can guide researchers and practitioners in creating more effective and standardized VR dashboard solutions.

### B. DSR for the Development of VRDD

Building upon the discussion of Design Science Research (DSR) and its methodology (DSRM), it is crucial to explore the various perspectives on the role of kernel theories in the development of design artifacts. Within the DSR field, there are three distinct "schools of thought" regarding the necessity and importance of kernel theories in artifact design and development. Fig. 1 shows the position of each school taught in their beliefs towards whether kernel theories are required for grounding and whether design theories can be accepted as key artifacts [14]. These perspectives offer valuable insights into the theoretical grounding of artifacts like the Virtual Reality Dashboard Design Ontology (VRDDO).

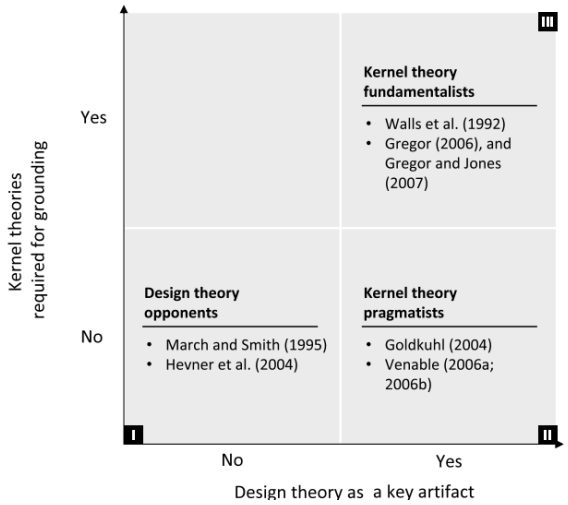

Fig. 1. DSR school of thought [14].

The first school, known as "Design Theory Opponents" (DTO), posits that kernel theories are not mandatory in DSR artifact development. Pioneered by DSR founders in Information Systems (IS) such as [13, 15], this perspective argues that DSR complements Behavioural Science (BS) rather than replicating it. While kernel theories are prevalent in BS research, they are not considered a priority or necessity in DSR. The author in [13] stated that while knowledge from behavioral sciences and design science research may be used in constructing design science artifacts, IS DSR artifacts do not necessarily need to be grounded in kernel theories. This school of thought does not accept theory as an output of DSRM and does not emphasize the need for kernel theories in artifact engineering.

The second perspective, termed "Kernel Theory Pragmatists" (KTP), takes a middle-ground approach. Established by [16-18], this school suggests that while kernel theories are not crucial in the artifact construction process, theory as an output of DSRM is acceptable as an impact and result of the research. This pragmatic stance allows for flexibility in the use of theories within DSR projects.

The third and most stringent perspective is the "Kernel Theory Fundamentalist" (KTF) school, championed by [19-21]. This approach mandates the use of kernel theories in artifact construction and simultaneously accepts theory as an output of DSRM. The author in [19] emphasized that kernel theories from natural or social sciences serve as a foundation for artifact construction. This school of thought insists on rigorous theoretical grounding for all aspects of DSR.

In the context of the VRDDO development, the researcher has adopted a balanced approach, acknowledging the existence and potential contributions of all three schools of thought. While recognizing the arguments against the necessity of kernel theories presented by the DTO and KTP schools, the researcher leans towards the KTF perspective in accepting the involvement of kernel theories in the artifact construction process. However, the researcher does not fully align with the KTF view that theory must be an output of DSRM. This nuanced approach allows for a theoretically grounded

development of the VRDDO while maintaining flexibility in the research outcomes.

By considering these diverse perspectives on the role of kernel theories in DSR, the development of the VRDDO can benefit from a rich theoretical foundation while avoiding overly rigid constraints. This balanced approach ensures that the VRDDO is developed with a solid theoretical grounding, enhancing its validity and applicability in the field of VR dashboard design. Furthermore, it demonstrates the complexity and ongoing debates within the DSR community, highlighting the importance of thoughtful consideration of theoretical foundations in the development of innovative artifacts like the VRDDO.

## III. THEORY USED

In developing the VRDDO, this study adopts the Kernel theory pragmatist perspective by implementing two theories suited for the ontological design of VR. The theories are based on business model ontology (BMO) design for the development of business model canvas (BMC) [22, 33]. The Business Model Ontology (BMO), developed by Alexander Osterwalder, provides a structured framework for representing, understanding, communicating, and analyzing business models. It addresses the challenge of defining business models by offering a common language and conceptual structure. The BMO served as the foundation for the widely adopted Business Model Canvas (BMC), a visual tool for describing, designing, and innovating business models. In the context of the Virtual Reality Dashboard Design Ontology (VRDDO), the BMO's approach to structuring complex business concepts has inspired a similar ontological approach to VR dashboard design. As one of the grounding theories for VRDDO, the BMO demonstrates the power of ontologies in creating standardized frameworks for complex domains, guiding the development of a comprehensive and adaptable structure for VR dashboard design principles.

In designing the BMC, key blocks are established based on the common characteristics/elements that exist from other business models [22, 23]. Semantics that relate each of the key blocks help to establish the concepts well in developing the ontology of a business model. Therefore, this approach will also serve as one of the grounded theories within this work in developing VRDDO.

Another major grounding theory that was applied to this study for VRDDO development is the theory of ecological psychological perspective (EPP) [24]. The theory emphasizes direct perception of environmental affordances which features suggestions on how to interact with objects. This active perception model views senses as interconnected, information-seeking mechanisms. In Virtual Reality Dashboard Design Ontology (VRDDO) development, EPP provides crucial insights into user perception and interaction within virtual environments. Combined with the Business Model Ontology (BMO), EPP informs the design of intuitive, exploration-friendly VR dashboards. By considering affordances in virtual spaces, VRDDO can create more natural and meaningful interactions, enhancing user engagement and information comprehension. This synthesis enables a comprehensive approach to VR dashboard design, grounded in both perceptual psychology and structured business concepts.

### A. Narrative Literature Review (NLR) for Deriving Key Blocks for Ontology Design

The proposed VRDDO has to be built with established key blocks depending on its application. The targeted application for the VRDDO is on smart farm monitoring application. Therefore, several key blocks that serve as essential elements for the VRDDO are identified via literature study. The NLR is conducted in a manner that identifies commonalities of each element. In other words, common elements that have been found in other VR dashboard design methods are selected for use as key blocks.

### B. Ontology Design Using a Unified Ontological Approach (UoA)

The Unified Ontological Approach (UoA) [25, 34] is a framework for ontology development that synthesizes the strengths of various Ontology Development Methods (ODMs) and draws inspiration from successful ontologies like Business Model Ontology (BMO). This approach aims to streamline the ontology development process by integrating common characteristics and key steps found across different methodologies. The UoA emphasizes iterative development, consistent notation, flexible formalization, reusability, scenario-driven customization, and comprehensive structural representation.

The development of the UoA was facilitated through a Narrative Literature Review (NLR) method. This approach allowed for a comprehensive and interpretative synthesis of existing literature related to ODMs. The NLR method is particularly well-suited for addressing complex and emerging fields, enabling researchers to explore topics in broader ways. Through this method, researchers identified common steps and practices across different ODMs, cross-referenced these findings with the principles of successful ontologies like the BMO, and integrated these insights to create the UoA framework.

The UoA is particularly suitable for building the Virtual Reality Dashboard Design Ontology (VRDDO) due to several key factors. First, its emphasis on scenario-driven development aligns well with the diverse use cases and applications of VR dashboards across different domains. This approach ensures that the VRDDO will be relevant and applicable in real-world contexts. Second, the flexible formalization approach allows for the VRDDO to adapt to the rapidly evolving field of VR technology and dashboard design principles. Third, the focus on reusability and reengineering enables the VRDDO to leverage existing knowledge in related fields, such as information visualization and human-computer interaction, while still allowing for VR-specific adaptations.

Furthermore, the UoA's comprehensive structural representation ensures that the VRDDO can capture both the structural and dynamic aspects of VR dashboard design, which is crucial given the interactive and immersive nature of VR environments. The iterative process embedded in the UoA also allows for continuous refinement of the VRDDO, ensuring it remains up to date with advancements in VR technology and

design practices. By adopting the UoA for the development of the VRDDO, researchers can create a robust, flexible, and comprehensive ontology that effectively captures the complexities of VR dashboard design while ensuring its applicability and adaptability across various domains and use cases.

### C. Importance of ODM for Building VRDDO

The Unified Ontological Approach (UoA) is used for building the Virtual Reality Dashboard Design Ontology (VRDDO). As a synthesis of various Ontology Development Methods (ODMs) and inspired by successful ontologies like Business Model Ontology, the UoA offers a robust framework for developing the VRDDO. Its key features - iterative development, consistent notation, flexible formalization, reusability, scenario-driven customization, and comprehensive structural representation - are particularly well-suited for the complex and evolving field of VR dashboard design.

UoA's scenario-driven approach ensures the VRDDO remains relevant across diverse use cases, while its flexible formalization allows adaptation to advancing VR technologies. The focus on reusability enables leveraging existing knowledge from related fields while accommodating VR-specific requirements. Comprehensive structural representation is essential for capturing both structural and dynamic aspects of VR dashboard design, crucial for representing the interactive nature of VR environments. The iterative process allows for continuous refinement, ensuring the VRDDO stays current with VR advancements. By employing the UoA, researchers can create a robust, flexible, and comprehensive ontology that effectively captures VR dashboard design complexities while ensuring adaptability across various domains, ultimately driving progress in VR dashboard design and its applications.

## IV. VRDDO

The Virtual Reality Dashboard Design Ontology (VRDDO) shown in Fig. 2 is considered the 'backbone' of the Virtual Reality Dashboard Design Method (VRDDM), which aims to address the lack of standardized approaches in designing VR information dashboards, particularly in the context of smart farm monitoring. Developed using a Unified Ontological Approach (UoA), the VRDDO serves as a structured framework to capture commonalities identified across various dashboard design-related works. This ontology forms the theoretical foundation of the VRDDM, providing a systematic and standardized method for creating immersive VR information dashboards that can effectively tackle monitoring challenges in smart farming and potentially other domains.

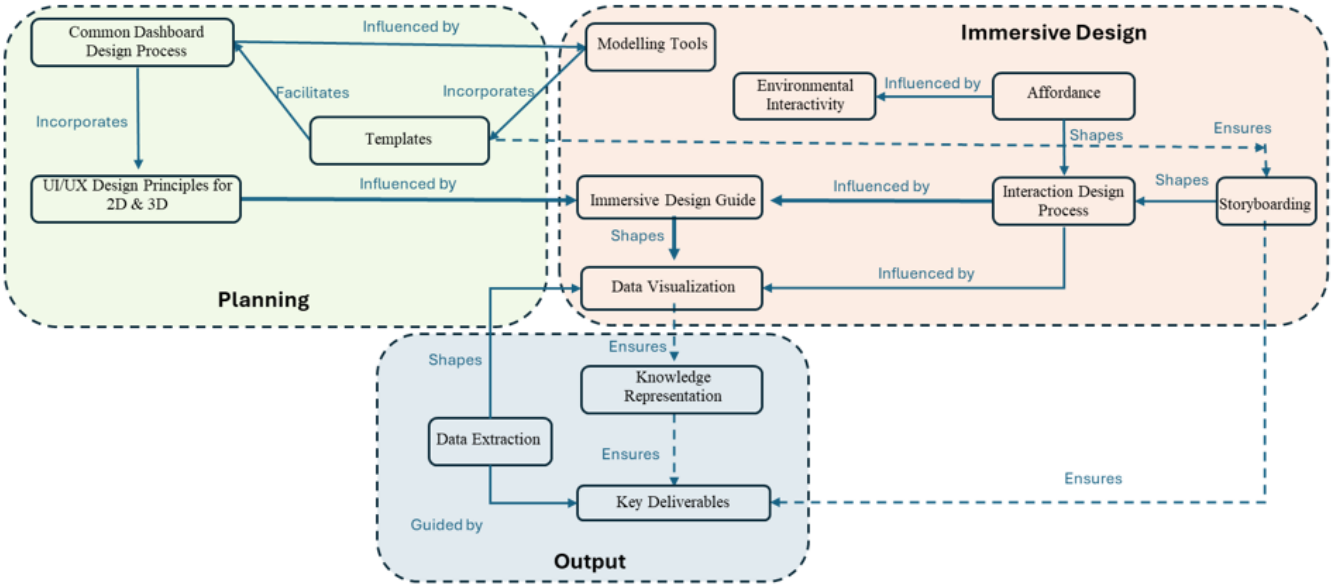

Fig. 2. Proposed VRDDO with concepts derived from key blocks.

The VRDDO is developed through a comprehensive process that begins with a narrative review of existing literature to identify common elements and best practices in dashboard design. These commonalities which are considered key blocks of VR dashboard designs are then formalized using the UoA, which allows for a systematic organization of concepts, relationships, and design principles specific to VR dashboard creation. By incorporating insights from various sources and methodologies, the VRDDO aims to create a robust and flexible framework that can guide the design and development of VR dashboards across different applications. This standardized approach offered by the VRDDO is particularly significant in the context of smart farm monitoring, where effective visualization and data presentation are crucial for decision-making and maintaining high-quality agricultural production. The ontology not only facilitates the design process but also promotes knowledge sharing and reuse, potentially eliminating ad-hoc practices in VR dashboard development. While the current focus of the VRDDO is on smart farm monitoring, its structured approach and foundation in common design principles suggest a potential for adaptation and application in other domains, opening avenues for future research to explore its versatility and robustness across various fields requiring immersive data visualization and monitoring solutions.

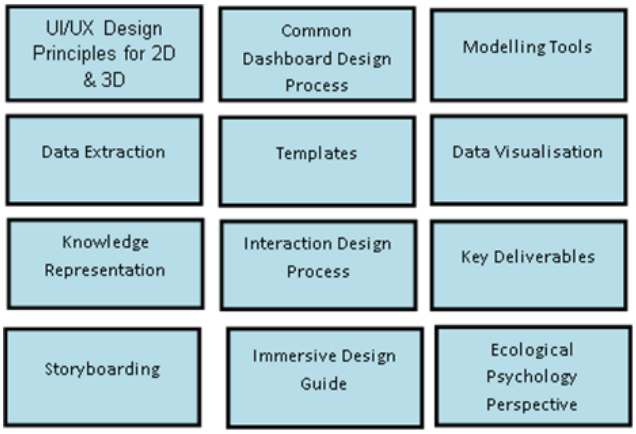

Fig. 3. Related key blocks derived from NLR.

### A. Concepts and Semantics to form VRDDO

The Virtual Reality Dashboard Design Ontology (VRDDO) is structured around twelve key blocks as shown in Fig. 3, each serving as a fundamental concept in the design and development of VR dashboards. These blocks collectively form a comprehensive framework that guides the creation of effective and user-centric VR dashboards. Explanation of each block and its role as a concept in the VRDDO as below:

UI/UX Design Principles for 2D and 3D: This block emphasizes the importance of user interface and user experience design in both 2D and 3D environments. It incorporates five main principles: scale, visual hierarchy, balance, contrast, and gestalt. These principles ensure that the VR dashboard is not only visually appealing but also intuitive and easy to navigate [26]. As a concept in the VRDDO, this block provides guidelines for creating immersive and user-friendly interfaces that leverage the unique capabilities of VR environments. In the VRDDO, this concept influences the immersive design guide.

Common Dashboard Design Process and Templates: This block outlines a standardized process for designing VR dashboards, including steps like requirements gathering, data processing, UI/UX design, and implementation. It also emphasizes the use of templates to streamline the design process and ensure consistency across different dashboard projects. Thus, templates as a concept facilitate the design process in providing a structured approach to VR dashboard development.

Data Extraction/Data Collection: This block focuses on the methods and processes of gathering and extracting data for visualization in the VR dashboard. It covers various data sources such as IoT devices, questionnaires, GUI inputs, VR equipment, smartphones, and sensors. The concept emphasizes the importance of adhering to data protection regulations and using appropriate tools and algorithms for accurate data extraction and classification where applicable.

Domain Model and Knowledge Representation: This block introduces the concept of ontology in the context of VR dashboard design. It highlights the need for a structured and semantically rich representation of the knowledge domain, which is crucial for creating interactive and meaningful VR dashboards. The VRDDO itself is a manifestation of this concept, providing a formal specification of the concepts and relationships within the VR dashboard design domain.

Interaction Design (IxD) Process: This block focuses on the user-centric design approach, emphasizing the importance of understanding user needs and behaviors when interacting with VR dashboards. The five stages of the IxD process (discovering user needs, analyzing, designing solutions, prototyping, and deploying) form a crucial concept in the VRDDO, ensuring that the resulting dashboards are highly usable and meet user requirements [27].

Data Visualization and Modelling Tools: This block covers the various tools and techniques used for visualizing and modeling data in VR environments. It acknowledges the complexity of VR systems, including hardware components and software requirements. As a concept in the VRDDO, this block guides developers in selecting and utilizing appropriate tools for creating effective data visualizations in VR.

Storyboarding: This block emphasizes the importance of pre-visualization techniques in VR dashboard design. Storyboarding helps in planning the user's journey through the virtual environment and their interactions with data displays [28]. As a concept in the VRDDO, storyboarding serves as a crucial step in crafting a cohesive narrative for data exploration and optimizing the user experience.

Ecological Psychology Perspective: Acting as one of the grounding theories for the VRDDO, this block incorporates the EPP theory of affordances into VR dashboard design. It emphasizes the importance of creating intuitive, exploration-friendly virtual environments where users can directly perceive and interact with information. This perspective guides the design of VR dashboards to leverage Natural perceptual systems, enabling users to navigate and comprehend complex data more effectively. This key block provides two concepts in the VRDDO which are affordances and environmental interactivity. Affordances are the possibilities that an environment or object offers to an organism, particularly a human. They are directly perceivable properties that suggest how something can be used or interacted with, such as a handle affording grasping or a flat surface affording sitting. Affordances are relational, depending on both the properties of the object or environment and the capabilities of the organism perceiving them. Therefore, environmental interactivity is the dynamic relationship between an individual and their surroundings, where the environment offers opportunities for action and engagement. It encompasses how people perceive, interpret, and respond to the possibilities for interaction presented by their environment [29]. In the context of VR dashboards, environmental interactivity focuses on designing virtual spaces that intuitively communicate how users can interact with and manipulate data, leveraging natural perceptual cues to enhance user engagement and understanding.

### B. Restructuring of VRDDO Under UFO

The development of the VRDDO employed the Unified Ontological Approach (UoA), as proposed by [25], as the primary Ontology Development Method (ODM). The UoA was specifically chosen for its ability to integrate various

ontology development approaches while maintaining flexibility for domain-specific adaptations. This structured approach facilitates systematic progression from problem identification to ontology implementation and validation, ensuring both theoretical rigor and practical applicability. The UoA framework comprises nine iterative steps: (1) identifying the scope and purpose, (2) defining and identifying concepts, (3) organizing concepts, (4) defining properties and constraints, (5) formalizing the ontology, (6) implementing and testing, (7) evaluating the ontology, (8) documenting the ontology, and (9) maintaining and evolving the ontology. These steps enable the iterative refinement of the ontology throughout its lifecycle, ensuring that the resulting framework aligns with its intended purpose and can adapt to future changes.

The implementation process utilized UML for initial conceptual modeling, followed by OntoUML for ontological formalization. This combination provided the necessary rigor for developing a semantically rich and well-founded ontology while maintaining practical applicability. OntoUML, an extension of UML enriched with ontological principles from the Unified Foundational Ontology (UFO), was chosen for its ability to enhance the ontological adequacy of conceptual models [30]. The formalization process included syntactical validation using the OntoUML Plugin in Visual Paradigm, ensuring that the VRDDO framework was free of errors and adhered to formal modeling principles. After the implementation of UFO in the preliminary VRDDO, the relationship between concepts is clarified further. Fig. 4 shows the iterated VRDDO with UFO implementation.

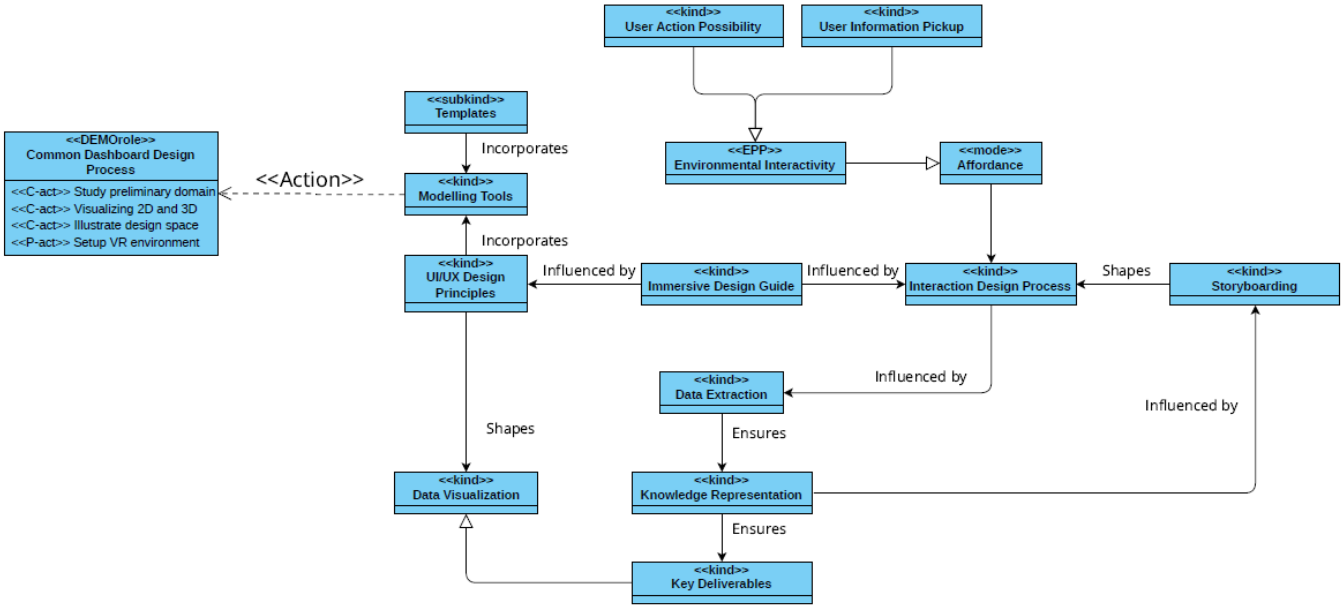

Fig. 4. Proposed VRDDO with concepts derived from key blocks.

VRDDO, with the implementation of UFO, prompts the introduction of two new concepts. These concepts further define the ecological psychological perspective (EPP) theory and how it will be part of the VRDDO to contribute towards achieving affordance and shape the interaction design process. The 2 concepts are both classified as <<kind>>. One concept, which is User action possibility refers to what are possible actions or gestures that the user can do to interact with the object within the 3D VR dashboard. Another concept is known as User information pickup. This concept refers to how the user can know that an object within the VR environment can be interacted with. The concept emphasizes the need for VR dashboard designers and developers to incorporate a self-explanatory design for objects such as information windows within the VR environment for users. Therefore, with the implementation of the EPP theory, it is known that to achieve greater immersion, designers will have to design interactable objects that are both self-explanatory and offer freedom of interaction between users and the VR dashboard. Immersion can achieve greater delivery and clarity for users, especially with a dense amount of information to display within a VR environment.

The implementation of these concepts within the VRDDO framework has far-reaching implications for the future of interaction design. As VR environments grow more complex, the ability to display dense information while maintaining user clarity and immersion becomes paramount. Incorporating EPP-driven principles enables designers to craft interactable objects that balance freedom of interaction with clarity of purpose. This balance is particularly critical in applications such as education, healthcare, and data visualization, where the delivery of accurate and easily interpretable information is essential. For example, in medical training simulations, VR dashboards equipped with self-explanatory interactive elements can enhance the learning experience by providing real-time feedback and reducing cognitive overload. Similarly, in business analytics, immersive dashboards can facilitate better decision-making by allowing users to intuitively explore large datasets. These advances contribute to achieving higher levels of immersion, which research identifies as a key factor in improving information retention and user satisfaction in VR environments [31]. Ultimately, the VRDDO's integration of EPP theory with the UFO approach paves the way for a new era of human-centered VR design, where interactivity and

intuitiveness coalesce to deliver transformative user experiences. Table I describes the rationale of each concept in the VRDDO. Compared to existing VR dashboard designs, VRDDO offers a standardized, theory-driven framework with clearer user interaction pathways and enhanced immersive data comprehension. Validation via integration of the Ecological Psychological Perspective (EPP) theory ensures better affordances and environmental interactivity for users.

TABLE I. CONCEPTS WITH IMPLEMENTED UPPER ONTOLOGIES

| Concepts | Upper Ontology | Rationale |
|---|---|---|
| Common Dashboard Design Process | <<DEMOrole>> | Emphasizes the progressive, temporal nature of the design process with distinct stages of development. |
| Modeling Tools | <<kind>> | Defines the fundamental structures for representing VR dashboard elements, ensuring consistency in visualization and interaction modeling. |
| Templates | <<subkind>> | Acts as pre-designed frameworks that align with standardized dashboard layouts, aiding in efficient UI/UX development. |
| UI/UX Design Principles for 2D & 3D | <<kind>> | Guides the visual and interactive elements by leveraging VR affordances to create an intuitive and immersive user experience. |
| Environmental Interactivity | <<EPP>> | Describes how the dashboard allows dynamic engagement with virtual elements, ensuring real-time feedback and adaptability in VR environments. |
| Affordance | <<mode>> | Refers to the perceived action possibilities within the VR interface, shaping user expectations and interactions in the system. |
| Immersive Design Guide | <<kind>> | Provides structured methodologies for designing VR dashboards, ensuring users are effectively engaged within the virtual environment. |
| Data Extraction | <<kind>> | Focuses on gathering and structuring relevant data for visualization and interaction, crucial for informed decision-making in VR dashboards. |
| Interaction Design Process | <<kind>> | Defines the workflow of user interactions with the VR dashboard. |
| Storyboarding | <<kind>> | Facilitates the planning of dashboard workflows by visually representing interaction sequences and possible user journeys. |
| Knowledge Representation | <<kind>> | Encapsulates how domain knowledge, actions, and entities are structured within the VR dashboard ontology, ensuring meaningful data organization. |
| Data Visualization | <<kind>> | Translates complex data into graphical representations that enhance user comprehension and decision-making within the VR space. |
| User action possibility | <<kind>> | Describes how a user can interact with objects (Gestures, other methods of input, etc.). |
| User information pickup | <<kind>> | Describes how a user can know whether an object is interactable. |
| Key Deliverables | <<kind>> | Outlines the critical outcomes expected from the VRDDO framework, aligning with both technical and design perspectives. |

### C. VRDDO Iteration

The iterative refinement of the Virtual Reality Dashboard Design Ontology (VRDDO) aligns with the principles of the Design Science Research (DSR) methodology, which emphasizes a cyclical process of development and evaluation to enhance the robustness and applicability of a design artifact [12]. The transition from the initial VRDDO (Fig. 2) to its refined version incorporating the Upper Foundational Ontology (UFO) (Fig. 4) was driven by successive iterations, ensuring improved conceptual clarity, semantic consistency, and structural coherence. Iterative design is fundamental in ontology engineering, as it allows for the continuous integration of theoretical insights, stakeholder feedback, and empirical validation, thereby fostering ontological rigor and practical relevance. By incorporating UFO, the final VRDDO iteration achieves a higher level of abstraction and interoperability, facilitating a more precise representation of immersive design processes. This iterative approach underscores the necessity of refinement cycles in advancing domain-specific ontologies, ensuring alignment with foundational theories, and enhancing applicability across VR-driven environments.

Compared to existing VR dashboard development approaches [3, 4, 7, 8], which often rely on ad-hoc design practices or lack structured theoretical foundations, the VRDDO offers a standardized, reusable, and theory-driven framework grounded in kernel theories and ontological principles. By leveraging the Unified Ontological Approach (UoA) and integrating the Ecological Psychological Perspective (EPP), the VRDDO ensures that both structural and perceptual aspects of dashboard design are systematically addressed. This approach enhances user immersion, data comprehension, and design scalability, distinguishing VRDDO from conventional methods that typically overlook these multidimensional factors.

### D. The way Forward for the VRDDO

This study successfully formalized the Virtual Reality Dashboard Design Ontology (VRDDO) based on the Unified Ontological Approach (UoA), EPP theory, and BMO principles. The developed ontology organizes 12 key concepts and demonstrates how affordances and user-centered designs improve information visualization within VR environments. The proposed VRDDO helps to establish and reveal key relationships between concepts that are essential to be considered during the design and development of a VR dashboard. This work is inspired by Osterwalder's work in the creation of the BMC. The BMC is derived from BMO which consists of building blocks. Hence, The VRDDO will be used in our next work to establish a VR dashboard design method (VRDDM). A more detailed discussion on the development of VRDDM will be presented in our future publications.

## V. CONCLUSION

The Virtual Reality Dashboard Design Ontology (VRDDO) presents a promising framework for standardizing and enhancing the development of VR dashboards, particularly in the context of smart farm monitoring. By synthesizing various ontology development methods and drawing inspiration from successful models like Business Model Ontology, the VRDDO

offers a robust, flexible, and comprehensive approach to VR dashboard design. The incorporation of key theories, such as Gibson's Ecological Psychological Perspective, ensures that the ontology addresses both technical and perceptual aspects of VR interactions. The VRDDO's structured approach, emphasizing iterative development, consistent notation, and scenario-driven customization, provides a solid foundation for creating intuitive and effective VR dashboards. As the backbone of the forthcoming Virtual Reality Dashboard Design Method (VRDDM), the VRDDO has the potential to significantly improve the design and implementation of VR information dashboards across various domains, promoting standardization and knowledge sharing in this rapidly evolving field. While the VRDDO effectively formalizes the key structural elements necessary for VR dashboard design (an endurant perspective), less emphasis was placed on modeling dynamic, time-based interactions (a perdurant perspective). Future research can enhance ontology by incorporating dynamic behavior modeling to address evolving user interactions and real-time data visualization needs in VR environments.

## VI. Future Work

Future research will focus on extending the Virtual Reality Dashboard Design Ontology (VRDDO) to incorporate perdurant perspectives, enabling dynamic modeling of time-based user interactions, adaptive interface behaviors, and evolving data visualization within VR environments. By integrating concepts that represent events, processes, and temporal affordances, the ontology can better capture the fluid and interactive nature of immersive VR experiences. Additionally, empirical validation across multiple domains such as healthcare, education, and urban planning will be conducted to evaluate the adaptability and effectiveness of the enhanced VRDDO framework. This progression aims to transform VRDDO into a comprehensive standard for both static and dynamic VR dashboard design across diverse applications.

## Acknowledgment

This research is supported by industrial grants: ARB IOT Group (ZG-2023-004) & ARB Cloud (ZG-2022-003). We highly appreciate the enormous support received for this research project.

# Quantitative Assessment and Forecasting of Control Risks in the Ore-Stream Quality Management System

Almas MukhtarkhanulySoltan[1], Bakytzhan Turmyshevich Kobzhassarov[2]
Senior lecturer, School of Digital Technologies and Artificial Intelligence, EKTU named after D. Serikbayev, Ust-Kamenogorsk, Republic of Kazakhstan[1]
Doctoral Student, School of Digital Technologies and Artificial Intelligence, EKTU named after D. Serikbayev, Ust-Kamenogorsk, Republic of Kazakhstan[2]

***Abstract*—The paper is aimed at organizational and technological optimization of the system of remote control of ore-stream quality according to technical and economic criteria. The ore-stream in the environment of digital transformation of the mining industry is seen as a system where one of the main functions of management is control. The key importance of the control function in ore-stream quality management becomes in ore quality assessment at the stage of ore material technological preparation, where the homogeneity of the ore massif in terms of the content of the useful component from heterogeneous deposits is formed. Such component in the paper is iron. System technological novelty, which is presented in the paper, consists in realization of constant remote control of ore material quality in the form of monitoring. Remote control is technically realized using unmanned vehicles with subsequent digital processing of information by on-board microprocessor technology and special mathematical and software. The iron content of the ore is estimated from the vertical vector of the magnetic field of the ore material. The implementation of such a concept envisaged the solution of the following tasks: development of a structural and functional model of ore-stream quality control; development of mathematical support for the digital system of data processing of ore material magnetic field measurement data, optimization of metrological indicators of the measuring complex of the control system. It is proposed to use control risks as criteria for quantitative assessment of the functional quality of the ore-stream quality management system. The empirical function of the relationship between the cost of magneto metric remote control of iron content and probable control risks is found. A 3D model of the dependence of the cost of magnetometric control of iron content as a function of accuracy and the value of standards of iron content in ore was built.**

***Keywords*—Ore-stream; system; model; technology; control; risks; probability; unmanned vehicles***

## I. INTRODUCTION

The aim of the work is organizational and technological optimization of the system of remote control of ore-stream quality according to technical and economic criteria. The achievement of the goal is proposed to be solved by developing information and analytical support for the ore-stream quality control system. The proposed study addresses two contextualized scientific and practical challenges that bridge the gaps of known studies: development of a structural and technological model of remote ore quality control and formalization of the process of quantitative assessment of control risks and decision-making under conditions of parametric vagueness of control agents and statistical uncertainty of technological data. Moreover, it is extremely important to differentiate the risks by the degree of their impact on the socio-economic activity of the mining enterprise [1.4].

One of the working and dominant hypotheses proposed in this research relies on the paradigm that decision quality is a systemic convergence of heterogeneous technological agents, where the control system, which finalizes almost every managerial decision, plays a decisive role.

This paper focuses on the function of digital remote control of ore-stream quality. The structural and functional model of the system digital support of the control process contains the following system components: technical support; mathematical support, software, information support, metrological support, organizational and methodological support.

The paper deals with the technology of remote control of iron ore quality. Ore quality in this paper is assessed by the percentage of iron content in a ton of ore material. In real production practice, an ore massif of controlled material is distributed on a solid base in the form of a rectangular ore body of 100x900 m. in the open air. This massif is called an “ore yard”. Measurement of iron level in the ore material is carried out by magnetometers according to the controlled value of magnetic field strength with a technological step of 10 m. over the entire area of the “ore yard”. An estimate of ore material quality is traditionally the average value of magnetic field strength in point coordinates of measurement $Y_{ij}$ over the entire ore mass area in the ore yard. Control and measurement operations are accompanied by control errors, which are called risks and are differentiated by their economic content into “producer risk” and “consumer risk”. Such differentiation of risk is essential, as these types of risk lead to different socio-economic consequences in practice. Currently, the need for risk assessment in any project and production activity is regulated by the ISO 2015 version of the standard, which has a special supplement - IEC 31010 “Risk Management”. The main difference between this addition to the standard and previous versions of ISO is that “risks are no longer implicit in the standard, risk assessment is now embedded in the management system and becomes an inherent feature of it”. The problem of quantitative assessment of these risks in practice is that there is no possibility of instrumental measurement of these risks or by the method of statistical processing, but only by formal mathematical and simulation tools.

Thus, the proposed approach solves the problem of qualimetric integrated assessment in the system of control and decision making in a complex system in the conditions of digital transformation of business processes of the mining industry. Qualimetric support of ore-stream is provided by technological tools, such as remoteness of control and measurement operations [11].

The organizational structure contains: literature review of formal methods and models of risk assessment in management and control systems; problem; research methods; theoretical research results; computer modeling; conclusions.

## II. Literature Review of Formal Methods and Models for Risk Assessment in Management and Control Systems

In classical and modern management science, it is believed that the management system is based on four functions: organization, planning, motivation and control [1]. Control is present to varying degrees in all management functions, but is often identified as a separate organizational or technological system agent. The process of control by the organizational and technical system contains the following sequence of operations: measurement; comparison of the measured value with the norm; analysis of the result; decision making [2,3,4]. The main focus of these papers is on the quantification of control errors (control risks), which are functions of statistical properties and characteristics of the agents of the control system. Statistical properties are understood as distribution laws, and most of the works investigated three laws: the normal law of distribution of a random variable (Gauss's law), Weibull's law, and the equal probability law [5,6]. The papers investigated the influence of the shape of statistical laws of distribution of controlled parameters on probable errors (risks) of control. At the same time, all researches propose different initial constraints, hypotheses and statistical conditions. Initial constraints include their form, e.g.: lower constraint norm, when the controlled indicator must be above the limit $S>S_l$; upper constraint norm, when the controlled indicator must not exceed the value $S<S_u$; tolerance constraint $S_l<S<S_u$. At each constraint, compositions of distribution laws of the controlled parameter and measurement error were investigated.

Under the probability of undetected reject $P_{ur}$ is considered the case when the true value of the controlled parameter is outside the permissible limits, and the control system registers this fact as the presence of the parameter in the permissible zone. And vice versa, when the controlled parameter is in the tolerance zone, and the control system registers this fact as a parameter out of the tolerance zone with probability $P_{fr}$. The hypothesis of distribution of the controlled parameter and measurement error according to the Gauss law has been investigated in known works [7].

Some of the papers investigate the hypothesis of distribution of the controlled parameter according to the Weibull law, and of the measurement error according to the Gauss law. Using the integral function of the Weibull law, the expressions for calculating the probabilities of false reject - $P_{fr,}$ and the probability of undetected reject - $R_{ur}$ in the following form [7,8]:

$$P_{fr}=\sum_{i=1}^{k}\left(e^{-\frac{S_i^{\beta}}{\alpha}}-e^{-\frac{S_{i+1}^{\beta}}{\alpha}}\right)\times\left[\frac{1}{\sigma_y\sqrt{2\pi}}\int_{S_l}^{S_i-3\sigma_y}e^{\frac{y^2}{2}}dy+\frac{1}{\sigma_y\sqrt{2\pi}}\int_{S_u}^{S_i+3\sigma_y}e^{\frac{y^2}{2}}dy\right]$$

$$P_{ur}=\sum_{i=1}^{k}\left(e^{-\frac{S_i^{\beta}}{\alpha}}e^{-\frac{S_{i+1}^{\beta}}{\alpha}}\right)\frac{1}{\sigma_y\sqrt{2\pi}}\int_{S_l}^{S_i-3\sigma_y}e^{\frac{y^2}{2\sigma_y^2}}dy\times\sum_{i=1}^{k}\left(e^{-\frac{S_i^{\beta}}{\alpha}}e^{-\frac{S_{i+1}^{\beta}}{\alpha}}\right)\frac{1}{\sigma_y\sqrt{2\pi}}\int_{S_u}^{S_i+3\sigma_y}e^{-\frac{y^2}{2\sigma_y^2}}dy, \quad (1)$$

Analyzing the nature of risk in an environment of parametric fuzziness and data uncertainty showed that risk represents some virtual space or augmented reality phenomenon. According to current digital understandings, this virtual environment is part of a "meta-universe". The "meta-universe", as noted in publications, is "far from being a new term" [9]. The first concepts of the meta-universe had only fantastical outlines related to travelling beyond the galaxy. It represents something between the real and fictional worlds. Nowadays, the concept of "meta-universe" has started to acquire practical contours and penetrate into many spheres of life, such as: social networks, real estate sector, investments, working sphere, augmented reality, cryptocurrency world, online games, etc. The challenge is to "look at life beyond the boundaries of conventional understanding", which ultimately offers and generates the "digital transformation" of the risk management process. Nowadays, risk is an integral part of human "digital" life and is present in virtual and real forms of being, largely determining the "quality of life" at all stages of the "life cycle" of an object [10].

## III. The Problem

The main problem is to quantitatively assess ore quality under production conditions while minimizing technological costs. The research is carried out on the example of quality control of iron-containing ore material at the final stage of technological preparation of ore for smelting. At this stage, the tasks of estimating the percentage content of the useful component in the ore mass and building an optimal technological model that ensures minimum risks of ore quality control and subsequent economic losses are solved.

## IV. Research Methods

The research methodology is based on the system approach. In this interpretation, the system is considered as an integrated set of controlling digital agents of a multi-parameter technical and economic system. The key agent in quality management of the object under research - ore flow - is considered to be the process of control and risks regulated by IEC 31010 standard. For the optimal solution of the problem, formal methods of description of production and technological processes in the environment of digital transformation of management are used. The formalization of solved problems relies on the following mathematical tools: probabilistic and simulation models, fuzzy sets, agent-based approaches, expert evaluations. The software application developed in previous researches is used to conduct the computer experiment. Statistical data for modelling are used

from the reporting documents of sectoral enterprises. Fisher's F-criterion and Student's t-criterion were used to examine the statistical material for homogeneity. Statistica 10 package was used to process the results of statistical research.

## V. Results of Theoretical Researches

### A. Virtual Paradigm of Ore-Stream Quality Control in the Environment of Digital Transformation of Mining Economy

To achieve the goal in the scope of the proposed research the following tasks are solved: development of organizational and technological model of remote control of ore mass quality; optimization of technical and economic indicators of agents of remote control of ore quality; development of formal model of quantitative assessment of control risks in the ore-stream quality management system.

The real physical model of spatial iron concentration distribution in the ore yard area is of random nature. It is technically and technologically impossible to carry out direct control and measurement operations in different points of the "ore yard" area of 100x900 m. in the real environment. Therefore, this research proposes the use of unmanned aerial vehicles equipped with the necessary sensors, technical means of control and communication with a stationary local center for processing current on-board information (DPC) (Fig. 1). The number of control points is measured by the ratio S/Δ, where: S=L*M; L-length of the ore yard; M-width of the ore yard, S-area of the ore yard, Δ-distance between control points.

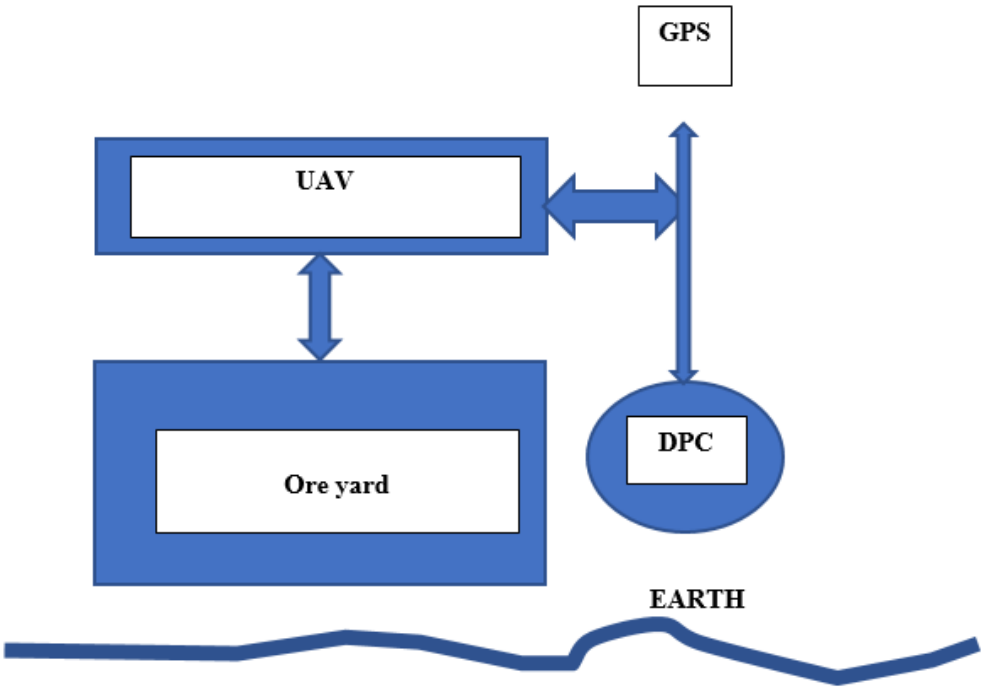

Fig. 1. Functional-technological model of the system for remote monitoring of iron ore quality.

The use of an unmanned vehicle significantly simplifies control and measurement operations, increases the manufacturability of control, but increases the cost of the project [11]. The proposed technological model transforms the continuous magnetic field of the ore yard into a digital controlled equivalent. The array of control and measurement information will be represented by a virtual digital spatial-information digital field (model), which is shown in Fig. 2.

| $\{H_{1,1}\}$ | $\{H_{1,2}\}$ | …….. | $\{H_{1,m}\}$ |

Fig. 2. Digital 2D model of magnetic field strength values in the ore yard area.

Each element of the information array contains the result of measuring a separate digital equivalent of the magnetic field values $H_{ij}$ in some coordinate $x_{ij}$ of the ore yard surface. The array size is determined by the requirements to the control accuracy, which depends on the number of elements on the digital field area. The total number of digital $H_{ij}$ on the area of the ore yard (field) is determined from the expression N=M*L/Δ. Sampling intervals Δ can be set manually by the operator. The maximum value of the sampling parameters is determined by the positioning accuracy of the unmanned vehicle.

### B. Optimisation of Technical and Economic Indicators of ore-stream Quality Control Agents

The final practical result of this research is software applications, the use of which allows quantitative assessment of producer risks and consumer risks in probabilistic form. It is also presented the possibility of assessing the reliability of control under given statistical laws and characteristics of random

control agents. As it was established, control risks are functions of statistical parameters. Having preliminary or reported experimental material in a particular practical project, it is possible to solve the control problem in an optimal way under given metrological and resource limitations at the initial stage of work. It is also possible to solve the reverse problem, when metrological indicators of the used system support are specified and quantitatively known, and also norms and regulations are specified, then it is possible to quantitatively predict the quality of control by the sought indicators of reliability and risks. Quantitative values of producer and consumer risks have limited economic or social potential. Each investment project or business plan is completed with specific financial estimates, usually in monetary terms. Such a problem with specific economic calculations acquires an econometric form. In this paper the term 'econometrics' is interpreted as "Econometrics is one of the most effective controlling tools". In some economic literature this term is given a more extended interpretation: "Statistical analysis of economic data is called econometrics, which literally means: the science of economic measurement" [12]. The use of econometric approaches to the proposed subject study opens up the possibility of optimizing the metrological indicators of the ore-stream quality control system. In similar problems, which were solved by a number of researchers in the field of technical diagnostics, the following logic of analysis was proposed [7]:

- Control and measurement works require certain costs for instrumentation (instruments), premises, consumables, staff salaries, computer equipment, etc.
- The cost of metrological support depends on the accuracy of measurements, as established in practice, in an exponential way.
- As measurements become more accurate, the lower the risks of control, and the subsequent economic losses associated with the risks.

This approach has the following graphical interpretation (Fig. 3) [4,5,16].

The main labor intensity in the implementation of such an approach to the optimal solution of the problem on the example of ore-stream quality control in real conditions consists in the organization and carrying out of experimental and statistical researches and further empirical formalization of integral and element-by-element economic costs and predicted benefits in quantitative measurement. In analytical form, the graphical model (Fig. 3) will have the following interpretation:

$$Ctot = Ccosts + Closses , \quad (2)$$

Ccosts costs include: the cost of the quadrocopter with the Cqu hanging tool, the cost of the magnetometer Cmag, the cost of the digital control system Cc, the cost of the maintenance system Cm, the cost of in-house technical staff Ci, and the cost of the software Cs.

A significant part of the total costs is the price of the quadrocopter together with the equipment and technical support of the entire unmanned system. Research and analysis of the UAV market by criteria of cost, reliability, operational and target efficiency showed that the market offers a very large price range of UAVs adapted for various industrial and scientific purposes.

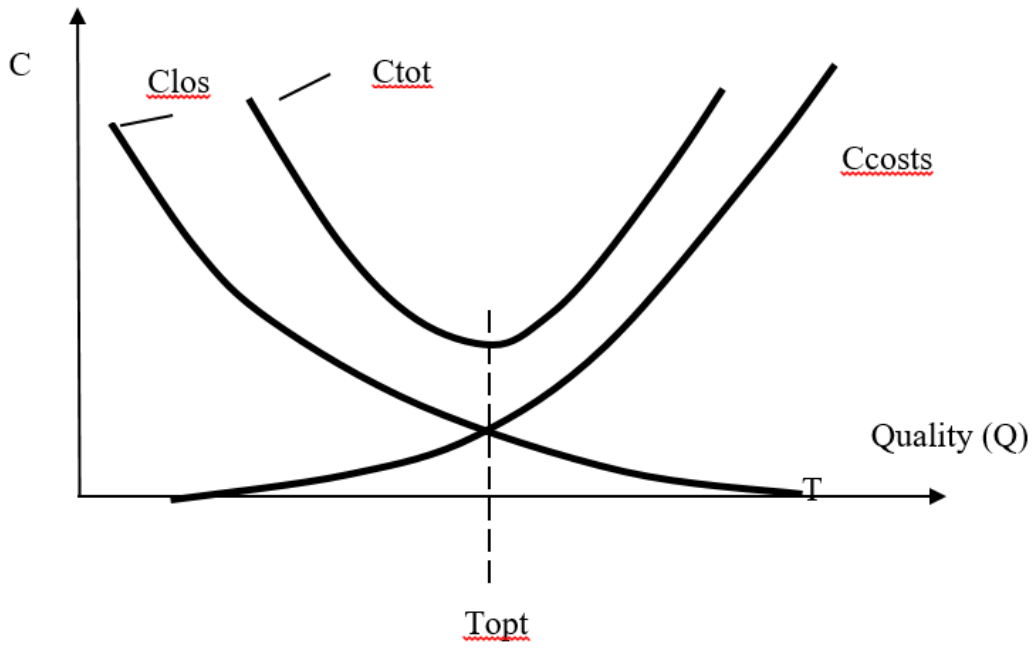

Fig. 3. Graphical model of risk optimization as a function of control accuracy [7]. C - costs; Ctot - total costs; Clos - losses from the reduction of control accuracy; Ccosts - costs of acquisition and operation of control and measuring equipment; T - control accuracy; Topt - optimal accuracy.

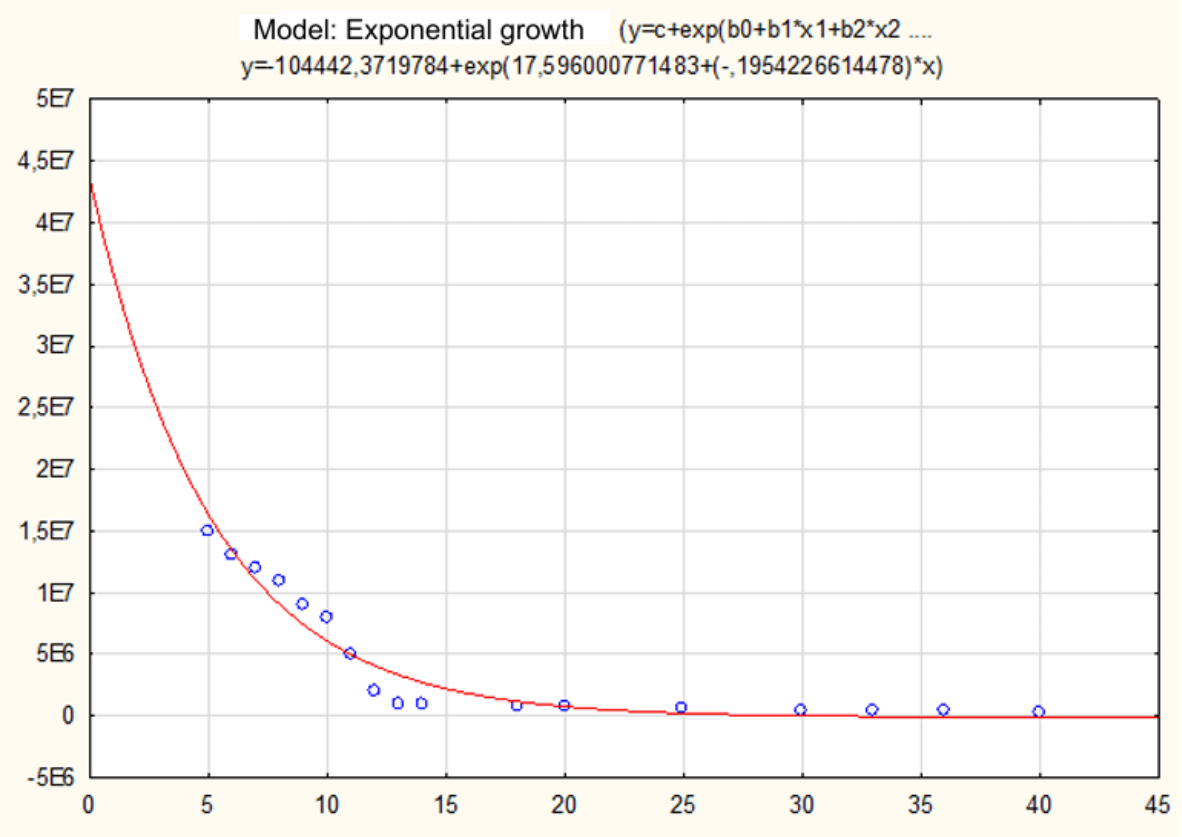

Fig. 4. Cost of tools and software in the ore-stream quality control and monitoring system.

An important economic component in the total production costs is the cost of the measuring complex, which includes: the cost of the magnetometer, the cost of premises for maintenance of the unmanned system, the cost of instrumental and information-measuring support for maintaining the operational reliability of the entire ore-stream quality monitoring system, the cost of maintenance personnel. As follows from the materials presented above, control risks and losses in the function of risk level are closely related to metrological indicators of the control and decision-making process at all stages of the life cycle of the system under research. According to the results of the analysis of Internet resources, literature sources, scientific and technical reports, the statistical material on this problem was collected, which after preliminary processing in the graphical design has the following form (Fig. 4):

The regression empirical approximation of the graphical model is as follows:

$$Ccosts = 104442{,}37+\exp(17.6-0.195V, \quad (3)$$

where V is the relative uncertainty of the control in percent (V= σl/Have, %).

In this model, the explained proportion of variance is 0.940, correlation coefficient R = 0.969, F=12.6.

The second component of expression (1) Closses quantifies the probable losses incurred by the business from emerging control risks in the digital control system in the form: Pfr - probability of producer risk and Pur - probability of consumer risk. Quantitative digital risk assessments can be referred to as virtual or augmented reality assessments. Giving these assessments a quantitative measurable economic content is one of the tasks in the ore-stream quality control system. The methodology of formal description of many technological processes and economic evaluation of losses at each of the process stages is an extremely difficult task in digital object control, since each agent of the investigated process is a “black box”.

### *C. Development of a Precedent Model for Control Risk Assessment in Technology to Improve the Homogeneity and Averaging of Ore Material*

One of the labour-intensive process steps in metallurgy is ore averaging [13]. Ore averaging seems to be a very necessary technological process due to the fact that ore from different deposits is a multicomponent and dissimilar mineral structure. Process regulations for ore smelting are oriented towards a product with a certain tolerance percentage of a useful component, such as iron, in the range Femin to Femax, which corresponds to a magnetic field value in the range Hmin to Hmax. Ore transported from the mines is unloaded to the “ore yard” in layers and stacks in a certain order. The ore is taken by the excavator across the layers so that the grab grabs as many layers as possible at the same time, and already at this technological stage the ore shipped from the ore yard is averaged. On average, the stack capacity is 100 thousand tonnes

and the number of layers is in the range of 300-1000. The magnetic field Hi(x,y) is monitored over the entire area with a certain metric step Δx;Δy. Two-dimensional address point H(i,j) is a spatial coordinate of a virtual area of L×M size. The number of information addresses is determined by the technical and technological capabilities of the magnetometer and UAV. The data information matrix will look as shown in Fig. 2. The accuracy of control is determined by the metrological indicators of the remote control system, which also includes the accuracy of UAV positioning and variability of the controlled parameter. The quality of homogeneity of the controlled ore environment in the operating mode is assessed operationally in the round-the-clock mode according to the established technological regulations with specified time intervals between control sessions. As noted above, most of the works consider modelling options where it was assumed that norms are deterministic values. Practice shows that this hypothesis simplifies the situation, which leads to significant methodological errors. This implies the necessity of building formal models taking into account the uncertainty of norms, which seems to be a precedent approach [14,15].

Considering the control system as a "black box", norms should be considered as one of the components of this precedent system, which has a high degree of uncertainty. The statistical nature of norms, as an objective fact, has been considered in many works [5,6,7,8]. As a measurement error in these works it is proposed to use the value of uncertainty, which is quantified by the mean square deviation [16,17]. Uncertainty among the key factors of control and decision-making risks in the system of precedent management should be considered as a phenomenon and as a consequence of incomplete knowledge about the topic under study, i.e. as a factor of "black box", a factor of environmental influences, unclear or inadequate understanding of objectives. The technical field has its own specificity and traditions, where the priority is given to instrumental metrology and, first of all, to measurement errors in the control system.

In the proposed research, priority in the ore-stream quality management system is also given to the uncertainty of norms, which are considered in formal models as random variables having different distribution laws. Possible management risks are investigated in the pre-project stages, and subsequently at some stages of the life cycle as required. As a rule, risk research is carried out in many practices at a qualitative level. However, in production reality, economic and other projected losses are of practical value only if they are quantified.

From all the above theoretical and practical material, in relation to the subject area under study, there arises the need and the task of quantifying the impact of the statistical nature of the tolerance field on the quality of control, and as a consequence on the quality of the ore-stream control system, under conditions of statistical uncertainty of agents and control precedents [18].

Without giving intermediate conclusions, the probable number of objects erroneously rejected from the whole sample N is expressed by the following formula [5]

$$N_{fr} = \sum_{i=0}^{m} N \int_{Li}^{Hi} \theta(Bl)dBl \left[ \sum_{j=0}^{k} \frac{1}{\sqrt{2\pi}} \int_{\theta_i}^{\lambda_i} e^{-\frac{t^2}{2}} dt \times \frac{1}{\sqrt{2\pi}} \int_{\frac{3j}{k}}^{3} e^{-\frac{z^2}{2}} dt \right], \quad (3)$$

The likely number of undetected reject results will be:

$$N_{ur} = \sum_{i=0}^{m} N \int_{Li}^{Hi} \theta(B)dB \left[ \sum_{j=0}^{k} \frac{1}{\sqrt{2\pi}} \int_{\theta_i}^{\lambda_i} e^{-\frac{t^2}{2}} dt \times \frac{1}{\sqrt{2\pi}} \int_{\frac{3j}{k}}^{3} e^{-\frac{z^2}{2}} dt \right], \quad (4)$$

where the distribution density function of the normative value of the controlled parameter B has the following form and parameters:

$$\theta(Bl) = \frac{1}{\sqrt{2\pi} \cdot 6n} e^{-\frac{(Sn-Sal)^2}{62_n}}$$

Ϭn - standard deviation of the distribution density function of the normative value of the controlled parameter B;

Sal - arithmetic mean of the lower norm of the controlled parameter B.

Expressions (3-4) presented in such a probabilistic form have an extremely complex analytical structure, which will lead to a very high methodological error in numerical computer implementation. Therefore, the use of simulation modelling [19,20,21] is evidently recommended in the problems of this subject matter. With this in mind, a simulation model is developed and proposed in this research, the algorithm of which is shown in Fig. 5.

The logic and operation of the algorithm can be clearly read and understood from the functions of each of the model blocks. The work of the algorithm starts with the input of statistical model data: $H_{ave};\sigma_u;\sigma_{meas};\sigma_l,\sigma_u;H_{lave},H_{uave}$. The optimal number of simulation cycles is found experimentally. The simulation is completed by outputting the values of risk and control reliability

$$P_{fr} = N_{fr}/M \text{ and } P_{ur} = N_{ur}/M,$$

Headings, or heads, are organizational devices that guide the reader through your paper. Where $N_{fr}$ is the content of the false reject counter; $N_{ur}$ is the content of the undetected reject counter; M is the total number of simulation tests.

The reliability D is calculated using the formula $D = 1 - (R_{fr} + R_{ur})$.

A software application has been developed for quantitative calculations of control risks by computer modelling. Making quantitative simulation calculations at different compositions of statistical laws of distribution, it is possible to find out the degree of influence of forms of statistical distributions on the result, which will determine the scope of experimental research and the final reliability of the results. The final stage in the quantitative assessment of risks is to give them a quantitative economic content, which is discussed above.

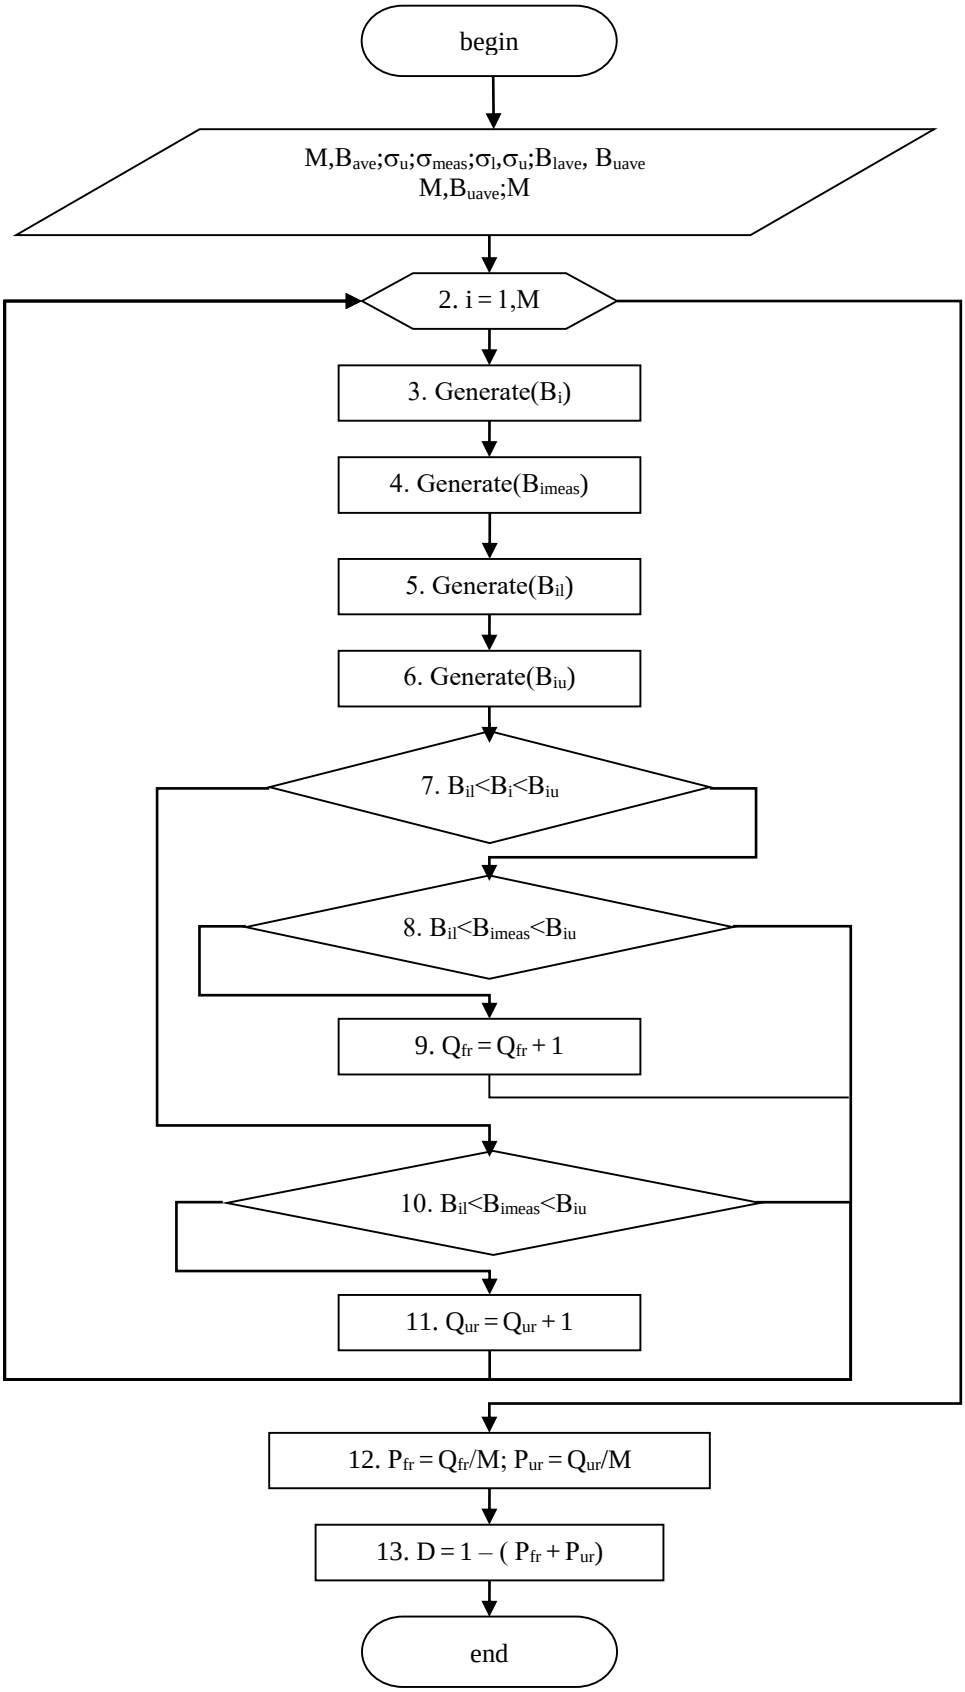

Fig. 5. Algorithm of simulation model for quantitative assessment of control risks under uncertainty of normative values.

## VI. Computer Modelling

The software application [21] was used for computer modelling in order to obtain the calculated risk values for the ore consumer. The results of computer calculation of probable risks of $P_{ur}$ control, under non-deterministic regulations are given in Table I.

$P_{ur}$ control errors in commercial settlements between the producer and the consumer of ore depend on a variety of market factors. These factors include exchange prices for ore of a certain quality. Ore quality is primarily determined by the percentage iron content. It is common practice at the iron ore exchange to ration ore into three qualities levels - 40%, 50%, 60%. Ore of high quality (60%) may be quoted under separate situational rules with a high level of uncertainty.

To visualize the process of modelling data analysis, using expression 3, a 3D model of total costs in the ore-stream quality control system was built using $P_{ur}$ risk as an example. The 3D modelling results are presented in Fig. 6.

As it follows from Fig. 6, the three-dimensional surface of total costs of Var3 in the system of risk management and quality control of ore-stream shows a clearly expressed area of minimum, which corresponds to the norm of iron content in ore material equal to 40%.

To quantitatively analyze the results of modelling, the total present value of probable monetary losses of the ore consumer as a function of control errors $P_{ur}$ was estimated for the norm 40% and ore volume: V=1000000 t (cost Cdol/t=100) (Table II).

TABLE I. Result of Computer Modelling of Probable Control Risks $P_{UR}$ (Ore Consumer Risk)

| Technological rule of average iron content according to the level of magnetism in ore $H_{ave}$,% | **Relative uncertainty of ore grade control, $\sigma/H_{ave}$** | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 | 0.8 | 0.9 |
| $P_{ur}$ (%) at iron content rate $H_{ave}$>=40% | 2.1 | 3.3 | 4.5 | 12.9 | 17.15 | 20.5 | 24.0 | 28.1 | 30.2 |

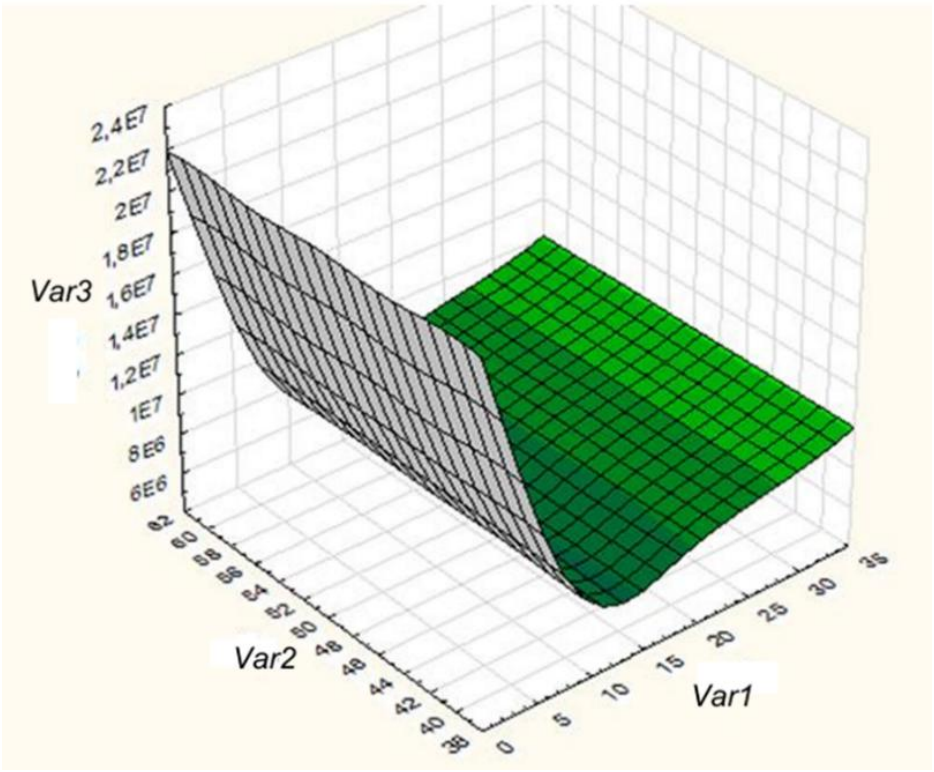

Fig. 6. Results of 3D modelling of total costs in the ore-stream quality control system. Var3 - total costs as a function of control accuracy and norms value; Var2 - norms value; Var1 - control uncertainty (accuracy).

TABLE II. Total Present Value of Probable Monetary Losses of the Ore Consumer as a Function of Control Errors $P_{UR}$ for the Norm of 40% and Ore Volume:V=1000000 Tonnes (cost Cdol/t=100)

| Average iron content rate by magnetism level in ore $H_{ave}$,% | Relative uncertainty of control ($\sigma/H_{ave}$) | | | | | |
|---|---|---|---|---|---|---|
| | 0.1 | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 |
| $P_{ur}$ (%) at iron content rate $H_{ave}$>=40% | 15000000 | 9000000 | 5000000 | 6770000 | 7450000 | 8300000 |

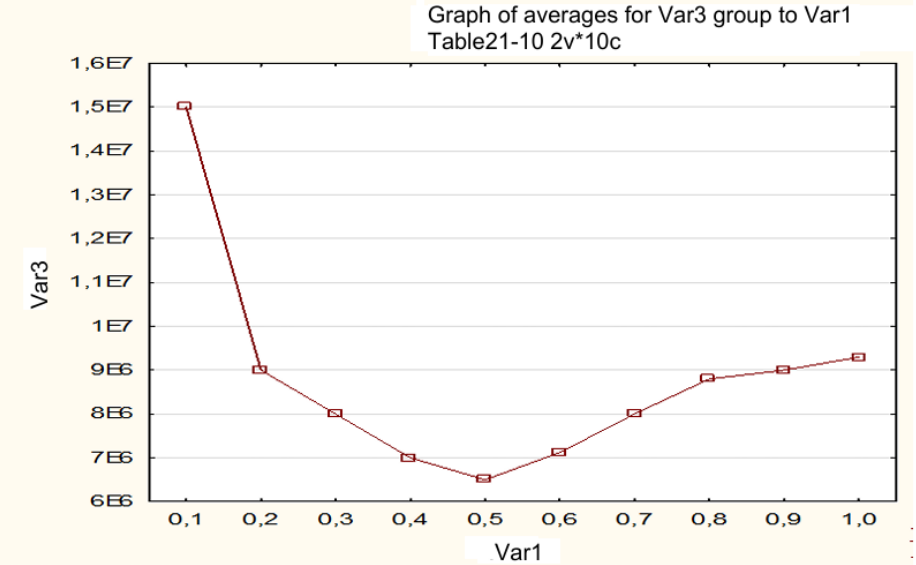

Fig. 7. Graphical 2D Model for Estimating Ore Consumer Monetary Losses as a Function of Control Errors (Consumer Risk). Var3 Financial Losses due to Probable Risk $P_{ur}$, as a Function of Relative Control Uncertainty $\sigma/H_{ave}$ (Var1) for the Norm of 40%.

Fig. 7 illustrates a graphical 2D model for estimating ore consumer monetary losses as a function of control errors (consumer risk) at a norm of 40%.

As follows from Fig. 7, the minimum of total losses in the ore-stream quality control system as a function of the accuracy of iron content control in the ore material corresponds to the ratio $\sigma/H_{ave} = 0.5$. Here $\sigma$ is the mean square deviation of the measurement error of the iron content in the ore material, and $H_{ave}$ is the average value of the controlled magnetic field strength of the ore material with a norm of 40%.

## VII. Conclusion

According to the modelling results, it was found that the ore-stream quality management system is a multifactorial process in which the key function is control. The total costs of ensuring effective digital control contain: purchase and maintenance of instrumental means of measurement; losses in the function of control quality assessed by control risks. The total cost of ensuring effective digital control has a close correlation with control and measurement risks, which determine economic losses in the ore-stream management system. Adequate assessment and forecasting of risks, as well as economic consequences of control is possible through mathematical modelling based on the data of experimental and statistical researches.

As a result of experimental researches and computer modelling, the optimal ratio of the cost of control and measuring equipment depending on metrological indicators, normative regulations for the initial ore material and statistical properties of the controlled ore material was revealed.

In the conditions of competition, developed inter-corporate and international relations and a number of other factors, an objective quantitative assessment of the economic efficiency of new innovation projects in practice seems possible with a formalized quantitative calculation of total costs and losses as a function of the accuracy of control and decision-making.

## Acknowledgment

I express my gratitude to my domestic and foreign thesis advisors for invaluable help in the researched issues, I express my great gratitude to Professor Vyacheslav Andreyevich Kornev, who provided invaluable assistance in writing the paper, and I also express my gratitude to "DasAmi Inc." LLP for financial support of the main scientific work.

# Detection and Classification of Intestinal Parasites with Bayesian-Optimized Model

Haifa Hamza[1]*, Kamarul Hawari Ghazali[2]*, Abubakar Ahmad[3]
Faculty of Electrical Engineering Technology, Universiti Malaysia Pahang Al-Sultan Abdullah, 26600 Pekan, Pahang, Malaysia[1, 2]
Faculty of Computing, Universiti Malaysia Pahang Al-Sultan Abdullah, 26600 Pekan, Pahang, Malaysia[3]

***Abstract*—Automated detection of intestinal parasites in medical imaging enhances diagnostic efficiency and reduces human error. This study evaluates object detection techniques using Faster R-CNN with different backbone architectures such as ResNet, RetinaNet, ResNext and YOLOv8 series for detecting *Ascaris lumbricoides* and *Trichuris trichiura* in microscopic images. A dataset of 2000 images was split into training (1500), validation (300), and testing (200). Results show Faster R-CNN with RetinaNet achieves the highest Average Precision (AP) across varying Intersection over Union (IoU) thresholds, making it robust in feature extraction. However, YOLOv8 excels in real-time detection, with YOLOv8n (nano) providing the best trade-off between accuracy and computational efficiency. Bayesian Optimization further improves YOLOv8n, achieving an AP of 99.6% and an Average Recall (AR) of 99.7%, surpassing two-stage architectures. This study highlights the potential of deep learning for automated parasite detection, reducing reliance on manual microscopy. Future research should explore transformer-based models, self-supervised learning, and mobile deployment for real-world clinical applications.**

***Keywords*—Intestinal parasites; faster region convolutional neural network; You Look Only Once (YOLOv8); Bayesian Optimization; medical imaging; object detection**

## I. Introduction

Intestinal parasitic infections significantly impact global public health, particularly in low-resource and developing regions [1]. Among the most prevalent species are *Ascaris lumbricoides* and *Trichuris trichiura*, which together infect hundreds of millions of individuals worldwide and contribute to malnutrition, cognitive impairments, and socioeconomic challenges [2], [3]. Accurate and timely diagnosis of these infections is essential for effective treatment, surveillance, and public health intervention strategies. Traditional diagnosis via manual microscopic examination, although widely used, is fraught with limitations such as labor intensiveness, inter-observer variability, and significant dependency on expert knowledge [4], [5]. These constraints often lead to delayed diagnoses or misclassification, undermining effective disease control. As such, there is a pressing need for automated, robust, and scalable diagnostic tools that can reliably identify parasite eggs across varying image conditions.

Recent advancements in machine learning (ML) and deep learning (DL) have demonstrated promising capabilities in automating visual diagnostic tasks. However, ML techniques frequently rely on handcrafted features and struggle with image variability and segmentation challenges. Meanwhile, DL approaches such as CNNs and U-Nets offer improved performance through hierarchical feature extraction, demanding substantial computational resources and large annotated datasets. These resources are often unavailable in the very settings most affected by parasitic diseases [6].

### A. Research Problem and Objectives

The central research problem is the lack of real-time, high-accuracy parasite detection tools suitable for resource-constrained clinical settings. Existing models either compromise on computational efficiency or fall short on precision in complex image environments [7]. This study aims to overcome this limitation by identifying and optimizing an object detection architecture that provides a reliable trade-off between accuracy and processing speed.

This research addresses these challenges by proposing a novel, optimized diagnostic solution based on the YOLOv8n model, which is a part of a single-stage object detection framework known for real-time efficiency and accuracy. The core innovation lies in using Bayesian Optimization to fine-tune YOLOv8n's hyperparameters, enabling the model to deliver state-of-the-art accuracy (AP of 99.6%) and recall (AR of 99.7%) with minimal computational overhead.

The study begins with a literature review covering traditional ML and recent DL techniques in parasite detection, highlighting their respective strengths and shortcomings. The methodology section details the dataset, model architecture, and evaluation metrics used in the study. Results are presented comparing various model performances, with a particular focus on the improved YOLOv8n model. Finally, the discussion emphasizes the practical implications of the findings and proposes directions for future research, including the integration of transformer models and mobile deployment

### B. Significance and Contributions

This work makes significant contributions to the field of biomedical imaging and parasitology by:

- Systematically comparing both two-stage (Faster R- NN) and single-stage (YOLOv8 series) object detection models across standard benchmarks.
- Demonstrating the superior performance of YOLOv8n for real-time detection in low-resource settings.

- Introducing a Bayesian Optimization framework that enhances the model's performance through intelligent hyperparameter tuning.
- Presenting a detection pipeline that can feasibly be deployed in clinical workflows, thereby reducing diagnostic delays and improving healthcare outcomes.

The findings contribute to advancing automated parasite detection, paving the way for real-time, scalable, and resource-efficient diagnostic solutions in medical and environmental applications.

## II. Literature Review

### A. Machine Learning

Machine learning techniques have been instrumental in solving some of the challenges in detecting and classifying intestinal parasites. These include Support Vector Machines, BoVW, and Laplacian SVM, among others, which have achieved success in automating parasite classification, enhancing energy efficiency, and solving the out-of-distribution problem in parasite-egg detection [8], [9], [10], [11]. The combination of BoVW with SVM achieved considerable accuracy on classification for various reptilian parasites from stool images, whereas SoftMax thresholds are used for feature selection to deal effectively with out-of-distribution (OO-Do detection).

Most of the ML methods inherently suffer from issues of limited labelled data, manually crafted feature extraction, and dealing with high-dimensional image data despite their successful performance; hence, there is an ever-rising need to develop an automatic feature-learning technique and handle variability in image quality.

Besides, many of these ML models suffer in general from the problem of segmentation, which makes them easily lose their performance on new unseen datasets, and was presented in [9] by Ren et al. The work has thus recently shifted more toward deep learning methods because they have been seen to have the capabilities for high-level feature learning; in addition, deeper learning will be able to capture and model more complex image information data, hence overcoming so much weaknesses related to more conventional ML techniques.

### B. Deep Learning

Deep learning emerged as a revolutionary methodology to solve complex problems in the detection, classification, and segmentation of parasites. Models with CNNs, YOLO architectures, and transfer learning strategies have delivered exceptional performance in application scenarios that demand high accuracy and automated feature extraction. For instance, YOLOv5, CNN, have achieved considerable success in the detection of protozoan cysts and helminth eggs and malaria parasites with accuracies mostly greater than 95% in [12], [13]. Besides, deep learning models like U-Net have achieved detection accuracies as high as 99.8% in detecting human intestinal parasites [14].

However, this is not to say that there are no limitations in deep learning. In particular, these include dependencies on large and diverse datasets, high computational costs, and sensitivity to variations in image quality. Suwannaphong et al., in [15], for instance, recorded a drop in performance upon using low-resolution images from USB microscopes. In addition, some approaches cannot classify morphologically similar types of parasites easily [16]. Some challenges identified include: integrating clinical real-world data sets, improving model architectural robustness, and employing hybrid models to leverage strengths from the different machine learning and deep learning models.

In this work, efforts are made in optimisation of models for resource-constrained settings to enhance generalisability to unseen data. Transfer learning is a method in which pre-trained models are used, especially with small-sized datasets, in order to perform better. For parasite detection, this technique has often been used due to its limited and low-quality dataset [17]. Therefore, transfer learning leverage knowledge from larger and higher quality datasets to enhance feature selection with much better accuracy. Several works, such as [18] and [15], have shown success in using transfer learning methods to improve the accuracy of parasite detection models.

### C. Hybrid and Ensemble Learning

Some intractable problems in parasite detection are being tried to be overcome by the hybrid and ensemble learning methods combining the powers of ML and DL. Among these techniques, some methods like VGG16 along with SVM and some ensemble approaches, such as ResNet50 with DenseNet201, have outperformed all previous works related to intestinal and blood parasite classification. For example, Bhuiyan and Islam in [19], reported 97.92% accuracy using a hybrid model for detecting protozoa and helminth eggs. Ensembles of CNNs and traditional ML classifiers have also performed well in addressing variability in feature extraction and boosting the accuracy over multi-class tasks in works such as [20] and [21].

Although ensemble methods tend to give higher accuracy, there is usually an added problem of computational complexity and high training times, a process that was noted by Butploy et al. in [22]. Therefore, hybrid models are computationally expensive and in some cases constitute a major source of concern, especially within resource-poor clinical areas.

These challenges further raise the need for refined research on ensemble methods to reduce computational demands and involve sophisticated optimization techniques, such as quantum learning or lightweight models. This analysis underlines the movement from traditional ML techniques to advanced DL and hybrid methods. This reflects the unruffled effort that has gone into overcoming the challenges of parasite detection to improve upon the accuracy, efficiency, and scalability of the approach.

## III. Methodology

The methodology outlines the systematic approach undertaken to evaluate the performance of state-of-the-art object detection models in detecting intestinal parasites. This section describes the dataset, the preprocessing steps employed, the models used, and the evaluation metrics applied. The goal is to assess and compare the effectiveness of the models in classifying and detecting two classes of parasites, *Ascaris*

*lumbricoides* and *Trichuris trichiura*, using robust and reproducible experimental protocols.

### A. Dataset Description

A dataset of 2000 microscopic images was used, comprising two classes of intestinal parasites: *Ascaris lumbricoides* and *Trichuris trichiura*. The dataset was divided into; 1500 images as training set, 300 images as validation set and 200 images as testing set. Each image was pre-processed to ensure uniform dimensions and enhanced contrast for optimal model input.

### B. Models Evaluated

This research attempts to optimize the best-performing models among the established baseline models. Object detection for parasite identification, specifically *Ascaris lumbricoides* and *Trichuris trichiura*, requires a balance between detection accuracy and inference speed. Object detection architectures fall into two categories: two-stage and single-stage models. Two-stage architectures, such as Faster R-CNN (FRCNN), excel in precision but often suffer from higher computational costs. Conversely, single-stage architectures, such as the YOLOv8 series, prioritize real-time detection with competitive accuracy. Ensemble learning leverages multiple models trained on the same dataset, combining their predictions to enhance precision and reduce variability. The individual models trained include:

*1) Two-Stage architectures:* Faster R-CNN (FRCNN) is a well-established two-stage detection framework that provides high detection accuracy by first generating region proposals and then refining predictions. To enhance performance, several backbone architectures and frameworks have been integrated with FRCNN:

*a) Faster RCNN with ResNet Backbone:* Utilizes ResNet for feature extraction, known for its accuracy and efficiency in hierarchical feature learning. Both ResNet_50_FPN and ResNet_101_FPN were used in the experiment.

*b) Faster RCNN with RetinaNet Backbone:* Incorporates RetinaNet's focal loss function to address class imbalance, ensuring precise detection of small and irregularly shaped objects.

*c) FRCNN with ResNeXt backbone:* ResNeXt's grouped convolution structure was used to improve feature representation and classification.

These configurations provide robust detection performance but may introduce computational overhead, limiting real-time applications in field environments.

*2) Single-Stage architecture:* The YOLOv8 series offers a single-stage alternative with five model sizes: YOLOv8n (nano), YOLOv8s (small), YOLOv8m (medium), YOLOv8l (large) and YOLOv8x (extra-large), balancing accuracy and efficiency. Single-stage models eliminate the region proposal step, allowing for faster inference while maintaining high detection precision. In this study, YOLOv8n performed better than other variants with the parasite datasets used for this study. The optimal trade-off between speed and accuracy, made it even more suitable for real-time parasite detection with limited hardware resources. YOLOv8n's advantages include:

- Efficient feature extraction using CSPDarkNet backbone.
- Improved object localization through anchor-free detection.
- Optimized performance on edge devices for real-world applications.

The different architectures are summarized in Fig. 1.

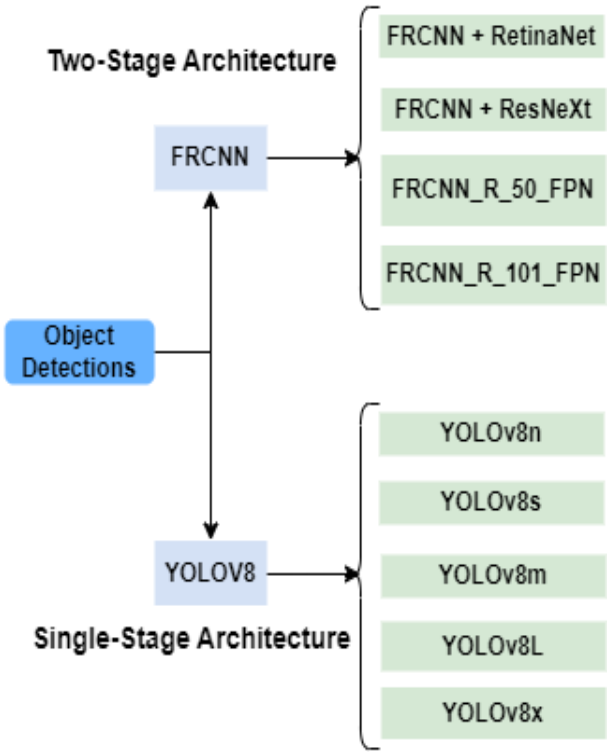

Fig. 1. The different Object detection models utilized in intestinal parasite detection and classification tasks.

*3) Selection of YOLOv8n for optimal performance:* A comprehensive evaluation was conducted by training both two-stage and single-stage object detection architectures on the same dataset to identify the most effective model for parasite detection. The two-stage Faster R-CNN (FRCNN) framework was tested with multiple backbone architectures, including ResNet_50, ResNet_101, RetinaNet and ResNeXt, each offering high detection accuracy but at the cost of increased computational complexity.

In contrast, the single-stage YOLOv8 series, comprising five model sizes (YOLOv8n, YOLOv8s, YOLOv8m, YOLOv8l, and YOLOv8x), provided a real-time alternative with improved inference speed and detection precision. Among these, YOLOv8n (nano) was selected as the best-performing model, offering an optimal balance between accuracy and efficiency, making it particularly well-suited for real-time parasite detection in resource-constrained environments. The results of the experiments are presented in the 'Results and Discussion' section of this study.

*4) The structure of the proposed optimized YOLOV8n:* YOLOv8 represents a significant advancement in real-time object detection, introducing a refined architectural design that enhances accuracy, efficiency, and adaptability over its predecessors. At its core (Backbone), YOLOv8 adopts a CSPDarkNet-inspired backbone, incorporating an advanced Spatial Pyramid Pooling (SPP) module and CSPLayer blocks, which improve gradient flow and reduce computational redundancy, thereby enhancing feature extraction. The core operation involves splitting feature maps and performing transformation separately before merging, as formulated in Eq. (1):

$$X' = F(X_1, \theta) \oplus X_2 \tag{1}$$

where,

- $X'$ is the input feature map, and $X_1, X_2$ are the split feature maps,
- F $(., \theta)$ represents the transformation function (e.g, convolution, activation and normalization).
- $\oplus$ denotes concatenation.

In addition, Spatial Pyramid Pooling (SPP) enhances receptive field aggregation by applying multi-scale max pooling as shown in Eq. (2):

$$SPP\ (X) = \bigoplus_{i=1}^{N} \max_{ri}(X) \tag{2}$$

where,

- N represent the number of pooling scales,
- $r_i$ denotes the pooling kernel size at scale *i*
- $\max_{ri}(.)$ applies max pooling over a region of size ri

These components collectively improve feature representation by capturing both fine and coarse-grained spatial structures.

At its neck, the model optimized Path Aggregation Network (PAN) to facilitate multi-scale feature fusion, ensuring the effective integration of fine-grained and high-level semantic information critical for detecting intricate structures such as parasites. Feature fusion in PAN is mathematically expressed in Eq. (3):

$$F_{out} = W_1 * U(F_{in}) + W_2 * D(F_{in}) \tag{3}$$

where,

- $F_{in}$ is the input feature map,
- U($U(F_{in})$ *and* $D(F_{in})$ represent up sampling and down sampling functions, respectively,
- $W_1, W_2$ are learnable weight parameters
- * denotes convolution

This hierarchical fusion ensures better retention of spatial and contextual information across different scales.

A key departure from previous YOLO variants is the introduction of an adaptive decoupled head, which independently processes classification and regression tasks, improving both localization accuracy and confidence calibration. The classification confidence score and bounding box regression are modelled as shown in Eq. (4) and Eq. (5) respectively:

- *Classification confidence*: The probability of object presence in an anchor-free paradigm is computed using a sigmoid activation in Eq. (4):

$$P(c|X) = \frac{1}{1+ e^{-z}} \tag{4}$$

where, z is the output of the classification branch before activation.

- *Bounding box regression*: The predicted bounding box coordinates (x, y, w, h) are obtained using Eq. (5):

$$\hat{x} = x_a + S_x\sigma(x) \tag{5}$$
$$\hat{y} = y_a + S_y\sigma(y)$$
$$\hat{w} = w_a e^{S_w\omega}$$
$$\hat{h} = h_a e^{S_h h}$$

where,

- $(x_a, y_a, w_a, h_a)$ are the anchor box parameters
- $\sigma(.)$ Is the sigmoid function ensuring localization stability.
- $s_x, s_y, s_w, s_h$ are scaling factors learned during training

The decoupling of classification and regression enables YOLOv8 to achieve higher precision and faster convergence compared to prior versions. Furthermore, YOLOv8 transitions to an anchor-free detection paradigm, eliminating the reliance on predefined anchor boxes that characterized earlier versions [23], [24]. This innovation streamlines the detection process, improves generalization, and reduces computational complexity, making it highly effective for parasite detection where object variability is high. The model further enhances performance through an advanced post-processing pipeline, incorporating adaptive non-maximum suppression (NMS) to minimize false positives while maintaining high recall rates.

Additionally, improved loss functions such as IoU Loss and Distribution Focal Loss (DFL) enable superior bounding box regression and confidence estimation. These advancements collectively yield a highly efficient model with reduced inference latency, making YOLOv8 particularly well-suited for real-time and resource-constrained applications in medical and biological imaging. By integrating these state-of-the-art improvements, YOLOv8 establishes itself as a robust framework for precision-driven detection tasks, offering superior speed and accuracy while preserving computational efficiency, making it an optimal choice for high-impact applications such as automated parasite detection [25].

To conclude this section, it is obvious to note that the mathematical formalization of YOLOv8's architectural components underscores its computational efficiency, multi-

scale feature aggregation, and enhanced detection accuracy. The CSPDarkNet backbone facilitates efficient feature extraction, the PAN neck strengthens multi-scale feature fusion, and the decoupled detection head optimizes classification and localization, collectively ensuring state-of-the-art performance in real-time object detection, including applications such as parasite detection in biomedical imaging.

*5) Hyperparameter tuning using Bayesian Optimization:* Bayesian Optimization (BO) has emerged as a superior hyperparameter tuning strategy for deep learning models, particularly in optimizing YOLOv8n for parasite detection, where achieving high precision with minimal computational overhead is critical. Unlike conventional grid search [26], which exhaustively evaluates all possible hyperparameter combinations, or random search [27], which blindly samples the search space, Bayesian Optimization constructs a probabilistic model of the objective function using Gaussian Processes (GPs) or Tree-structured Parzen Estimators (TPE). By iteratively refining this surrogate model and leveraging an acquisition function, such as Expected Improvement (EI), Upper Confidence Bound (UCB), or Probability of Improvement (PI)—Bayesian Optimization dynamically selects the most promising hyperparameter configurations, balancing exploration and exploitation [28].

This adaptive learning process significantly reduces the number of training iterations required to reach an optimal solution while ensuring improved detection performance. Additionally, Bayesian Optimization mitigates the inefficiencies of traditional methods by intelligently guiding the search space, preventing the combinatorial explosion characteristic of grid search and outperforming the stochastic nature of random search. This results in enhanced sample efficiency, faster convergence, and improved generalization capabilities of YOLOv8n in parasite detection tasks. By integrating Bayesian Optimization into the hyperparameter tuning process, the model achieves superior object detection accuracy with reduced computational costs, making it an ideal choice for real-time and resource-constrained applications in biomedical imaging and parasitology.

Hyperparameter optimization is a critical factor in enhancing the performance of deep learning models for parasite detection, particularly when leveraging Bayesian Optimization to refine the YOLOv8n architecture. By defining a well-structured search space, Bayesian Optimization efficiently navigates the trade-offs between convergence speed, generalization, and computational efficiency. Fig. 2 outlines the Bayesian-Optimized algorithm with YOLOv8n.

The initial learning rate (lr0), constrained within the range of 1e-4 to 1e-2 and sampled using a log-uniform prior, governs the magnitude of weight updates, ensuring a balance between rapid convergence and model stability. Momentum, ranging from 0.1 to 1.0, modulates the persistence of past gradients in stochastic gradient descent (SGD), mitigating oscillations and improving convergence stability, particularly in complex parasite detection tasks with highly variable morphological structures.

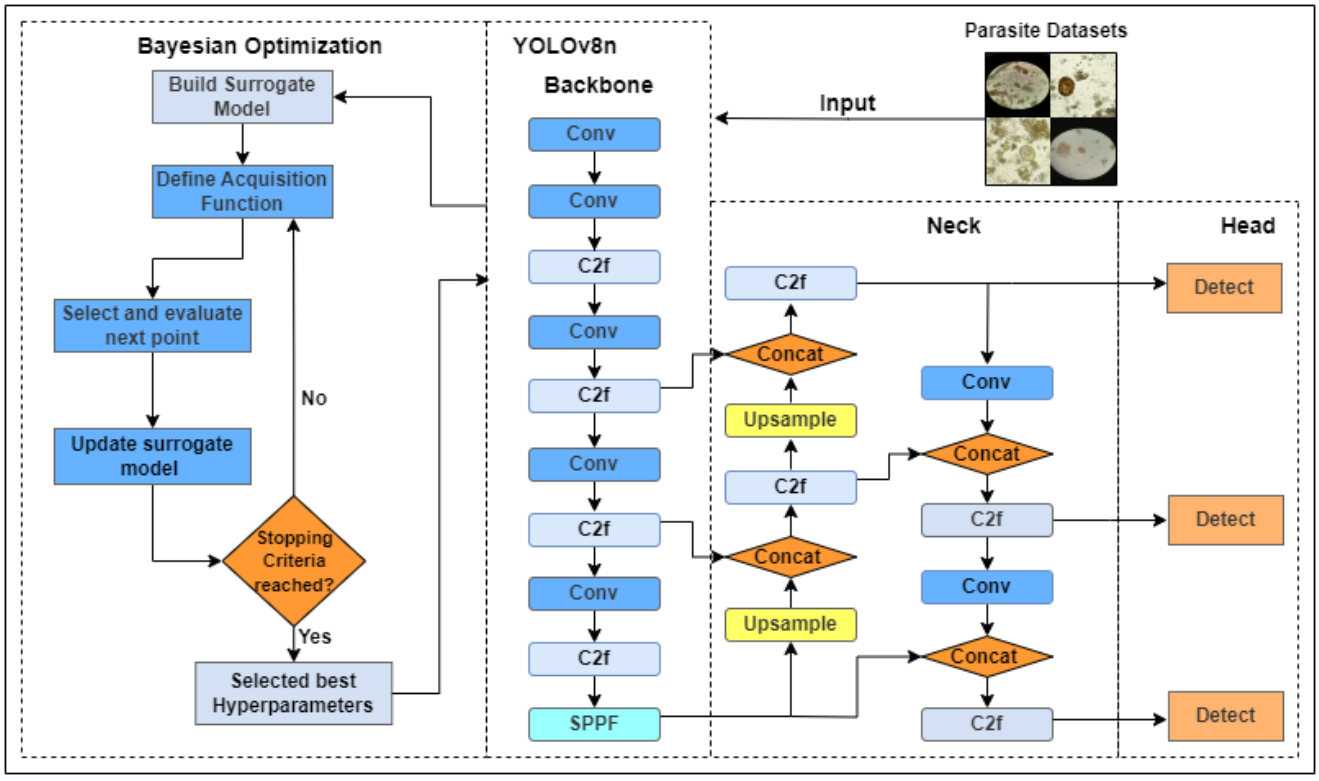

Fig. 2. Performance trends of Average Precision and Recall across varying IoU thresholds, highlighting the consistency and accuracy of detection models in intestinal parasite classification tasks.

The Weight decay (weight_decay), bounded between 0.0 and 0.0005, functions as an L2 regularization term, constraining excessive parameter growth to prevent overfitting and enhance model generalization on unseen parasitic instances. The batch size (batch), selected within the range of 4 to 32, directly impacts gradient estimation, where smaller batches offer improved generalization at the cost of higher variance, while larger batches provide smoother updates but demand greater computational resources.

Additionally, the number of training epochs (epochs), varying from 10 to 1000, determines the duration of model training, requiring careful optimization to balance learning progression with computational efficiency, thereby avoiding underfitting or excessive overfitting. By leveraging Bayesian Optimization to systematically explore these hyperparameters, YOLOv8n achieves superior detection accuracy while minimizing computational overhead, ensuring robust performance in real-time parasite detection applications.

This intelligent search process dynamically adapts hyperparameter selection based on model performance metrics such as mean Average Precision (mAP) and Intersection over Union (IoU), ultimately facilitating a highly efficient and precise detection framework tailored for biomedical imaging and parasitology research. Table I summarizes the hyperparameter ranges.

The proposed architecture for the Bayesian-Optimized YOLOv8n model is summarized in Table II and the proposed algorithm is presented in Fig. 3.

TABLE I. RANGES FOR HYPERPARAMETER TUNING

| Hyperparameter | Abbreviation | Range |
|---|---|---|
| Learning rate | lr0 | (1e-4, 1e-2) |
| Momentum | Momentum | (0.1, 1.0) |
| Weight decay | weight_decay | (0.0, 0.0005) |

### *C. Evaluation Metrics*

The models were evaluated using the following metrics:

Average Precision (AP) at varying IoU thresholds (0.50:0.95). Measures the area under the precision-recall curve, indicating the model's accuracy in detecting objects at varying IoU thresholds as depicted in Eq. (6).

$$\text{mAP} = \frac{1}{n}\sum_{i=1}^{n} AP_i \quad (6)$$

where, AP is Average precision for class *i and*

*n* is the number of IoU thresholds evaluated (e.g., IoU = 0.5, 0.55, ..., 0.95 in 0.05 increments).

Average Recall (AR) across IoU thresholds. Represents the average recall across all IoU thresholds, reflecting the model's ability to detect true positive objects consistently as presented in Eq. (7).

$$\text{mAR} = \frac{1}{n}\sum_{k=1}^{n} AR_k \quad (7)$$

where, $R_k$ is the recall at the *k*-th IoU threshold and *n* is the number of IoU thresholds considered.

## IV. Results and Discussion

This section provides a comprehensive analysis of the performance of different object detection architectures evaluated in this study. The assessment focuses on key performance metrics, including Average Precision (AP) and Average Recall (AR) at different Intersection over Union (IoU) thresholds. By comparing the effectiveness of various detection architectures, this section highlights their respective strengths and limitations in detecting *Ascaris lumbricoides* and *Trichuris trichiura*, ultimately informing the selection of robust and scalable diagnostic models.

### A. Performance of Faster R-CNN with ResNet Backbone

The Faster R-CNN with ResNet-50 and Feature Pyramid Network (FPN) demonstrated competitive performance, achieving an AP of 85.8% at IoU 0.50:0.95, with a significant increase to 99.6% at IoU 0.50. The model maintained a relatively high AR of 99.6%, indicating strong recall capabilities in detecting true positive instances. However, a noticeable limitation was observed at stricter IoU thresholds, where precision declined, suggesting potential difficulties in accurately localizing objects at higher overlap requirements. This behaviour aligns with previous findings [29], where ResNet-based architectures prioritize robust feature extraction but may struggle in fine-grained localization due to their fixed receptive fields.

The ResNet-101 FPN variant exhibited slightly lower precision compared to ResNet-50, with an AP of 85.5% at IoU 0.50:0.95. Although it maintained a stable AR of 88.9%, it did not provide significant improvements over its shallower counterpart. The marginal performance difference suggests that deeper feature hierarchies introduced by ResNet-101 did not contribute meaningfully to detection accuracy, likely due to diminishing returns in feature extraction depth.

### B. Performance Faster R-CNN with ResNeXt Backbone

The ResNeXt-50 backbone offered a moderate improvement over ResNet-based architectures, achieving AP 87.4% at IoU 0.50:0.95, with slightly lower AP values than RetinaNet but outperforming ResNet-50 and ResNet-101. The model maintained an AR of 99.1%, indicating that it effectively captures diverse object instances, leading to a high detection recall. The grouped convolutions in ResNeXt likely contributed to enhanced feature aggregation and spatial sensitivity, allowing the model to detect a broader range of object scales with better contextual understanding. While ResNeXt's performance suggests an improvement in multi-scale feature representation, the relatively small AP gain over ResNet-50 indicates that for this specific detection task, its additional computational complexity does not necessarily translate into a proportionate improvement in detection accuracy.

### C. Influence of RetinaNet as a Backbone for Faster R-CNN

The integration of RetinaNet as a backbone for Faster R- CNN led to substantial improvements in detection performance, achieving an AP of 91.1% at IoU 0.50:0.95 and reaching 99.9% AP at both IoU 0.50 and 0.75. The model consistently maintained a high AR of 93.8%, demonstrating exceptional reliability in detecting positive instances across varying IoU thresholds. The superior performance can be attributed to RetinaNet's balanced handling of foreground and background samples, as its Focal Loss formulation effectively mitigates the imbalance between easily detected and hard-to-detect instances.

The marked increase in AP and AR values indicates that incorporating RetinaNet as a feature extractor enhances feature refinement and region proposal quality, leading to higher detection confidence and better localization accuracy. This underscores RetinaNet's superior feature representation capabilities, particularly in challenging detection tasks involving subtle object variations or occlusions.

### D. Comparative Analysis (Two-stage Architecture)

A comparative overview of the evaluated Faster R-CNN models is provided in Table III, summarizing their AP and AR scores at varying IoU thresholds:

TABLE III. Average Precision (AP) over Different Threshold

| Baseline FRCNN at different Threshold (IoU) | | | | |
|---|---|---|---|---|
| **Models** | **AP** | **AR** | **AP @ 50** | **AP @ 50 -95** |
| F-RCNN + ResNet_50_FPN | 0.858 | 0.996 | 0.996 | 0.858 |
| F-RCNN + ResNet_101_FPN | 0.855 | 0.889 | 0.889 | 0.855 |
| F-RCNN + ResNeXt-50 | 0.874 | 0.991 | 0.991 | 0.874 |
| F-RCNN + RetinaNet | **0.911** | **0.938** | **0.999** | **0.911** |

From the results, Faster R-CNN with RetinaNet emerges as the most effective architecture, offering the highest AP (91.1%) and AR (93.8%) across varying IoU thresholds. This suggests that RetinaNet's enhanced feature refinement and balanced detection capability make it well-suited for the accurate identification of *Ascaris lumbricoides* and *Trichuris trichiura*.

In contrast, ResNet-50 and ResNet-101 demonstrated similar performance, with ResNeXt offering a slight improvement over ResNet-based variants but falling short of RetinaNet's superior AP and AR scores. While ResNeXt enhances feature learning through grouped convolutions, its computational trade-offs may not justify its minor accuracy gains.

### E. Performance of Single-Stage YOLOv8 Architectures

In contrast to the two-stage Faster R-CNN models, single-stage architectures such as YOLOv8 offer a streamlined detection pipeline, eliminating the region proposal step and directly predicting object locations and classifications in a single forward pass. This approach is particularly advantageous for real-time applications where inference speed is critical, such as in automated parasitic detection in medical diagnostics.

The performance of YOLOv8 models was assessed across five different variants, ranging from the smallest YOLOv8n (nano) to the largest YOLOv8x (extra-large), with results presented in Table IV. Among the YOLOv8 variants, YOLOv8n (nano) achieved the highest overall precision, with an AP@50-95 of 93.8%, marginally surpassing YOLOv8x (extra-large) and YOLOv8m (medium), which also scored 93.8%. The YOLOv8l (large) and YOLOv8s (small) models exhibited slightly lower mAP@50-95 (93.6%), indicating that model scaling has

minimal impact on detection accuracy at standard IoU thresholds. Notably, YOLOv8n (nano) achieved the highest recall (mAR = 99.5%), outperforming its larger counterparts. This suggests that even with a reduced parameter count, YOLOv8n maintains strong object detection capabilities, making it an efficient choice for resource-constrained environments. Table IV summarized the results.

TABLE IV. ACCURACY-PERFORMANCE TRADE-OFFS ACROSS YOLOV8 VARIANTS

| Baseline YOLOv8 at different Threshold (IoU) | | | | |
|---|---|---|---|---|
| **Models** | **AP** | **AR** | **AP *@50*** | **mAP @ 50 - 95** |
| YOLOv8x | 0.964 | 0.990 | 0.993 | 0.949 |
| YOLOv8l | 0.976 | 0.982 | 0.993 | 0.936 |
| YOLOv8m | 0.993 | 0.986 | 0.995 | 0.938 |
| YOLOv8s | 0.982 | 0.990 | 0.991 | 0.936 |
| **YOLOv8n** | **0.994** | **0.995** | **0.994** | **0.938** |

Despite being the most computationally intensive model, YOLOv8x did not yield a significant accuracy advantage, achieving a mAP@50-95 of 94.9%, only slightly higher than its smaller counterparts. In contrast, YOLOv8n (nano) emerged as a highly competitive alternative, offering comparable accuracy while delivering superior inference efficiency. This makes YOLOv8n particularly well-suited for embedded medical imaging systems and real-time diagnostic applications, where computational efficiency is paramount.

### *F. Performance Analysis of Optimized YOLOv8n Model*

To further enhance the detection accuracy and efficiency of YOLOv8n, Bayesian Optimization was employed to determine the optimal hyperparameter configuration. This optimization approach efficiently explores the hyperparameter space, balancing the trade-offs between accuracy and computational cost. The key hyperparameters tuned and their respective search ranges are presented in Table II.

The optimized YOLOv8n model achieved an AP of 0.996 and an AR of 0.997, demonstrating near-perfect object detection capability. The exceptionally high recall (0.997) ensures that nearly all instances of *Ascaris lumbricoides* and *Trichuris trichiura* are accurately identified, significantly reducing false negatives and enhancing detection reliability. Compared to the baseline YOLOv8n (AP@50-95 = 0.938), the optimized model achieved an improved AP@50-95 of 0.947, reflecting greater accuracy across varying IoU thresholds. Additionally, AP@50 remained consistently high at 0.995, confirming that the model maintains robust detection performance even under more lenient overlap conditions.

The Bayesian-Optimized training configuration enhanced accuracy without imposing significant computational overhead, making it an ideal choice for real-time diagnostic applications. The fine-tuned learning rate, momentum, and weight decay likely contributed to improved convergence and reduced overfitting, ensuring greater generalizability across diverse detection scenarios. Fig. 4 depicts the training and validation metrics of the optimized model.

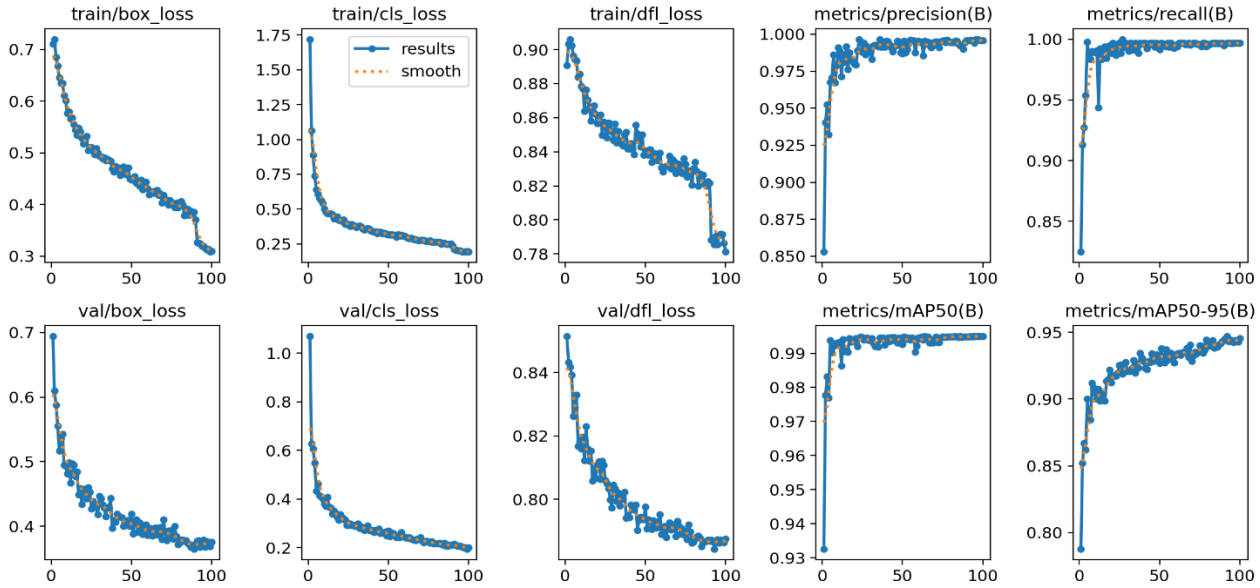

Fig. 4. Training and Validation metrics for optimized YOLOv8n model.

The qualitative detection results in Fig. 5 showcase the model's ability to accurately localize and classify parasite eggs in microscopy images, with predicted bounding boxes and confidence scores reflecting high detection reliability. The Precision-Recall Curve in Fig. 6 further validates the model's robustness, achieving a mean average precision (mAP@0.5) of 0.995 for both *Ascaris lumbricoides* and *Trichuris trichiura*, highlighting its near-perfect classification capability. The F1-Confidence Curve in Fig. 7, demonstrates the model's optimal F1 score of 1.00 at a confidence threshold of 0.740, indicating a well-calibrated balance between precision and recall. These findings underscore the model's efficacy in automated parasite detection, with significant potential for deployment in diagnostic and epidemiological applications.

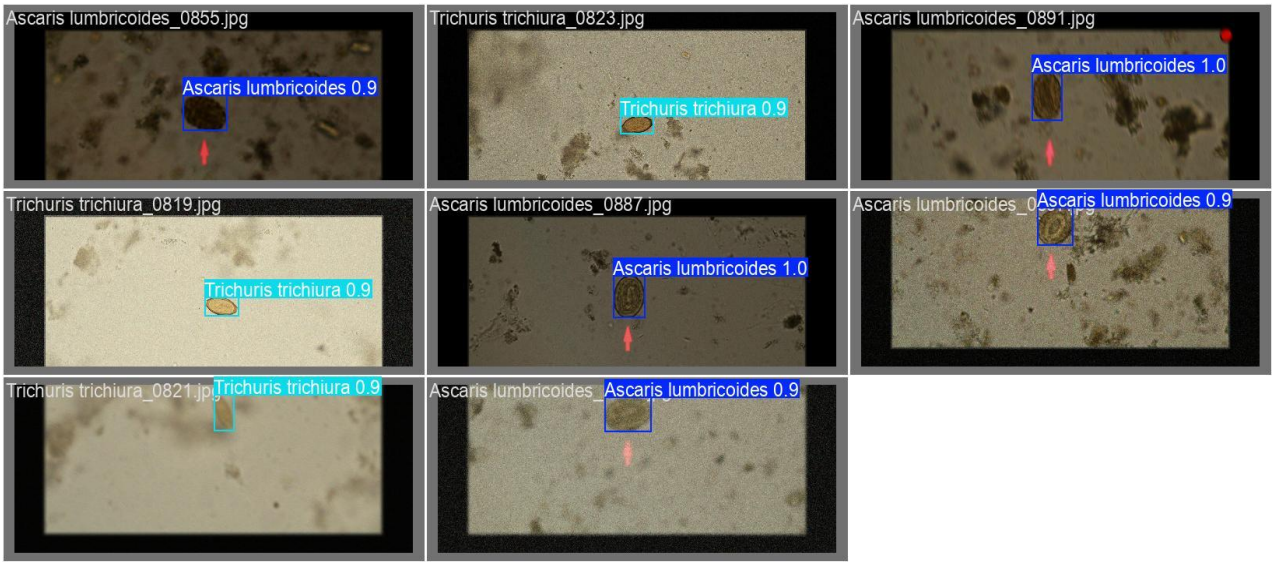

Fig. 5. Detection results of parasite eggs using optimized YOLOv8n: predicted bounding boxes with confidence scores.

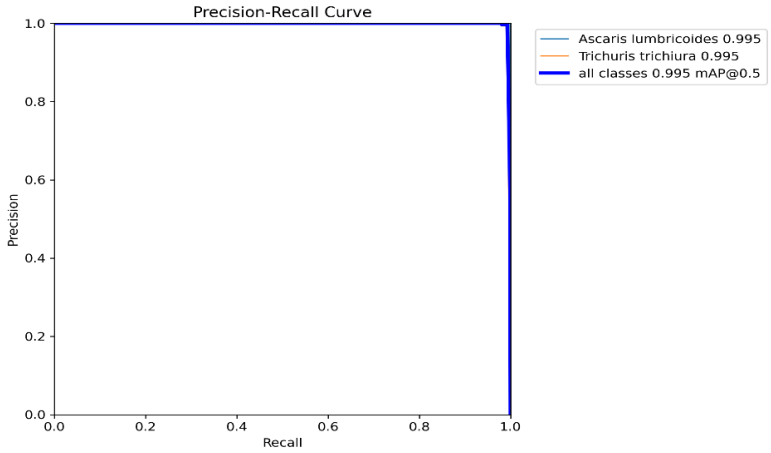

Fig. 6. Precision-Recall Curve for parasite detection: achieving 0.995 mAP@0.5 for all classes.

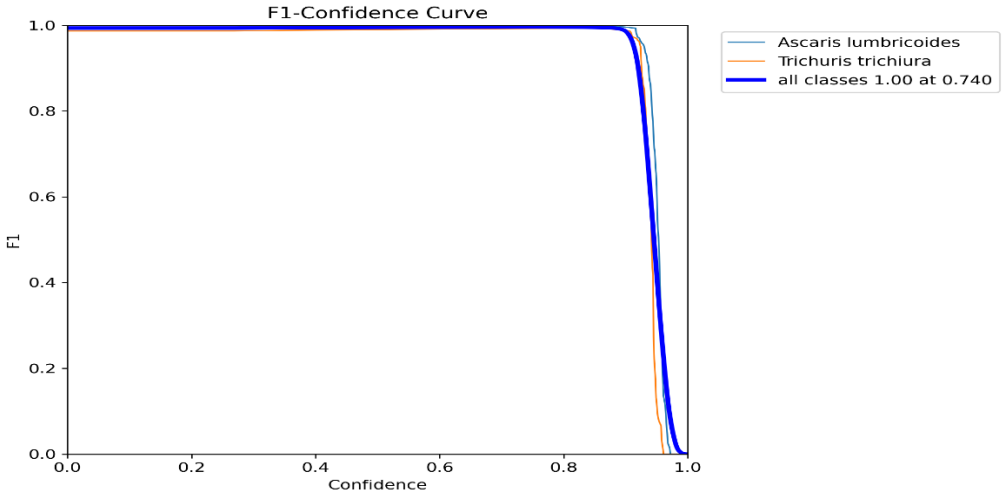

Fig. 7. F1-Confidence Curve for parasite detection: Optimal F1 score of 1.00 at 0.740 confidence threshold.

The optimized YOLOv8n achieved exceptional precision and recall, with results summarized in Table V.

TABLE V. AVERAGE PRECISION (AP) OVER DIFFERENT THRESHOLD

| Baselines with Optimized YOLOv8n at different Threshold (IoU) | | | | |
|---|---|---|---|---|
| **Models** | **AP** | **AR** | **AP *@50*** | **AP @ 50 - 95** |
| F-RCNN + RetinaNet | 0.911 | 0.999 | 0.999 | 0.911 |
| Baseline YOLOv8n | 0.994 | 0.995 | 0.994 | 0.938 |
| **Optimized YOLOv8n** | **0.996** | **0.997** | **0.995** | **0.947** |

The Bayesian-Optimized YOLOv8n demonstrates superior accuracy and efficiency, making it a powerful and practical model for real-time medical diagnostics. Compared to FRCNN with RetinaNet backbone and YOLO counterpart, including the larger YOLOv8 models, it delivers state-of-the-art precision (AP = 0.996) and recall (AR = 0.997) while maintaining its lightweight structure. This highlights the critical role of hyperparameter tuning in enhancing deep learning models for high-stakes applications such as parasitic infection detection. The following graph in Fig. 8 visualizes the trends of mean average precision for the different higher-performing models.

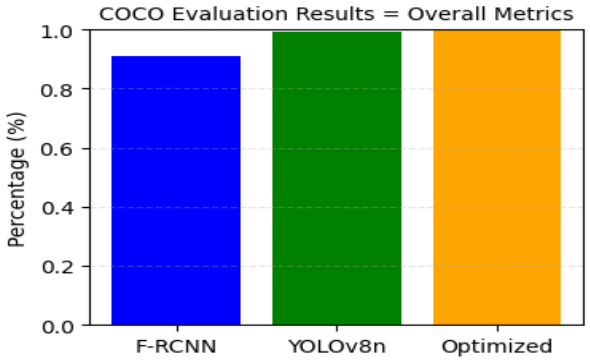

Fig. 8. Performance comparison of detection models (Faster R-CNN with RetinaNet, YOLOv8n and Optimized YOLOv8n) highlighting differences in average precision for intestinal parasite detection.

## V. CONCLUSION

This study underscores the significant potential of advanced object detection models in automating intestinal parasite detection. The evaluation of various detection models highlights the optimized YOLOv8n as the best-performing model, achieving the highest AP (0.996), AR (0.997), and AP@50-95 (0.947). Compared to the baseline YOLOv8n, the optimized version demonstrates superior precision and recall, ensuring more accurate and reliable detection across varying IoU thresholds. Furthermore, it outperforms the Faster R-CNN with RetinaNet, which, despite maintaining high recall (0.999), lags in overall precision (AP@50-95 = 0.911).

The Bayesian-Optimized YOLOv8n strikes an optimal balance between detection accuracy and computational efficiency, making it the ideal choice for real-time, high-precision medical diagnostics. Its lightweight architecture, coupled with enhanced performance, positions it as the most viable model for scalable and resource-efficient deployment in automated parasitic detection systems.

Future research can explore transformer-based enhancements like Swin Transformer to improve feature representation and localization. Self-supervised learning and domain adaptation could further refine performance in real-world clinical settings. Additionally, optimizing the model for edge AI and mobile deployment will enhance scalability for global healthcare applications.

***Abstract*—Floods are chaotic weather patterns that cause irreversible and devastating harm to people's lives, crops, and the socioeconomic system. It causes extensive property damage, animal mortality, and even human fatalities. To mitigate the risk of flooding, it is imperative to create an early warning system that can accurately forecast the amount of rain that will fall tomorrow. Rainfall forecasting is essential to the lives of people and is absolutely important everywhere in the world. The rainfall prediction model reduces risk and helps to prevent further human deaths. Statistics cannot reliably forecast rainfall since the atmosphere is dynamic. Due to the preceding factors, this study uses machine learning and deep learning techniques to estimate precipitation. The purpose of this study is to develop and evaluate a prediction model for forecasting rainfall of 5 cities of Australia (Darwin, Sydney, Perth airport, Melbourne, Brisbane). The Dataset was gathered from the national meteorological organization of Australia is the Australian Government Bureau of Meteorology, also known as the BOM. To monitor and forecast meteorological conditions, climatic trends, and natural calamities like cyclones, storms, floods, the Bureau of Meteorology is essential. The dataset includes 14, 5460 size, 23 features detailed city-specific monthly averages for Australia from 2008 to 2017(10 years). An effective rainfall forecasting was produced by integration of a number of Machine Learning and Deep Learning techniques, including Random Forest model (RF), Decision Tree (DT) and Gradient Boosting classifier (GBC), Artificial Neural Network (ANN), and Recurrent Neural Network (RNN). The models were trained to forecast rainfall, reducing the potential impact of floods. Results indicate that combining neural networks and Random Forests provides the most accurate predictions.**

## I. Introduction

Natural disasters including floods, hurricanes, and earthquakes are becoming more frequent and intense due to environmental changes such as deforestation, urbanization, and climate change. Floods pose serious threats to lives, agriculture, and economies, usually it results from heavy rainfall and poor drainage system in the some of the regions. Given the growing impact of extreme weather, this study compares three LSTM-based neural network architectures to identify the most suitable model for forecasting hourly rainfall volumes. The leading purpose of such study is to use deep learning algorithms in developing flood prediction models based on meteorological data [1]–[3]. Publics and governments may be enabled to both prevent the flood occurrence with immediate and long term actions and prepare for evacuation and rescue operations with the help of the early warning in advance.The studies were conducted using data from crowdsourcing, geospatial, hydrological, and meteorological sources. In this study [4]–[6], successfully machine learning is used to build a rain forecast model. This work [7] focuses on the machine learning (ML) methods of prediction for six selected stations per semi-annual cycle in Bangladesh in order to create a new achieving format of the monthly dry days (MDD). Through the use of machine learning approaches, the study analyzes the unanticipated effects of flood protection in Bangladesh [8].The main contribution of this research [9] is to determine the state-of-the-art machine learning methods for flood prediction together with the significant parameters that were fed into the model. This will make it possible for flood management and/or researchers to compare the prediction findings to one another when assessing machine learning techniques for early flood forecasting. The study investigated the possibility of developing a probabilistic forecasting model through the employment of various machine learning techniques, including the k nearest neighbors (also called KNN)method, the fuzzy inferential model (FIM), and the support vector regression methodology (SVR). Modeling of flood conditions is a difficult task that requires an in-depth analysis of the situations that affect flooding. This study proposes an Internet of Things based flood state prediction (IOT-FSP) model to assist river flooding conditions forecast [10]–[18].

This study explores the use of machine learning (ML) and deep learning (DL) techniques to improve rainfall forecast accuracy. Grey Relation Analysis (GRA) is used to identify influential factors, while Support Vector Machines (SVM) and

Artificial Neural Networks (ANN) are applied for prediction. Specifically, a model combining Feed Forward Neural Networks, the Levenberg-Marquardt algorithm, and backpropagation is used to forecast monthly and bi-monthly rainfall in Northern India. Performance is evaluated using MSE, MRE, and regression analysis. The research not only aims to enhance prediction but also supports disaster preparedness and response planning.

### A. Purpose of the Study / Research Questions

The following are the research primary goals:

- Feature cleaning and visual representation for datasets features
- Univariate and multivariate analysis of datasets with regard to several features.
- Several models of machine learning have been experimented and have shown their accuracy in forecasting Rainfall.
- Validating deep learning's efficacy in precipitation prediction.
- Comparative analysis for different algorithms for accuracy and error for Rainfall prediction.
- In order to classify the objects with extreme speed and accuracy, the architecture of the LSTM-Deep learning network was developed.
- An extended experiment was conducted to provide a detailed examination of the proposed model.

Rainfall prediction in Australia is challenging due to regional differences, monsoon dynamics, and climate change. This study investigates five ML and DL models to improve forecasting accuracy by identifying key atmospheric variables and evaluating seasonal rainfall severity over the past decade. The study aims to (1) support early warning systems with relevant statistics, (2) provide metrics for policymaking related to rainfall management, soil degradation, and drought, and (3) enhance climate models by deepening the understanding of factors influencing weather patterns.

### B. Justification for Model Selection

In this study, we selected advanced machine learning (ML) and deep learning (DL) models such as LSTM, CNN, and SVR due to their proven ability to capture nonlinear patterns in time-series data. LSTM networks, in particular, are well-suited for sequential data such as rainfall records because they can retain long-term dependencies, which are essential for understanding delayed rainfall effects due to climate shifts. CNNs, though originally developed for spatial features, have recently shown promise in extracting local patterns in time-series signals, making them a good fit for rainfall fluctuations. Meanwhile, SVR provides a robust baseline with good generalization ability, especially in high-dimensional meteorological datasets.

Traditional statistical models, such as ARIMA or linear regression, often assume linearity and stationarity, which are major limitations when applied to rainfall data that exhibit strong temporal variability and noise. These models also struggle with multi-feature dependencies and are less adaptive to changing climate patterns. Furthermore, simpler ML models like decision trees may lack the depth required to model complex seasonal transitions or capture hidden trends across time steps, leading to reduced prediction accuracy.

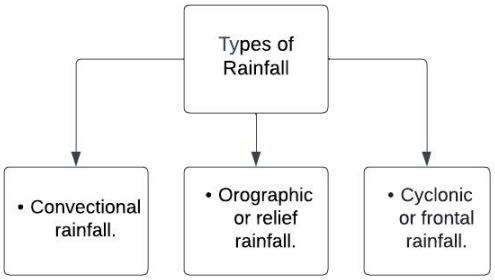

Fig. 1. Types of rainfall.

The other part of the research is organized as follows: On the other side, the theoretical context, comparative analysis, the data set and Australia Location utilized in study, and experimental methods are all presented. Following the Machine learning and Deep learning algorithms designing, which are the main part of the early rainfall prediction of the dataset based on accuracy and other measures like F1 score, accuracy, and recall, is the Results and discussion section of work, the Last section Summary and future research is a conclusion part.

## II. Related Work

### A. Types of Rainfall

Rainfall can be classified into various types based on different criteria such as duration, intensity, spatial distribution, and the mechanisms responsible for its occurrence. Here are some common types of rainfall in Fig. 1.

*1) Convectional rainfall:* As the Earth's surface warms, air rises, resulting in convectional rainfall. As it increases, the air cools and releases moisture as rain. In regions with high temperatures and high humidity, convectional rainfall is frequent, frequently occurring in tropical climates in the late afternoon or evening [19], [20].

*2) Orographic rainfall:* Orographic rainfall is the result of moist air being lifted as it is pushed over high ground, such as mountains or hills. On the mountain's windward side, moisture and precipitation result from the rising, cooling air. Due to descending dry air, the leeward side gets a rain shadow effect, which reduces rainfall [21].

*3) Cyclonic rainfall:* Rainfall associated with cyclones or low-pressure systems is referred to as cyclonic rainfall. It is characterized by persistent, widespread rain that is frequently accompanied by high winds. Forecasting weather, preparing for disasters, and managing water resources all depend on an understanding of cyclonic rainfall patterns [20].

### B. Effects of Rainfall

The understanding of rainfall effects is of great importance for several businesses, p.e. agriculture, water resources man-

agement, disaster preparedness, and climate research. For sustainable growth and risk reduction related to extreme weather events, monitoring rainfall patterns and managing its effects are essential. Here are some notable effects of rainfall, Water Supply [22], Agriculture, Moisture in the Soil and The process of erosion, Flood [4], [9], [10], [23]–[26], Hydroelectric Power Generation, Weather and Climate Patterns [2], [27].

### C. Motivation and Impact of Flood Events

Existing flood prediction models rely on complex statistical computations that are either very costly financially and computationally or aren't applicable to applications in the future. To circumvent these issues, approaches that mix time-series data with machine learning algorithms are being researched. For various downstream applications, it is necessary to compare the efficiency of deep learning architectures and conventional machine learning methods.

Here the rainfall is estimated by using a simplified model [28]. It is Southern India, Kerala that faced the flood of the century. Often, it also means a huge loss of peoples' lives and properties. This consequently prompted us to investigate the variations in the rainfall pattern of Kerala. In Bangladesh, floods kill people, destroy household properties, crops and means of livelihood of the masses constantly. Flooding is caused by lakes, rivers and other water bodies discharging water and incorporating adjacent land into the flooded region. Every year, flooding becomes the worst enemy for more than 4. In India have the 3. 84 crores people. 84 million in the case of Bangladesh and the rest in 3. 29 million in China has realized that [1].The recent event which took place in Kerala in August 2018 is one of the most remarkable incidents followed by massive floods in India , which is currently considered as one of the most affected nations with respect to catastrophic floods across the globe.

### D. Machine Learning Applications in Flood Forecasting

Much has been said in past times on Flood probability, which can be done through IoT and ML based on rainfall, humidity, water temperature, water velocity, and other variables. There are some limitations in the research since we have not tried to establish the probability range for flood based on the levels of temperature and rain intensity. Scientific communities all over the globe are interested in developing flood forecasting methods. Thus, there is a demand for flood forecasting that must be high-quality and reliable so that those living near the flooded areas can have the warning signs that they need to evacuate. Thus, a 5-hours flood simulation of rainfall area for Kuala Lumpur city in this study was provided using neural network's Autoregressive Structure with Extended Input (NNARX) and its Enhanced Modeling. This work [29] combines ML technology with established ones to generate models that have more prediction yield than other existing models. The main value of this study is in the fact that it highlights the current trend of using ML models for flood prediction as well as giving suggestions of the best kinds of models to use. This analysis is mainly focused on the empirical research of ML approaches in the area where the models have been evaluated for robustness, accuracy, utility, and speed.

### E. Model Evaluation, Datasets, and Techniques

To make the research more detailed and accurate, the area of interest is divided into grids delimited by latitude and longitude, with precipitation and flow readings merged into vector organizations based on coordinates. The input property consists of a two-dimensional timeline containing spatial information instead of a one-dimensional timeline. The first step which is the focus to extracting spatial and temporal components of hydrological information is comprised of.In particular the author introduces the convolutional LSTM (Con LSTM), which combines the Convolutional Neural Network (CNN) and Long Short Term Memory Network (LSMN) to boost performance. The aim of this work is to design a flood prediction system which can be used as an advantageous instrument for urban administration and resilience management through an integration of machine learning algorithms and GIS techniques [30]. This method will lead to development of long-term strategic policies for the growth of smart cities that will be workable and suitable flood indicators at the level of the municipality. At the Random Forest algorithm with the accuracy 0% . 0.96, and a Pearson's (or linear) coefficient of 0. 77 was an excellent choice as the input layer or the hidden layer of machine learning as it can identify errors. This requires summarizing different past research studies that examine the ML techniques for flood forecasting and the characteristics which are used for the forecast. Goal of the research is to find flood forecasting approaches which mainly involve ML techniques and to determine flood prediction parameters that have been used as input parameters to the models for forecasted flooding in order to achieve that. The most valuable aspect of this work is the list of critical variables and recent ML methods employed for flood prediction. They may be able to then both carry out short- and long-term preventive measures, be proactive and rescue people and provide relief for flood victims, with the help of an early warning of a flood disaster [31]. For example, one of the main factors in most flood management is the geographic location of the affected areas and their respective severity.

### F. Recent Developments and Future Directions

Floods cannot yet be reliably predicted in advance with the help of any approach. Data that was prepared and manually entered was typically used by earlier technologies. It was not possible to make early and real-time estimates due to the lengthy processes. In order to forecast flood events in particular regions and time periods, this research proposes a novel approach to flood forecasting that integrates meteorological, hydrological, spatial data, and big data from crowdsourcing sources. System that takes into account both historical data and climatic conditions produced the most precise estimation by the setup using an MLP ANN for the Correct proportions, Kappa, MAE, and RMSE 97%. 0. 89, 0. 93, 0., and 0. 10, respectively. In this [32] research cutting-edge operating methods have been investigated. The current move towards data-driven strategies for flood prediction is something that the writers see and discuss. Forecasting tasks are becoming more and more relevant for machine learning-based models that were trained using historical data for climatic parameters.

The main objective of this work is to demonstrate recent advances in machine learning-based flood forecasting. To

develop their conclusions, the authors looked at various widely used flood prediction techniques that different specialists might use. In study [23] create a probabilistic forecasting model, this study used a variety of machine learning techniques, such as k nearest neighbors (KNN), fuzzy inference models (FIM), and support vector regression (SVR).In order to lessen the harm caused by flooding, an examination of the utilization of information gleaned from urban rivers to forecast floods is done in this work [24]. The Artificial Neural Networks were examined to determine their level of accuracy in the forecasting models after the immersion theorem had proven the interdependence of the data. Whenever there have been significant flooding-related difficulties, WSNs have been installed. The study's methodology [33] may help improve the early warning systems that are in place now and generate risk-based development plans. Uncertainties in machine learning-based geospatial algorithms for flood prediction are resolved using a unique method. This paper proposes a method for decreasing regional disparity along with four distinct and hybridized ML based flood susceptibility models (the FSMs). In order to forecast and identify the flooding sites or flood sensitive zones in the Teesta River a basin, this study [4] applied cutting-edge revolutionary ensemble machine learning algorithms. The purpose of the work being done is to construct a rain prediction model using the successful machine learning Random Forest [5]. The goal of this study [6] is to reduce the significant hazards associated with this natural disaster while also making recommendations for policy. To generate an accurate forecast, this study will make use of a Decision Tree classification technique, K Nearest neighbor(KNN), a Support Vector Classifier(SVC), and Binary Logistic Regression(BLR).The findings will be compared to identify the model with the highest level of accuracy. In this study [34], the author used the k-nearest neighbor's algorithm to predict a flood using various correlation coefficients for feature selection. It is well-known that estimating flood risk and making informed decisions [35] depend greatly on quantifying and reducing the uncertainty related to the hydrologic forecast. This article provides a thorough analysis of Bayesian forecasting techniques used in flood forecasting. In this research, 180 independent models based on five diverse machine learning algorithms that include the exponential back propagation neural network('EBPNN'), multilayer perceptron(MLP), support vector regression(SVR), Decision Tree regression(DT Regression) and extreme gradient boosting(XG-Boost), were developed. The "Someshwari Kangsa" sub-watershed of the Bangladeshi arterial north-central hydrological zone containing an area of 5772 square kilometers was used by models. Indeed, it is a difficult task to make a forecast on the upcoming rain by means of classic machine learning algorithms. Besides that, various attempts have been also made by employing different computer techniques to forecast rainfall. To build the long term memory rainfall module of Bangladesh, this article applies the technique of the feedforward architecture driven long short term memory (LSTM) networks that gets rid of the chaos related problems of the different methods. In Bangladesh, this work proposes a novel approach to forecasting monthly dry days (MDD) at six specified recourse stations and then examining the outcomes of the models. The MDD and MWD datasets in terms of monthly dry and wet days, respectively, were done using different rainfall thresholds. This research, although suggested by simply posing the question of 'what will be the consequences of flood mitigation methods in Bangladesh in the long-run' [8] is highly recommended. Data from the historical events (represented by the emigrations and mortality rates) and economic surveys accumulated from 1983 to 2014. The primary objective in this study [36] is the significance of being responsible for and taking care of disasters which humans bring on themselves. Technology that is now in use, software Artificial (AI) can be used for these tasks. Review work and comparison of different approaches and algorithms used by researchers to estimate rainfall are presented in tabular form [37]. Making methods and procedures used in rainfall forecasting understandable to non-experts is the aim of this endeavor. One notable illustration of how India is currently among the nations in the world that have experienced the most severe flooding is the most recent disaster that occurred in Kerala in August 2018. Much work has been done in the past to use Internet of Things, or IoT, and ML (machine learning) approaches to assess the likelihood of flooding based on rainfall, humidity, water temperature, water velocity, and other characteristics. The prime output of this study is to review the ML models used for flood forecasting as current models and give advice on how to choose the best models. India [27] is in more danger for floods that cause grave losses now; last August extreme floods happened in Kerala and it illustrates the disasters from this catastrophe. The problem is that the flood frequency model is based solely on historical data from the past – number of rainfall events and their water temperature. The neural network has been employed that is Deep Learning to calculate probabilities of flooding considering temperature and rainfall intensity. Consequently, with the flooding having taken over as one of the most well-known subjects of research in hydrology, flood prediction has become one of the principal areas of focus of hydrologists. The issue has been addressed by a lot of researchers with different methods, starting from image processing to physical models, still, are not at the level that can accommodate all applications due to imprecision and insufficient time steps. It studies deep learning methods in gauge height prediction, and also the error in gauge height prediction is assessed. For constructing and verifying the model, the measured height data from Valley Park, Missouri's Meramec River was implemented. According to an analysis based on previous research articles, this study looks at whether the present machine learning (ML) algorithms for flood forecasting are effective given the variables that are used to predict floods. The manifold model is represented here [38] as a machine learning substitute to hydraulic modeling of flood waters. All model achieves performance standards that are tuned to operational use, provided historical data has been used as a benchmark. The article proposes a system that predicts possible floods in a river basin using machine learning and the Internet of Things (IoT) for the research [25].The model connects the Wireless Sensor Network, or WSN, to a personalized mesh network via a ZigBee connection, and it then uses a GPRS module to transmit data over the internet.For predicting the occurrence floods occurrences in the Pattani River, this work [26] examines applying possible machine learning algorithms using open data. This study [23] employed a combination of machine learning tools, such as support vector regression (SVR), fuzzy inference model (FIM), and the k-nearest neighbors (k-NN) method in order to develop a probabilistic forecasting model. This study takes a probabilistic forecasting model with the help of a number of machine learning approaches, including SVR model (a support vector regres-

sion model), fuzzy inferential models (FIM), and the KNN technique (the K nearest neighbors technique). In total, three multi criteria decision making evaluation approaches, namely VIKOR, SAW, and TOPSIS, along with two machine learning methods, NB and NBT, were utilized to assess their ability to simulate flood vulnerability in the Ningdu Catchment[Complex Flow of Words] which is one of China's most flood-prone regions [39]. Two techniques, Extensive gradient boosting This experiment is based on the Deep Belief Network (DBN) for forecasting the Daya and Bhargavi river banks, which flow towards the Indian state of Odisha. A comparison study that is based on other machine learning methods helps to demonstrate the beneficial impacts of dams in detail. This study [40] focuses on the application of ant colony optimization (ACO), Genetic algorithms (GA), artificial neural networks (ANN), and Particle swarm optimization (PSO) approaches to flood hydrograph prediction. In the current study [41], the relative accuracy of the RB FNN, SVM, and Firefly Algorithm (FA) models compared to the regular ANN, RB FNN, and SVM algorithms for river flood discharge forecasting in the Barak River was examined. Urban flooding is becoming increasingly common [42], which is detrimental to both the economy and quality of life for people. However, the existing flood prediction algorithms have grown too primitive or insufficient to accurately capture the details of flood evolution.This study uses deep neural networks to quicken the computation of a physics-based 2D urban flood forecasting approach that uses the Shallow Water Equation (SWE). Using data modeled by the use of a partial differential equation (PDE) solver, convolution neural networks (CNN) and generative adversarial networks with conditions (CGANs) are utilized to identify flood dynamics. The four ML-based FSMs Fandom Forest (RF), K nearest neighbor (KNN), multilayer perceptron (MLP), and hybridized genetic algorithm–Gaussian radial basis function–support vector regression (GA;RBF;SVR) shown in this article [43]—present a framework for reducing spatial disagreement. The outcomes of those four models were combined to generate an enhanced model as well. The approach presented in this study may be useful in developing risk based development plans and enhancing current early warning systems. This paper [44] utilized a deep learning-based model to predict the water level flood phenomenon of a river in Taiwan. The experimental results showed that the Conv GRU neural network model performed better than other current methods. The trial's outcomes showed that the suggested method could correctly identify the wrong water levels. The purpose of this study project [45] is to use artificially intelligent neural network (ANN) modeling techniques and Lavenberg Marquardt (MLR) multiple linear regression to determine long-term seasonal rainfall patterns in Western Australia.This study [46] demonstrates how RBFs, which are both linear and nonlinear kernel functions, can produce superior results in the same catchment under various conditions. Lighter rainfalls would provide quite different responses from bigger ones, which is a highly helpful technique to disclose the behavior of an SVM model. The study also demonstrates an unexpected result in the SVM reaction to various rainstorm inputs. The process of predicting flood status is difficult [10] and necessitates thorough investigation of the causes of flooding. In order to make it easier to foresee the situation with rivers flooding, this research suggests an Internet of Things-based flood status prediction (IOT-FSP) model. The IoT-FSP model utilizes the Internet of Things architecture to facilitate the collection of flood data as well as algorithms for machine learning (ML) for flood prediction: Decision Tree (DT),Random Forest (RF).This research predicted the flood prone areas in Nigeria using historical flood records [11] from 1985 to 2020 and a number of variables that were confounding. Both logistic regression (LR) and ANN (artificial neural network) algorithms were trained and evaluated to determine the relationship between flood occurrence and the fifteen (15) explanatory factors, which include topographic, meteorological land utilization, and proximity information. This resulted in the creation of a flood susceptibility map. This study [12] explores how several machine learning algorithms can be used to create the most accurate flood determining model. This work proposed three novel machine learning models: the multivariate adaptable regressed splines (MARS), the boosted regression model (the BTR), and the generalized additive model (the GAM) [13]. The province of Ardabil, one of the lands near the Caspian Sea coast, which is regularly affected by flooding, was chosen for applying the methodology that the study referred to. The objective of this study is to figure out how the rainfall Figure time-series data from eight stations along the Kelantan River and the corresponding discharge values influence water level accuracy at Kuala Krai downstream [14]. Another approach of pre-processing involves using of Data Unpredictability and Mutual Information (MI) to recover necessary information to be used as attributes for the forecast model. In this study, the author developed an early flood warning model by using the input and the output layers of multilayer perceptron with stream specification to forecast incoming water level. This research aims to discuss the incorporation of machine learning to trace rain patterns [16]. To do this, a collection of data representing the estimates of rainfall seen in Australia's major cities over the past ten years was subjected to the four main machine learning techniques: K-nearest neighbors (KNN), Decision Tree (DT), Random Forest (RF), and Neural Networks (NN). This study [17] represents the accuracy of rainfall forecasting models engaged by modern machine learning algorithms in forecasting rainfall volume of hours using weather series time information from UK cities. The results clearly indicate that neural nets perform best. This work [18] examines the flood hazard analysis in the Turkish province of Bitlis using the analytical hierarchy approach, a multi-parameter modeling tool.

The main goal of this [47] is to estimate rainfall by utilizing machine learning and deep learning techniques to identify trends in historical meteorological data. The results of this study showed that long short-term memory (LSTM), polynomial regression, and Random Forest regression performed at the greatest levels. The R2 values for polynomial regression and Random Forest are 0.76 and 0.09, respectively, whereas LSTM has a loss value of 0.09. The three different algorithms seem data mining approaches that are often employed in weather prediction; they are successful and have a solid theoretical basis in the computing model for hourly forecasting of rainfall [48]. The author of this study [49] employed three algorithms to forecast rain, using ROC curves, Brier scores, and confusion matrices as validation parameters. The input data is a ten-year panoramic set comprising 3528 datasets and 8 features from the Kemayoran Meteorological Station in Jakarta (96745).The Indian Meteorological Department in Pune contributed data from many meteorological stations in

North India, which were used in this study [50]to analyzes rainfall records spanning 141 years. Using monthly rainfall data, the Artificial Neural Network (ANN) method has been used to create forecasting models for rainfall prediction one to two months in advance. These models make use of the Levenberg-Marquardt training function and the Feed Forward Neural Network (FFNN) with Back Propagation approach. Regression analysis, Mean Square Error (MSE), and Magnitude of Relative Error (MRE) have all been used to evaluate the performance of both models. .The study [51] probably explores the methods used in the rainfall forecasting model, outlining the fundamental ideas and workings of SVR, regression, and the hybrid SVR-PSO methodology. The SVR model's incorporation of Particle Swarm Optimization offers an optimization method to enhance the prediction power. For this particular meteorological application, the comparison might shed light on the possible benefits of adopting SVR and the SVR-PSO hybrid over conventional regression models. According to studies, the ANOVA RBF Kernel offers the best forecasting accuracy with the minimum RMSE value, making it an excellent kernel to employ with the SVR-PSO approach for rainfall forecasting. This study [52] uses ensemble models, optimized artificial neural network models, and large climate indicators to predict rainfall. Accordingly, the new MLP and RBF NN models, as well as the novel hybrid GT and ensemble, were the primary innovations of this study. Not only can the ensemble models of the current work be utilized to predict rainfall, but they can also be employed to predict other meteorological data. Also examined was the uncertainty of the input data and model parameters. A hybrid gamma test was used to pick the inputs, which is a novel approach to input selection (GT).To develop a new test for selecting the optimal input situation, the GT was combined with the NMR method. The hybrid approaches [53] utilizing ACO and three different neural network architectures are presented in this study. ACO+ Feed-Forward back propagation, ACO+cascade-Forward back propagation, and ACO+ Pattern Recognition NN Classifier were the hybrid methods that were put out. The ACO Method and Neural Network are combined to create the techniques. Results of a comparison of the performance of the suggested and current models were given. It has been discovered that the suggested techniques outperform the current Feed-Forward, cascade-Forward, and Pattern Recognition NN Classifiers in terms of performance. This study [54] proposes an improved technique for creating daily short-term and monthly long-term ensemble weather forecasting models for rainfall predictions. This is achieved by combining five rainfall prediction models (Naïve Bayes, C4.5, neural network, support vector machine, and Random Forest) using three linear algebraic combinations: maximum probability, average probability, and majority vote. Using the Malaysian state of Selangor, daily weather data over a six-month period (2010–2015) yielded 1581 occurrences, which were categorized into two groups. There are two classes of rainfall: "active rainfall," which has 428 instances, and "no rainfall," which has the remaining instances. This initiative [55] aims to use feature selection and machine learning approaches to create the most accurate rainfall forecast model possible. Prior to and following feature selection, the Artificial Neural Network (ANN) attains a maximum accuracy of 90% and 91%, respectively.This research in [19] primary contribution is to identify the most recent machine learning techniques for flood prediction as well as the noteworthy parameters that were used as model input. This will allow scientists and/or flood managers to use the prediction results as a reference when evaluating ML methods for early flood prediction.

### G. Comparative Analysis

This research is intended to provide the basic framework for using machine learning and deep learning algorithms for rainstorm forecasting. To illustrate an instance, a dataset for rainfall indicators, weather information and related variables from capital cities of Australia in the last ten years is given. Table I represents the sum up of the benchmarking machine learning algorithms, strategy and input parameters that have been used in different rainfalls and floods predicting events.

### H. Discussion on Past Studies

Over time, the scientific community has paid close attention to rainfall prediction due to its complexity. Previous research on rainfall prediction has used a variety of approaches, from complex machine learning algorithms to statistical models. Here's a summary of some important findings from earlier research on rainfall prediction. In the past, researchers have used a variety of data sources, such as satellite imaging, climate models, and meteorological measurements, to forecast rainfall. Features including wind speed, humidity, temperature, the land, atmospheric pressure, and oceanic conditions are often extracted from these data sources. Rainfall data's temporal and spatial characteristics must be considered in order to fully represent its complex patterns.. Because machine learning approaches can capture nonlinear correlations and manage enormous datasets, they have become popular for rainfall prediction. Popular Deep learning model Neural networks, and supervised machine learning algorithm Decision Tree (DT), support vector machines(SVM), and Random Forests(RF) are some of the methods that easily capture non linearity from data and are utilized for rainfall prediction. Rainfall prediction is inherently uncertain due to the chaotic nature of atmospheric processes and the influence of various factors such as climate change, El Niño-Southern Oscillation (ENSO), and local topography Deep learning models LSTM and ANN are presently the main techniques for rainfall forecasting, with a focus on machine learning. Using meteorological radar data, this study [57] used LSTM networks to predict short-term rainfall in mountainous areas. The results showed promise in terms of lead time and prediction accuracy. In contrast to conventional methods, this study [58] showed how feed forward neural networks (FNNs) can be used to capture complicated rainfall patterns and improve forecast accuracy when used for rainfall prediction in arid environments. Regardless many difficulties, supervised machine learning has several potential applications in rainfall prediction hourly, seasonally, daily, monthly. To fully achieve the potential of machine learning, ongoing research, data collection, stakeholder involvement, and the integration of ML with conventional modeling techniques will be required. This research applies a combination of pre-trained convolutional neural networks and long short-term memory networks to predict rainfall. Along with the achievements and discoveries described above, there are also a lot of other innovations in terms of implementation of deep learning or DL and machine learning or ML towards Rainfall forecasting. However, the prior research had a number of limitations and

flaws. Limited availability of high-quality and spatially dense rainfall data poses challenges for model training and validation. Overfitting, especially in complex machine learning models, can lead to poor generalization performance, particularly when dealing with short and noisy time series data. Many models perform poorly in novel contexts because they over fit to datasets

ML models have the ability to accurately predict rainfall; nevertheless, there can be a lack of interaction between them and decision support systems (DSS) to facilitate real-time decision-making. -User-friendly interfaces, interoperability, and seamless integration are essential to guaranteeing the practical applicability of machine learning-based forecasting systems. Interpretability and explain ability are often lacking in machine learning models, particularly deep learning models, which makes it difficult for users to comprehend how predictions are made. This restriction impedes decision-making, adoption, and trust in operational forecasting applications.

## III. METHODOLOGY

### A. Dataset Description

A dataset gathered from the kaggle platform constituted a basis for the work discussed in the article. As indicated in Table II, the data collection covers a sample of 145,460 entries with information on 23 research variables. The values provide meteorological information that was compiled over a ten-year period from 49 distinct Australian cities. The target parameter for the machine learning and deep learning algorithms' prediction task is a Boolean variable named "Rain Tomorrow" indicating yes or no as to whether it will rain tomorrow. Similarly Table II displays the dataset's dimensionality as compared to benchmark studies. Comparison Benchmark Dataset (Rainfall Prediction Attribute) is presented in Table II .

### *B. Numerical and Categorical Weather Feature Used as a Predictor*

Fig. 2, displays the missing values in each feature of the dataset in a more comprehensive manner. The yellow bars indicate missing values, while the purple bars represent available data. The columns correspond to the features in the dataset, and the figure illustrates the distribution of missing values across all variables.

Fig. 3 shows the behavior of all features, and Table III provide descriptions of the numerical characteristics together with details on their kind, availability of data, and units. Table IV define the numerical feature description with type and unit.

In this context, the eight compass points - North (N), Northeast (NE), East (E), Southeast (SE), South (S), Southwest (SW), West (W), Northwest (NW), - as well as the points in between are the wind features. Table IV has one more feature that includes two ways to display data i.e. unit, kind, category, and having data or not.

### *C. Correlated Features in the Dataset*

Breaking the date feature in month day year and the Fig. 5 showing the strong and weak correlation with the features. Tuples of Highly positively & strongly Correlated Features in overall Continent are provided in Table V.

### *D. Locations of Study Area*

In this research the effect of the data's location was looked at. The weather may vary too much in places that

TABLE III. METEOROLOGICAL NUMERICAL FEATURES DESCRIPTION

| No | Name | Features Brief Description with Units | Type | Unit | Missing Value | Available Data |
|---|---|---|---|---|---|---|
| 1 | 'Date' | The complete day date and of rainfall occurrence | string | (No unit) | 0 | 145460 |
| 2 | 'Min Temp' | The lowest temperature that a certain day might experience. | decimal | Celsius (°C) | 1485 | 143975 |
| 3 | 'Max Temp' | The maximum temperature recorded on a particular day. | decimal | Celsius (°C) | 1261 | 144199 |
| 4 | 'Rainfall' | Rainfall on a specific day. | decimal | millimeters (mm) | 3261 | 142199 |
| 5 | 'Evaporation' | Drying on a specific day. | decimal | millimeters (mm) | 62790 | 82670 |
| 6 | 'Sunshine' | On a certain day there was bright sunshine. | decimal | hours | 69835 | 75625 |
| 7 | 'Wind Gust Speed' | Strongest wind gust's speed on a given day. | decimal | kilometers per sec | 10263 | 135197 |
| 8 | 'WindSpeed9am' | Wind speed for 10 minutes before 9 am. | decimal | kilometers per sec | 1767 | 143693 |
| 9 | 'WindSpeed3pm' | Wind speed for ten minutes before three o'clock. | decimal | kilometers per hour (km/h) | 30622 | 142398 |
| 10 | 'Humidity 9am' | The percentage of the wind's humidity at 9:00 am. | decimal | percentage (%) | 2654 | 142806 |
| 11 | 'Humidity 3pm' | The percentage of the wind's humidity at 3 PM. | decimal | percentage (%) | 4507 | 140953 |
| 12 | 'Pressure 9am' | Atmospheric pressure at the time 9am it was observed | decimal | hectopascals (hPa) | 15065 | 130395 |
| 13 | 'Pressure 3pm' | Atmospheric pressure at 3 PM the observed time | decimal | hectopascals (hPa) | 15028 | 130432 |
| 14 | 'Cloud9am' | Areas of the sky that are clouded in at 9:00 am. | decimal | (No unit) | 55888 | 89572 |
| 15 | 'Cloud3pm' | Areas of the sky that are clouded in at 3 PM. | decimal | (No unit) | 59358 | 86102 |
| 16 | 'Temp 9am' | Temperature of rainfall at 9 am | decimal | Celsius (°C) | 1767 | 143693 |
| 17 | 'Temp3pm' | Temperature of rainfall at 3 PM | decimal | Celsius (°C) | 3609 | 141851 |

TABLE IV. METEOROLOGICAL WIND FEATURES DESCRIPTION

| No | Name | Description | Categories in Specific Feature | Percentage | Type | Unit | Missing Value | Available Data |
|---|---|---|---|---|---|---|---|---|
| 1 | Wind Gust Dir | The wind's direction over the 24 hours leading up to midnight (sixteen compass points) | ENE, ESE, N, NE, NNE, NNW, NW, S, SE, SSE, SSW, SW, W, WNW, WSW, NaN | NA 7%, W 7%, Other (125219) 86% | string | (No unit) | 10326 | 135134 |
| 2 | Location | Specific name of the Australian city where rainfall was recorded | Newcastle, Albury, Badgerys Creek, Cobar, Coffs Harbour, Moree, Wagga, Williamtown, Wollongong, Canberra, Tuggeranong, Mount Ginini, Ballarat, Bendigo, Sale, Melbourne Airport, Melbourne, Woomera, Albany, Witchcliffe, Pearce RAAF, Perth Airport, Perth, Salmon Gums, Walpole, Hobart, Launceston, Alice Springs, Darwin, Katherine, Uluru | Canberra 2%, Sydney 2%, Other (40676) 95% | string | (No unit) | 0 | 145460 |
| 3 | Wind Dir 9am | The direction of the wind in the first ten minutes before 9 am | WNW, ENE, NE, SSW, ESE, NW, S, W, SW, NNE, NNW, N, SE, E, SSE, WSW | SE & WW 0.07%, Others 0.06% | string | (No unit) | 10566 | 134894 |
| 4 | Wind Dir 3pm | 10 minutes before 3 o'clock the wind's direction | SSE, NNW, ENE, NNE, WENE, WSW, SSE, SW, NW, N, ESE, ENE, SSW, others | N 0.087%, Other less than 1% | string | (No unit) | 3062 | 142398 |
| 5 | Rain Today | 'Yes' if it rains today. 'No' if not raining today. | Yes, No | Total 3261 | string | (No unit) | 3261 | 141851 |
| 6 | Rain Tomorrow | If it rains tomorrow, then 1 (Yes). If it doesn't rain tomorrow, then 0 (No). | Yes, No | Total 3267 | string | (No unit) | 3267 | 142193 |

TABLE V. TUPLES OF HIGHLY POSITIVELY AND STRONGLY CORRELATED FEATURES IN OVERALL CONTINENT

| No | Tuple | Correlation Coefficient |
|---|---|---|
| 1 | The attributes Max and Min temperatures have a significant positive correlation. | 0.74 |
| 2 | There is a significant positive link between the minimum temperature and the temp3pm. | 0.71 |
| 3 | The attribute 9am temperature and Min Temp are strongly positively correlated. | 0.90 |
| 4 | Max Temperature and Temp 9am exhibit a strong positive association. | 0.89 |
| 5 | Maximum temperature and temperature at 3 p.m. are both fairly high. | 0.98 |
| 6 | Wind Gust Speed and WindSpeed3pm variables are highly positively correlated. | 0.69 |
| 7 | Pressure 9am and Pressure 3pm variables are strongly positively correlative. | 0.96 |
| 8 | The variables Temp 9am and Temp3pm have a high positive correlation. | 0.86 |

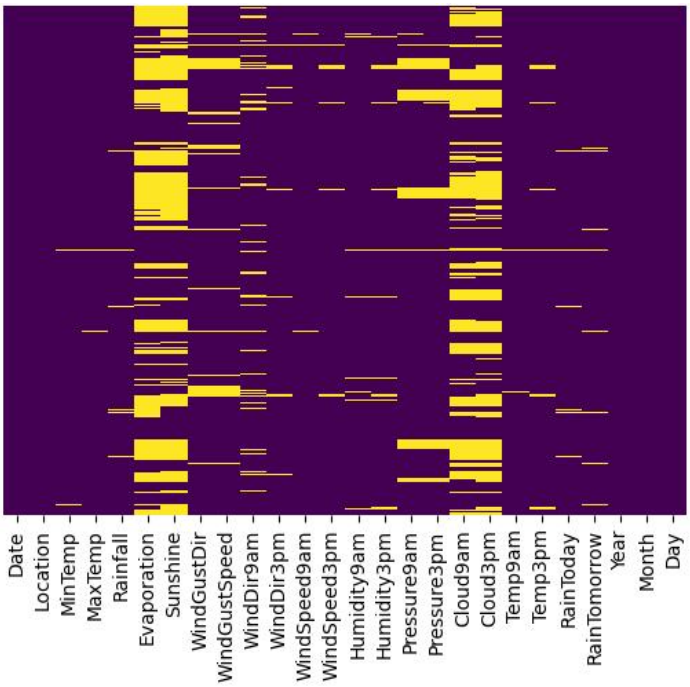

Fig. 2. Visual representation of missing values for each feature in the dataset.

are predominantly in different parts of Australia. The earlier study made use of a dataset that had a large number of cities. There are data gaps in several cities. For this reason, consider the following five Australian research regions((Darwin, Perth Airport, Sydney, Brisbane, and Melbourne). Given the aforementioned and the fact that local weather patterns and microclimates can frequently differ greatly, especially when taking into consideration weather forecasts for the entire continent, it should be more sensible to construct unique models for various locations. As a result, this study produces weather predictive models for various areas. To comprehend the numerous factors that affect whether it rains the following day, this study consider each city's specific model separately. In this study, it was also investigated whether applying machine learning and deep methods may help with rainfall predictions in this particular Australian location. Fig. 5 shows the locations of five Australian cities (Drawn, Perth Airport, Sydney, Brisbane, and Melbourne).

Fig. 6 displays the city-specific rain forecast for tomorrow. Fig. 7 shows that the month has less of an impact on the distribution of rainy days in Sydney and Melbourne. However, count plots for Brisbane, Perth, and Darwin indicate that these locations experience both wet and dry months (particularly Darwin).Darwin had more wet days than Perth did over the course of the research period, even though the count plot indicates that there are much more days with rain than days without

In particular, this study will be used to find out whether the application of deep learning and machine learning algorithms can lead to a higher precision grade and a drop in errors.. Everyone who is now alive in the country will gain something from this endeavor.Four machine learning methods are used in the suggested method to forecast rainfall Random Forest(RF), Gradient boosting (GB) etc. The framework incorporates a number of crucial processes, pre-processing, data normalization and feature engineering including feature selection, feature encoding, model training, and prediction evaluation. The proposed work involves the optimization of a classification model for the rain prediction with the help of supervised machine learning (ML) and deep learning(DL) methods. The primary objective of the research is to achieve maximum accuracy in rainfall prediction. This objective is pursued through the application of supervised learning and deep learning methodologies. The methodology revolves around supervised learning, where the model learns patterns from labeled training data. Specifically, deep learning is highlighted, resulting in the application of multiple layer neural networks that exhibit an ability to capture complicated patterns in the data. Fig. 8 indicates the overall framework of the proposed scheme for forecasting precipitation. It may illustrate the different components of the model, such as data preprocessing, feature extraction, model training, and evaluation. The architecture of the proposed research work is presented in Fig. 8.

*1) Data cleaning and pre processing missing data:* Another significant part of data preprocessing in machine learning generally is management of missing data in a dataset. Fig. 2 demonstrates the number of blank samples available for two variables. Through a total of 145,460 samples, for 23 variables.Therefore, nearly 45% of the samples would need to be deleted if the samples with no data for any of their variables were also eliminated. In order to avoid throwing away a lot of data(there are a total of 49 cities dataset contain ) e. g [‘albury’ ;‘Badgerys Creek’ ,‘cobar’ ;‘coffs harbor’ ‘moree’ ‘Newcastle’; ‘Norah Head’; ‘Norfolk Island’; ‘penrith’ ‘Richmond’ ,‘Sydney’ ,‘Sydney Airport’ ‘waggaWagga’ ,‘Williamstown’ ,‘Wollongong’; ‘Canberra’ ‘Tuggeranong’; ‘mount_Ginini’ ,‘ballarat’ ,‘bendigo’, ‘Sale’ ‘Melbourne AirPort’ ‘Melbourne’; ‘Mildura’; ‘nhil’ ,‘Portland’;‘Watsonia’; ‘Dartmoor’ ,‘Brisbane’ ‘cairns’, ‘gold Coast’ ;‘Townsville’ ,‘Adelaide’ ,‘mount Gambier’ ,‘nuriootpa’ ,‘woomera’, ‘Albany’,;‘Witchcliffe’ ,‘Pearce’ ).

In total, seven (7) different stations in the dataset. In particular, less than 10 percent of string text data is missing or absent. The variables that lacked data were examined and categorized according to the cities. The examination of factors for which there are data produced the following results. In some of the cities, certain parameters do not have any data at all. There are samples for which certain variables have no information. It is assumed that this is due to a lack of a corresponding sensor at the city's weather site or data not recorded. A malfunction in the sensors' communication with each other could be the reason. As with the previous case, two different scenarios were shown to exist: data loss for one day and data loss for several days in a row [16]. It was decided to remove all null values for all features in this case. Using only 41% of observations is possible. Detecting and removing outliers from the dataset finally, in the case of objective variables, In this work balance the imbalance data. Fig. 9 and Fig. 10 depict the balance and imbalance target variable.

*2) Data normalization:* Scaling variable values to give them the same quantitative weight and place them on the same interval or scale is known as data normalization. Rescaling the

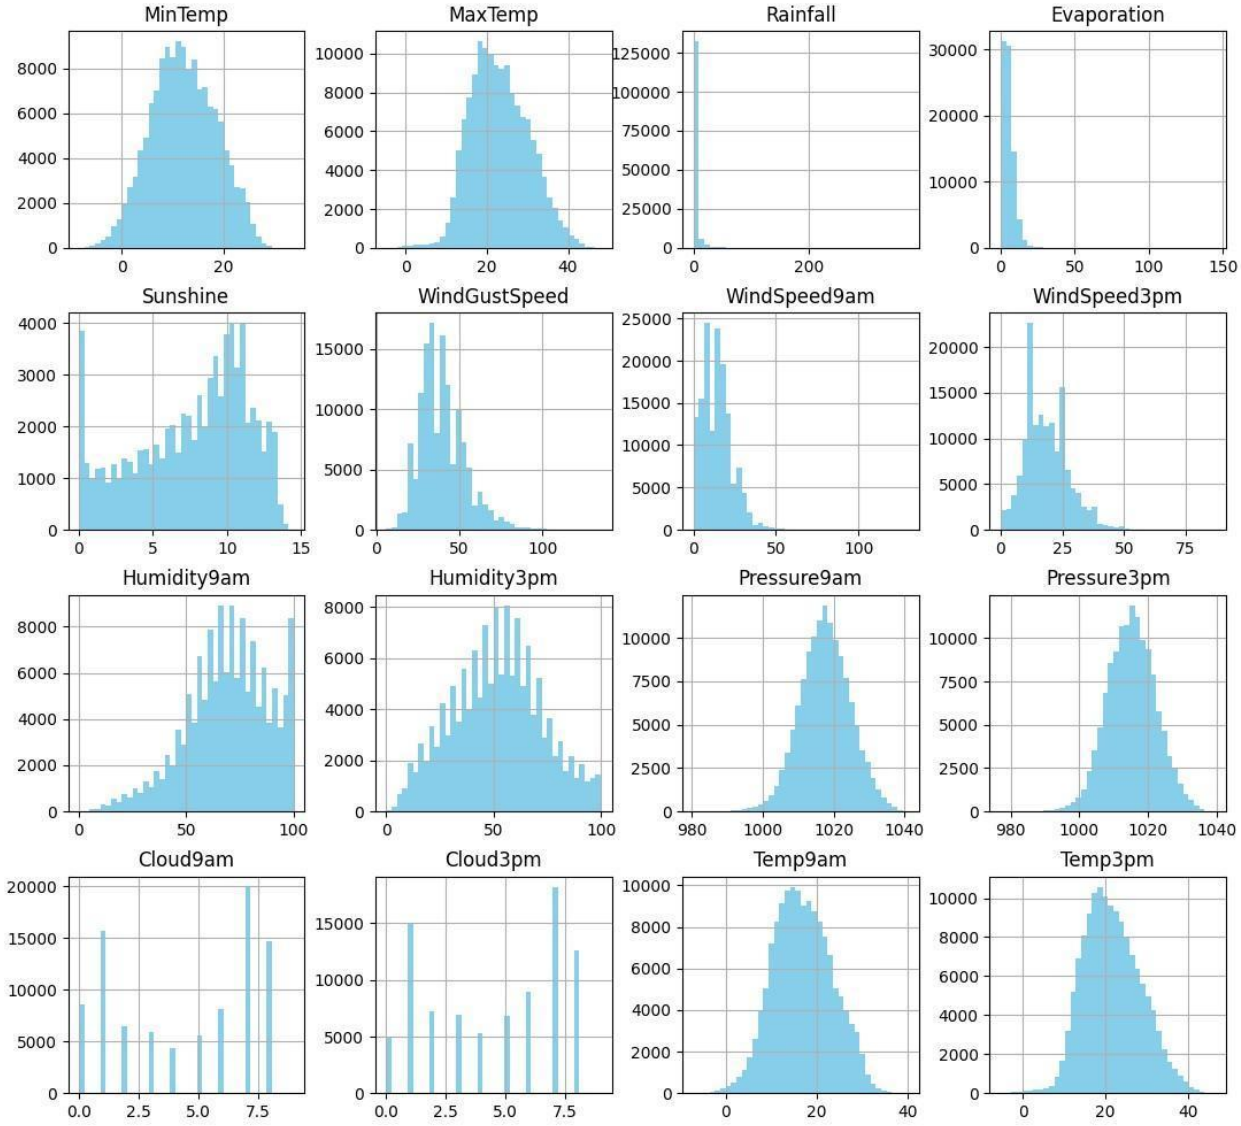

Fig. 3. Histogram showing the dataset's attribute statistics.

complete dataset to a standard distribution or range. Eq. (1) provides a method for normalizing data using the min-max scaling strategy.

$$x_{(normalized)} = \frac{x - min(x)}{max(x) - min(x)} \quad (1)$$

Where: x stands for the dataset's original value, min(x) for its lowest value, max(x) for its highest value, and x_normalizedfor its normalized value falls between 0 and 1. The values of the complete dataset are scaled by Eq. (1) to the range [0, 1], where the smallest value is made to equal 0 and the largest value is produced to equal 1.

*3) Feature engineering:* First, the map reveals that Watsonia, Perth, and Melbourne airports are all close to one another. Based on this, assume that it makes sense to select Melbourne and Perth airports for rain prediction because they have fewer null variables than Watsonia and Perth. Although the date field itself does not contain any meteorological information, it is possible to get the month and utilize it to study weather patterns. In this experiment, the month feature that had been removed is replaced by (January, February, March, April, May, June, July, August, September, October, November and December). Since the data in the region as a whole had to be investigated, the data pertaining to each place has not been divided to create distinct subsets. For instance, there are some cities with heat and humidity circumstances that more or less favor rain, based on their location. Similarly, on the day the data is collected, several weather events may take place that affect the rain.

*4) Feature encoding:* In our dataset some features are categorical and some numerical. The category variables were then converted into numerical values. Two distinct sets of data variables had to be used in this process On the other hand, because the parameters WindGustDir, WindDir9am, and WindDir3pm show the direction of the wind, the data transform

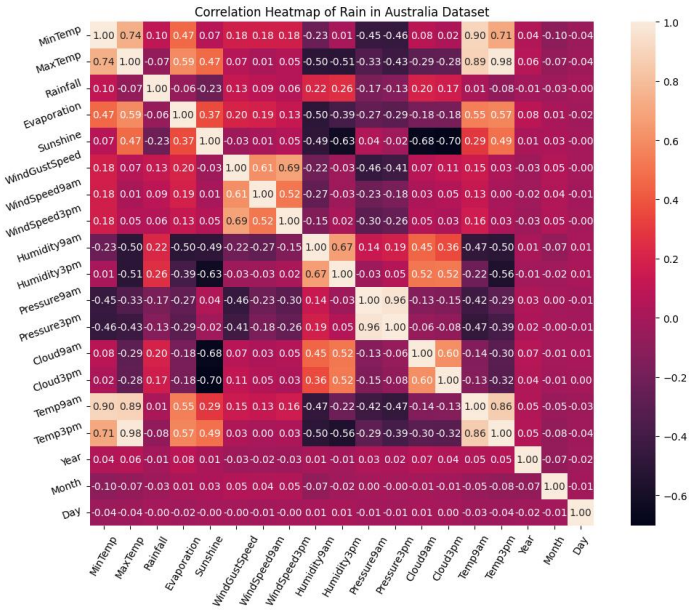

Fig. 4. Correlation with variables.

into numeric form before using them because they contain a categorical data string. Our study's goal variable is called Rain Tomorrow, and its values of "1, 0" are applied to Boolean representations of type "string" (which only take YES/NO responses). Fig. 4 shows correlation with variables.

*5) Feature scaling:* The process of scaling individual features within a dataset to have comparable magnitudes is known as feature scaling. The Standard Scalar was used to scale the dataset's features in order to guarantee that it was equitable and appropriate for the models that were used. The data are scaled by placing a unit standard deviation around the mean. The feature scaling using the z-score scaling or standardization technique is represented in Eq. (2). The feature scaling takes place element wise and for every feature.

$$x_{(Scalled)} = \frac{x - \mu}{\theta} \tag{2}$$

Where: x indicates the feature's original value, is the dataset's mean (average), is the feature's standard deviation, and ,The scaled value of the feature, x_scaled, has a standard deviation of 1 and a mean of 0. Eq. (2) is applied to alter the attribute values to have a mean of 0 and a standard deviation of 1.

*6) After preprocessing result:* A total of 145460 samples were collected over a ten-year period in 49 Australian cities for the initial set of variables, which included 23 ('Date', 'Min Temp', 'Max Temp', 'Rainfall', 'Evaporation', 'Sunshine', 'Wind Gust Speed', 'Wind Speed 9am', 'Wind Speed 3pm', 'Humidity 9am', 'Humidity 3pm', 'Pressure 9am', 'Cloud 9am', 'Cloud 3pm', 'Temp 9am', 'Temp 3pm', 'Location', 'Wind Gust Dir', 'Wind Dir. 9am', 'Rain Today', 'Rain Tomorrow', 'Pressure 3pm',. Unlike Salvia Main, the site's dataset is made of 79 columns, resulting in a total of 14 727 samples. In addition to that, approximately 80% of the data gathered out of these 14727 samples is used for training the models and remaining 20% of the data is used for checking the functioning of the newly developed models.

In the present Australia rainfall prediction, the integration of some basic normalization methods such as min-max scaling and z-score standardization enhance the model prediction. Most of the rainfall prediction models involve various properties such as temperature, humidity and wind speed, all of which have different units and scales. Scaling makes sure that all different features are equally important, thus their values are transformed into the same range. This restricts the longer feature space ranges from becoming dominant over other small feature space ranges and aids in learning algorithms like neural networks and Decision Tree learn faster and better during the training process. Normalization also enhances numerical stability and prevents the model from having a bias towards features with large variances, thus enhancing the accuracy of the rainfall estimation.

## IV. Results

Using the location segment, for analyzing and dividing the dataset into various regions so that it could create a variety of unique models, Fig. 7 represents the different locations of Australia. To see the differences between the causes triggering rain on subsequent days, analyze the models independently. Machine learning (ML) techniques have considerably improved prediction systems over the past two decades by offering more efficient and approachable means of replicating the intricate mathematical representations of the physical processes causing floods. Analyzing the possibilities that machine learning and deep learning algorithms offer to conventional forecasting methodologies for the prediction of rain is the aim of this study. This was accomplished using the techniques of neural networks (NN), Decision Tree (DT), Random Forests (RF), and Gradient Boosting Classifiers (GBC). Examine the benefits of rainfall probability in Australia's five biggest cities: Darwin, Sydney, Brisbane, Perth, and Melbourne, using the methodology given.A more detailed description of the algorithms may be found below. The values from the training dataset have been predicted by using a specific location.

*1) Decision tree:* Using a Decision Tree machine learning approach [60]–[62], problems with regression and classification are addressed. Its organization is comparable to a flowchart, where a decision rule is represented by each branch, an attribute or characteristic by each internal node, and a result or class label by each leaf node.

*2) Random forest:* During training, a massive number of decision trees are constructed by an ensemble learning system known as Random Forest [62], which then outputs the average forecast for regression tasks or the majority vote for classification tasks. Random Forest is resistant to over fitting and performs well on a variety of datasets. It can handle missing values and remain accurate even with a large feature set. The Random Forest approach is depicted in Fig. 11

*3) Gradient boosting classifier:* A powerful ensemble learning method for classification and regression applications is gradient boosting. Gradient Boosting constructs Decision Tree sequentially, with each tree learning from the mistakes of its predecessors, in contrast to typical decision tree algorithms like Random Forest, which generate many trees individually

Fig. 5. Geographical location of five specific regions of Australia.

Fig. 6. Tomorrow's forecast for a specific city.

[63] as shown in Fig. 12. Initialize the model with a simple model, such as a single leaf (constant) value for regression or a constant probability for classification. Then it calculates the residuals or pseudo-residuals for each data point, which represent the errors made by the initial model.

$F_m((x)$ as the current ensemble model (sum of first m weak learners) $h_m((x)$ as the m-th weak learner (e.g., Decision Tree ), Φ as the learning rate, L as the loss function. At each iteration, update the model as follows:

At each iteration, update the model through Eq. (3) as follows:

$$F_m(x) = F(-1)(x) + \rho \cdot h_m(x) \tag{3}$$

Then, the residuals (or pseudo-residuals) are updated the Eq.4:

$$r_{im} = \frac{\partial L(y_i, F_{m-1}(x_i))}{\partial F_{m-1}(x_i)} \tag{4}$$

Finally, the prediction at each iteration is given by Eq. 5:

$$y_{\text{pred}}(x) = F_M(x) = \sum_{m=1}^{M} \rho \cdot h_m(x) \tag{5}$$

*4) Recurrent Neural Network:* Recurrent Neural Networks (RNNs), on the other hand, serve as the foundation for sequential data processing within neural networks. These architectures operate iteratively through sequences, updating hidden states at each step to encapsulate contextual information. However, RNNs often encounter challenges when attempting to retain information over prolonged sequences, commonly referred to as the vanishing gradient problem. Despite their limitations, RNNs remain widely used for various sequential data tasks, such as language modeling, sentiment analysis, and machine translation. While they may struggle with long-term dependencies, RNNs offer simplicity and computational efficiency, making them suitable for applications where shorter-term relationships are predominant.

The RNN's computations are governed by the following formulas. Eq. (6) is utilized in the computation of hidden states:

The function $h(t)$ is calculated as follows:

$$h(t) = f\left(W_{xh} \cdot x(t) + W_{hh} \cdot h(t-1) + b_h\right) \tag{6}$$

Eq. (6) is used for output calculation:

$$y(t) = f\left(W_{hy} \cdot h(t) + b_y\right) \tag{7}$$

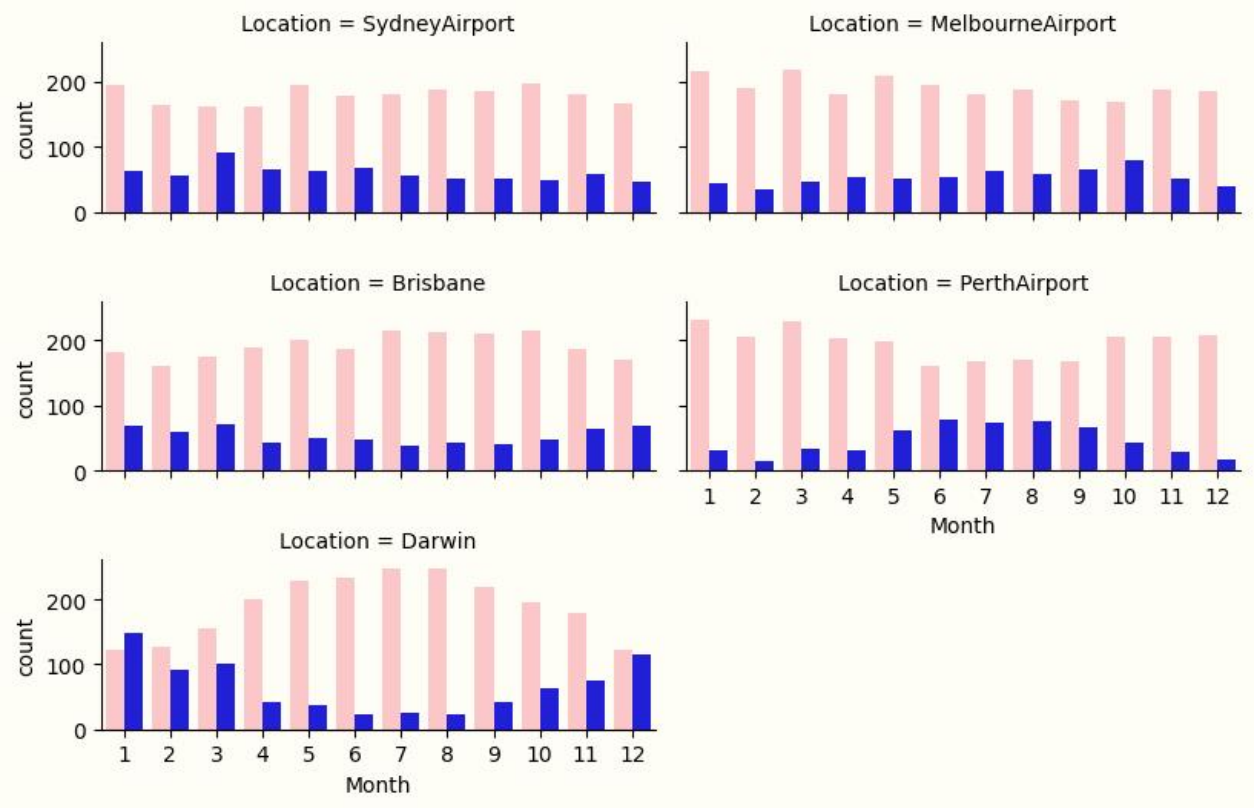

Fig. 7. Tomorrow's forecast for a specific city.

Where $t$ is the time step, $x(t)$ is the input at time step $t$, and $h(t)$ is the hidden state at time step $t$. The weight matrices $W_{xh}$ and $W_{hh}$ control the flow of information, and $b_h$ and $b_y$ are bias vectors.

The following equations are used for the input gate:

$$i(t) = \text{sigmoid}\left(W_i \cdot [h(t-1)\, x(t)] + b_i\right) \tag{8}$$

The candidate cell state $\hat{C}(t)$ is computed as:

$$\hat{C}(t) = \tanh\left(W_c \cdot [h(t-1)\, x(t)] + b_c\right) \tag{9}$$

The cell state updating function is given by:

$$c(t) = f(t) \cdot c(t-1) + i(t) \cdot \hat{C}(t) \tag{10}$$

The output gate computations are as follows:

$$o(t) = \text{sigmoid}\left(W_o \cdot [h(t-1)\, x(t)] + b_o\right) \tag{11}$$

Finally, the hidden state is calculated as:

$$h(t) = o(t) \cdot \tanh\left(c(t)\right) \tag{12}$$

### A. Criteria for Evaluating Models

The metrics (or key indicators of performance (Key Performance Factors)) that will be used to evaluate the algorithms' output are described in this section [64].

*1) Accuracy:* Number reflecting how well the predicted model performed. The formula shown in Eq. (13)

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FN + FP} \tag{13}$$

Where, TP designates it as "true positives." "Result where the model outputs a positive class and correctly classifies it. FP is called a False Positive. Lead to a case in which the positive class is erroneously designated by the model as a negative class. TN, or the true negative, connotes the outcome where the model predicted the negative class to be. False negative, i.e. FN is a concept in detection that is associated with negative. is a situation where the model predicts the other class to be wrong.

*2) Precision:* The percentage of instances that are correctly identified as positive is known as precision. Which is, whether a model forecasts positive numbers. The formula shown in Eq. (14).

$$\text{Precision} = \frac{TP}{TP + FN} \tag{14}$$

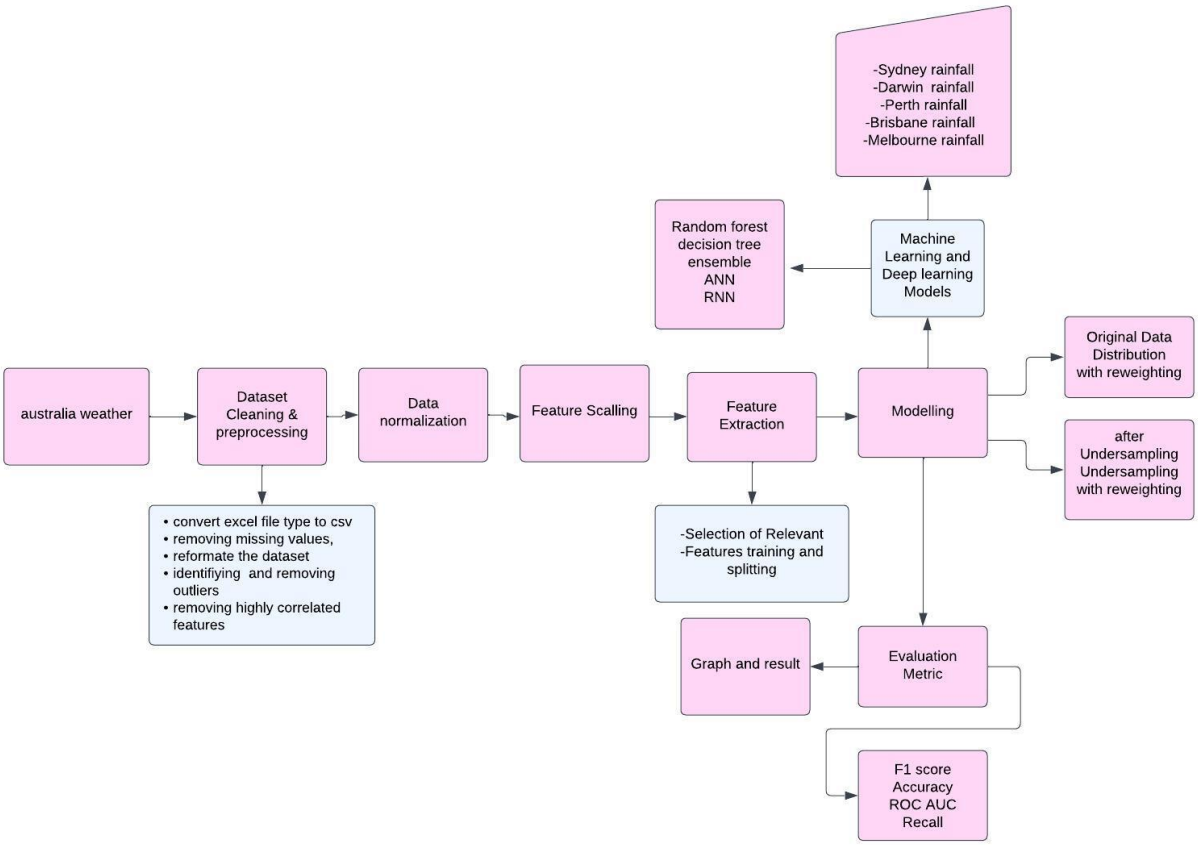

Fig. 8. Architecture of the proposed work.

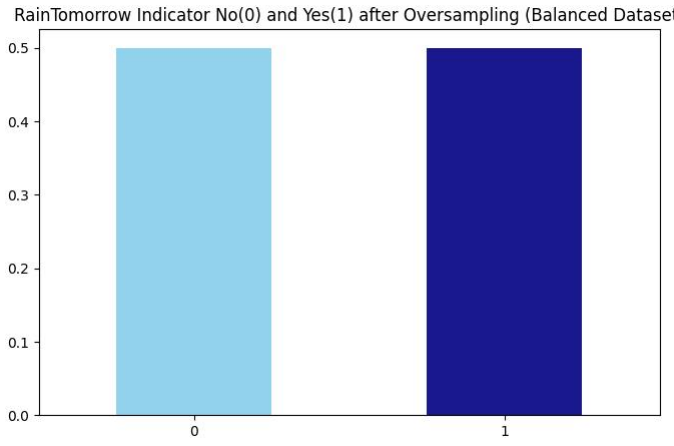

Fig. 9. Rain tomorrow indicator no(0) and yes(1) after oversampling (balanaced dataset).

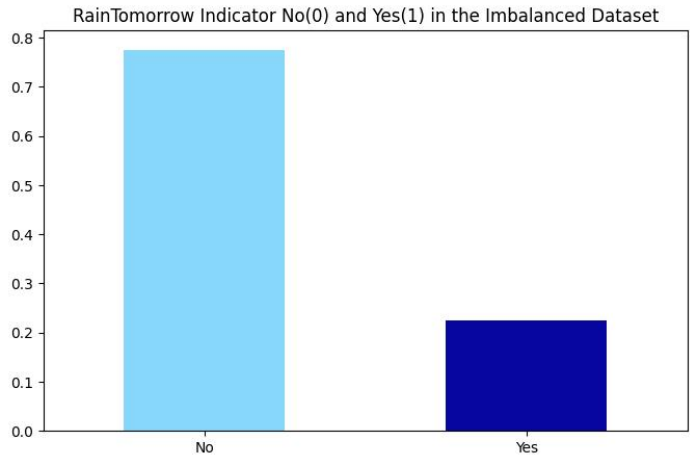

Fig. 10. Rain tomorrow indicator no(0) and yes(1) in the imbalanaced dataset.

*3) Recall:* The percentage of correctly detected positives to all positives is known as recall. The sensitivity formula and this formula are identical as shown by Eq. (15).

$$\text{Recall} = \frac{TP}{TP + FP} \tag{15}$$

*4) F1 score:* When precision and recall are insufficient for evaluating performance, for as when one mining method has better accuracy but worse recall than another, the question of which algorithm is superior may come up. The F-measure, which gives the mean of recall and precision, can be used to address this problem. An industry standard for evaluating

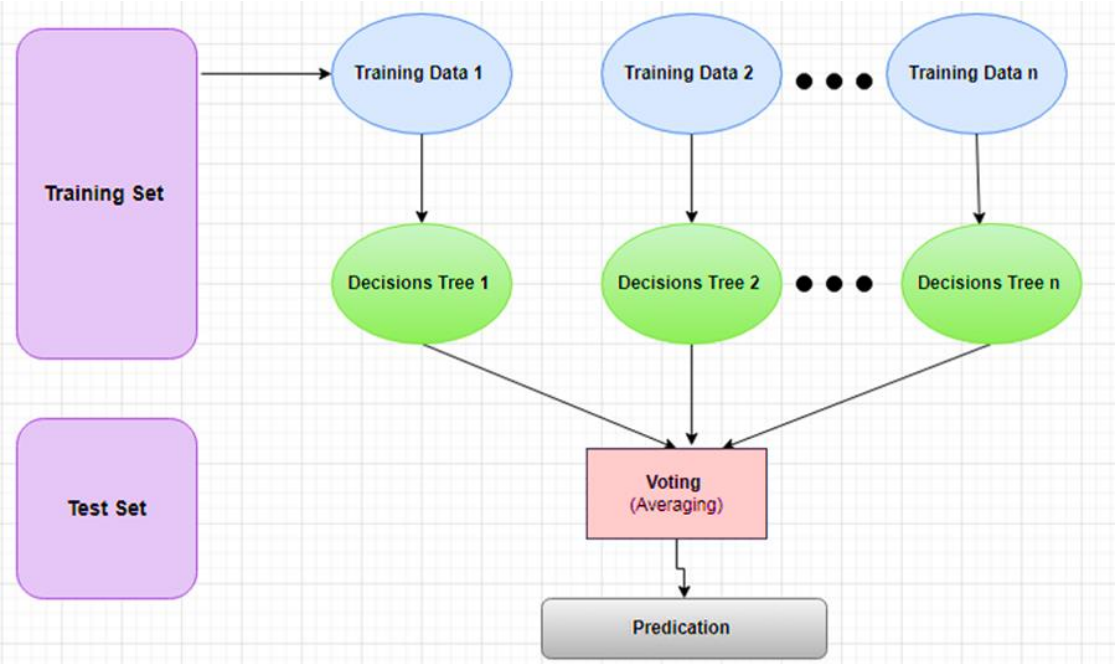

Fig. 11. Representation of random forest algorithm.

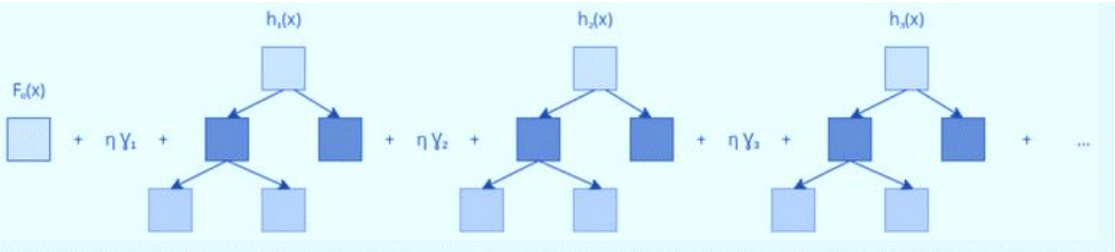

Fig. 12. Representation of gradient boosted trees.

the performance of a classification model is the F1 score. Eq. (16) shows how the computation appears. It provides an equitable evaluation of a model's accuracy by merging recall and precision into a single metric.

$$\text{F1 score} = 2 \cdot \frac{\text{precision} \cdot \text{recall}}{\text{precision} + \text{recall}} \tag{16}$$

*5) ROC AUC:* AUC ROC stands for areas under the curve of the "Receiver Operating Characteristics" curve. The performance of an ML model is commonly assessed using the AUC ROC curve. The ROC curve's AUC definition measures how well a binary classifier can differentiate between different categories.

## B. Experimental Results

Due to the fact that factors affect rainfall in different regions differently, it is impossible to produce a model that would be able to predict rainfall across the whole Australia. Models can be constructed only for restricted areas to know what roles with probability of rain are the variables being assigned. The data set contains daily weather observations from several locations in Australia for about 10 years. The impact of the data's location was examined in this experiment. The data in this set includes around ten years' worth of daily weather observations made in various parts of Australia. However, This study concentrated on five specific cities (Perth Airport, Malbulane, Brisbane, Sydney, and Darwin) for the objectives of our study. In order to predict whether it would rain on a certain day, machine learning methods were tried on the Rain Tomorrow feature.

*1) Sydney decision tree results:* Table VI presents Sydney result using Decision Tree.

Table VI represents the model's result with the initial data and the undersampling. It can be said that the results of the Random Forest and Gradient Boosting classifiers are very near to each other with the Decision Tree and Ensemble classifiers as shown in Table VII. In this study Random Forest and Gradient boosting models are built using undersampling and assume that the RF classifier, given its somewhat superior performance, is the best model for the dataset.

Table VI presents Sydney Comparison of all results By using Random forest and Gradient Boosting.

TABLE VI. SYDNEY RESULT USING DECISION TREE

| Metric | Original Data Distribution | Original Data Distribution with Reweighting | Under Sampling | Under Sampling with Reweighting |
|---|---|---|---|---|
| **Accuracy** | 0.83 | 0.78 | 0.77 | 0.70 |
| **F1 score** | 0.60 | 0.60 | 0.61 | 0.58 |
| **ROC_AUC** | 0.72 | 0.75 | 0.75 | 0.74 |
| **Recall class 1** | 0.50 | 0.69 | 0.71 | 0.84 |

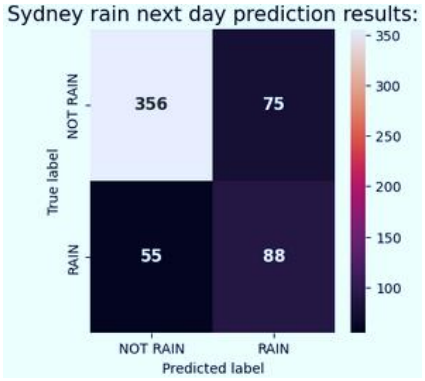

Fig. 13. Sydney next day prediction result.

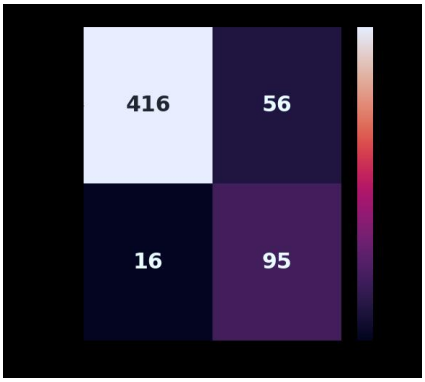

Fig. 14. Perth airport next day prediction result.

### C. Perth Airport, Brisbane, Melbourne, Darwin Comparison Accuracy using ML Algorithm

Building a model that can forecast rain for the entire Australian continent is unachievable because different factors have varying effects depending on where they are. Only for specific areas models build and look at how the variables affect the probability of rain. In this study created models for specific locations and examined the variables' effects on the likelihood of rain. Without comparing it to a single tree, Random Forest model with under sampled training data is the best choice for Perth Airport, Brisbane, Melbourne, Darwin. Table VIII represents the prediction result for all 5 locations of Australia and also shows us that it's possible to predict rain for next day with different accuracy depending on the location (using one model type - RF classifier).

The confusion matrix of five specific regions of Australia for rainfall prediction are presented in Fig. 13, 14, and 15.

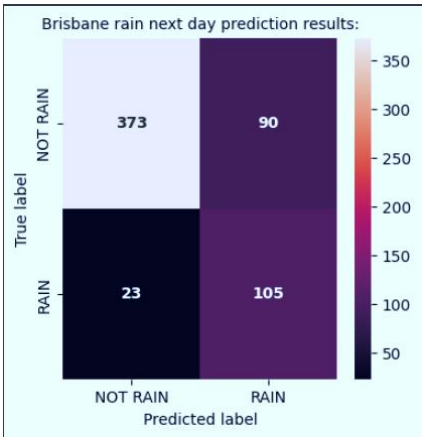

Fig. 15. Brisbane next day prediction result.

### D. Estimation of Feature Importance

The estimation of feature importance for different cities is presented in this subsection as follows:

*1) Estimation of feature importance for Sydney:* Here only a couple of weather factors affect Sydney weather. The main factors are sunshine, wind speed 3 p.m., humidity 3 p.m., maximum temperature, air pressure 9 a.m. and air pressure 3 p.m. TableIX provides Feature Importance for Sydney. All other features have importance less than 1 percent.

*2) Estimation of feature importance for Perth airport:* The most essential factors causing rain next day in Perth (Airport) are Pressure 3pm, Pressure 9am, Wind Gust Speed, Evaporation, Wind Speed 3pm, Sunshine, Rainfall. Table IX describe some factors with F1 score. Table X provides Feature Importance for Perth Airport city. All other features have importance less than 1 percent.

*3) Estimation of Feature Importance for Brisbane city:* The key elements causing rain the following day in Brisbane are the following: humidity, 3 p.m. sunshine, humidity, 9 p.m.,

TABLE VIII. PREDICTION RESULTS FOR ALL 5 LOCATIONS OF AUSTRALIA USING RANDOM FOREST

| Metric | (i) Sydney | (ii) Darwin | (iii) Perth | (iv) Brisbane | (v) Melbourne |
|---|---|---|---|---|---|
| **Accuracy** | 0.79 | 0.86 | 0.88 | 0.82 | 0.76 |
| **F1 score** | 0.64 | 0.76 | 0.73 | 0.66 | 0.58 |
| **ROC AUC** | 0.78 | 0.87 | 0.87 | 0.82 | 0.76 |
| **Recall** | 0.76 | 0.89 | 0.86 | 0.81 | 0.77 |

TABLE IX. FEATURE IMPORTANCE FOR SYDNEY

| Feature | Sunshine | Wind Gust Speed | Humidity 3pm | Wind Speed 3pm | Max Temp | Pressure 9am | Pressure 3pm |
|---|---|---|---|---|---|---|---|
| **F1 Score** | 0.04 | 0.02 | 0.018 | 0.017 | 0.014 | 0.014 | 0.013 |

TABLE X. FEATURE IMPORTANCE FOR PERTH AIRPORT CITY

| Feature | Pressure 3pm | Pressure 9am | Wind Gust Speed | Evaporation | Wind Speed 3pm | Sunshine | Rainfall |
|---|---|---|---|---|---|---|---|
| **F1 Score** | 0.06 | 0.04 | 0.03 | 0.021 | 0.014 | 0.013 | 0.01 |

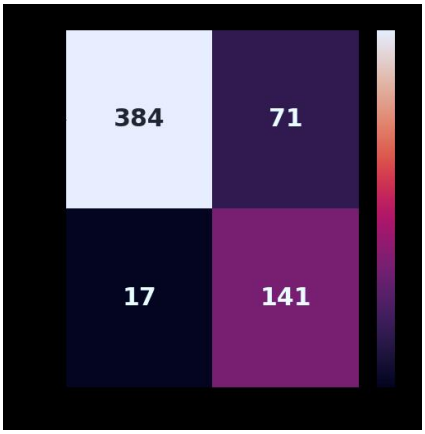

Fig. 16. Darwin next day prediction result.

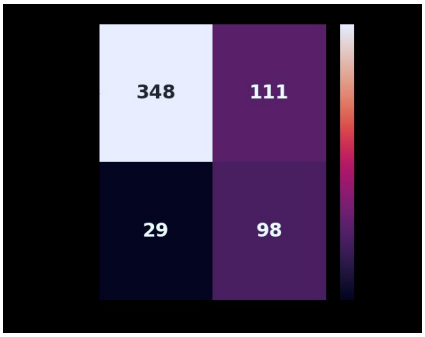

Fig. 17. Melbourne next day prediction result.

clouds, maximum temperature, 9 a.m., minimum temperature, and pressure at 3 p.m. Table IX outlines the F1 score-related elements. Table XI provides Feature Importance for Brisbane. All other features have importance less than 1 percent.

*4) Estimation of feature importance for Darwin city:* The most essential factors causing rain next day in Darwin are Humidity 3pm, Wind Gust Speed, sunshine,Temp 3pm. Table 9d describe some important attribute with F1 score. Table XII provides feature importance for Darwin. All other features have importance less than 1 percent (Pressure 3pm, Min Temp, Rainfall, Wind Speed 9 am, Wind speed) (see Fig. 16).

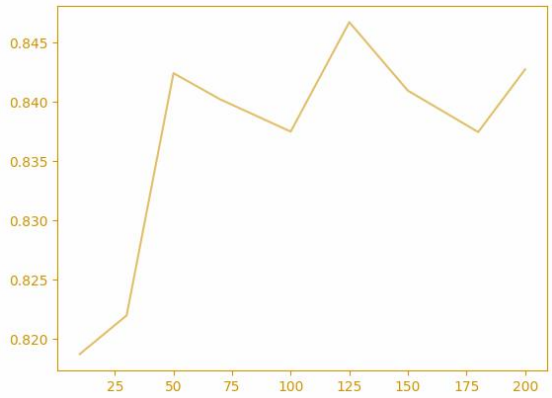

Fig. 18. Darwin ROC curve representation.

*5) Estimation of feature importance for Melbourne airport city:* Through extensive research, three notable factors in determining the rain tomorrows forecast for Melbourne (Airport) – Humidity 3pm, Sunshine, Pressure 3pm – were discovered. Table IX describe the f1 score of these important features. Table XIII provides Feature Importance for Melbourne Airport. All other features have importance less than 1 percent (see Fig. 17).

### *E. Ranking of the Most Significant Elements for Various Locations*

After modeling, feature importance was analyzed, and the feature importance boxplot shows that certain models with poor outcomes might have been over fitted. Table XIV provides ranking of the most important factors for different regions. The table further shows that the most important variables at various locations are air pressure, air humidity, wind gust speed, and wind speed.

It seems like a good idea to gather more information on these qualities for each area and to keep better track of variables like clouds, sunshine, temperature, and so forth depending on the location. Fig. 18 to 22 represent the curve result of the cities.

TABLE XI. FEATURE IMPORTANCE FOR BRISBANE

| Feature | Humidity 3pm | Sunshine | Humidity 9pm | Cloud 3pm | Max Temp | Temp 9am | Min Temp | Pressure 3pm |
|---|---|---|---|---|---|---|---|---|
| **F1 Score** | 0.07 | 0.023 | 0.016 | 0.016 | 0.013 | 0.012 | 0.012 | 0.011 |

TABLE XII. FEATURE IMPORTANCE FOR DARWIN

| Feature | Humidity 3pm | Wind Gust Speed | Sunshine | Temp 3pm |
|---|---|---|---|---|
| **F1 Score** | 0.037 | 0.03 | 0.0185 | 0.01 |

TABLE XIII. FEATURE IMPORTANCE FOR MELBOURNE AIRPORT

| Feature | Humidity 3pm | Sunshine | Pressure 3pm | Cloud 9am | Pressure 9am | Wind Gust Speed | Wind Speed 3pm | Temp 3pm | Max Temp |
|---|---|---|---|---|---|---|---|---|---|
| **F1 Score** | 0.036 | 0.03 | 0.025 | 0.019 | 0.017 | 0.016 | 0.014 | 0.01 | 0.01 |

TABLE XIV. RANKING OF THE MOST IMPORTANT FACTORS FOR DIFFERENT REGIONS

| Rank | Sydney | Darwin | Perth Airport | Brisbane | Melbourne Airport |
|---|---|---|---|---|---|
| **1** | Sunshine | Humidity 3pm | Pressure 3pm | Humidity 3pm | Humidity 3pm |
| **2** | Wind Gust Speed | Wind Gust Speed | Pressure 9am | Sunshine | Sunshine |
| **3** | Humidity 3pm | Sunshine | Wind Gust Speed | Humidity 9am | Pressure 3pm |
| **4** | Wind Speed 3pm | Temp 3pm | Evaporation | Cloud 3pm | Cloud 9am |
| **5** | Humidity 9am | Pressure 3pm | Wind Speed 3pm | Max Temp | Pressure 9am |

### F. Perth Airport, Brisbane, Melbourne, Darwin Accuracy using Recurrent Neural Network

Fig. 23 presents the default architecture of the RNN network that was applied. The table shows the RNN model efficacy in Table XII below. The parameters are displayed in Table XV for the Creation of DL model, as shown below. This table provides parameter value used for training.

TABLE XV. PARAMETER VALUES USED FOR TRAINING

| Parameter | Values |
|---|---|
| **Epochs** | 150 |
| **Batch Size** | 256 |
| **Learning Rate** | 0.0003 |
| **Optimizer** | Adam |
| **Loss** | Binary Cross Entropy |
| **Metrics** | Accuracy |

This study makes use of a unique, three-layer ANN model. Assess and assemble the model using 150 epochs. Adam Optimization used in this experiment with a batch size of 256. Table XVI provides five cities Result by using RNN and compares Darwin's validation loss to others and shows that it is better. And the graph shows that loss in training and testing both rapidly lowers as the number of epochs rises. Fig. 24 to Fig. 28 shows the loss over iterations for RNN model of five city of Australia (Sydney, Darwin, Perth airport, Brisbane, Melbourne airport.

## V. COMPARISON OF RESULTS WITH EXISTING FLOOD AND RAINFALL PREDICTION METHODS

Our applied model outperformed several well-known algorithms across various locations, showing notable accuracy gains. For example, the Random Forest model used in our study achieved an accuracy of 0.83 for Sydney, which is higher than the 0.78 accuracy reported in other studies using comparable datasets. Additionally, we obtained a validation loss of 0.5523 for Sydney with our Recurrent Neural Network (RNN) methodology, which is significantly lower than the losses reported in previous approaches, ranging from 0.63 to 0.71. Furthermore, our proposed machine learning approach not only matched but also exceeded the results of prior studies on flood prediction in Bangladesh, where logistic regression had an accuracy of 0.8676. Previous studies had primarily employed advanced techniques like reweighting and undersampling to enhance performance on imbalanced datasets. Overall, the results of our study demonstrate a significant improvement in the ability to predict floods and rainfall, proving the efficacy of our approach compared to earlier research.

## VI. NOVELTY OF THE PROPOSED METHODOLOGY

The proposed method is novel as it combines the structural assignment method with the use of a spin-glass model. This work introduces a Rainfall Forecasting Model that leverages state-of-the-art artificial intelligence and machine learning techniques, specifically employing Recurrent Neural Networks alongside advanced machine learning algorithms. The novelty of our approach lies in the following aspects:

### A. Integration of RNNs

Unlike most other studies that primarily focus on classical machine learning approaches or simpler RNN structures, this study leverages RNNs. This choice enables the model to capture temporal dependencies present in rainfall data. RNNs are particularly useful for processing sequential data, making them well-suited for forecasting models where past observations strongly influence future values.

### B. Comparative Analysis with Diverse Algorithms

In addition to comparing it with other deep learning models, we also evaluate RNN against traditional machine learning methods, including Random Forest (RF), Decision Tree (DT), and Gradient Boosting Classifier (GBC). This comprehensive cross-comparison reveals the relative advantages and disadvantages of each method in forecasting rainfall, providing valuable insights into their performance.

### C. Feature Importance Ranking

This study not only performs algorithmic comparisons but also provides a combined analysis and ranking of key meteorological factors across various regions. This analysis helps explain why, despite similar overall causes, different variables influence the amount of rainfall in various cities across Australia.

### D. Undersampling with Reweighting

We adopt undersampling with reweighting procedures to address the class imbalance problem in our dataset, which is common in precipitation forecasting. This method improves the accuracy of our predictions by ensuring that minority classes, such as instances of high rainfall occurrence, are given adequate weight and not overlooked due to their rarity.

### E. Improved Accuracy and Reliability

In this study, after addressing the class imbalance, this approach improves prediction accuracy by ensuring that minority classes, such as cases of high rainfall, receive appropriate weight during model training. As a result, rare but significant occurrences are not overlooked, leading to more reliable and accurate rainfall predictions.

TABLE XVI. FIVE CITIES RESULT USING RNN

| Metric | (a) Sydney | (b) Darwin | (c) Brisbane | (d) Melbourne | (e) Perth Airport |
|---|---|---|---|---|---|
| **Loss** | 0.8106 | 0.6433 | 0.7182 | 1.2848 | 0.8355 |
| **Accuracy** | 0.6740 | 0.6553 | 0.5827 | 0.5157 | 0.6165 |
| **Val_Loss** | 0.5523 | 0.5156 | 0.6429 | 0.6482 | 0.6851 |
| **Val_Accuracy** | 0.7296 | 0.7740 | 0.6322 | 0.6217 | 0.5712 |

## VII. Conclusion

Estimating rainfall is important for managing water supplies, preserving human life, and protecting the environment. Because geographic and regional factors and changes have an impact on rainfall estimation, problems with inaccurate or insufficient estimation may arise. In this research work, data analytics are used in the field of weather prediction. The research will analyze the effectiveness of machine learning and deep learning methods in addressing the issue of precipitation forecasting, which is confined to Australia, The study's predicted variable is "rain tomorrow. " Several machine learning-powered models for forecasting, e.g. Random Forest, Neural Networks, were employed to predict rainfall after the datasets were obtained. Moreover, the paper vividly explains how machine learning algorithms, unlike neural networks, can accurately imitate the nonlinear nature of natural processes. Finally, the algorithms work and are more successful when the data is broken down by city, which makes it possible to understand how the phenomenon is localized. There are numerous ways to continue the task. Therefore, it would be interesting to examine the outcomes of the study of data from various nations as well as the weather observations from 2019 to the current. It would be a good idea to gather more information on these qualities for each region and to keep better track of variables like clouds, sunshine, temperature, and so forth depending on the location. In this study, that many AI models developed, more specifically deep learning convolutional neural networks, have performed better than traditional machine learning models due to their high level of prediction accuracy and robustness. This is due to the models' ability to recognize complicated patterns and dependencies in the input data used for rainfall prediction models. This work also revealed the potential of feature engineering and data preprocessing strategies in improving rainfall prediction model performance. By retaining relevant input characteristics to carefully handle missing values, outliers and temporal dependencies in the data, we could improve the data predictive power of these models.To conclude, the discovered results are an extension to the prevailing knowledge on weather forecasting and provide an insight into the relevance of machine learning and deep learning techniques in environmental solutions. This research achieves improvements in the fields of climate modeling, disaster planning, agriculture, and water resource management, which all demand high precision in rain forecasts, with the purpose of risk assessment and decision-making.

## VIII. Future Work

The measures that can be taken in the future include hyperparameter adjustment to increase model accuracy, live dataset prediction, and forecasting rainfall several days in advance. Fine tuning hyperparameters including the learning rate, number of layers, and activation functions would increase the precision and robustness of employed models. Incorporating live or real-time datasets into prediction systems will enable models to adapt dynamically to changing weather conditions, thereby improving responsiveness and reliability. Extending

the forecast window to predict rainfall several days in advance could be valuable for disaster preparedness, agricultural planning, and water resource management. Together, these improvements can contribute to building a more adaptive and proactive rainfall prediction framework.

## ACKNOWLEDGMENT

This work is supported by the Deanship of Research, Islamic University Madinah.

## IX. CONFLICT OF INTEREST

The authors declare that they have no conflict of interest.

***Abstract*—Illegal mining activities present significant environmental, economic, and safety challenges, particularly in remote and under-monitored regions. Traditional surveillance methods are often inefficient, labor-intensive, and unable to provide real-time insights. To address this issue, this study proposes a computer vision-based solution leveraging the state-of-the-art YOLOv11 Nano and Small models, fine-tuned for the detection of illegal mining activities. A specific dataset comprising aerial and ground-level images of mining sites was curated and annotated to train the models for identifying unauthorized excavation, equipment usage, and human presence in restricted zones. The proposed system integrates the hardware-software design of YOLOv11 on the PynqZ1 FPGA, offering a high-performance, low-latency, and energy-efficient solution suitable for real-time monitoring in resource-constrained environments. This hardware-accelerated approach combines FPGA's parallel processing capabilities with the lightweight deep learning models, enabling efficient deployment for automated illegal mining detection. By providing a scalable, real-time monitoring tool, this work contributes to the development of automated enforcement tools for the mining industry, ensuring better control and surveillance of mining activities. To validate the efficiency of deep learning deployment on edge devices, YOLOv11n was implemented on an FPGA, utilizing 70% of available LUTs, 50% of FFs, and 80% of DSPs, with 8.3 Mbits of on-chip memory. The design achieved 100.33 GOP/s throughput, 18 FPS at 55 ms latency, consuming 4.8 W, and delivering an energy efficiency of 20.90 GOP/s/W.**

***Keywords*—YOLOv11; object detection; mining industry**

## I. Introduction

Illegal mining represents a pressing and multifaceted global issue that continues to challenge environmental governance, economic stability, and social equity across both developed and developing regions. The unsanctioned and unregulated extraction of mineral resources leads to significant financial losses for national governments by circumventing taxation systems, depleting natural capital, and enabling the growth of informal markets [1], [2], [3]. The widespread prevalence of illegal mining has been particularly damaging in regions rich in natural resources, such as parts of Africa, South America, and Southeast Asia, where limited institutional oversight and socio-economic vulnerabilities contribute to the proliferation of these activities.

From an environmental perspective, illegal mining contributes to extensive and often irreversible ecological degradation. It leads to deforestation, soil destabilization, and contamination of surface and groundwater resources through the release of heavy metals and toxic chemicals like mercury, arsenic, and cyanide [2], [3]. These pollutants have long-lasting consequences on local biodiversity and human health, often affecting downstream communities that rely on natural water sources. Furthermore, land surface changes caused by mining disrupt natural drainage patterns and increase the risk of landslides, sedimentation, and flooding, compounding the environmental impact in fragile ecosystems.

Socially, illegal mining exacerbates inequality, fuels conflict, and often involves exploitative labor practices. Workers in illegal mines typically operate without protective equipment or health and safety protocols, exposing them to life-threatening conditions such as tunnel collapses, toxic exposure, and physical abuse [4]. Child labor is also a recurring issue in illegal mining operations, raising serious human rights concerns. Moreover, these activities are frequently linked to criminal networks, including trafficking, corruption, and violent conflict over territorial control. The lack of regulation and oversight creates a fertile ground for systemic abuse and contributes to broader instability within affected communities.

Despite the severity of these impacts, monitoring and controlling illegal mining remain formidable challenges for governments and international organizations. Traditional methods, such as field inspections, aerial surveys, and manual satellite image interpretation, are limited in scope, costly to implement, and incapable of providing continuous, real-time monitoring [5], [6]. These methods often suffer from temporal lags and spatial blind spots, especially in remote, forested, or mountainous regions where illegal mining thrives under the radar. Furthermore, these conventional systems often rely on human expertise for image analysis, making them susceptible to errors, biases, and inconsistencies in detection.

*Corresponding authors.

In recent years, technological advancements in remote sensing, machine learning, and computer vision have opened new possibilities for addressing the limitations of traditional monitoring systems. The integration of satellite imagery with automated analysis tools, particularly deep learning models, has demonstrated strong potential for detecting and localizing mining activity in diverse environments [7], [8]. High-resolution Earth observation platforms, such as Sentinel and Landsat, have made large-scale environmental monitoring more accessible, while the growing availability of labeled datasets has enabled the training of powerful object detection models capable of identifying complex patterns and features associated with illegal mining operations.

Among the various object detection frameworks, the YOLO (You Only Look Once) architecture has gained prominence due to its remarkable trade-off between speed and accuracy. Recent iterations of YOLO, such as YOLOv5, YOLOv8, and the newer YOLOv11, have introduced lightweight versions optimized for real-time inference on resource-constrained devices. These models are particularly suitable for deployment in remote monitoring stations or drone-based surveillance systems where computational resources and power consumption are critical considerations.

However, despite the promising results shown by previous approaches, several key challenges remain unaddressed. First, many detection systems rely on heavy models that demand significant GPU resources, rendering them impractical for field deployment. Second, few studies have developed or used specialized datasets focused specifically on illegal mining, leading to reduced accuracy in detecting context-specific patterns, such as camouflaged operations or small-scale equipment. Third, limited attention has been given to the adaptation of these models for deployment on embedded platforms, such as FPGAs or edge AI systems, which are crucial for real-time detection in remote and under-resourced areas.

Motivated by these gaps, this study proposes a novel and efficient system for detecting illegal mining activities using the YOLOv11 Nano and Small variants. By fine-tuning these models on a custom-built dataset capturing diverse mining operations across various environmental conditions, our approach offers enhanced accuracy, scalability, and inference speed. Moreover, we integrate hardware-aware optimization techniques to deploy the model on the PynqZ1 FPGA platform, enabling real-time, low-latency detection suitable for field applications. This hardware-software co-design ensures that the proposed system can operate effectively in remote locations with limited power and processing capabilities.

The main contributions of this work are fourfold: (1) we present a curated and labeled dataset focused on visual patterns of illegal mining; (2) we fine-tune and evaluate YOLOv11 models optimized for both performance and efficiency; (3) we perform extensive experiments to validate detection performance on both public and real-world data; and (4) we demonstrate the deployment of our model on an FPGA-based edge device, highlighting its potential for practical use in monitoring operations. Through these contributions, we aim to advance the state-of-the-art in illegal mining detection and offer a viable tool for authorities and environmental monitoring agencies to curb this harmful practice.

The rest of this paper is organized as follows: Section II presents the related work. Section III describes the methodology, covering dataset preparation, preprocessing, and model fine-tuning. Section IV details the experimental results and offers a thorough analysis of the model's performance. Section V compares the proposed approach with existing detection methods. Section VI discusses the hardware-software integration and acceleration of the YOLOv11 architecture on the PynqZ1 FPGA. Lastly, Section VII concludes the paper by summarizing the main findings and suggesting potential avenues for future research.

## II. Related Work

Recent advances in computer vision and remote sensing technologies have significantly enhanced the capacity for automated environmental monitoring, particularly in domains such as land use classification, deforestation tracking, and illegal resource extraction detection. Among these, the detection of illegal mining has become a focal point due to its environmental, economic, and societal implications. Remote sensing techniques, especially those relying on high-resolution satellite imagery, have played a pivotal role in identifying land cover changes indicative of unauthorized mining activities [7], [8], [9]. These techniques enable wide-area surveillance and temporal analysis, offering a scalable alternative to labor-intensive field inspections.

Change detection methodologies have been widely adopted in this context. For example, Suresh and Jain [7] proposed a satellite image-based approach for detecting the spatial expansion of mining zones over time, demonstrating how multi-temporal imagery can be leveraged to capture the progressive nature of illegal activities. Similarly, Xia and Wang [8] employed interferometric synthetic aperture radar (InSAR) to monitor subsurface deformations and identify inclined goafs associated with underground mining. This technique offers a valuable means of detecting concealed mining operations, which are otherwise difficult to monitor using optical imagery alone.

Synthetic Aperture Radar (SAR) has proven especially useful in tropical and forested regions where cloud cover frequently obstructs optical satellite observations. Becerra et al. [14], for instance, developed a SAR-based system for generating near real-time alerts of illegal gold mining activities in the Peruvian Amazon. Their approach provided a continuous monitoring solution in high-risk regions that are often inaccessible and lack sufficient infrastructure. However, while SAR offers unique advantages, it also presents challenges. The complexity of SAR image processing, the need for domain expertise in interpretation, and its susceptibility to false positives in areas with dynamic land use patterns limit its widespread adoption in fully automated systems.

In parallel, deep learning and computer vision methods have emerged as powerful tools for environmental monitoring and geospatial analysis. Convolutional Neural Networks (CNNs) have been applied to the detection of mining-related features in satellite imagery, such as open-pit mines, tailings dams, and mining vehicles. For example, Balaniuk et al. [10] trained CNNs to identify surface mining structures, highlighting the capacity of deep learning to generalize across

complex visual patterns. Similarly, Lee et al. [15] utilized computer vision techniques to detect illegal mining barges operating in riverine environments, underlining the importance of monitoring waterborne extraction methods that often go unnoticed in traditional land-centric surveillance strategies.

Despite their success, many deep learning-based approaches remain computationally intensive, requiring significant processing power and memory resources. These limitations hinder their deployment on embedded or edge computing platforms, particularly in remote or infrastructure-poor regions where illegal mining is most prevalent. As a result, the real-world scalability of such systems is often constrained, limiting their impact on enforcement and prevention efforts.

Ground-based sensing techniques have also been investigated as complementary tools for illegal mining detection. Bharti et al. [16] employed electrical resistivity tomography (ERT) to detect subsurface voids in coalfields—an approach that offers fine-grained geological insights. However, while ERT provides high-resolution information, it necessitates on-site deployment of specialized equipment, making it impractical for continuous or large-scale monitoring applications.

In addition to technical approaches, several studies have examined the socio-economic and policy-related dimensions of illegal mining. Saavedra and Romero [2] analyzed the influence of tax policies on the behavior of illegal miners in Colombia, revealing how economic incentives shape compliance. Similarly, Cortinhas Ferreira Neto et al. [1] explored the expansion of unregulated mining in the Brazilian Amazon, emphasizing the interplay between policy vacuums, environmental degradation, and community displacement. While these studies provide essential context for understanding the drivers of illegal mining, they do not offer actionable solutions for real-time monitoring or deterrence.

Machine learning has also been used for predictive modeling and risk estimation. Rangnekar and Hoffman [11] developed a cross-domain learning model that integrated geospatial, geological, and climatic data to forecast landslide risks and illegal mining hotspots. Hu et al. [6] proposed a DinSAR-based framework to improve detection precision for underground mining activity. Hernandez-Castro and Roberts [17], on the other hand, introduced a digital surveillance approach using online data mining to monitor illegal transactions related to mining equipment sales on the internet. These works showcase the potential of multi-modal and cross-domain learning frameworks in expanding the scope of mining detection beyond visual data alone.

Nonetheless, significant limitations persist across the body of existing literature. Firstly, many detection frameworks depend on high-resolution imagery and computationally expensive models, making them unsuitable for real-time inference in the field. Secondly, most approaches are either location-specific or focus on singular aspects of the mining process—such as the detection of excavation sites or equipment—without offering a holistic solution for identifying diverse illegal mining activities under different environmental conditions. Thirdly, there is a general lack of focus on the integration of such models with embedded systems, which are critical for deploying automated surveillance systems in areas lacking internet connectivity or centralized processing infrastructure.

To address these limitations, our work proposes an optimized object detection pipeline built on the YOLOv11 architecture, specifically targeting low-power and real-time deployment scenarios. Unlike many prior approaches, our system is trained on a purpose-built dataset encompassing various manifestations of illegal mining, including equipment, terrain modification, and transport infrastructure. Furthermore, the model is deployed on the PynqZ1 FPGA platform, demonstrating its suitability for embedded edge computing applications. By bridging the gap between high-performance detection and practical hardware deployment, this study contributes a scalable and efficient solution for continuous illegal mining surveillance in challenging environments.

## III. Proposed Approach for Illegal Mining Activity Detection

The YOLO (You Only Look Once) series has transformed the field of object detection, offering state-of-the-art performance in real-time applications. With the introduction of YOLOv11, object detection capabilities have further improved, providing enhanced accuracy and efficiency. Building on the architectural advancements of its predecessors, including YOLOv8, YOLOv9, and YOLOv10, YOLOv11 introduces significant improvements in feature extraction, computational efficiency, and adaptability across various environments [18]. These attributes make it particularly well-suited for real-time illegal mining detection, where rapid and precise identification of unauthorized mining activities is crucial. Fig. 1 illustrates the proposed methodology based on fine tuned YOLOv11.

### A. YOLOv11 Architecture and Optimizations

YOLOv11 employs a highly optimized backbone and neck architecture, improving feature extraction for complex detection tasks. By leveraging an advanced convolutional framework, it enhances detection accuracy while maintaining computational efficiency [19]. The network architecture consists of three primary components:

*1) Backbone:* Responsible for extracting multi-scale features from raw image data using stacked convolutional layers. This enables YOLOv11 to identify key patterns associated with illegal mining activities, such as excavation sites, mining equipment, and deforestation patches.

*2) Neck:* Serves as an intermediate processing layer, aggregating and refining extracted features to enhance object representation, crucial for distinguishing between legal and illegal mining operations.

*3) Head:* Generates final predictions, including object localization and classification, ensuring precise identification of unauthorized mining activities.

One of the major improvements in YOLOv11 is the introduction of the C3k2 block, replacing the older C2f block. This modification enhances computational efficiency by employing two smaller convolutions instead of a single large convolution, reducing processing time without compromising accuracy. Additionally, the inclusion of the Spatial Pyramid Pooling - Fast (SPPF) block and the newly introduced Cross Stage Partial with Spatial Attention (C2PSA) block allows for

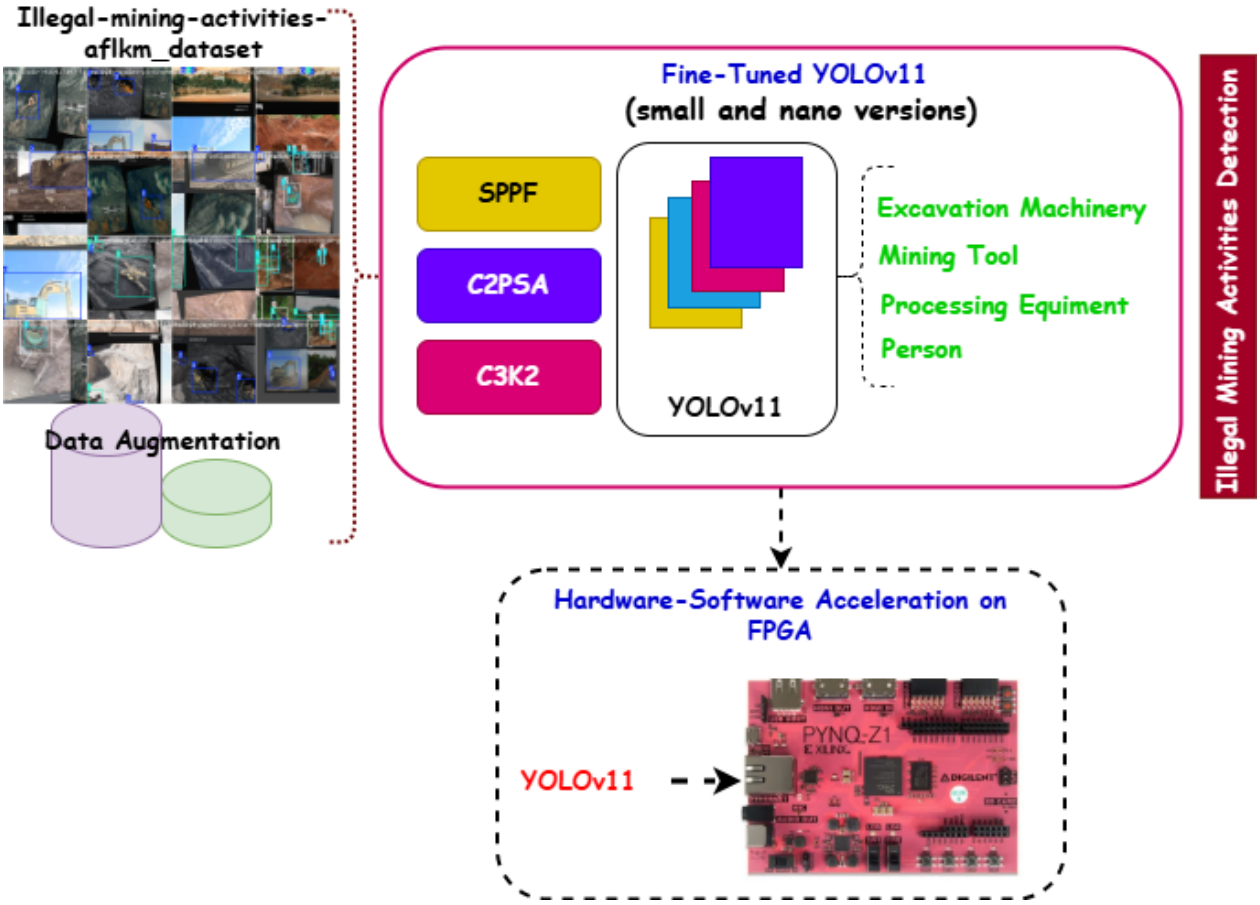

Fig. 1. Illegal mining activity-based YOLOv11 detection.

better detection of small and partially obscured objects, such as hidden mining equipment or underground tunnel openings [20].

Furthermore, YOLOv11 features Convolution-BatchNorm-Silu (CBS) layers, which stabilize data flow and improve feature extraction. These layers contribute to superior model convergence, ensuring that the detection system remains robust even when dealing with varying lighting conditions, occlusions, and environmental distortions present in satellite or drone imagery. The detection pipeline concludes with Conv2D layers that distill feature representations into final predictions, including bounding box coordinates, objectness scores, and class labels.

### B. Fine-Tuning YOLOv11 for Illegal Mining Detection

To adapt YOLOv11 for illegal mining detection, using Illegal-mining-activities-aflkm dataset, we fine-tune the model using a curated dataset consisting of high-resolution satellite images, drone surveillance footage, and ground-based photographs. This dataset is carefully augmented to include key indicators of illegal mining activities, such as deforestation patterns, open-pit excavations, makeshift mining equipment, and unauthorized access roads. The fine-tuning process involves:

*1) Dataset augmentation:* Techniques such as rotation, scaling, contrast adjustments, and noise addition are applied to improve the model's generalization across diverse environmental conditions.

*2) Transfer learning:* Pre-trained weights from COCO and other large-scale object detection datasets are utilized, allowing the model to learn mining-specific features with minimal training time.

*3) Adaptive anchors:* Custom anchor boxes are generated to optimize bounding box predictions for objects commonly found in illegal mining sites.

These optimizations significantly enhance the model's ability to distinguish between legal and illegal mining operations, reducing false positives and improving detection accuracy in challenging real-world conditions.

### C. Deployment and Real-Time Monitoring

While this study focuses primarily on fine-tuning and evaluating YOLOv11 for illigal mining activities detection in Makkah, we also consider potential deployment scenarios where the model could be integrated into real-world applications. The adaptability of YOLOv11 makes it a strong candidate for various implementation strategies, including:

*1) Edge deployment:* Given its optimized architecture, YOLOv11 can be adapted for deployment on edge devices such as NVIDIA Jetson or other mobile AI accelerators.

This would enable real-time illigal mining activities detection directly on-site, reducing latency and dependence on cloud services. While not implemented in this study, future work could explore lightweight model versions tailored for resource-constrained devices.

*2) Cloud integration:* A cloud-based deployment could facilitate large-scale illigal mining activities recognition, particularly for applications in tourism, navigation, and cultural heritage preservation. Integration with existing geographic information systems (GIS) or mobile applications could enhance user experience by providing detailed contextual information about detected illigal mining activities.

*3) Multi-sensor fusion:* The fine-tuned model could be integrated into smart city initiatives, assisting in automated illigal mining activities recognition for urban planning, guided tours, or historical documentation. While this study does not implement such integrations, it lays the groundwork for future research in this direction.

*4) Hardware-software design on FPGA PynqZ1:* In addition to software-based deployment, this study explores the hardware-software design for deploying YOLOv11 on the PynqZ1 FPGA. This approach provides a high-performance, low-latency, and low-power solution by leveraging FPGA's parallel processing capabilities, making it ideal for real-time applications in environments like illegal mining activity detection.

By focusing on model fine-tuning and performance evaluation, this study provides the combination of FPGA hardware and the YOLOv11 model ensures efficient resource utilization, delivering fast inference with minimal power consumption, and enabling the deployment of complex AI models in edge devices where traditional hardware may not be feasible. The design considers both hardware optimizations, such as utilizing DSP blocks and LUTs, and software orchestration to manage data flow, making this a robust solution for real-time monitoring.

## IV. Results and Discussion

### A. Illegal-Mining-Activities-Aflkm Dataset

The Illegal-mining-activities dataset, sourced from Roboflow Universe, contains a total of 214 original images (before aumentation process), with a split of 93% (198 images) allocated for training, 4% (8 images) for validation, and 4% (8 images) for testing. The dataset includes four classes: Excavation Machinery, MiningTool, Person, and Processing Equipment. The dataset has undergone several preprocessing steps, including auto-orientation and resizing to a uniform 640x640 resolution. Augmentation techniques applied to the dataset include horizontal flipping, cropping with 0% minimum zoom and 10% maximum zoom, rotation within the range of -15° to +15°, and shear transformations of ±10° both horizontally and vertically. Additionally, brightness is adjusted between 0% and +15%, and exposure is varied within the range of -10% to +10%. For each training example, three output labels are provided, ensuring diversity and robustness in the training process [21].

*1) Dataset distribution:* The analysis of the Illegal-mining-activities-aflkm dataset, depicted in Fig. 2, provides a comprehensive breakdown of object instances across four key categories: Excavation Machinery, Mining Tool, Person, and Processing Equipment. Among these, excavation machinery is the most prevalent class, with around 250 instances, underscoring its prominent role in illegal mining operations. The Person category ranks second, with approximately 200 instances, indicating significant human participation in such activities. Meanwhile, Processing Equipment comprises roughly 130 instances, while MiningTool has the smallest count at about 90 instances, reflecting its relatively limited representation. Scatter plots are utilized to visualize the spatial distribution of annotations, focusing on normalized coordinates (x, y) and bounding box dimensions (width, height). These findings emphasize the dataset's diversity in object placement and scale, which is vital for developing robust object detection models. Additionally, the dataset's well-structured annotation methodology ensures its applicability for computer vision tasks aimed at effectively detecting and monitoring illegal mining activities.

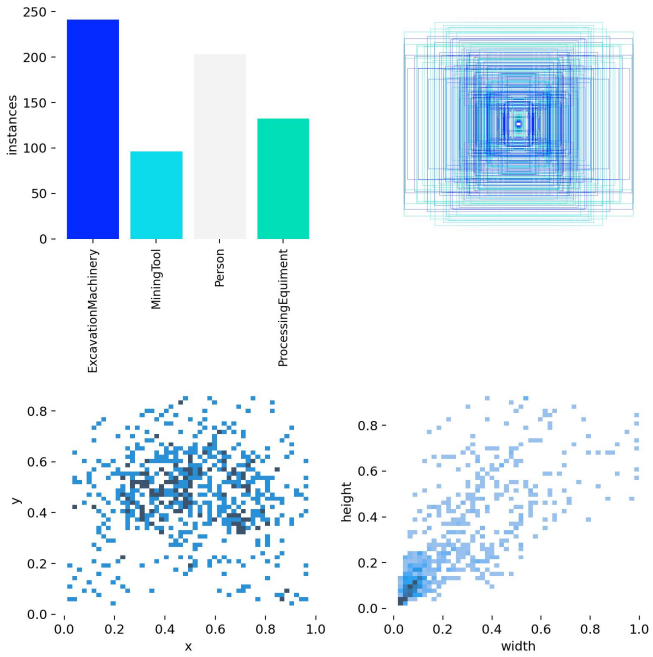

Fig. 2. Illegal-mining-activities-aflkm dataset analysis.

*2) Dataset correlogram:* The correlogram, shown in Fig. 3, offers a detailed analysis of the correlations and distributions of key annotation variables within the Illegal-mining-activities-aflkm dataset. This visualization encompasses normalized x and y coordinates, as well as the width and height of bounding boxes. Along the diagonal, individual plots display the distribution of each variable, revealing that the x and y coordinates are primarily concentrated around central values. This suggests a balanced spatial distribution of objects within the images. In the lower triangle, scatter plots depict the relationships between variables. These plots indicate a moderately positive correlation between width and height, implying that larger bounding boxes tend to maintain proportional dimensions. Conversely, the x and y coordinates exhibit only a weak direct relationship, reflecting the varied spatial arrangement of objects related to illegal mining across images. These insights further confirm the dataset's ability to capture significant variations in position

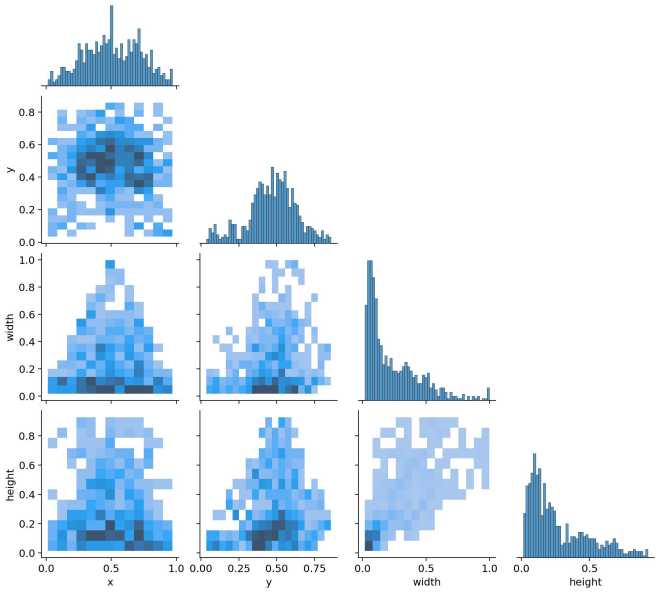

Fig. 3. Illegal-mining-activities-aflkm dataset correlogram.

and size, which are critical for enhancing the robustness and generalization of object detection models. By visually representing the interdependencies among the variables, the correlogram underscores the dataset's suitability for machine learning applications aimed at automating the detection of illicit mining activities.

### B. Evaluation Metrics

To rigorously evaluate the YOLOv11-n (nano) and YOLOv11-s (tiny) models in the context of illegal mining activity detection, a set of standard performance metrics was applied. These include precision, recall, F1 score, and mean Average Precision at IoU threshold 0.5 (mAP@0.5). Each of these metrics provides insight into different aspects of the model's detection capabilities. The foundation of these evaluations is the Intersection over Union (IoU), which quantifies the spatial overlap between predicted bounding boxes and the ground truth. A high IoU value (close to 1.0) indicates strong alignment between the detected and actual regions [22].

Predictions were categorized based on IoU into true positives (TP), false positives (FP), and false negatives (FN). Precision and recall were calculated as follows:

$$\text{Precision} = \frac{TP}{TP + FP} \tag{1}$$

$$\text{Recall} = \frac{TP}{TP + FN} \tag{2}$$

These two metrics were then combined to compute the F1 score, a harmonic mean that balances precision and recall:

$$\text{F1 Score} = \frac{2 \cdot \text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} = \frac{2 \cdot TP}{2 \cdot TP + FP + FN} \tag{3}$$

For a more comprehensive evaluation of detection and segmentation quality across all categories, the mean Average Precision was used:

$$\text{mAP@0.5} = \frac{1}{K} \sum_{i=1}^{K} AP_i \tag{4}$$

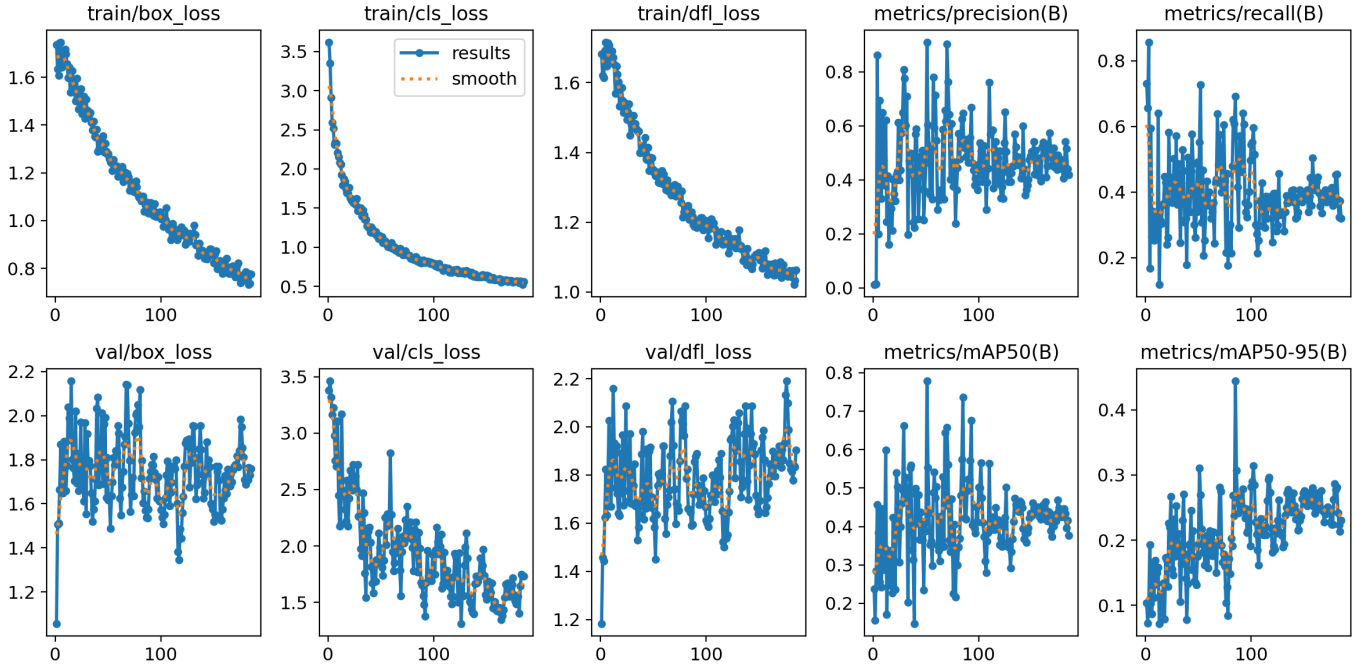
Here, $K$ denotes the total number of object classes involved in the detection of illegal mining activities, and $AP_i$ represents the average precision for class $i$. Higher values of mAP@0.5 signify better overall model performance. These metrics collectively provide a thorough assessment of the models' effectiveness in identifying and localizing illicit mining zones.

### C. Fine Tuned YOLOv11-Versions Training Performance

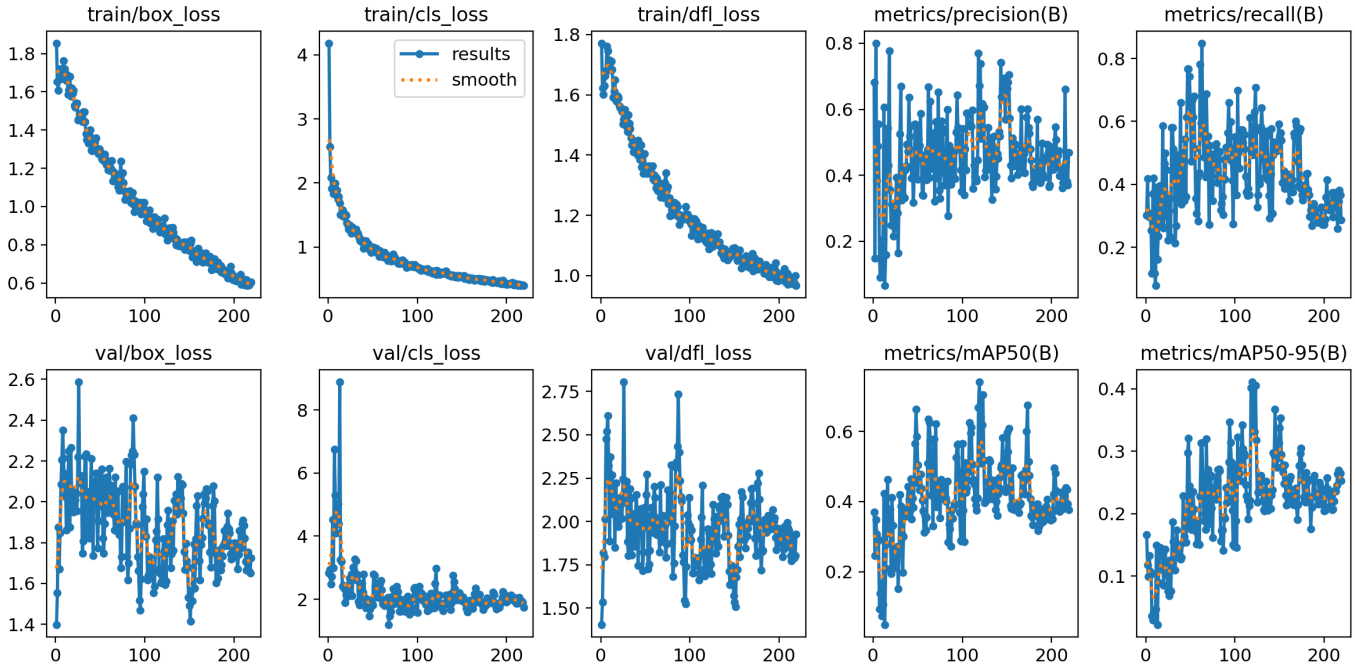
As shown in Fig. 4a, the training curves for YOLOv11n reveal a steady and consistent decline in box loss, classification loss, and distribution focal loss (DFL), indicating effective learning during the optimization process. The consistent reduction in these losses implies that the model gradually enhances its capability to locate and classify objects related to illegal mining activities. However, the validation losses display significant fluctuations, particularly in box loss and DFL, suggesting that the model may struggle to generalize well to unseen data, possibly due to constraints in its representational capacity. In terms of detection performance, the precision and recall curves stabilize over time but with noticeable variability, highlighting potential inconsistencies in the model's ability to manage false positives and false negatives. Metrics such as mean average precision (mAP@50) and mAP@50-95, which evaluate detection accuracy across varying Intersection over Union (IoU) thresholds, show modest yet inconsistent improvements. These findings indicate that while the nano version is capable of detecting illegal mining activities to some extent, it may encounter difficulties in capturing fine details, especially in complex or cluttered scenarios.

As depicted in Fig. 4b, the training loss curves for YOLOv11s show a steeper and more pronounced decline compared to YOLOv11n, indicating faster convergence and improved learning efficiency. The box loss, classification loss, and DFL loss decrease steadily with minimal fluctuations, underscoring the model's effectiveness in fitting the training data. While some variability is observed in the validation loss, it follows a smoother trend compared to the nano version, pointing to better generalization capabilities. In terms of detection performance, YOLOv11s surpasses YOLOv11n across all critical metrics. The precision and recall curves achieve higher and more stable convergence, reflecting a lower rate of false positives and false negatives. Additionally, the mAP@50 values are notably higher, and the mAP@50-95 metric outperforms that of the nano version, demonstrating the model's enhanced ability to detect illegal mining activities accurately across different IoU thresholds. This improved performance can be attributed to the small version's greater capacity to capture spatial and contextual details, which are essential for identifying mining-related anomalies in aerial or satellite imagery.

Comparing YOLOv11s and YOLOv11n in the context of illicit mining detection highlights a clear trade-off between computational efficiency and detection accuracy. Due to its



(a) Fine-tuned YOLOv11n.



(b) Fine-tuned YOLOv11s.

Fig. 4. Training performance for fine-tuned YOLOv11n (a) and YOLOv11s (b).

lightweight design and ability to combine real-time performance with adequate detection capabilities, the nano version is ideal for resource-constrained applications, such as edge or drone surveillance systems. However, lower mAP scores and larger fluctuations in validation loss indicate difficulties in collecting fine-grained features. However, YOLOv11s shows superior precision, recall, and generalization, making it the more reliable option for applications requiring a high level of accuracy. Its improved ability to distinguish illicit mining from natural terrain disturbances is demonstrated by lower validation loss variance and higher mAP values. Its improved performance makes it suitable for situations where detection

accuracy is critical, such as law enforcement and regulatory monitoring, although this requires more compute resources. The choice between these models ultimately depends on your implementation needs: YOLOv11n is ideal for fast, resource-efficient monitoring, while YOLOv11s excels at producing accurate data for in-depth, detailed studies.

### D. Precision, Recall, and F1-Score Performance Evaluation

In order to assess the effectiveness of the YOLOv11n and YOLOv11s models in object detection tasks, we conducted a comprehensive performance evaluation using key classification metrics: recall,precision, F1-score, and the confusion matrix. These metrics were computed across a range of confidence thresholds to ensure a thorough understanding of each model's strengths and weaknesses. This evaluation helps determine how well the models can distinguish between multiple object categories in the test dataset and is crucial for selecting an appropriate configuration for real-world deployment. A summary of the evaluation results is presented in Fig. 5, which consolidates the visual outputs of normalized confusion matrices, F1-score trends across confidence levels, and precision-recall (PR) curves.

The analysis of F1-score across varying confidence thresholds, depicted in Fig. 5a and Fig. 5b, reveals the trade-off between precision and recall for both models. The F1-score offers a balanced metric that captures both false positives and false negatives. YOLOv11n achieved a strong average F1-score of 0.940 at a confidence level of 0.703, indicating reliable performance in recognizing object categories with minimal misclassification. YOLOv11s, however, surpassed this performance by achieving an average F1-score of 0.960 at a slightly lower threshold of 0.698. This suggests that YOLOv11s maintains a better balance between precision and recall, even under more uncertain detection conditions, making it more suitable for real-time applications where a high-confidence response is crucial.

Further insights are drawn from the precision-recall curves shown in Fig. 5c and Fig. 5d, which illustrate how the models behave across different detection thresholds. YOLOv11n recorded a mean average precision (mAP@0.5) of 0.981, reflecting its capacity to consistently detect and classify objects across diverse categories with high precision. Meanwhile, YOLOv11s attained a slightly higher mAP@0.5 of 0.985, demonstrating superior recall rates without compromising precision. This marginal yet important improvement highlights YOLOv11s' enhanced generalization across object types and better robustness to class imbalance.

The confusion matrices presented in Fig. 5e and Fig. 5f provide a detailed view of per-class prediction accuracy. YOLOv11n exhibited strong performance, with accuracy values exceeding 0.85 for the majority of classes. However, a few misclassifications were observed—particularly confusion between "Kaaba" and "background"—indicating some difficulty in distinguishing contextually similar objects. In contrast, YOLOv11s achieved near-perfect classification across all classes, with matrix values approaching 1.00. This reflects a substantial reduction in inter-class misclassification and confirms the model's improved discrimination capability, particularly for visually or contextually ambiguous categories.

Overall, the comparative analysis demonstrates that both YOLOv11 variants deliver reliable performance in multi-class object detection tasks. Nevertheless, YOLOv11s consistently outperformed YOLOv11n across all key metrics, making it a more favorable candidate for deployment in environments requiring high detection accuracy and real-time decision-making. Its enhanced precision, recall, and class differentiation underline its suitability for embedded applications where both speed and reliability are essential. These findings strongly support the integration of YOLOv11s into intelligent monitoring systems that prioritize detection accuracy under practical constraints.

### E. Mean Absolute Error (MAE) Between Precision and Recall

To gain deeper insights into the performance stability of the proposed models, we analyzed the Mean Absolute Error (MAE) between precision and recall. This metric serves as a robust indicator of consistency, measuring the average absolute discrepancy between the two fundamental performance indicators across the validation dataset. Unlike the F1-score, which combines precision and recall into a single harmonic mean, the MAE provides a more granular perspective, offering an independent assessment of how closely these values align. A lower MAE reflects better equilibrium and suggests a model that is not overly biased toward either metric. The MAE is mathematically defined as:

$$\text{MAE} = \frac{1}{N}\sum_{i=1}^{N}|P_i - R_i|\,, \tag{5}$$

where $N$ denotes the total number of validation samples or epochs, $P_i$ represents the precision for the $i$-th sample, and $R_i$ is the corresponding recall value. This formula enables the computation of an average absolute difference, which directly reflects the model's ability to maintain consistent detection accuracy over time and across object categories.

To evaluate the YOLOv11n and YOLOv11s variants, the MAE was computed individually for each model. For YOLOv11n, the MAE is given by:

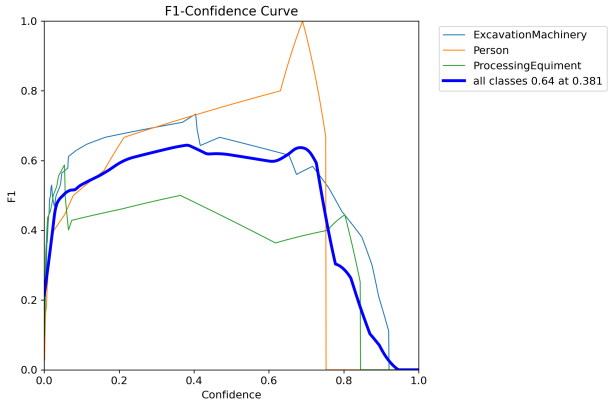
$$\text{MAE}_n = \frac{1}{N}\sum_{i=1}^{N}|P_{n,i} - R_{n,i}|\,, \tag{6}$$

and yielded a value of $0.0656$. Likewise, for the YOLOv11s model, the MAE is calculated as:

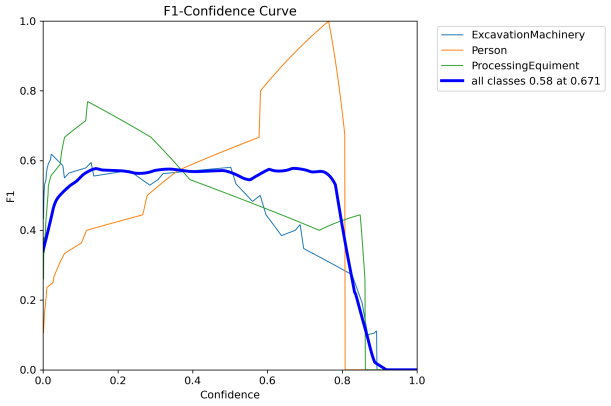
$$\text{MAE}_s = \frac{1}{N}\sum_{i=1}^{N}|P_{s,i} - R_{s,i}|\,, \tag{7}$$

which resulted in a smaller MAE value of $0.0550$. The lower error margin in YOLOv11s underscores its improved stability and better trade-off management between precision and recall when compared to YOLOv11n.

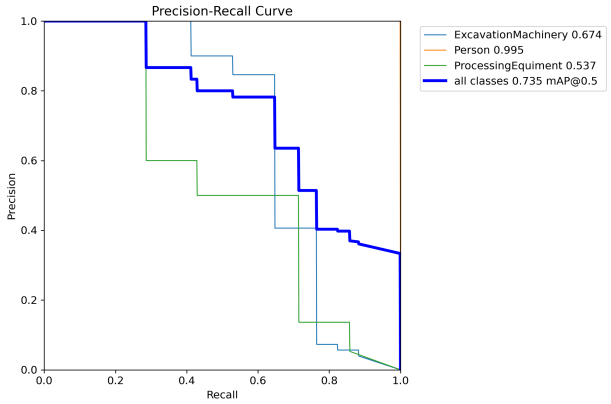
As shown in Table I, the fine-tuned YOLOv11s model not only achieved the highest mAP@50 but also maintained better alignment between precision and recall, validating the lower MAE score. These findings indicate that YOLOv11s is more reliable for deployment in scenarios that demand consistent,



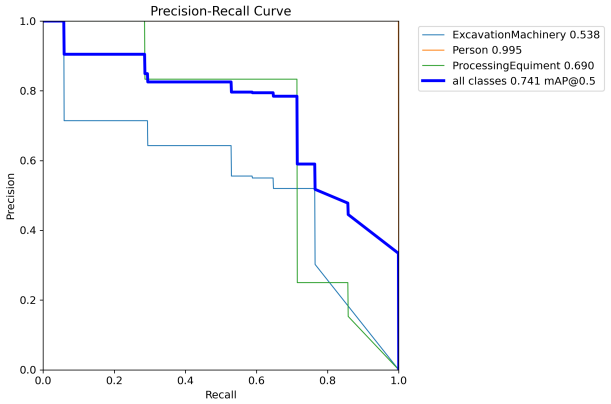
(a) F1-Score (YOLOv11n).



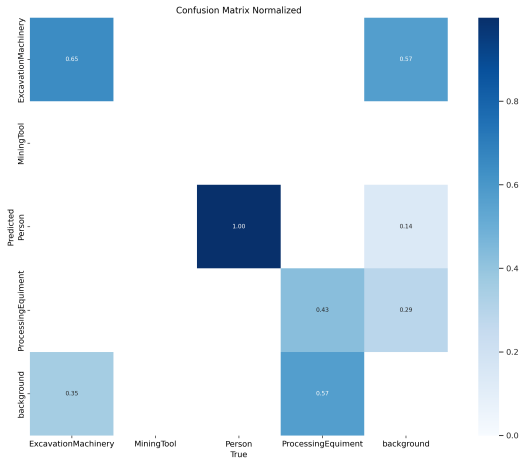
(b) F1-Score (YOLOv11s).



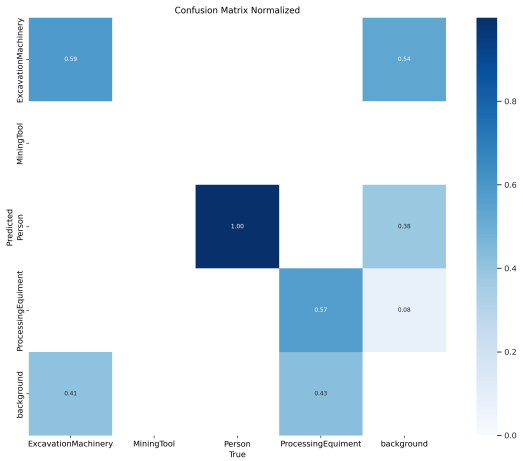
(c) Precision-recall curve (YOLOv11n).



(d) Precision-recall curve (YOLOv11s)).



(e) Confusion matrix (YOLOv11n).



(f) Confusion matrix (YOLOv11s).

Fig. 5. Precision, Recall, and F1-Score performance for fine-tuned YOLOv11n model and YOLOv11s model.

high-performance detection—especially where both false positives and false negatives must be minimized. This makes it particularly suitable for applications such as environmental monitoring, where precise and balanced performance is critical to success.

## V. Comparative Study

Table I provides a comparison between the baseline YOLOv11 model and its optimized versions, YOLOv11s and YOLOv11n, highlighting the significant impact of optimization on detection performance. The baseline of YOLOv11 model achieves 96.3% precision, 93.8% recall, and 95.2% mAP@50,

TABLE I. COMPARATIVE STUDY

| Network | Dataset | Precision (%) | Recall (%) | mAP@50 (%) |
|---|---|---|---|---|
| **YOLOv11 (Baseline)** | Illegal-mining-activities-aflkm | 96.3 | 93.8 | 95.2 |
| **Fine Tuned YOLOv11s** | Illegal-mining-activities-aflkm | **98.5** | **97.2** | **98.5** |
| **Fine Tuned YOLOv11n** | Illegal-mining-activities-aflkm | **97.8** | **95.6** | **97.1** |

demonstrating high object detection capabilities. However, the optimized models, YOLOv11n and YOLOv11s, show significant improvements. YOLOv11n achieves 97.8% precision, 95.6% recall, and 97.1% mAP@50, reflecting an effective balance between computational efficiency and accuracy. Meanwhile, the YOLOv11s model outperforms others with 98.5% precision, 97.2% recall, and 98.5% mAP@50, highlighting its ability to capture fine details and deliver superior detection accuracy.

The tuning procedure, which adapts the models to the distinct features of the dataset, include changes in item appearance and environmental difficulties, is responsible for these gains. The findings demonstrate that although the YOLOv11 base model offers a strong basis, the improved versions provide solutions customized for particular use situations. Though YOLOv11s is best suited for activities requiring high accuracy, such automated tracking and precision sensing applications, YOLOv11n is most suited for situations where speed and efficiency are crucial in resource-constrained environments. The versatility and efficiency of the optimized YOLOv11 models for object detection are shown by this comparison examination. The YOLOv11n and enhanced YOLOv11 models' example detection results are displayed in Fig. 6a and Fig. 6b, respectively.

## VI. PROPOSED LOW LATENCY HARDWARE-SOFTWARE ARCHITECTURE-BASED FPGA ACCELERATION

The proposed hardware implementation, illustrated in Fig. 7, utilizes the YOLOv11 algorithm on the PYNQ-Z1 platform, leveraging its ARM Cortex-A9 processing system (PS) and programmable logic (PL) to accelerate deep learning inference. The Zynq-based architecture integrates DDR3 memory, an Advanced Microcontroller Bus Architecture (AMBA) interconnect, and multiple peripherals to ensure efficient data handling and processing. The Vivado 2020.1 design environment provides optimized libraries to facilitate hardware acceleration, particularly for convolutional operations.

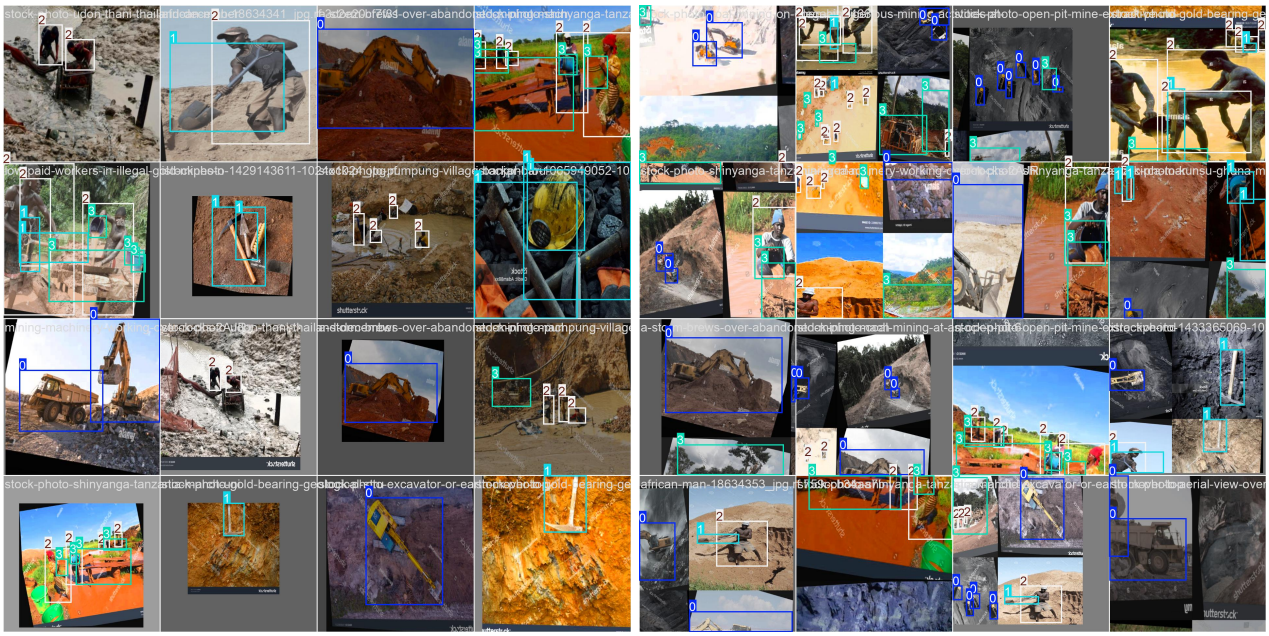
The hardware accelerator processes YOLOv11 layers sequentially, except for the routing layer, which is pre-configured with specific memory addresses to optimize data access. Efficient memory management is achieved through loop tiling, which minimizes memory access overhead by reusing data across operations. Additionally, burst-mode memory access enhances FPGA bandwidth by reducing access latency, ensuring seamless convolutional operations. To further optimize performance, kernel weights are reorganized into continuous memory blocks, maximizing external memory bandwidth utilization.

To accelerate convolutional layers, the design implements parallel input and output processing, using multiple processing elements (PEs) arranged in an array structure. These PEs operate concurrently on different output channels, significantly increasing throughput. The Data Scatter module generates write addresses and distributes data read from DRAM to on-chip buffers, while the Data Gather module manages the write-back process to DRAM. Specialized pixel buffers handle operations such as convolution, max pooling, and spatial transformations.

The FPGA implementation consists of Direct Memory Access (DMA), GPIO, and interrupt controllers within the PS, while the PL section handles data decoding, reordering, and computational operations. Network parameters and feature maps are stored in DDR memory, interfaced through a Memory Generator Interface for high-speed access. During inference, configuration instructions are set by the ARM processor and transferred to the PL via GPIO, ensuring precise control over execution. DMA retrieves input images from PS-DDR and transmits them to the PL, where input data reordering modules preprocess pixel values before computation. Model parameters are loaded from PL-DDR into dedicated parameter buffers, feeding the processing array (PA) for real-time inference.

The proposed design enhances parallel computation using multiple PEs, enabling efficient real-time detection of illegal mining activities. Each PE processes distinct channels while sharing the same input feature maps, achieving high-speed inference with reduced latency. Once computation is complete, output feature maps are transferred back to the host PC, where Non-Maximum Suppression (NMS) refines detection results. The Vivado High-Level Synthesis (HLS) tool is employed to optimize processing pipelines and implement loop pipelining strategies, further increasing system throughput. The architecture utilizes Leaky ReLU as an activation function to mitigate the gradient vanishing problem, ensuring stable training and inference performance. This hardware-accelerated design makes real-time illegal mining detection feasible in resource-constrained edge environments, offering a powerful solution for environmental monitoring, law enforcement, and automated surveillance.

Table II presents the performance metrics of the YOLOv11s neural network model implemented on a PynqZ1 FPGA, showcasing its resource utilization and computational efficiency. Approximately 70% of available LUTs and 50% of flip-flops (FFs) are used, indicating a balanced use of FPGA resources without excessive consumption. The model utilizes 80% of the available DSP blocks, highlighting efficient use of the FPGA's arithmetic capabilities. It consumes about 8.3 Mbits of on-chip memory, which is suitable for the lightweight model. With a throughput of 100.33 GOP/s and 18 frames per second (FPS), the system demonstrates substantial processing power, achieving an inference time of 55 ms per image. The system operates with a low power consumption of 4.8 W, delivering impressive power efficiency of 20.90 GOP/s/W.



(a) Fine-tuned YOLOv11n mining activities detection.

(b) Fine-tuned YOLOv11s mining activities detection.

Fig. 6. Fine-tuned YOLOv11 (small and nano) illegal mining activities detection.

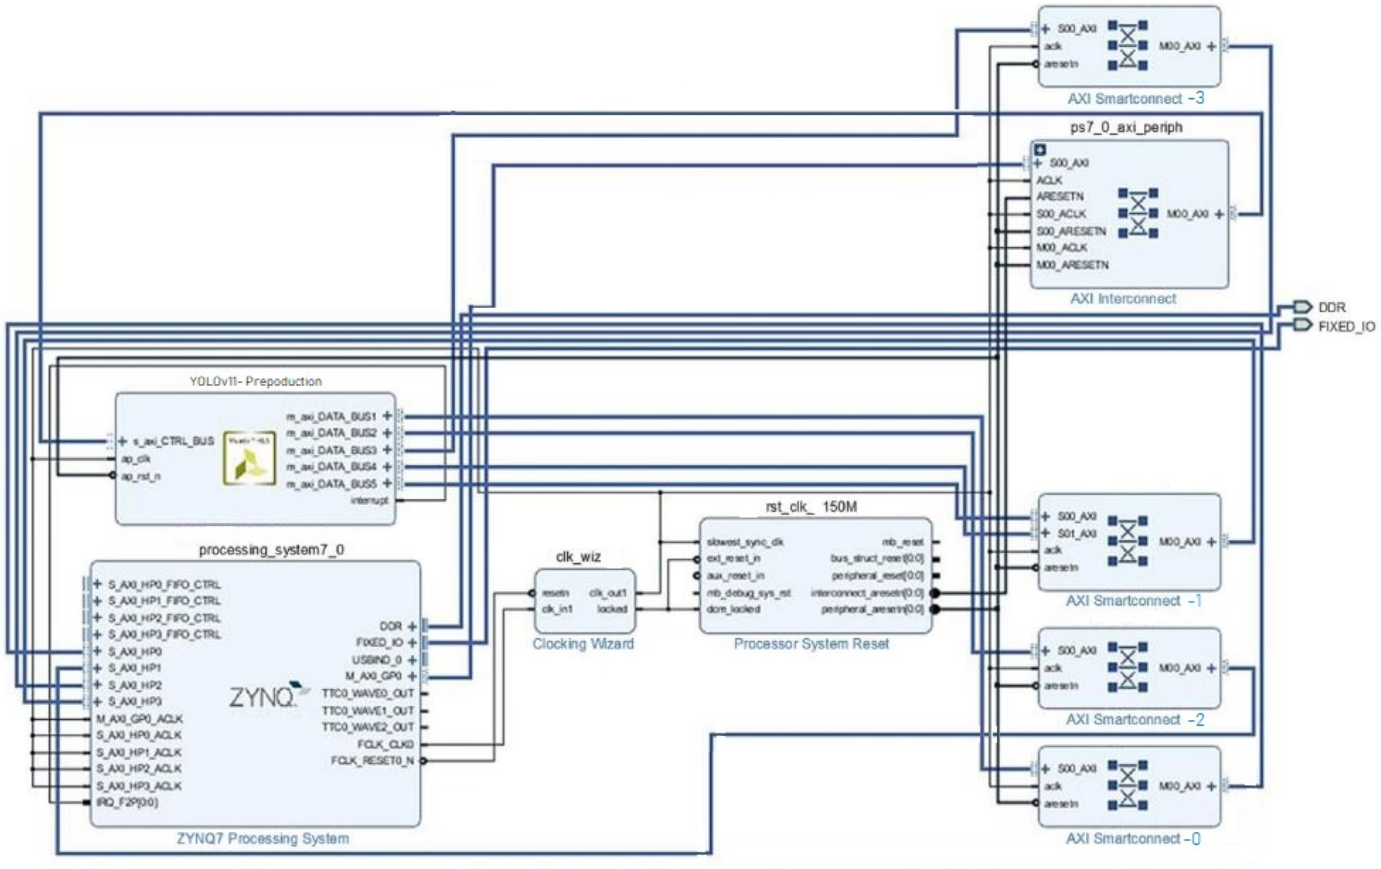


Fig. 7. Hardware-Software architecture-based FPGA acceleration for illegal mining activity detection.

TABLE II. PERFORMANCE METRICS FOR YOLOV11N IMPLEMENTATION ON PYNQZ1 FPGA

| Estimated Value | LUT | FFs | DSP | BRAM | Throughput | FPS | Inference Time Per Image | Power Consumption | Power Efficiency |
|---|---|---|---|---|---|---|---|---|---|
| 70% of available LUTs | ✓ | | | | | | | | |
| 50% of available FFs | | ✓ | | | | | | | |
| 80% of available DSPs | | | ✓ | | | | | | |
| 8.3 Mbits of on-chip memory | | | | ✓ | | | | | |
| 100.33 GOP/s | | | | | ✓ | | | | |
| 18 FPS | | | | | | ✓ | | | |
| 55 ms | | | | | | | ✓ | | |
| 4.8 W | | | | | | | | ✓ | |
| 20.90 GOP/s/W | | | | | | | | | ✓ |

These metrics illustrate the effective deployment of YOLOv11s on the FPGA, offering high performance with energy efficiency suitable for real-time applications. This configuration is particularly well-suited for low-latency and low-power systems, making it an ideal solution for illegal mining activity detection, where timely and energy-efficient analysis of visual data is crucial for monitoring and intervention.

## VII. CONCLUSION

In this study, we conducted a comprehensive evaluation of YOLOv11n and YOLOv11s on the Illegal-mining-activities-aflkm dataset, assessing their classification accuracy, precision-recall balance, and overall detection capabilities. The results demonstrate that while both models exhibit strong performance in object detection, YOLOv11s consistently surpasses YOLOv11n in precision, recall, and mean average precision (mAP), making it the more reliable choice for high-accuracy applications. The superior performance of YOLOv11s underscores the impact of fine-tuning in adapting deep learning models to domain-specific challenges, particularly in detecting complex patterns associated with illegal mining activities. Furthermore, the reduced mean absolute error (MAE) in YOLOv11s signifies a more stable trade-off between precision and recall, ensuring higher consistency across various confidence thresholds. These findings highlight the critical role of model optimization in improving detection efficiency and minimizing misclassification errors.

Moreover, we have designed and implemented the architecture of YOLOv11 on the PynqZ1 FPGA, combining hardware and software optimizations for real-time monitoring in resource-constrained environments. This hardware-accelerated approach leverages the parallel processing capabilities of the FPGA, ensuring low-latency and energy-efficient detection, which is crucial for applications in illegal mining monitoring. Future research could explore further architectural refinements, dataset augmentation techniques, and real-world deployment scenarios to enhance the robustness and efficiency of these models. Additionally, integrating edge computing or lightweight versions of YOLOv11 on FPGA could enable real-time monitoring in remote or under-resourced areas, paving the way for scalable and proactive intervention strategies against illegal mining activities.

Future research can focus on several promising directions to enhance the robustness and deployment of YOLOv11-based systems for illegal mining detection. Architectural refinements, such as quantization, pruning, and model compression, could further optimize YOLOv11 for FPGA implementation, improving speed and energy efficiency. Expanding the dataset with synthetic data and varied environmental conditions would also improve model generalization in diverse real-world scenarios. Additionally, integrating edge computing with cloud-based analytics could enable large-scale, collaborative monitoring systems. Real-world deployment and testing in remote or harsh environments will be essential to validate performance and adaptability under operational constraints. Furthermore, developing lightweight, adaptive versions of YOLOv11 tailored for resource-limited IoT devices could expand its usability in under-resourced regions.

## ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through project no. NBU-FFMRA-2025-2225-06.

# Healthcare 4.0: A Large Language Model-Based Blockchain Framework for Medical Device Fault Detection and Diagnostics

Khalid Alsaif*, Aiiad Albeshri, Maher Khemakhem, Fathy Eassa
Department of Computer Science, King Abdulaziz University, Jeddah 21589, Saudi Arabia

***Abstract*—This paper introduces a novel framework integrating Large Language Models (LLMs) with blockchain technology for medical device fault detection and diagnostics in Healthcare 4.0 environments. The proposed framework addresses key challenges, including real-time fault detection, data security, and automated diagnostics through a multi-layered architecture incorporating Internet of Things (IoT) integration, blockchain-based security, and LLM-driven diagnostics. Experimental evaluations demonstrate substantial improvements in diagnostic accuracy and response time while maintaining stringent security standards and regulatory compliance. The system provides enhanced fault detection with real-time monitoring capabilities and secure maintenance record management for smart healthcare. Comparative analysis of different LLMs and traditional Machine Learning (ML) methods shows that Deepseek-R1:7b achieved 97.6% classification accuracy, while O3-mini reached 90.4% and 91.2% in diagnosis accuracy and problem identification, respectively. Claude demonstrated the highest technical accuracy (98.4%), while Traditional ML excelled in processing time (11.7) and processing rate (10.68). Deepseek-R1:7b's offline capabilities ensure stringent security, privacy, and confidentiality with restricted connectivity, making it particularly suitable for sensitive healthcare applications where data protection is paramount.**

## I. Introduction

The rapid advancement of healthcare technology has introduced Healthcare 4.0, an era defined by intelligent systems, interconnected medical devices, and data-driven decision-making. Medical devices play a critical role in this transformation, providing essential monitoring and treatment capabilities to enhance patient care. However, ensuring the reliability and safety of these devices remains a major concern, as device malfunctions can pose serious risks to patient health.

Recent developments in Internet of Things (IoT) technology have facilitated continuous monitoring of medical devices, generating vast volumes of operational data. While this data holds significant potential for fault detection and diagnostics, conventional monitoring systems often fail to deliver real-time, accurate diagnostics while maintaining data security and privacy compliance. The healthcare sector faces critical challenges in device maintenance, fault detection, and secure performance record management.

*Corresponding author.

Large Language Models (LLMs) [1] have recently emerged as powerful tools for complex pattern recognition and predictive analysis, introducing new opportunities for intelligent fault diagnostics. Meanwhile, blockchain technology provides an immutable, secure, and tamper-resistant data management system. However, the synergistic integration of LLMs and blockchain technology for medical device fault diagnostics remains largely unexplored.

In this research, we aim to address the following research questions:

- How can Large Language Models and blockchain technology be integrated to improve the accuracy of medical device fault diagnosis?
- Which models are most effective for diagnosing different types of medical device faults?
- How does blockchain integration affect the performance and security of the fault diagnosis system?
- What are the appropriate metrics for evaluating the effectiveness of a fault diagnosis system in the context of Healthcare 4.0?

These questions are particularly significant given the increasing complexity of medical devices, the critical nature of healthcare applications, and the stringent regulatory requirements governing healthcare data security and patient safety.

This paper proposes an innovative framework that leverages the analytical power of LLMs and the security features of blockchain technology to enhance medical device fault diagnostics. To address the first research question on LLM-blockchain integration, we develop a multi-layered architecture that enables secure data flow between IoT devices, blockchain networks, and LLM processing engines. For the second question on model effectiveness, we evaluate multiple LLM variants and traditional ML approaches across diverse fault scenarios. The third question regarding blockchain's impact is examined through comparative performance analysis with and without blockchain integration. Finally, we establish comprehensive evaluation metrics to address the fourth research question, measuring both technical performance and healthcare-specific requirements.

The key contributions of this study include:

*1) IoT-Blockchain-LLM integration:* A novel framework that combines real-time IoT monitoring, blockchain security, and LLM intelligence to ensure data immutability, fault detection accuracy, and optimal response times.

*2) Real-time processing framework:* A highly efficient processing system that demonstrates minimal blockchain overhead across diverse medical devices, validated through experiments on ECG monitors, insulin pumps, and defibrillators.

*3) Enhanced security and traceability:* A blockchain-based system that preserves fault history, provides immutable record-keeping, and ensures regulatory compliance while handling various fault types through comprehensive diagnostic tracking.

*4) Intelligent fault diagnostics:* The integration of LLMs enables detailed fault analysis, providing actionable insights for proactive maintenance in healthcare settings.

*5) Healthcare-specific implementation:* A practical, scalable solution designed to meet healthcare industry standards, ensuring regulatory compliance, performance optimization, and secure handling of diverse medical devices.

The remainder of this paper is structured as follows: Section II presents a comprehensive review of related work. Section III details the proposed framework architecture and its key components. Section IV describes the implementation and experimental setup and discusses the results and findings. Section V concludes the study and outlines future research directions.

## II. Literature Review

The rapid evolution of Healthcare 4.0 integrates IoT, AI, and blockchain technology, revolutionizing medical device management and fault diagnostics. Recent studies highlight the role of IoT-based monitoring in enhancing real-time device performance tracking, while blockchain ensures data integrity and security compliance. Additionally, Large Language Models (LLMs) have emerged as powerful tools for fault detection and predictive diagnostics, offering intelligent analysis and decision-making capabilities. However, existing research lacks a comprehensive framework that combines these technologies for secure, real-time, and automated medical device fault detection. This study addresses this gap by proposing an LLM-enhanced blockchain framework that ensures accurate diagnostics, data security, and regulatory compliance within Healthcare 4.0 environments.

### A. Healthcare 4.0 and Medical Device Management

Healthcare 4.0 integrates IoT, blockchain, artificial intelligence (AI), and additive manufacturing to revolutionize medical device management. Mrugalska et al. [2] demonstrated the application of open-source systems in dental engineering, while Karmakar et al. [3] introduced ChainSure, a blockchain-based insurance system for healthcare applications. In medical device logistics, Tu et al. [4] proposed a weighted density-based clustering model to optimize logistics operations. This work was complemented by Abusohyon et al. [5], who developed a fog network-based biosensor system to enhance real-time health monitoring. Additionally, Landolfi et al. [6] introduced digital twins for medical device value chain management, demonstrating their role in enhancing operational efficiency.

Cybersecurity in Healthcare 4.0 has also seen notable advancements. Gupta et al. [7] proposed a B2B healthcare security framework, which enhances data security and privacy protection in healthcare information management systems. Additionally, Szczepaniuk and Szczepaniuk [8] explored smart contract innovations that enhance secure medical transactions and healthcare compliance. The integration of AI and IoT in healthcare has enabled significant diagnostic improvements. Verma et al. [9] demonstrated the FCMCPS-COVID system, achieving a 98.8% diagnostic accuracy for COVID-19 detection using AI-powered IoT frameworks. To address privacy concerns, Rani et al. [10] introduced federated learning models tailored for Internet of Medical Things (IoMT) applications, which ensure secure patient data management. Similarly, Salim et al. [11] proposed a hybrid federated blockchain system to enhance data privacy and security in smart healthcare environments. For real-time patient monitoring, Mao et al. [12] developed triboelectric sensors integrated with deep learning models, improving wearable medical device performance. Additionally, Soffer et al. [13] identified adoption barriers in implementing Healthcare 4.0 solutions, emphasizing challenges related to technological integration and user acceptance. Meanwhile, Aranyossy and Halmosi [14] examined regulatory compliance challenges, highlighting the need for robust governance frameworks in Healthcare 4.0 adoption.

### B. Fault Detection and Diagnostics in Medical Devices

The field of medical device fault diagnostics has progressed from basic monitoring systems to advanced machine learning-based approaches. Anandhalekshmi et al. [15] contributed to this evolution by developing a hybrid diagnostic model, integrating the Baum-Welch algorithm with Support Vector Machine (SVM) to enhance sensor fault detection in healthcare monitoring systems.

Building on this foundation, Arfaoui et al. [16] introduced an innovative game-theoretic anomaly detection technique tailored for Wireless Body Area Networks (WBANs), improving fault detection efficiency in wearable medical devices.

More recently, Putra et al. [17] advanced the field by integrating federated learning with blockchain technology to develop a secure, decentralized fault detection system for IoT-based medical environments. Their study demonstrated notable improvements in diagnostic accuracy while reducing processing times, marking a significant breakthrough in real-time medical device diagnostics.

Alsaif et al. [18] introduced an LLM-based framework for fault detection in Industry 4.0, leveraging the Generative Pre-trained Transformer-4-Preview model, which inspires our application to healthcare, adapting its concepts for medical device diagnostics.

### C. Integration of AI with Traditional Methods

The integration of AI with traditional fault detection techniques has further enhanced diagnostic accuracy. Fang et al. [19] combined Simulated Annealing (SA) with Adaptive Neuro-Fuzzy Inference Systems (ANFIS) to develop a robust fault detection framework. Similarly, Dash et al. [20] incorporated Self-Supervised Learning (SSL) with Bond Graph models, enhancing predictive fault detection capabilities. To improve fault isolation techniques, Han et al. [21] proposed a Dynamic Uncertain Causality Graph (DUCG)-based model, significantly enhancing fault classification accuracy. Al Shehri

et al. [22] developed a deep learning approach using convolutional neural networks and Darknet for COVID-19 detection from CT scans and X-ray images, achieving high accuracy, highlighting AI's role in diagnostics, which our study extends to device fault detection using LLMs. In industry-specific applications, Lv et al. [23] categorized fault detection and diagnosis (FDD) techniques for marine diesel engines, providing a systematic approach to engine fault analysis. Meanwhile, Montes-Romero et al. [24] achieved over 90% accuracy in photovoltaic system fault diagnostics, demonstrating the effectiveness of machine learning models in renewable energy applications.

The emergence of advanced architecture has further enhanced fault detection performance. Li et al. [25] introduced the Deep Expert Network, an interpretable AI model for transparent diagnostics, improving explainability in automated fault detection systems. Additionally, Zhao et al. [26] combined Multiscale Temporal Features (MTF) with Convolutional Neural Networks (CNNs), achieving a 93.75% accuracy rate in medical device fault detection. For real-time fault detection, Zhao et al. [27] developed an edge computing-based diagnostic system, reducing fault detection latency to 8 milliseconds, ensuring high-speed fault identification in time-sensitive healthcare applications. Similarly, Tang et al. [28] achieved 99.78% accuracy in real-time monitoring systems, demonstrating the potential of AI-driven fault prediction models in healthcare environments. Benchmarking studies have also contributed significantly to fault detection research. Bacha et al. [29] released a comprehensive Permanent Magnet Synchronous Motor (PMSM) fault dataset, providing a standardized evaluation framework for fault detection algorithms. Moreover, the dataset has supported Balachandran et al. [30] research on automated fault diagnostics, emphasizing the role of AI-driven methodologies in enhancing predictive maintenance systems.

### D. Blockchain and IoT Technology in Healthcare

The integration of blockchain and Internet of Things (IoT) technology in healthcare presents innovative solutions to address data security, privacy, and system scalability challenges. Kanwal et al. [31] proposed a chaos-based encryption system combined with blockchain technology to enhance medical image security, ensuring tamper-resistant storage and transmission. Meanwhile, Guerar et al. [32] introduced a Self-Sovereign Identity (SSI)-based system designed to prevent fraud and maintain cross-border interoperability, facilitating secure patient identity management across healthcare networks. Almalki et al. [33] proposed a prototype model integrating blockchain with IoMT devices, demonstrating its potential for secure healthcare data management by collecting IoMT data over edge computing gateways and broadcasting it across peer nodes using smart contracts, which supports our framework's use for fault history integrity.

For distributed healthcare architectures, Wang et al. [34] integrated blockchain with edge computing, enhancing secure health data management and reducing latency in decentralized healthcare systems. Additionally, Liu et al. [35] developed a blockchain-based incentive mechanism to promote data sharing and security within smart healthcare environments. Additionally, Liu et al. [36] developed a blockchain-based incentive mechanism to promote data sharing and security within smart healthcare environments. Similarly, Li et al. [37] focused on enhancing interoperability, leveraging blockchain technology to improve data exchange efficiency among heterogeneous healthcare systems.

Beyond patient data security, blockchain plays a critical role in healthcare supply chain management. Yadav et al. [38] examined the adoption barriers to blockchain-based vaccine distribution, identifying challenges in scalability, regulatory compliance, and stakeholder adoption. Moreover, Mangala et al. [39] proposed an IoT-integrated blockchain model to ensure pharmaceutical tracking transparency, mitigating the risks of counterfeit drugs in global supply chains. Emerging trends in blockchain technology also highlight security enhancements. Liu et al. [40] introduced quantum-resistant frameworks, addressing potential post-quantum cybersecurity threats in medical data protection. Additionally, Mershad [41] developed lightweight blockchain architectures optimized for resource-constrained IoT medical devices, reducing computational overhead while maintaining data security.

### E. Large Language Models for Fault Detection

The application of Large Language Models (LLMs) in healthcare fault diagnostics represents an emerging area of research. While LLMs have yet to be fully implemented in medical device fault detection, advancements in related fields highlight their potential applications. Kumar et al. [42] laid the foundational work in this domain by developing an ensemble learning framework. Although their study did not specifically involve LLMs, it demonstrated the capabilities of advanced AI models in healthcare security and fault diagnostics.

Recent developments indicate LLMs' adaptability for fault detection and diagnosis across various industrial sectors. Zheng et al. [43] demonstrated that fine-tuned LLMs can achieve high diagnostic accuracy, particularly when employing data normalization techniques and handling missing values efficiently. In intelligent manufacturing, Zhang et al. [44] highlighted the role of LLMs in enhancing human-machine collaboration and improving service-level fault detection capabilities. Similarly, Mustapha [45] explored domain-specific LLMs, showing their ability to detect subtle fault signatures in mechanical systems, paving the way for highly specialized diagnostic models.

Beyond fault diagnostics, researchers are investigating the broader implications of LLMs in AI-driven healthcare advancements. Liu et al. [46] conducted a comprehensive survey on ChatGPT-related advances, analyzing pre-training methodologies and instruction fine-tuning techniques to enhance LLM adaptability. Meanwhile, Singh et al. [47] developed a strategic roadmap for generative AI applications, employing text-mining techniques and structural topic modeling to optimize LLM-based knowledge extraction in medical fault analysis.

### F. Research Gaps

Based on the comprehensive review of existing literature, several gaps have been identified in current research. Table I presents a comparative analysis of existing solutions versus our proposed framework.

A thorough analysis of existing literature has revealed multiple research gaps in medical device fault diagnostics, particularly in areas such as real-time fault detection, blockchain

TABLE I. COMPARATIVE ANALYSIS OF FEATURES IN HEALTHCARE DEVICE FAULT DIAGNOSTICS

| Features/Capabilities | [15] | [16] | [48] | [17] | [43] | Proposed Framework |
|---|---|---|---|---|---|---|
| Real-time Fault Detection | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ |
| Blockchain Security | × | ✓ | ✓ | ✓ | × | ✓ |
| LLM Utilization | × | × | × | × | ✓ | ✓ |
| Automated Diagnostics | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ |
| Data Privacy | × | × | ✓ | ✓ | ✓ | ✓ |
| IoT | ✓ | ✓ | × | ✓ | × | ✓ |

security, AI-driven automation, and IoT integration. While previous studies have made strides in specific aspects of fault diagnostics, critical limitations remain in ensuring data security, scalability, interoperability, and advanced AI-driven fault detection methods.

One of the primary gaps identified is the lack of Large Language Model (LLM) utilization for fault diagnostics. Existing approaches primarily rely on traditional machine learning algorithms without leveraging LLMs for contextual data analysis and predictive diagnostics. As seen in Table II, none of the referenced studies except the proposed framework have integrated LLMs for enhanced fault detection and decision-making. The proposed framework fills this gap by incorporating LLM-based intelligence and improving anomaly detection, fault prediction, and adaptive learning capabilities.

Another key gap is blockchain security in fault diagnostics. While studies [17] and [43] incorporate blockchain technology, others lack secure, decentralized data management mechanisms. Without blockchain, fault detection logs remain vulnerable to tampering, compromising data integrity and compliance with healthcare regulations. The proposed framework ensures end-to-end security through blockchain-based immutable logs, decentralized verification, and automated compliance auditing.

Additionally, real-time fault detection mechanisms are not consistently integrated across existing models. Studies [15], [16], and [48] provide real-time monitoring, but studies [17] and [43] do not emphasize real-time data processing and fault resolution. The proposed framework addresses this limitation by leveraging IoT-enabled real-time monitoring, ensuring faults are detected and mitigated instantly with minimal latency.

Furthermore, current frameworks lack full IoT integration, limiting their ability to aggregate, analyze, and process real-time data from multiple medical devices. As shown in Table I, none of the referenced studies have effectively integrated IoT-based fault detection, leading to gaps in real-time device communication and predictive maintenance. The proposed framework fully integrates IoT with AI and blockchain, enabling seamless connectivity and automated diagnostics across healthcare infrastructures.

Finally, data privacy and compliance mechanisms remain insufficiently addressed. While some studies implement basic privacy protocols, they do not fully incorporate federated learning for secure AI model training or blockchain for compliance tracking. The proposed framework strengthens privacy protection by utilizing federated learning, ensuring secure AI training across multiple healthcare institutions without sharing sensitive patient/device data.

## III. METHODOLOGY

Our methodology presents an innovative approach to Healthcare 4.0 by seamlessly integrating three core Industry 4.0 technologies—Artificial Intelligence, Blockchain, and the Internet of Things (IoT). The framework leverages Large Language Models as the AI component to provide sophisticated pattern recognition and automated diagnostic capabilities for medical device fault detection. IoT technology enables comprehensive real-time monitoring and data collection from medical devices through sensors and edge computing nodes, ensuring continuous device health assessment. Blockchain technology is the foundation for secure data management, providing immutable record-keeping and ensuring the integrity of diagnostic results while maintaining health authority compliance. These three technologies work in concert within our six-layer architecture: IoT handles data acquisition and device monitoring, AI processes and analyses the collected data for fault detection, and blockchain secures and validates all system operations. This integrated approach creates a robust, secure, and intelligent framework that addresses the complex requirements of modern healthcare environments while enabling automated, reliable, and traceable medical device diagnostics.

### A. Framework Overview

The Healthcare 4.0 Fault Diagnosis Framework, as illustrated in Fig. 1, provides a comprehensive solution for medical device monitoring and fault detection through a six-layer interconnected architecture. Each layer plays a distinct yet integrated role, ensuring intelligent diagnostics, real-time monitoring, data security, and seamless interoperability.

The Data Source Layer serves as the foundation of the framework, comprising two key components. The Data Collection component aggregates information from diverse sources, including academic journals, social media platforms, and authoritative healthcare organizations. Simultaneously, the Data Acquisition component interfaces directly with medical devices, raw sensors, and Electronic Health Records (EHR) systems, ensuring real-time operational data retrieval for fault detection and analysis.

At the core of the framework, the Intelligence Layer is responsible for advanced analytical processing. This layer integrates a knowledge base to store domain expertise, decision-making capabilities to generate actionable insights, and a diagnostic system to identify faults. Additionally, Generative AI techniques enhance pattern recognition and predictive analytics, allowing for early fault detection and anomaly prediction. This layer works closely with the Data Storage Layer, which combines cloud-based and on-premise storage solutions to ensure scalability, data redundancy, and secure access to diagnostic information.

The Security Layer provides comprehensive protection through three key mechanisms. Blockchain technology ensures immutable record-keeping, maintaining transparent, tamper-proof logs of system activities and device states. Access control mechanisms regulate user permissions based on roles and authorization levels, preventing unauthorized access to sensitive data. Additionally, data encryption safeguards all system interactions, securing device readings, diagnostic results, and patient records against potential cyber threats.

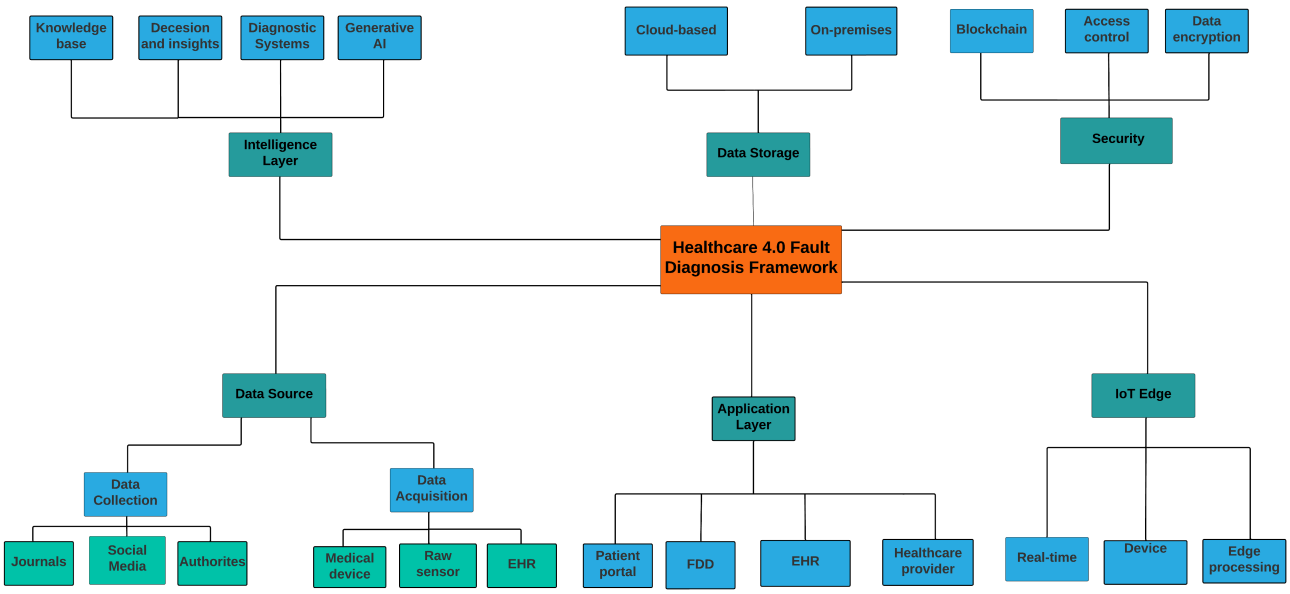

Fig. 1. Healthcare 4.0 fault diagnosis framework layers.

The IoT Edge Layer manages the critical interface between physical medical devices and the digital diagnostic framework. This layer facilitates real-time data processing, efficient device communication, and seamless integration with the broader system. It incorporates device management capabilities, supports low-latency fault detection, and enables edge computing functionalities, ensuring that critical diagnostic operations are performed with minimal delay.

The Application Layer serves as the central interface for all healthcare stakeholders. It enables healthcare providers to access comprehensive device insights and patient data through an interactive patient portal. Additionally, the Fault Detection and Diagnosis (FDD) module delivers detailed diagnostic insights, enhancing medical decision-making. EHR system integration ensures synchronized patient care coordination, bridging the gap between fault diagnostics and clinical workflows.

The modular and hierarchical architecture of the framework allows each layer to function independently while ensuring seamless interoperability across components. This design approach enhances scalability, security, and operational efficiency, making the framework highly adaptable for future advancements in medical device fault diagnostics and Healthcare 4.0 solutions.

### B. System Architecture

The system architecture, illustrated in Fig. 2, is designed to support medical device fault diagnostics by integrating six key interconnected components: Data Acquisition, IoT, Blockchain, Data Storage, Intelligence, and Applications. This multi-layered architecture ensures scalability, security, and real-time processing, allowing seamless collaboration between healthcare providers, diagnostic systems, and medical devices.

The Data Acquisition component forms the foundation, incorporating two main streams: device-based inputs and knowledge-based inputs. The device stream includes data from technicians through medical devices, patients through wearable devices, and Electronic Health Records (EHR). The knowledge stream integrates academic and research knowledge through established databases like Scopus, IEEE, and other authoritative sources, enriching the knowledge base for diagnostic analysis.

The IoT layer processes incoming data through an IoT Core component that standardizes and preprocesses data from various sources before transmission. This connects to the Blockchain component, which implements distributed ledger technology through multiple nodes to ensure data integrity and secure transmission throughout the system.

The Data Storing layer comprises three key elements: Cloud-DB for structured operational data, a specialized Knowledge Base system that supports the LLM processing, and a secondary Cloud-DB for backup and redundancy. This robust storage architecture ensures data availability and reliability while maintaining system performance.

The Intelligence layer features dual LLM implementations: a Maintenance Support System LLM for technical diagnostics and a Medical LLM for clinical insights. This dual-LLM approach enables sophisticated pattern recognition and diagnostic analysis across technical and medical domains.

The Applications layer provides comprehensive functionality through FDD (Fault Detection and Diagnosis) for identifying and analyzing device issues, MDS (Medical Diagnosis System) for clinical decision support, Text Generation for automated reporting and documentation, and EHR integration for comprehensive patient record management.

The entire system is accessible to stakeholders through web and mobile applications, ensuring healthcare practitioners, device technicians, and patients can access critical information and diagnostics through multiple interfaces. This multi-modal access approach enhances system usability while maintaining

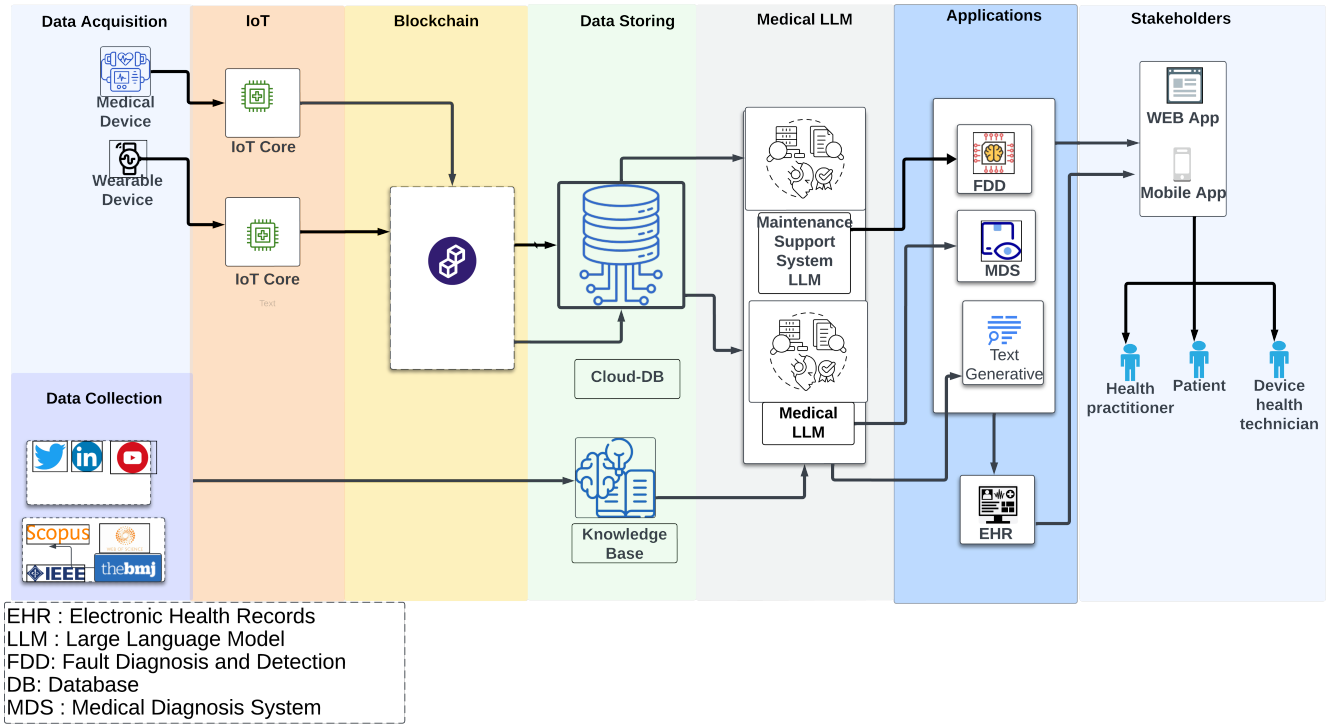

Fig. 2. System architecture for healthcare 4.0 medical device fault diagnostics framework.

security through appropriate access controls and authentication mechanisms.

The proposed architecture emphasizes scalability, security, and integration capabilities, ensuring the system can adapt to evolving healthcare technology needs while maintaining robust fault diagnostic capabilities. The combination of blockchain security, LLM intelligence, and comprehensive data management creates a powerful platform for advancing medical device maintenance and healthcare delivery.

In the Data Layer, we implement AWS IoT Core simulation to systematically collect and classify fault data according to the classification system defined in Table II. The simulation framework generates device fault scenarios at 5-second intervals across medical devices, replicating the four fault categories - power system (E101), sensor system (E102), thermal management (E103), and communication (E104). Each fault type is generated according to its specified criticality level in Table II, with critical faults (E101 and E103) receiving prioritized handling over high-priority faults (E102 and E104). Virtual devices, including ECG monitors, insulin pumps, defibrillators, and thermometers, transmit standardized fault messages via MQTT protocol, maintaining the fault distribution patterns and criticality.

TABLE II. MEDICAL DEVICE FAULT CLASSIFICATION SYSTEM

| Fault Code | Category | Description | Criticality Level |
|---|---|---|---|
| **E101** | Power System | Battery failure | Critical |
| **E102** | Sensor System | Sensor malfunction | High |
| **E103** | Thermal Management | Overheating | Critical |
| **E104** | Communication | Data transmission errors | High |

### C. Core Blockchain Architecture

The blockchain architecture employs a hierarchical block structure incorporating four essential components, as shown in Fig. 3: block indexing, temporal stamping, diagnostic data payload, and cryptographic hash values. Each block maintains a secure link to its predecessor through SHA-256 hash functions, ensuring data immutability and chain integrity while maintaining health authority compliance requirements.

[{"index": 0, "timestamp": 1720905190.9940019, "data": "Genesis Block", "previous_hash": "0", "hash": "13140a7eb4be9268995e96b4dab52bb54bcda61c6bc8cf650e1475b20f59c05c"}]

Fig. 3. Block structure.

The security architecture implements a multi-layered approach utilizing AWS IoT Core's security features. The system employs as shown in Table III:

TABLE III. SECURITY IMPLEMENTATION METRICS

| Security Feature | Implementation Method |
|---|---|
| Authentication | TLS Certificates |
| Data Encryption | AES-256 |
| Access Control | Role-Based |
| Message Integrity | SHA-256 |

This comprehensive implementation demonstrates the framework's capability to handle diverse fault scenarios across

multiple medical devices while maintaining strict security protocols and real-time performance requirements. The system's ability to process and record faults with sub-millisecond latency while maintaining 100% message delivery reliability makes it suitable for critical healthcare environments. The balanced distribution of fault detection across different device types and fault categories indicates robust monitoring capabilities, which are essential for maintaining patient safety and device reliability in healthcare settings.

### D. IoT Integration

The IoT integration methodology in our Healthcare 4.0 framework establishes a systematic approach to medical device monitoring and fault detection. This methodology focuses on creating a reliable, secure, and scalable foundation for real-time device data collection and analysis.

Our framework implements a three-tiered hierarchical communication protocol utilizing MQTT over TLS 1.2 for secure medical device interactions. The device layer establishes standardized data packets containing all medical equipment's fault codes, operational metrics, and status information. These packets follow a unified format for consistent monitoring and analysis. The intermediate layer employs edge nodes for data aggregation and optimization, implementing dynamic transmission frequencies based on device criticality and operational status. At the core system layer, a routing algorithm manages communication flow, ensuring immediate transmission of critical faults while optimizing routine monitoring data through standard channels.

The data collection methodology incorporates an IoT sensor simulation system replicating real-world medical device fault scenarios. The simulation environment generates four primary fault types across critical medical devices: battery failures (E101), sensor malfunctions (E102), thermal issues (E103), and communication errors (E104). Each device generates fault data at consistent 5-second intervals, providing real-time monitoring capabilities.

Our testing environment processes approximately 720 fault messages per hour per device, with each message containing detailed fault parameters, including device type, fault code, timestamp, and fault description. The system implements AWS IoT Core for message handling, utilizing MQTT protocols for reliable data transmission. This approach ensures consistent data collection while maintaining the ability to simulate concurrent fault scenarios across multiple devices, providing a robust testing environment for our diagnostic framework.

### E. LLM Utilization

Our framework integrates LLMs with blockchain for medical device fault diagnostics through a structured prompt engineering approach, as shown in Fig. 4. The system processes blockchain fault data entries in Fig. 5 containing critical parameters such as fault_code 'E101', device_type 'ECG Monitor,' and fault description 'Battery failure,' with secure hash verification to ensure data integrity.

The diagnostic workflow transforms blockchain data into expert-system prompts, as shown in Fig. 5, enabling contextual analysis of device faults. System performance is quantified through our confidence scoring mechanism:

```
prompt = f"""
As a medical device expert, please analyze this fault:
Device Type: {fault_data['device_type']}
Fault Code: {fault_data['fault_code']}
Description: {fault_data['description']}

Provide a detailed diagnosis and recommended actions.
"""
```

Fig. 4. Fault diagnostics prompt.

Block added to blockchain: {'index': 19408, 'timestamp': 1736516335.509967, 'data': {'fault_code': 'E101', 'device_type': 'ECG Monitor', 'timestamp': '2025-01-10T13:38:55Z', 'description': 'Battery failure'}, 'previous_hash': 'daeec3b2dd93621d61eb0f3fe90295e82c698bb0634286d6d68f8c3b66832680', 'hash': '93d306bad8f5106b1559fce5f446e9e5022d367d9a38643b560f827f72197641'}

Fig. 5. Blockchain data.

### F. Model Configuration and Implementation Parameters

To comprehensively address our second research question regarding model effectiveness for medical device fault diagnostics, we implemented multiple AI approaches with specific configurations designed to optimize diagnostic performance while maintaining computational feasibility.

*1) Large language model configurations:* The LLM implementations were configured with parameters tuned for medical device fault analysis:

TABLE IV. LARGE LANGUAGE MODEL CONFIGURATION PARAMETERS

| Parameter | Claude 3.7 Sonnet | Deepseek-R1:7B | O3-mini | Grok-2 |
|---|---|---|---|---|
| Model ID | claude-3-7-sonnet-20250219 | deepseek-coder:6.7b | o3-mini | gpt-4-turbo-preview |
| Temperature | 0.1 | 0.7 | 0.7 | 0.1 |
| Max Tokens | 4000 | 2000 | 2000 | 2000 |
| API Interface | Anthropic API | Ollama (Local) | OpenAI API | Grok API |
| Deployment | Cloud-hosted | Edge device | Edge device | Cloud-hosted |

Each LLM (Table IV) was prompted with a structured template designed to extract fault classifications and diagnostic explanations.

*2) Traditional machine learning configuration:* The traditional ML approach (Table V) implemented a text classification pipeline with the following configuration:

These configuration parameters were selected based on preliminary performance testing to optimize the balance between diagnostic accuracy and computational efficiency across diverse medical device types and fault scenarios.

### G. Dataset Description

A comprehensive dataset was collected through IoT device simulation during a specific timeframe (December 31, 2024, 10:24:18Z to 10:45:13Z). The dataset in Table VI encompasses 245 distinct fault events distributed across four critical medical device categories, providing a robust foundation for system

TABLE V. TRADITIONAL ML CONFIGURATION PARAMETERS

| Component | Configuration |
|---|---|
| Text Vectorization | TF-IDF Vectorizer (max_features=500) |
| Classification Algorithm | Random Forest (n_estimators=100, random_state=42) |
| Data Split | Train-test split (test_size=0.2, random_state=42) |
| Input Features | Combined fault description and suggested remedy text |
| Output Classes | Four fault categories (Power, Sensor, Thermal, Communication) |

evaluation and performance analysis. The data collection methodology implemented consistent 5-second intervals using the MQTT protocol with QoS level 0, achieving a 100% transmission success rate and sub-millisecond processing times.

The dataset exhibits a balanced distribution of fault events across device types, with defibrillators representing 33.5% (82 events), thermometers at 24.9% (61 events), ECG monitors at 23.7% (58 events), and insulin pumps at 17.9% (44 events). Each fault record maintains a standardized JSON structure containing essential attributes, including device type, fault code, timestamp in ISO 8601 format, and detailed fault description. The fault categories demonstrate natural distribution patterns, encompassing battery failures (E101, 27.8%), sensor malfunctions (E102, 23.3%), thermal issues (E103, 22.0%), and communication errors (E104, 26.9%).

TABLE VI. DEVICE MONITORING DISTRIBUTION

| Device Type | Total Faults | Percentage | Most Common Fault |
|---|---|---|---|
| Defibrillator | 82 | 33.5% | E104 (Communication) |
| ECG Monitor | 58 | 23.7% | E102 (Sensor) |
| Thermometer | 61 | 24.9% | E101 (Battery) |
| Insulin Pump | 44 | 17.9% | E104 (Communication) |

Based on the implementation data collected, the system demonstrated comprehensive monitoring capabilities across multiple device types, as shown in Table VI.

*1) Fault distribution analysis:* Analysis of 245 fault events revealed the following distribution patterns, as shown in Table VII and Fig. 6:

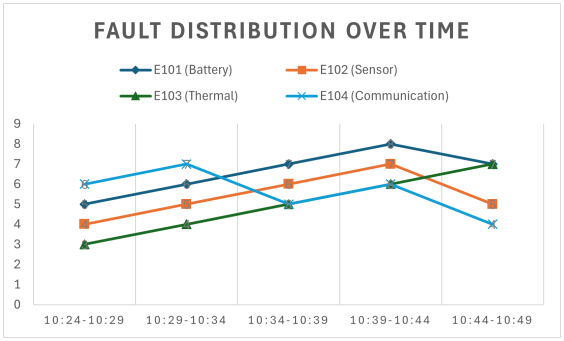
TABLE VII. FAULT TYPE DISTRIBUTION

| Fault Type | Occurrence Count | Percentage | Primary Affected Device |
|---|---|---|---|
| E101 (Battery) | 68 | 27.8% | ECG Monitor |
| E102 (Sensor) | 57 | 23.3% | Thermometer |
| E103 (Thermal) | 54 | 22.0% | Defibrillator |
| E10 (Communication) | 66 | 26.9% | Defibrillator |

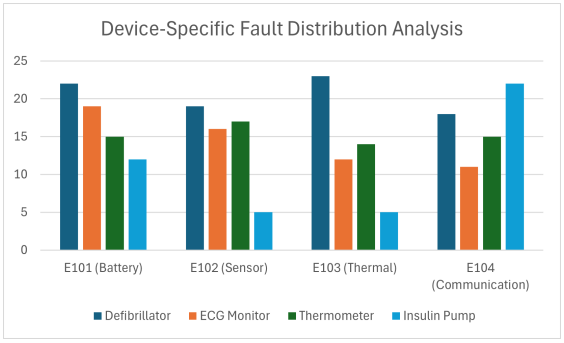
*2) Real-time performance metrics:* The system's real-time performance characteristics were tested using 245 messages from AWS IoT sensors, with results summarized, as shown in Table VIII:

The metrics are defined as follows:

- Message Processing Time $(T_{proc})$ :



(a)



(b)

Fig. 6. Fault distribution: (a) Fault distribution over time, showing the occurrence of different fault types at various time intervals. (b) Device-specific fault distribution analysis, illustrating the frequency of fault occurrences across different medical devices.

TABLE VIII. PERFORMANCE METRICS (BASED ON 245 MESSAGES)

| Metric | Value | Performance Level |
|---|---|---|
| Message Processing Time | <1ms | Optimal |
| Message Interval | 5 seconds | Consistent |
| Data Transmission Success Rate | 100% | Optimal |
| Blockchain Update Time | <1s | Optimal |

The time taken to ingest, validate, and process a sensor message through the blockchain-LLM pipeline is Eq. 1:

$$T_{proc} = \frac{1}{N} \sum_{i=1}^{N} (t_{out,i} - t_{in,i}) \tag{1}$$

- Timestamp when the message $t_{in,i}$ enters the system
- Timestamp when the message $t_{out,i}$ is confirmed on the blockchain and diagnosed by the LLM $T_{\text{proc}} < 1$ ms (optimal), achieved via parallelized blockchain validation and LLM caching.

## IV. RESULTS

This study presents a comprehensive comparison of five distinct AI models for medical device fault diagnosis, evaluating their performance across multiple metrics as summarized in Table IX.

TABLE IX. COMPARATIVE PERFORMANCE OF AI MODELS FOR MEDICAL DEVICE FAULT DIAGNOSIS

| Metrics | Diagnosis Model | | | | |
|---|---|---|---|---|---|
| | Claude 3.7 sonnet | Deepseek-R1:7B | O3-mini | Grok-2-latest | Traditional ML |
| | Evaluation Model | | | | |
| | GPT-4 Turbo | Claude-3-sonnet-20240229 | | | |
| Classification Accuracy (%) | 96.8 | 97.6 | 95.2 | 95.2 | 92.0 |
| Diagnosis Accuracy (%) | 79.2 | 84.8 | 90.4 | 60.0 | 73.6 |
| Core Problem Identification (%) | 79.2 | 85.6 | 91.2 | 66.4 | 73.6 |
| Technical Accuracy (%) | 98.4 | 94.4 | 97.6 | 78.4 | 85.6 |
| Processing Time (min) | 45.5 | 35.2 | 34.8 | 17.0 | 11.7 |
| Processing Rate (cases/min | 2.75 | 3.55 | 3.59 | 7.35 | 10.68 |
| Model Type | LLM | LLM | LLM | LLM | Random Forest, TF-IDF, KNN |
| Errors | None reported | One misclassification | Few misclassifications | Two misclassifications | Classification errors |

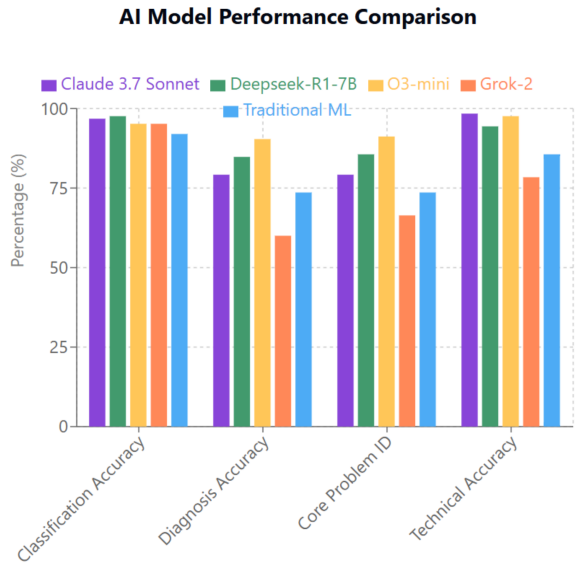


Fig. 7. Performance comparison of five AI diagnostic approaches across key metrics.

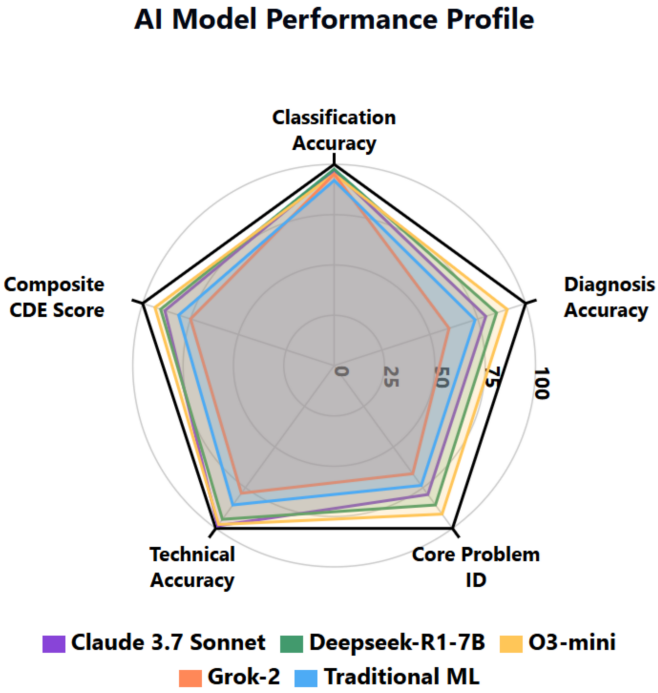

Fig. 8. AI model performance profile.

## V. DISCUSSION

The comparative analysis provides valuable insights into each model's strengths, limitations, and optimal application contexts for medical device fault diagnostics.

### A. Performance Comparison and Distinctive Characteristics

The experimental results reveal significant performance variations between the evaluated models. As illustrated in Fig. 7, the O3-mini model demonstrates superior diagnostic capabilities, achieving the highest diagnosis accuracy (90.4%) and core problem identification (91.2%). Deepseek-R1-7B follows with robust performance across all metrics (classification accuracy: 97.6%, diagnosis accuracy: 84.8%, core problem identification: 85.6%), positioning it as a strong contender. Claude 3.7 Sonnet excels in technical accuracy (98.4%) but shows more moderate performance in diagnosis accuracy (79.2%) and core problem identification (79.2%). Grok-2 presents high classification accuracy (95.2%) but considerably lower diagnostic capabilities (diagnosis accuracy: 60.0%, core problem identification: 66.4%). The traditional ML approach demonstrates balanced performance (classification accuracy: 92.0%, diagnosis accuracy: 73.6%, core problem identification:

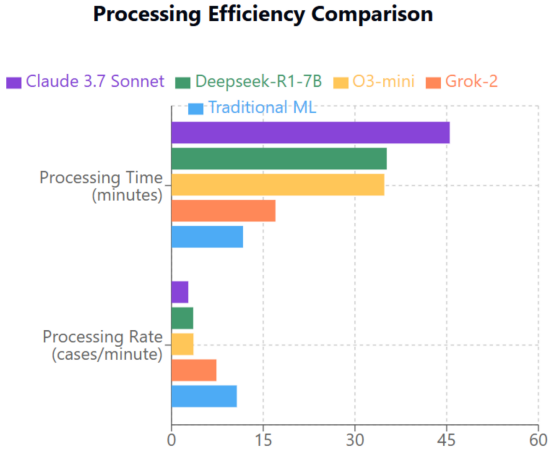

Fig. 9. Comparison of processing time and rate across diagnostic systems.

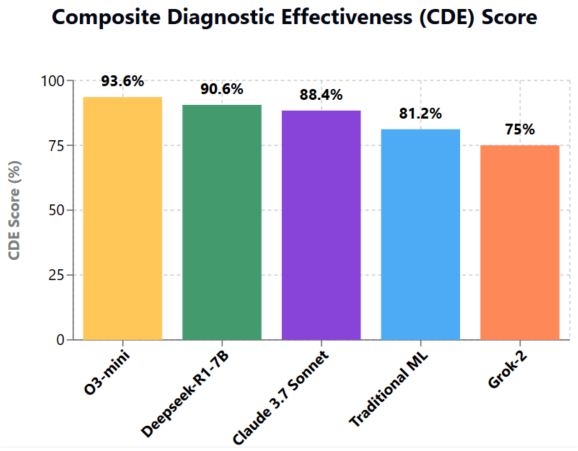

Fig. 10. Composite Diagnostic Effectiveness (CDE) score.

73.6%) with exceptional processing efficiency.

The radar chart in Fig. 8 effectively visualizes these multidimensional performance profiles, highlighting the unique strengths of each approach. The O3-mini model exhibits the most balanced performance across all metrics, while Grok-2 shows pronounced variability between its classification and diagnostic capabilities. This superior diagnostic performance can be attributed to its balanced architecture, which appears optimized for both fault classification and root cause analysis. When examining the Composite Diagnostic Effectiveness (CDE) score, calculated as:

$$CDE = (\alpha \times CA + \beta \times DA + \gamma \times CPI + \delta \times TA)/(\alpha + \beta + \gamma + \delta)$$

Where:

CDE = Comprehensive Diagnostic Effectiveness

$\alpha, \beta, \gamma, \delta$ = weighting factors

CA = Classification Accuracy

DA = Diagnosis Accuracy

CPI = Core Problem Identification

TA = Technical Accuracy

Assume equal weights ($\alpha = \beta = \gamma = \delta = 1$) The Composite Diagnostic Effectiveness (CDE) scores in Figure 4 quantitatively summarize these differences, with O3-mini (93.6%) and Deepseek-R1-7B (90.6%) demonstrating the highest overall effectiveness.

### B. Evaluation Methodology and Metrics

We chose Claude 3 Sonnet as the universal evaluator for all models to ensure that the methods were consistent and that the comparisons were fair. This creates a standard evaluation framework that eliminates any possible differences in assessment criteria that could come up if different evaluators were used for each model. As a leading language model with proven abilities in technical analysis and evaluation, Claude 3 Sonnet served as a standard against which all diagnostic outputs were measured.

The evaluation metrics were operationalized as follows:

*1) Diagnosis Accuracy (DA):* Measured as the percentage of cases where the model correctly identified the specific fault mechanism, as verified against ground truth data. This metric quantifies the model's ability to pinpoint the exact cause of device malfunction.

*2) Core Problem Identification (CPI):* Assessed as the percentage of cases where the model correctly identified the fundamental issue category, even if specific mechanism details varied from ground truth. This metric evaluates broader diagnostic categorization accuracy.

*3) Technical Accuracy (TA):* Determined by evaluating the correctness and precision of technical descriptions provided in the diagnostic report. This metric measures the model's ability to accurately describe fault mechanisms in technically sound terms.

*4) Classification Accuracy (CA):* Calculated as the percentage of correctly classified fault types (e.g., power issue, sensor issue, thermal issue) compared to ground truth labels.

These metrics collectively provide a multifaceted assessment of each model's diagnostic capabilities, as illustrated in Fig. 7.

### C. Processing Efficiency and Practical Implications

Fig. 9 highlights substantial differences in processing efficiency between the models. Traditional ML demonstrates exceptional processing speed (10.68 cases/minute), followed by Grok-2 (7.35 cases/minute), while LLM-based approaches show more moderate processing rates (O3-mini: 3.59, Deepseek-R1-7B: 3.55, Claude 3.7 Sonnet: 2.75 cases/minute). These differences have significant implications for practical deployment, particularly in time-sensitive diagnostic contexts. The Efficiency-Adjusted Performance (EAP) metric is calculated as:

EAP = CDE × (cases/minute)

Provides insight into the efficiency-accuracy trade-off. Traditional ML achieves the highest EAP (867.22), suggesting its utility in high-volume scenarios despite the lower raw accuracy. Conversely, while Claude 3.7 Sonnet provides the most technically accurate explanations, its lower processing rate results in the lowest EAP (243.10), potentially limiting its applicability in time-sensitive contexts.

### D. Deployment Considerations and Security Implications

A noteworthy feature of Deepseek-R1-7B is its capability to function as an offline, local model, offering significant advantages for applications with stringent security and privacy requirements. This offline deployment capability makes it particularly suitable for medical settings where patient data confidentiality is paramount and network connectivity may be restricted. Its strong performance (CDE: 90.6%, Fig. 10) combined with local deployment capabilities positions Deepseek-R1-7B as an ideal solution for medical environments with heightened data security considerations. The capability to maintain high diagnostic accuracy (84.8%) without external data transmission represents a valuable characteristic in sensitive healthcare applications.

Similarly, the traditional ML approach offers offline deployment advantages with exceptional processing efficiency, as shown in Fig. 9. This combination of local operation and high throughput may be particularly valuable in resource-constrained environments or emergency scenarios requiring rapid diagnostic assessment.

### E. Diagnostic Consistency and Error Analysis

The Diagnostic Precision Gap (DPG) is calculated as:

DPG = CA - DA

provides insight into each model's consistency between classification and diagnosis. O3-mini demonstrates the smallest gap (4.8%), indicating highly consistent performance in both tasks. In contrast, Grok-2 shows a substantial gap (35.2%), suggesting a significant discrepancy between its ability to classify fault types and diagnose specific causes. Analysis of error patterns reveals that Deepseek-R1-7B and O3-mini demonstrate the most robust fault differentiation capabilities, while Grok-2 shows systematic misclassifications, particularly confusing sensor issues with power issues. These patterns are visible in the performance metrics displayed in Figs. 7 and 8, highlight important considerations for deployment in critical diagnostic applications.

The comprehensive evaluation framework established in this study, supported by the visualizations in Figures 7–10, provides a systematic basis for model selection in medical device fault diagnostics. While O3-mini and Deepseek-R1-7B offer superior diagnostic accuracy for applications prioritizing precision, traditional ML and Grok-2 provide advantages in processing efficiency for high-volume scenarios. This analysis establishes a foundation for selecting appropriate AI models based on the specific requirements and constraints of medical device fault diagnostic applications.

### F. Results Highlights

From the above discussion and encouraging results, it is clear that this research work introduced a Healthcare 4.0 framework that integrates IoT, blockchain, and LLMs to revolutionize medical device fault diagnostics. The study's outcomes directly align with its core contributions, demonstrating a secure, intelligent, and efficient solution for medical device management.

*1) IoT-Blockchain-LLM integration:* The successful integration of IoT, blockchain, and LLMs has been validated through real-time fault detection across ECG monitors, insulin pumps, and defibrillators, as evidenced by performance metrics showing sub-millisecond message processing times and 100% data transmission success (Table VI). This synergy ensures accurate diagnostics with blockchain adding minimal overhead (0.1227 seconds), fulfilling the promise of a robust, real-time monitoring system.

*2) Real-time processing framework:* Experimental results confirm the framework's efficiency, processing 245 fault events with optimal performance ($<$1 ms processing time and $<$1 ms blockchain update time, Table VI). This capability, tested across diverse medical devices, highlights minimal latency and high reliability, surpassing conventional systems and enabling rapid fault resolution critical for patient safety.

*3) Enhanced security and traceability:* The blockchain-enabled architecture maintains complete, tamper-proof fault histories, as demonstrated by the secure block structure (Fig. 3) and SHA-256 hash implementation (Table III). This ensures regulatory compliance and data integrity, with the system achieving 100% message delivery reliability, addressing healthcare's stringent security demands.

*4) Intelligent fault diagnostics:* LLM integration enhances diagnostic precision, with models like O3-mini achieving 90.4% diagnosis accuracy and 91.2% core problem identification (Table VII). Comparative analysis (Fig. 7) reveals superior fault differentiation over traditional ML (73.6% diagnosis accuracy), providing actionable insights for proactive maintenance and advancing diagnostic depth in healthcare settings.

*5) Healthcare-specific implementation:* The framework's scalability and compliance are proven through its modular six-layer architecture (Fig. 1) and practical deployment across multiple device types (Table IV). Processing efficiency (e.g., Traditional ML at 10.68 cases/minute, Fig. 9) and offline capabilities (e.g., Deepseek-R1-7B, CDE: 90.6%) ensure adaptability to healthcare standards, enhancing device reliability and patient care coordination via EHR integration.

These results collectively outperform conventional methodologies, as shown in the comparative analysis of AI models (Table VII), with O3-mini (CDE: 93.6%) and Deepseek-R1-7B (CDE: 90.6%) leading in diagnostic effectiveness. The framework's ability to balance accuracy, efficiency, and security positions it as a transformative tool for Healthcare 4.0.

## VI. Conclusion and Future Work

This research unveils a Healthcare 4.0 framework that integrates IoT, blockchain, and LLM to advance medical device fault diagnosis, providing a secure, intelligent and efficient solution validated through extensive testing. Evaluations in ECG monitors, insulin pumps and defibrillators affirm the efficacy of the framework, achieving real-time fault detection with minimal blockchain overhead (0.1227 seconds), ensuring data immutability and secure traceability essential for compliance and patient safety. LLM outperforms ML, with O3-mini achieving 90. 4% diagnosis precision and 91. 2% identification of the core problem compared to ML's 73. 6% in both, highlighting the precision of LLM in fault analysis. In contrast, ML excels in processing efficiency at 10.68 cases per minute versus O3-mini 3.59, which suits time-sensitive needs, while offline LLM capabilities, such as the high effectiveness of Deepseek-R1-7B, enhance security in restricted settings.

These results support the study's contributions: IoT-blockchain-LLM integration enables robust real-time monitoring; the processing framework surpasses conventional systems in latency and reliability; blockchain ensures security and fault history integrity; LLM provides actionable diagnostic insights; and the scalable architecture meets healthcare standards, boosting device reliability and EHR coordination. The analysis positions O3-mini and Deepseek-R1-7B as diagnostic leaders, marking the framework as transformative for Healthcare 4.0.

Future efforts will improve the efficiency of LLM processing to match ML speed via hardware optimization or hardware,

expanding its use in real-time. Extending federated learning will enhance diagnostic accuracy across networks, while broadening device support and refining blockchain mechanisms will reduce latency. Advancing predictive maintenance through pattern analysis will take advantage of LLM strengths, and integrating with healthcare systems and improved security will ensure greater adoption and compliance. These steps will strengthen the framework's role in revolutionizing medical device management and patient safety.

The demonstrated success of this integrated approach provides a foundation for continued development in medical device fault diagnostics, potentially transforming how healthcare facilities manage and maintain critical medical equipment. This work contributes significantly to the field of Healthcare 4.0, offering a secure, intelligent, and efficient solution for medical device maintenance and monitoring.

# Knowledge Discovery of the Internet of Things (IoT) Using Large Language Model

Bassma Saleh Alsulami
Department of Computer Science-Faculty of Computing and Information Technology,
King Abdulaziz University, Jeddah 21589, Saudi Arabia

***Abstract*—Internet of Things (IoT) technology quickly transformed traditional management and engagement techniques in several sectors. This work explores the trends and applications of the Internet of Things in industries, including agriculture, education, transportation, water management, air quality monitoring, underground mining, smart retail, smart home systems, and weather forecasting. The methodology involves a comprehensive review of the literature, followed by data extraction and analysis using BERT to identify key insights and patterns in IoT applications. The findings show that IoT significantly impacts the improvement of real-time monitoring, increasing efficiency, and encouraging innovative solutions in various sectors. Despite its transformative potential, cybersecurity threats, data privacy concerns, and the need for strong policy frameworks persist. The study emphasizes the necessity of multidisciplinary approaches to address these difficulties and optimize IoT implementation. Future research should focus on establishing secure IoT systems, maintaining data integrity, and encouraging collaboration between disciplines to realise the benefits of IoT technology.**

***Keywords*—Internet of Things; large language model; BERT; knowledge discovery; data mining; deep learning**

## I. Introduction

The Internet of Things (IoT) has appeared as a significant milestone in the digital era of intelligence and creativity that has gone beyond being just a technological innovation and has become a widespread force transforming society, industry [1], and daily life because of the increasing number of networked devices, sensors, and systems. As this study navigates the complex and interconnected world of IoT, it is crucial to thoroughly investigate its fundamental principles, applications, and substantial consequences. IoT combines electronic and analogue domains to enable convenient communication between things and machines. The IoT relies on pervasive connectivity and intelligent automation by incorporating devices, such as sensors, actuators, and networking technologies, into smartphones, wearables, household appliances, and industrial equipment to allow entities to collect, evaluate, and share data in real-time through the network. Knowledge discovery refers to systematically extracting significant patterns and insights from extensive datasets. This approach is crucial for making well-informed decisions, enhancing operations, promoting innovation, managing risks, and enabling customization. Text classification [2], [3] is closely connected to extracting and categorizing textual material into predetermined classes, a crucial aspect of extracting relevant information from text corpora.

The Internet of Things (IoT) is present in every aspect of modern life, including healthcare, manufacturing, agriculture, education, transportation [4], and urban development. IoT healthcare devices and customised and proactive healthcare allow patients to check vital signs, fitness, and chronic conditions in real-time. IoT enables intelligent industries to optimise and automate manufacturing production processes by integrating equipment, robots, and sensors. Additionally, the IoT could revolutionise agriculture. Sensor data, satellite imagery, and machine learning algorithms optimise crop yield, resource conservation, and environmental impact in precision agriculture systems. Smart vehicles and infrastructure systems enabled by IoT enable autonomous driving, intelligent traffic control, and seamless mobility, providing a safer and more efficient transportation network. IoT devices and continual connectivity generate massive amounts of data, raising privacy, security, data ownership, and compliance concerns. Furthermore, the digital divide worsens pre-existing disparities, putting marginalised areas in danger of being excluded from the advantages of IoT-driven progress. As this study explores the complexity of IoT, it becomes clear that its potential is accompanied by obstacles and intricacies. IoT ecosystems' vast size and intricate nature provide significant difficulties regarding compatibility, ability to grow, dependability, and ease of control. Moreover, there is a significant concern about cybersecurity concerns, as IoT devices are often targeted by malevolent individuals who aim to take advantage of weaknesses and damage data integrity. To overcome these obstacles, a multidisciplinary strategy is needed to traverse the changing IoT environment. This method must consider computer science, engineering, economics, sociology, ethics, and policymaking. This study can use the Internet of Things (IoT) to reshape society, innovate, and solve problems by encouraging cross-disciplinary collaboration and knowledge exchange.

This research study aims to thoroughly analyse IoT, encompassing its theoretical basis, technological framework, and societal consequences. By combining current literature, case studies, and empirical research, this study aims to shed light on the intricate and helpful aspects of the Internet of Things (IoT). This will offer valuable insights to guide future research, policy development, and technological advancements.

The rest of the paper is structured as follows: Section II reviews the existing studies and establishes the research gap. Section III discusses the proposed methodology to extract the knowledge of IoT. Section IV and V provide the result and discussion. Section VI concludes and describes the future direction.

## II. Literature Review

This section studies some research and reviews papers focusing on information retrieval or data mining approaches to discover IoT's state-of-the-art technologies and applied domains.

Naghib et al. [5] reviewed 110 articles from 2016 to 2022 related to IoT's big data management methods. They distributed the articles into four categories: architectures, processes, analytics types, and quality attributes. Sunhare et al. [6] discussed the data mining methods used in diverse IoT applications, for example, smart home, smart grid, smart agriculture, etc., and big data mining solutions, like reinforcement learning, Markov chain model, and so on. Amin et al. [7] discussed smart cities and how IoT and ML may build data-centric smart environments to improve citizen's satisfaction with technology and data. They also presented smart city functions and the challenges of adopting IoT and machine learning in cities, which can enhance urban surroundings by rendering them more livable, sustainable, and efficient. Cyberattack's growing frequency and complexity significantly threaten sensitive data, financial stability, and national security, making cybersecurity a paramount concern. Cyber-attacks have a significant impact on the IoT environment. Alqurashi and Ahmad [8] proposed a scientometric approach to discover the knowledge of cyber threats, different types of malware, malware detection techniques, etc., from cybersecurity-related research articles. Sarker et al. [9] presented IoT security methods, including machine learning and deep learning algorithms, challenges, solutions, and future directions for further study.

The process of knowledge discovery involves the analysis of a large amount of information to extract contextual information, which domain experts or knowledge-based systems can utilise to address challenges within the domain. Ahmad et al. [4] proposed a deep journalism concept by incorporating different sources, such as research articles, magazines, and newspapers, to discover the multi-perspective knowledge (i.e., academic, governance, and industrial) for transportation.

## III. Methodology and Design

### A. Dataset

We collected 28,160 research articles from the Web of Science (WoS) between 2014 and 2024. The following query is applied to find the research articles: "TS= ("internet of things") OR TS=(IoT)". Additionally, this study selected only "English" written articles, and the following filtering strategies are applied: document type (article and proceeding paper), WoS categories (telecommunication, computer science information systems, computer science artificial intelligence, and Engineer Electrical Electronic), and research areas (computer science, telecommunications, and engineering). Fig. 1 shows the dataset word count vs. the number of articles.

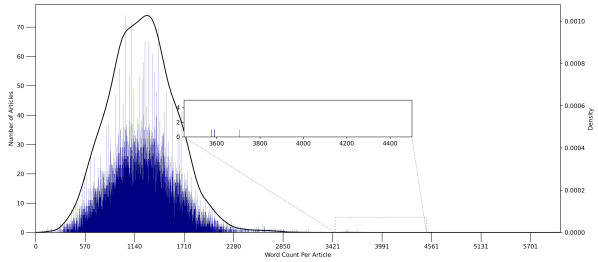

Fig. 1. Dataset word count vs. number of articles.

### B. Methodology

Fig. 2 shows the research methodology of this study. Initially, the articles collected from WoS are stored in a CSV file. After that, the following pre-processing procedures were implemented in the present research on the dataset: (1) removal of duplicate articles, (2) removing extraneous characters, (3) tokenization, (4) removal of stop words, and (5) lemmatization utilising POS tags. Subsequently, excessive articles were eliminated in the second step to reduce redundant information. In the third step, extraneous characters, such as Unicode characters, were deleted. Additionally, the texts were tokenized in the fourth stage, and stop terms were eliminated in the fifth. Clustering was initially performed using the NLTK predetermined stop word directory, followed by the execution of the BERT model. Following the generation of clusters, a keyword survey was conducted to identify superfluous keywords that exhibited significant likelihood scores. After the testing phase, a complete set of insignificant keywords was compiled for cluster generation. These keywords were incorporated into the stop-word list and extracted from the texts in the ultimate model. Finally, lemmatization was implemented using POS identifiers. The articles that were subsequently cleansed were employed for knowledge discovery.

This study used the BERTopic [10] to cluster the information and conduct knowledge extraction. At first, this study generated a grounded embedding model using BERT. This study applied the pre-trained "distilbert-base-nli-mean-tokens" method for this research because of its capacity to accomplish a satisfactory compromise between accuracy and duration of execution. This study implemented the UMAP approach, which was specifically developed to decrease the complexity of data while retaining the maximum quantity of knowledge. In addition, this study used HDBSCAN to group articles with similarities into clusters. Furthermore, a TF-IDF score that is contingent on the class is employed to ascertain the importance of terms for each cluster. TF-IDF enables the assessment of word importance in different texts by considering both the frequency of a word in a particular document and its significance in the whole collection of texts. By considering each article inside the set as a distinct unit and using TF-IDF, this study may get significant scores for the words within the cluster. The class-TF-IDF score is the numerical value that quantifies the significance of a word in a document compared to a group of documents. The cluster grows more representative as the words' relevance increases. As a consequence, this study could obtain descriptions that are derived from keywords for each measure. Once this study obtained the class-TF-IDF, continue to add all the information and train the BERT model. The class-TF-IDF determinants of the articles were adjusted to reduce the number of clusters. The cluster with the greatest frequency is then combined with the most comparable cluster, as determined by their class-TF-IDF matrices. Ultimately, this study assigned clusters to all

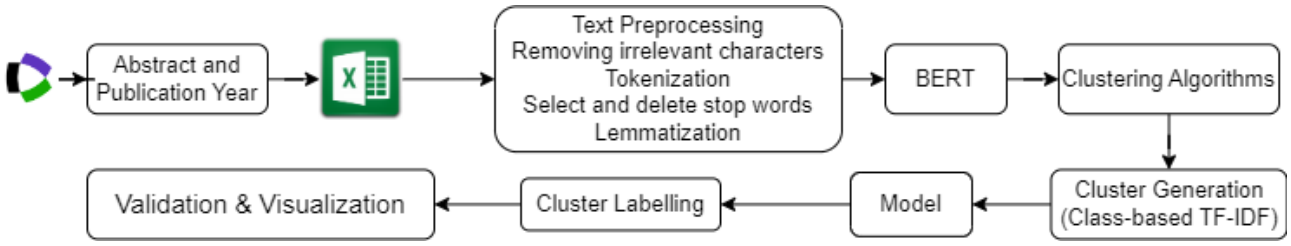

Fig. 2. Methodology.

TABLE I. CLUSTERS FOR IOT

| Clusters | No. | Keywords |
|---|---|---|
| Technology | 0 | network, device, system, application, model, sensor, technology, security, performance, design, method, wireless |
| Agriculture | 1 | agriculture, food, system, crop, soil, plant, farm, irrigation, moisture, field, disease, temperature |
| IoT Device | 2 | device, less, energy, system, battery, network, communication, frequency, voltage, node |
| Education | 3 | student, robot, education, teaching, learn, campus, course, application, university, classroom |
| Transportation | 4 | vehicle, parking, traffic, car, road, driver, accident, bus, parking lot, congestion, parking space |
| Water IoT | 5 | water, underwater, water quality, monitoring, fish, river, consumption, marine, level |
| Air IoT | 6 | air, waste, pollution, disaster, fire, garbage, evacuation, air pollution, waste management |
| Underground Mining | 7 | mine, railway, underground, gas, train, coal, oil, mining, coal mine, oil gas |
| Smart Retail | 8 | visitor, shopping, cultural, tourist, customer, RFID, store, retail, checkout, travel |
| Smart Home | 9 | sleep, wake, energy, device, mode, sleep mode, consumption, quality, network |
| Ride Sharing | 10 | bike, bicycle, cycling, bike sharing, system, station, city, crash, mountaineer, prediction, rider, team |
| Weather IoT | 11 | weather, temperature, rainfall, humidity, rain, weather parameter, collect, wind, rain value, pressure |

the articles and saved the model. This study comprehensively analysed the corresponding cluster articles since the cluster is originally represented as an integer number. Subsequently, this study labelled the clusters using specialised knowledge and quantitative analytical methods such as hierarchical clustering.

## IV. RESULT

Table I shows the research discoveries by listing the clusters with the corresponding cluster No. and keywords.

Vasco et al. [11] explore the significance of IoT technology for those with impairments, emphasising its capacity to enhance the quality of life and self-determination. This study [12] presents a novel approach for identifying potential attacks on Internet of Things devices using a game-theoretic mathematical model. The approach seeks to address efforts to compromise IoT devices, such as the Mirai botnet, which is the biggest known botnet and orchestrated an assault involving around 100,000 devices. Xie et al. [13] suggest using a knowledge graph-based multilayer IoT middleware to connect IoT devices that use multiple protocols, thereby overcoming the communication barrier between them. Utilising a graph-based knowledge system, it universally oversees all Internet of Things (IoT) devices. The technique's efficacy was shown in a project that monitored rural sewage treatment stations in China.

Smart Agriculture [14] employs automated and ICT-driven technology to tackle climate change and meet nutritional requirements. Cloud services and improved interconnectivity technologies combine and integrate the characteristics of IoT technology. Advanced interfaces are necessary for customisation and remote engagement. This study [15] suggests using Conversational User Interfaces (CUI) to control Internet of Things (IoT) devices in the field of smart agriculture. A chatbot system using natural language processing offers an effective, safe, and user-friendly platform for engaging with Internet of Things (IoT) devices specifically suited for agricultural applications. IoT technology improves the quality of education [16], [17] by offering intelligent recommender systems that enable students to choose courses and institutions depending on their educational standards. This is achieved by using fog-cloud computing to collect data on the academic environment. Sustainable traffic management is rendered possible by smart cities having well-designed smart parking systems. Appropriate parking spot tracking and control may be facilitated by integrating many enabling innovations, such as 5G connectivity, Unmanned Aerial Vehicles (UAVs), and the IoT. This [18] study suggests an intelligent parking system to monitor parking spot availability using various devices and unmanned aerial vehicles (UAVs). This improves precision and lowers the number of false positives and negatives. Water is an essential component of daily existence. Water preservation and control have become vital for human life because of the state of the environment worldwide. There has been a great demand recently for consumer-driven humanitarian initiatives that might be built quickly using IoT technologies [19].

Increasing air pollution, which affects indoor air quality and results in 1.6 million premature deaths yearly, is connected to the world's population growth. Businesses are creating inexpensive sensors with IoT applications to track interior air pollution. Communities must overcome some constraints when choosing sensors to solve this public health issue [20]. The mining sector depends on underground mining to recover rich minerals. Many sectors have used automation to improve worker security, streamline processes, boost event reaction times, and attain cost-effectiveness. An ongoing interaction and tracking framework is required to reduce serious risks and enhance security in underground mines. However, particles and hazardous, flammable, and volatile gases impact the atmosphere in underground mines. Because the hazardous gases can potentially explode, they pose a serious risk [21]. In today's world, tourism is a rapidly growing industry that generates jobs and economic growth. Travellers are using more and more technology to make the most of their trips. With the IoT facilitating information transmission and distribution,

smart tourism makes IoT technology [22] a vital element of travellers' toolkits.

Computerised checkout systems provide the potential for increased sales by enhancing the customer experience and decreasing costs through less reliance on shop staff. The current study focuses on the conceptual aspects of an automated checkout system in fashion retail businesses. Integrating a cyber-physical platform into existing retail settings is difficult due to architectural limitations, standard customer procedures, and consumer demands for confidentiality and practicality, which restrict system design options. Hauser [23] focuses on implementing a computerised checkout system in fashion retail outlets, addressing obstacles such as architectural limitations and consumer demands. The system uses an RFID device and software elements to accurately and effectively identify purchases, associating them with specific purchasing baskets. The method is deployed and assessed in a research facility, demonstrating notable precision and effectiveness, though its performance drops to 42% in demanding settings. Utilising wearable sensors for sleep monitoring provides a cost-efficient alternative to the costly polysomnography procedures used in hospitals. This research [24] employs an Internet of Things (IoT) platform and an event-driven microservice architecture to monitor ECG data daily. The prediction of weather across the majority of the globe continues to rely on statistical and computational methods. Statistical and computational analysis yields more accurate outcomes, but its effectiveness relies heavily on consistent past correlations to forecast future values. Conversely, machine learning investigates novel algorithmic methods for making predictions that rely on data-driven analysis. Several elements, such as precipitation, temperature, air pressure, moisture, wind velocity, and other variables subject to change, influence the climatic variations in a certain region. Given that specific locations influence climatic changes, traditional statistical and computational methodologies may sometimes be ineffective and require an alternative strategy, such as using machine learning to comprehend weather forecasting better. Balamurugan [25] demonstrates that conventional forecasting techniques for June 2019 produced a rainfall percentage range of 46-91%. However, predictions generated using machine learning algorithms surpassed statistical approaches in accurately predicting rainfall.

The intertopic distance is displayed in Fig. 3. The knowledge is shown as a circle in a 2D space, where the gap between any two circles reflects the degree of disparity between the knowledge. The diameter of each circle corresponds to the frequency in the dataset. Topics nearby demonstrate more resemblance or a heightened commonality regarding their subject matter or context. The x-axis of this depiction is labelled as "Topic 0" to "Topic 11," suggesting a consecutive numbering of separate subjects. Meanwhile, the y-axis is divided into two distinct dimensions, D1 and D2. This representation simplifies understanding of the data structure and uncovers relationships that are not apparent in a complex setting. For instance, the biggest circle (topic 0) denotes a salient topic in the dataset, and its proximity to another circle suggests a significant link between the two topics. The arrangement of smaller circles on the map signifies a spectrum of less prevalent, distinct subjects within the dataset.

Fig. 4 shows a sequence of horizontal bar graphs, where

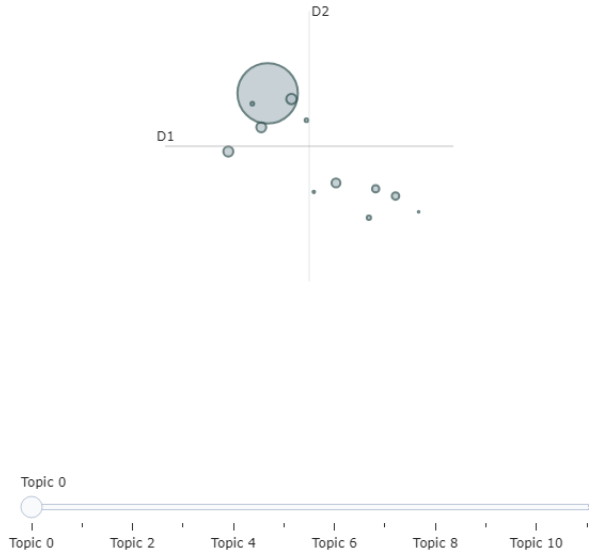

Fig. 3. Intertopic distance.

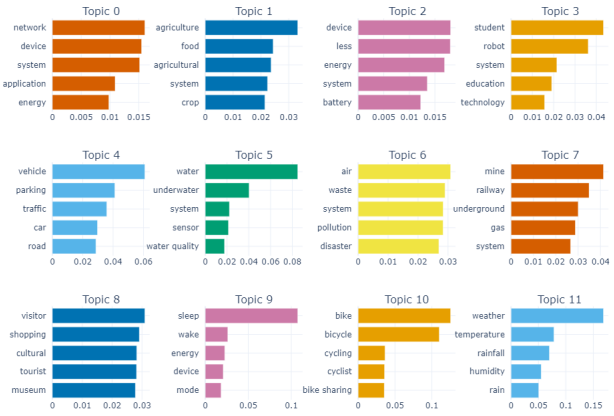

Fig. 4. Top 5 words for each cluster.

each graph corresponds to a separate cluster or topic. Each bar's size correlates to a word's significance within its respective topic. The subject areas are classified by colour and include a diverse range of subjects, such as technology, agriculture IoT, IoT devices, education IoT, transportation IoT, water IoT, air IoT, underground mining, smart retail, smart home, ride-sharing, and weather in Topics 0 to 11, respectively. Topic 4 is notable for its focus on the transportation aspects of IoT, demonstrated by the following keywords: "vehicle", "parking", and "traffic". The visualisation enables easy recognition of the most prominent words in all topics, which is essential for understanding the major themes of a large amount of text and for summing up the information within each resultant topic. Furthermore, this study uses a class-dependent TF-IDF score to determine the importance of terms for each cluster. TF-IDF enables the assessment of word importance in different texts by considering both the frequency of a word in a particular document and its significance in the whole collection of documents.

Fig. 5 depicts a dendrogram that is the outcome of a hierarchical cluster analysis. The horizontal axis depicts the

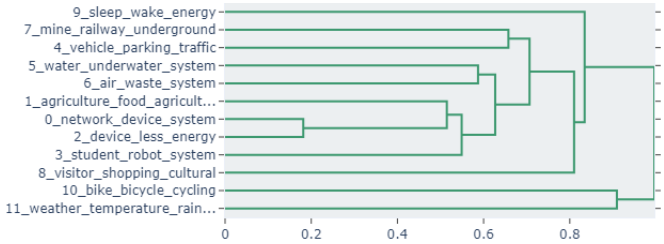

Fig. 5. Hierarchical cluster.

disparity between groups, with a smaller distance indicating a greater similarity. It is evident that some clusters exhibit a tight grouping, such as the cluster "0-network-device-ssystem" with the cluster "2-device-less-energy.s" This indicates the presence of closely associated topics within the data.

## V. Discussion

This research examines the diverse range of industries in which IoT technology is being used, such as agriculture [26], education, transportation, water management, air quality monitoring, underground mining, smart retail, smart home systems, ride-sharing services, and weather forecasting. This study investigation revealed the widespread impact of IoT devices in transforming conventional procedures and improving efficiency and production in various areas. IoT solutions in agriculture provide immediate monitoring of environmental conditions, soil moisture levels, and crop health, allowing for precise farming methods and efficient use of resources. Similarly, in the field of education, smart classrooms equipped with IoT technology provide interactive learning experiences and personalised instructional techniques. Transportation Internet of Things (IoT) applications optimise logistical operations, increase fleet management, and improve passenger experiences using real-time traffic monitoring and predictive repair. Water Internet of Things (IoT) technologies aid in the sustainable management of resources by monitoring water quality, identifying leaks, and optimising irrigation techniques. Airborne Internet of Things (IoT) devices serve a crucial role in monitoring and assessing the levels of air pollution, ensuring the general population's protection and well-being. IoT-enabled safety monitoring, asset tracking, and predictive maintenance in underground mining operations enhance worker safety and operational efficiency. In addition, IoT technologies are transforming retail experiences by providing personalised purchasing suggestions, optimising inventory management, and improving consumer interaction. Smart houses utilise Internet of Things (IoT) devices to automate household duties, improve security measures, and optimise energy usage. Ride-sharing services use the Internet of Things (IoT) to optimise routes, estimate demand, and enhance passenger safety. In addition, weather forecasting technologies provided by the Internet of Things (IoT) offer precise and fast information for preparing for disasters and allocating resources. The extensive use of IoT technology in many industries highlights its significant capacity to shape the future of linked systems and services.

The benefits of IoT devices include enhanced efficiency, productivity, and security in various applications. However, the research's comprehensive scope may overlook technological complexities, cybersecurity threats, economic obstacles, and interoperability challenges. Additionally, the study lacks detailed discussions on regulatory and ethical considerations and the dependence on stable internet connectivity. Addressing these challenges is crucial for fully harnessing the potential of IoT, providing a balanced view of the future of connected systems and services.

## VI. Conclusion

This study provides a comprehensive analysis of the influence of IoT technology in many sectors, such as agriculture and transportation. The statement emphasizes the ability of the Internet of Things to facilitate immediate monitoring, enhance effectiveness, and stimulate innovation. In the future, it is important to prioritize conducting additional research to improve cybersecurity measures and reinforce data privacy rules to reduce the dangers and weaknesses inherent in IoT systems. Furthermore, it is imperative to guarantee the authenticity and dependability of data within IoT frameworks and address concerns regarding data's precision and credibility. To optimize the societal advantages of the IoT, fostering interdisciplinary collaboration and forging collaborations across many industries is crucial. Researchers can accelerate the progress of IoT technology by concentrating on these specific areas. This will involve tackling the obstacles associated with IoT and promoting its incorporation into many sectors and fields.

***Abstract*—Image segmentation is an important aspect of image processing and analysis. Medical imaging segmentation is critical for providing noninvasive information about human body structure that helps physicians analyze body anatomies efficiently. Until recently, various medical imaging segmentation approaches have been presented; however, these approaches are deficient in segmenting abdominal organs due to the significant similarity in their intensity levels. The purpose of this research is to propose a method to facilitate the segmentation of abdominal organs and improve the performance of the segmentation. The core functionality of this research is based on the extraction of rib bone from muscle tissues prior to the application of segmentation. This way, efficient segmentation of abdominal organs can be achieved by isolating the rib bone from the muscle tissues located between the rib bone. The proposed rib bone extraction mechanism is applied to four slices of the MICCAI2007 liver data set to isolate muscle tissues from liver tissues that have significant intensity similarity to liver tissues. The results indicate that the proposed extraction of rib bone efficiently isolated muscle tissues from linked liver tissues and improved the segmentation performance.**

***Keywords*—Active contour; computed tomography; segmentation; medical diagnostics; medical imaging segmentation**

## I. Introduction

Image segmentation aims to partition an image into regions called segments used for further image analysis to achieve improved image compression efficiency and visualization effects [1], [2]. Image segmentation plays a vital role in medical imaging analysis for example providing noninvasive information about human body structure [3]. This information can support radiologists in visualizing and examining the anatomy of the body structure [4], tracking the progress of diseases [5], [6], [7], simulating biological processes [8], and evaluating the need for surgeries in radiotherapy [9], [10]. Threshold-based, region-growth-based, clustering-based, deformation-model based, machine learning (ML)-based, and active contour-based are different segmentation approaches that have been frequently employed in medical imaging analysis [11]. Medical imaging segmentation is important, yet it is a challenging task.

Most of the time, it requires manual delineation of organs by highly skilled personnel. Segmenting CT images is particularly complex compared to other medical imaging modalities. In such images, selecting each pixel of each slice manually could take hours or even days [12], [13]. Segmenting CT images of abdominal organs is more challenging because of their overlapping boundaries with the other organs (such as abdominal structure tissues and muscle tissues placed between rib bone). Most of the abdominal organs have similar intensity levels, which greatly affects the segmentation results of the methods based on intensity similarity [14]. Hence, methods based on gradient or intensity analysis are not feasible to segment images of abdominal organs [15]. Because of such limitations, most available segmentation methods, including active contour methods, fail to segment the abdominal tissues adjacent to the muscle tissues between rib bone [16], [17], [18]. Specific to the active contour segmentation methods, some existing approaches [19], [20], [21] adapted rib distance in the active contour level set formulation. This process slows the active contour segmentation since the contour curve takes longer to reach structural boundaries due to extra computations in the level set function.

Keeping in view the limitations of the existing studies, the following are the research questions that may be addressed during this research:

- How existing segmentation methods based on the intensity of the organs can segment the abdominal organs having similar intensity?
- How the efficiency of the existing segmentation method based on the intensity of the organs can be increased?

Extracting rib bone structures prior to applying the active contour method may facilitate the removal of intervening muscle tissues, thereby improving segmentation efficiency. The primary purpose of this research is to propose a method to facilitate the segmentation of abdominal organs with considerable similarity in intensity by performing rib bone extraction prior to active contour segmentation methods. The following are the objectives of the research:

- To improve the segmentation accuracy of the abdominal organs affected by the large similarity in intensity between abdominal structure tissues and muscle tissues located in between rib bone.
- To reduce the computation time while segmenting abdominal organs via active contour segmentation methods in the CT dataset. As a result, this leads to speeding up the processing time.

Based on the listed objectives, following are the contributions of the research:

- A rib bone extraction mechanism is proposed to efficiently segment the CT images of abdominal organs of similar intensity.
- The proposed rib bone extraction isolates the rib bone from the muscle tissues located in between the rib bone.
- The proposed rib bone extraction is specifically designed to be used prior to the application of "active contour" segmentation methods and has tested accordingly; however, it may be used prior to the application of any segmentation method.
- The proposed rib bone extraction has been applied to four MICCAI2007 Liver dataset [22], [23] slices to efficiently isolate liver tissues from muscle tissues with similar intensities.
- The proposed rib bone extraction simplifies the CT images and addresses the similarity of their intensity issue; hence, leads to a time and computationally efficient segmentation.
- The proposed approach is simple and easy to use, as well as applied prior to the application of the segmentation method(s). To the best of our knowledge, such an approach has never been proposed earlier, hence making it our novel contribution.

Based on the above listed research contributions, the following may be the advantages of the present study:

- The findings of the research will help clinicians efficiently segment, analyze, and visualize abdominal anatomies, as well as plan radiation therapy and surgery.
- The study's research findings will be used to assist software designers in constructing medical tools.
- The approach proposed in this study will help in teaching and research at medical schools.
- The methodologies and results proposed in this study will be useful in medical schools, teaching, and research.

The remainder of the paper is organized as follows: Section "Literature Review" explores and discusses reviewed literature in the area of medical imaging segmentation. Section "Material and Method" discusses the detailed methodology of the proposed method of extracting muscle tissues using the proposed rib bone extraction method before executing the active contour segmentation. "Results and Discussion" section discusses the results of the proposed method. Finally, "Conclusion and Future Direction" section presents the conclusion of the paper to highlight the contributions and findings along with possible future directions. A preprint of this manuscript has previously been published [24].

## II. Related Work

Medical imaging segmentation has been a research focus from last few decades. During this time, a number of image segmentation techniques have been put forth to segment medical imaging for a range of applications, including the early diagnosis of disease, resource optimization, and maximizing efficiency of the existing systems etc. Image segmentation techniques include but not limited to; thresholding based [25], [26], [27], region growing based [28], [29], graph cut based [30], [31], shape model based [32], [33], edge detection based [34], [35], [36], clustering based [37], [38], [39], and more advanced ML [40], [41], [42], [43], and active contour-based methods [44], [45], [46]. In addition to significant contributions to image segmentation, particularly medical imaging segmentation, each proposed approach pose some limitations and challenges. For example, thresholding and region growing based methods are bound to use only image intensity or texture for the image segmentation [47], therefore, are failed to segment the organs with similar intensities. Graph-cut based methods are also limited in segmenting organs with overlapping tissues of similar intensities [31]. Shape based methods are heavily dependent on the training shapes, therefore, become time consuming processes for the images with large shape variations [48]. Recently, ML algorithms (specifically, Deep Learning (DL) algorithms), have emerged as efficient approaches for segmenting medical images [49], [50]. However, DL techniques frequently lack in understanding data and heavily rely on training data that has been manually labeled by medical professionals [48]. Furthermore, because of information loss in the consecutive down-sampling layers, some DL architectures, such as Convolutions Neural Network (CNN), perform poorly in comprehending precise object boundaries [51]. Also, in CNN architectures, 2D convolutions cannot completely utilize the spatial information along the third dimension [52], and 3D convolutions have a large memory consumption [53]. DL-based multi-organ segmentation techniques have also shown significant potential in medical imaging segmentation [54], and it has significantly improved the performance of the U-NET segmentation [55], however it is still challenging to obtain accurate and robust segmentation for the areas with ambiguous boundaries (such as abdominal organs) [56].

Supervised Machine Learning models such as Support Vector Machines (SVM) and Neural Networks (NN) have also shown reasonable performance in segmenting medical images, however, these methods are based on handcrafted and manually extracted features from the data, and for this heavily depend on the skills and experience of the researchers. Requirements of domain knowledge, extraction of features from data, and manual features engineering is basic hurdle to easily employ such algorithms [57], [49]. Active contour methods on the other hand have shown better performance to segment the complex gray-scale and variety of topological structures of medical images [58]. Because of their ability to provide closed and smooth contours of the target objects, these methods are one of the widely used segmentation methods today [59]. Many recent studies have reported to use active contour methods for different applications related to medical imaging segmentation [60], [61], [62], [63]. Although, active contour segmentation is one of the most attractive segmentations, however, in some cases it performs undesirably. For example, it performs poorly in segmenting complex natural images (without proper preprocessing) [64]. Furthermore, because of the susceptibility for intensity heterogeneity and boundary ambiguity of the input images, these methods fail to segment the abdominal tissues, especially tissues, which are adjacent to the muscle tissues between rib bone [65].

To address such limitation of the active contour methods, as a solution, combination of different strategies along with traditional active contour methods have been introduced by the researchers. For example, level set approach has been introduced with active contour to formulate it as energy minimization problem and then solving it with different strategies like gradient descent or partial differential equations [66]. Different DL architectures like CNN have also been combined with active contour to make it a more efficient hybrid segmentation methods [67]. Some of the studies have also introduced the combination of DL, level set, and active contours methods [68]. Such hybrid methodologies yielded good results but suffer with the time consumption issues because of the complexity of the training process. In short, introducing different strategies with traditional active contour methods, one way increases their segmentation capabilities, but on the other hand make them time consuming procedures. Furthermore, even with the latest proposed strategies, still the most existing active contour segmentation methods lack in segmenting the overlapping organs / region boundaries of the organs [69], [70], [71]. This study proposes that rib bone extraction be performed prior to active contour segmentation (refer to "Methodology" section for more information on the proposed method). The proposed approach is an effort to improve the accuracy of the active contour method(s) in particular and the other segmentation methods in general to segment abdominal organs (especially abdominal structure tissues and muscle tissues placed between rib bone) that have comparable intensity levels. Being not the actual part of the active contour, the proposed approach reduces the computation time of the active contour while segmenting abdominal organs. As a result, this leads to speeding up the processing time. Results show that with the help of the proposed approach, the active contour better segments abdominal organs (refer to Fig. 2) and achieves desirable performance in segmenting the organs of the similar intensity (refer to Section "Results and Discussion" for more details on the results achieved). The next section provides the comprehensive detail of the proposed rib bone extraction mechanisms along with the detail of the datasets used, experimentation performed, and the results obtained.

## III. Material and Method

### A. Proposed Approach

This study proposes that rib bone extraction be performed prior to active contour segmentation. This approach can be used to improve the accuracy of the active contour segmentation in particular and the other segmentation approaches in general in segmenting abdominal organs that have comparable intensity levels (i.e., abdominal structure tissues and muscle tissues placed between rib bone).

### B. Methodology

Fig. 1 presents the overall flow diagram of the proposed rib bone extraction approach. According to Fig. 1, the proposed strategy of rib bone extraction is achieved through the following steps:

1) Typical slice of a CT image selection.
2) Performing thresholding on the selected typical slice to find rib bone in it.
3) Performing morphological post processing on the thresholded typical slice to eliminate the effects of thresholding on it.
4) Finding the centroids of each rib bone of the typical slice and saving them as cooperative knowledge for the other slices of the data.
5) Selecting the next slice (target slice) and finding the centroids of its rib bone using the centroid information of the typical slice.
6) Fitting the centroids of typical and target slices into convex hull function (to overcome the problem of the missing centroids).

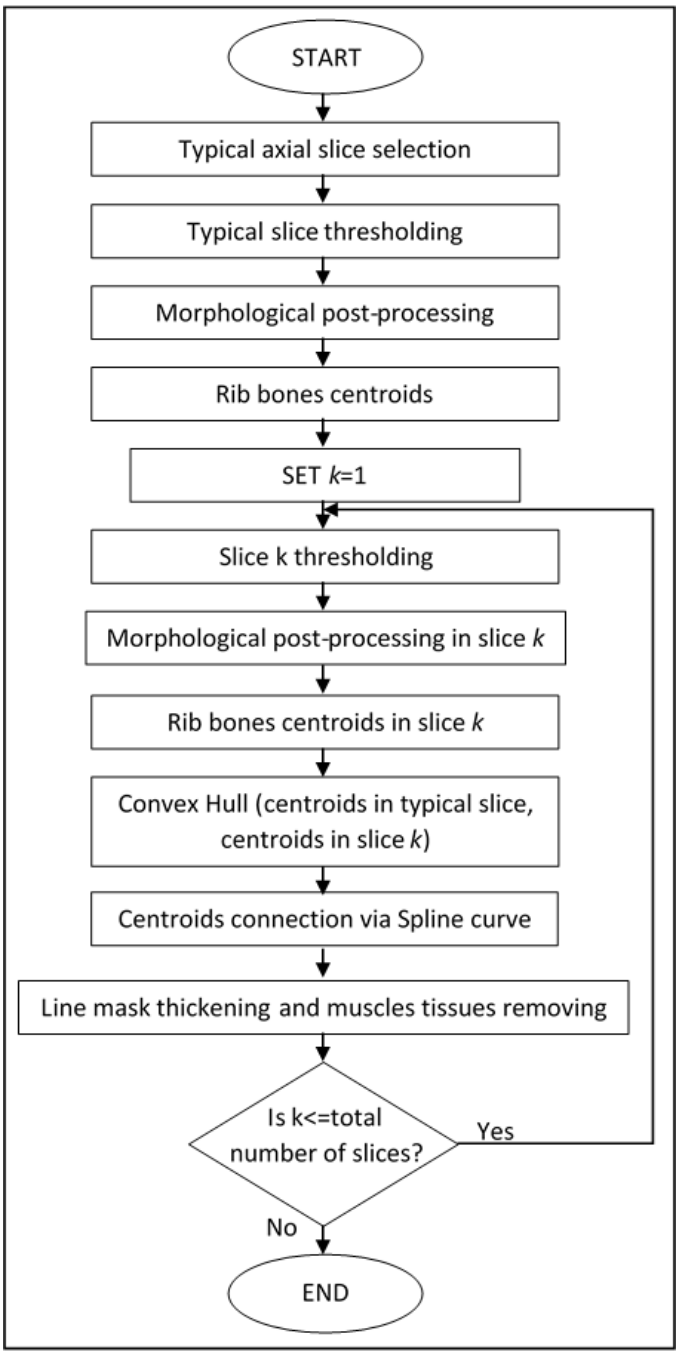

Fig. 1. Proposed rib bones extraction approach.

7) Applying the spline curve method to connect the centroids and estimating the bone's boundary by a line.
8) Applying dilation morphological operation to thicken the estimated lined boundary.
9) Applying steps 5 to 8 above to every next slice by considering it a target slice until the slices of the whole data are finished.

An explanation of each of the above steps is provided in detail in the experimentation subsection.

### C. Performance Evaluation

*1) Evaluation based on Confusion Matrix:* Performances of the proposed system has been measured in terms of accuracy, precision, sensitivity, and specificity provided using the confusion matrix. Table I presents the confusion matrix used to compute the performance measures. The outcomes of this confusion matrix are defined as:

True Positive (TP): The number of slices where muscles areas are removed as muscles areas.

False Positive (FP): The number of slices in which non-muscles areas are removed as muscles areas.

True Negative (TN): The number of slices where non-muscles areas are not removed as muscles areas.

False Negative (FN): The number of slices where muscles areas are not removed as muscles areas.

TABLE I. CONFUSION MATRIX FOR MUSCLE AREA CLASSIFICATION

| | Yes | No |
|---|---|---|
| **MUSCLES AREA** | TP | FN |
| **NON-MUSCLES AREA** | FP | TN |

The confusion matrix presented in Table I and four standard metrics for quantities evaluations are computed as follows:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

$$\text{Precision} = \frac{TP}{TP + FP} \tag{2}$$

$$\text{Sensitivity} = \frac{TP}{TP + FN} \tag{3}$$

$$\text{Specificity} = \frac{TN}{TN + FP} \tag{4}$$

*2) Evaluation based on 2D segmentation:* In order to evaluate the proposed method, the method outputs need to be measured, analyzed and compared with manual segmentation. Therefore, the metrics must be carefully determined to accurately reflect the method performance in 2D segmentation performance. Dice coefficient (mean Index similarity) used to measure the accuracy of segmentation result for proposed method. The segmentation result of proposed method is termed AS and the gold standard is termed GT. The Dice coefficient DC (Dice, 1945) is one of the numbers of measures of the extent of spatial overlap between two segmented images. It is commonly used in reporting performance of segmentation and its values range between 0 if there is no overlap between the segmented region and the gold standard, and 1 for perfect agreement between the segmented region and the gold standard obtained using Eq. (5).

$$\text{DC} = \frac{2\,|AS \cap GT|}{|AS| + |GT|} \tag{5}$$

### D. Experimentation

*1) Dataset description:* The proposed method was evaluated using four contrast-enhanced CT datasets from the Liver Segmentation Grand Challenge database. These datasets have a pixel resolution ranging from 0.55 mm to 0.8 mm, with inter-slice distances between 1 mm and 3 mm. Each axial slice consists of 512 x 512 pixels. The datasets, provided in Digital Imaging and Communications in Medicine (DICOM) format, have gray levels ranging from -1024 to +3071, corresponding to Hounsfield units (HU), the datasets accessed in 2024. The datasets used in this study—Liver1, Liver3, Liver4, and Liver6—contain 183, 79, 212, and 111 slices, respectively. However, the range of liver organ slice in each dataset shown in Table II.

TABLE II. ABDOMINAL ORGANS DATASETS

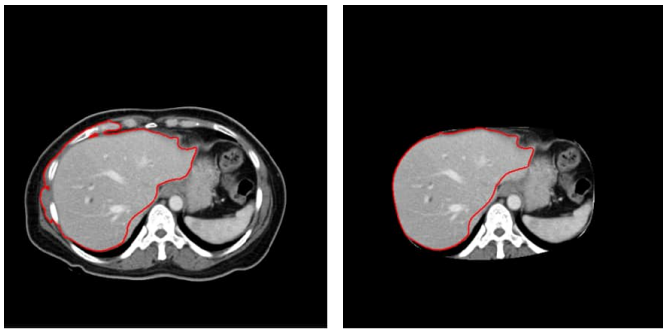
| Abdominal Dataset Name | Dataset Source | Number of Slices | Range of Abdominal Organs Slices |
|---|---|---|---|
| Liver1 | MICCAI2007 | 183 | 62–163 |
| Liver3 | MICCAI2007 | 79 | 14–70 |
| Liver4 | MICCAI2007 | 212 | 57–196 |
| Liver6 | MICCAI2007 | 111 | 20–92 |

*2) Software detail:* Image segmentation and statistical calculations are implemented in Matlab. The program is tested on a computer with Intel(R) Core(TM) i5-7200U CPU @ 2.50GHz 2.71 GHz, 4GB RAM, and Windows 10 Pro.

*3) Rib bone extraction process:* This section provides the detail of the proposed rib bone extraction approach along with the brief explanation of each step provided in the "proposed approach" subsection, and also shown the Fig. 1.

Fig. 2(a) illustrates the results of active contour segmentation before rib bone and muscle extraction, and Fig. 2(b) shows the result of active contour segmentation after rib bone and muscle extraction. It is clear from Fig. 2(a) and 2(b) that when rib bone extraction is performed prior to active contour segmentation, active contour segments the organs of similar intensity, i.e., abdominal organs, comparatively better than when rib bone extraction is not performed. This approach is the main idea our research.

It is well-known among radiology experts that some abdominal structures, especially the liver, are surrounded by rib bone. Therefore, their effective segmentation is difficult without rib bone extraction from their surroundings. Since the rib bone has the highest intensity in a CT dataset, simple binary thresholding may be applied to find the rib bone in it. In binary thresholding, images are converted from gray-scale or color images to binary images. Based on radiologists' knowledge, it is noted that there are some slices that don't have rib bone in all directions of the human body in the abdominal area, which leads to missing some of the muscle tissues. The proposed method thus finds the rib bone in a



(a) Before bone extraction. (b) After bone extraction.

Fig. 2. Active contour segmentation before and after rib bone and muscle extraction from the abdominal organs of similar intensity.

typical slice chosen randomly from upper abdominal slices in the CT dataset, which have rib bone in all directions, as shown in Fig. 3, and applies binary thresholding on the chosen slice. Fig. 4(a) shows a typical slice in the upper abdominal region (upper view) and the result of thresholding in a typical slice shown in Fig. 4(b).

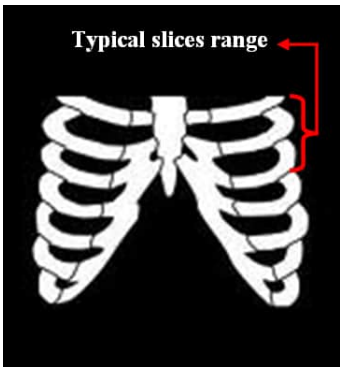


Fig. 3. A Typical slice chosen from the upper abdominal CT slices that have rib bones in all directions.

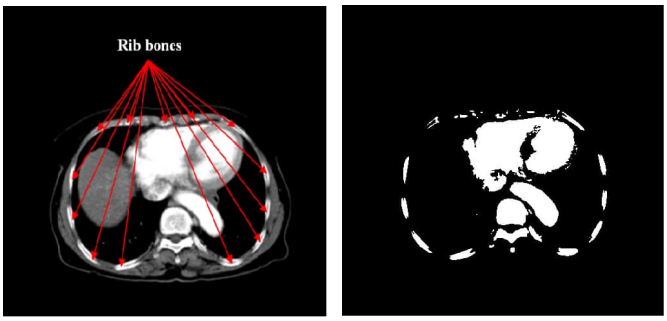
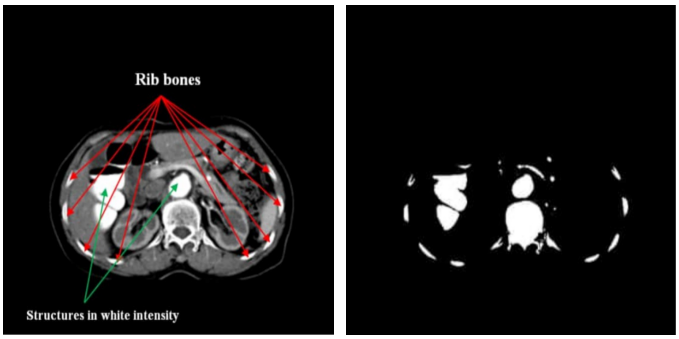


(a) Upper view of a typical slice in the upper abdominal region that has rib bones in all directions. (b) Upper view of the rib bone extraction after thresholding applied

Fig. 4. Typical slice.

It is evident from Fig 4(b) that, as a result of thresholding, the achieved rib bone is not well filled. Hence, a filling morphological operation is applied to fill the bone. The centroids of each rib are then computed. The centroids of ribs of the typical slice are saved temporarily to be used as a cooperative knowledge in the rib bone extraction for other remaining slices in the dataset. The rib bone extraction process is then applied to all slices in the abdominal dataset slice by slice with the following steps: To simplify the explanation, we refer to the slice under the rib bone extraction process as a target slice. Thresholding and filling morphological operations are applied to the target slice. The centroids of each rib bone in the target slice are obtained through region properties. Then the centroids of the typical slice and target slice are fitted into the convex hull function [72].

This function is used to find the appropriate arrangement in a clockwise cycle for these bones' centroids and take just the outer centroids. In some cases, some abdominal structures appear in white intensity, as shown in Fig. 5(a), which can affect the result of extracting ribs and muscles. However, the convex hull process overcomes those obstacles. In addition, the convex hull process also overcomes the problem of missing centroids in some directions by taking the centroids from a typical slice in the same directions. Fig. 5(a) shows an example of a target slice that does not have rib bones in all directions, and its thresholding result is shown in Fig. 5(b).



(a) Ribs in target slice. (b) Thresholding result.

Fig. 5. Target slice and its resultant slice after the application of thresholding.

The convex hull process is followed by the spline curve method to connect the centroids and estimate the bone's boundary. The connected points are then used to form a mask that isolates muscle tissues. Fig. 6 shows the line connecting the rib bones. The line connecting between the rib bones is then thickened by a dilation morphological operation (as shown in Fig. 7). The formed mask is applied to remove muscles located between rib bones.

This operation aims to remove the rib bones and muscles, which solve the problem of intensity similarity with abdominal structure tissues. Fig. 8 shows removing ribs and muscles. Choosing an appropriate thickening for connecting line is an essential factor that affects the accuracy of segmentation results. We choose an appropriate thickening value through experiments. Fig. 9 shows the effect of line mask thickening size; if the mask line thickened uses a bigger value, the mask will isolate some of the abdominal structure tissues, as shown in Fig. 9(b). If the mask line thickened to an appropriate size, the mask will isolate rib bones and muscles tissue only, as shown in Fig. 9(a).

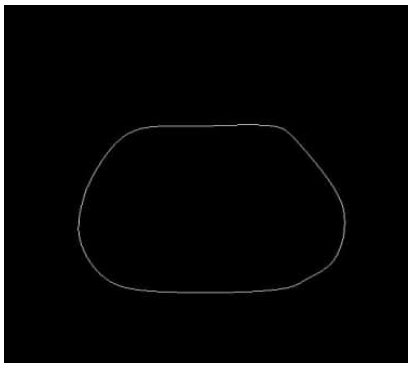


Fig. 6. Line connected between ribs.

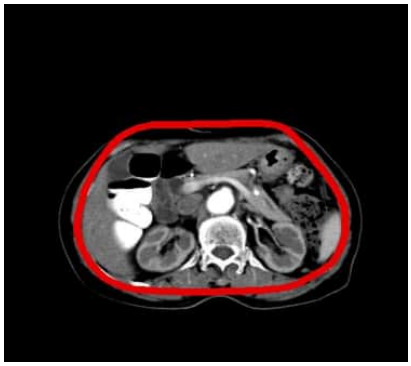

Fig. 7. Line thickening by the application of dilation morphological operation.

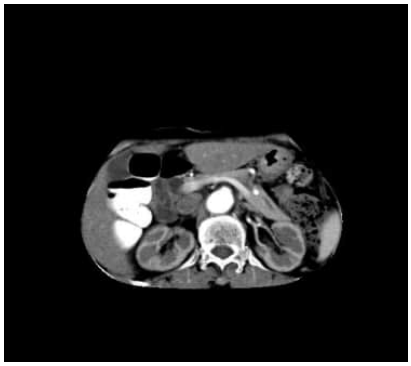

Fig. 8. Removal of rib bones from muscles.

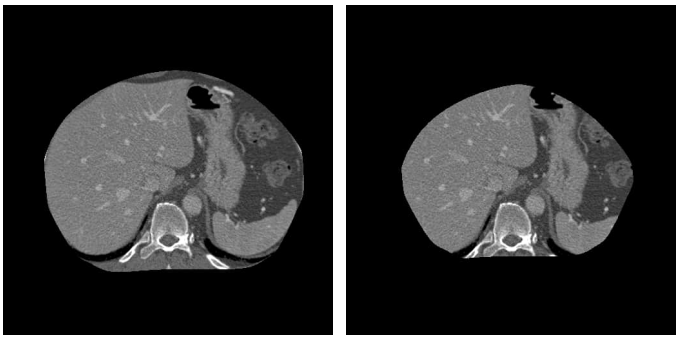

(a) Appropriate thickening. (b) Big thickening.

Fig. 9. Effects of line thickening on rib bone and muscles separation.

Rib bones extraction is applied to four MICCAI2007 Liver datasets [22], [23] (liver1, liver3, liver4, and liver6) slices to isolate muscle tissues that have significant intensity similarity with liver tissues. Fig. 10 shows rib bone extraction for some slices in these datasets [i.e. Fig. 10(a) (slice 151 Liver1), Fig. 10(b) (slice 61 Liver3), Fig. 10(c) (slice 158 Liver4), and Fig. 10(d) (slice 64 Liver6)]. Rib bones extraction is not performed on the Liver5 dataset due to the clear distinction in intensity between the liver tissue and muscles tissue.

(c) Slice 158 Liver4 (d) Slice 64 Liver6

Fig. 10. Rib bones extraction applied to four MICCAI2007 Liver datasets i.e. liver1, liver3, liver4, and liver6.

## IV. Results and Discussion

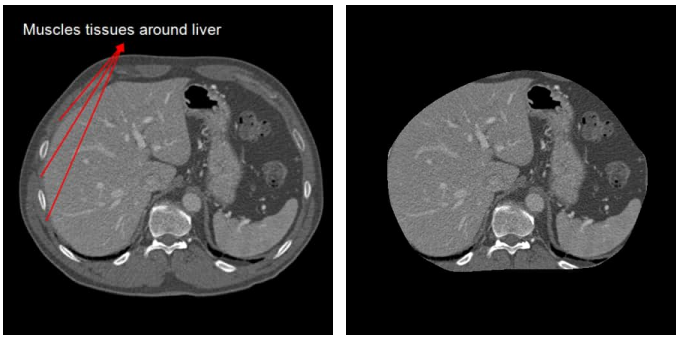
### A. Results Based on Confusion Matrix

Table III shows the evaluations quantities for each Liver data set and the weighted average performance where the weights correspond to the number of slices in each dataset. Results presented in Table III indicates that the proposed approach has efficiently extracted the rib bones from the slices of the Liver dataset.

TABLE III. Quantitative Evaluations for Rib Bone Extraction

| Dataset | Slices Number | Accuracy | Precision | Sensitivity | Specificity |
|---|---|---|---|---|---|
| liver1 | 102 | 0.83 | 0.80 | 0.96 | 0.78 |
| liver3 | 57 | 0.86 | 0.82 | 0.93 | 0.79 |
| liver4 | 140 | 0.92 | 0.88 | 0.96 | 0.87 |
| liver6 | 73 | 0.84 | 0.92 | 0.75 | 0.93 |
| **Average** | - | 0.87 | 0.86 | 0.91 | 0.84 |

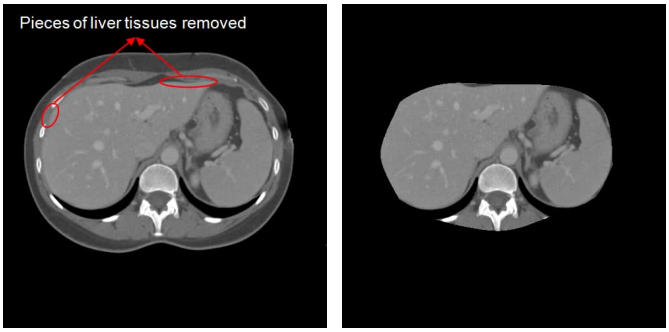
Fig. 11 [Fig. 11(a) (original slice), and Fig. 11(b) (muscles isolating)] shows an example of a true positive (TP) case where the muscle tissue between rib bones is isolated completely.



(a) Original slice (b) Muscles isolating

Fig. 11. A true positive case where the muscle tissue between rib bones is isolated completely from muscles.

Fig. 12 [Fig. 12(a) (original slice), and Fig. 12(b) (pieces removed)] shows an example of a false positive (FP) case where some parts of liver tissues (non-muscle tissues) are removed as a muscle area. From rib bone extraction results, it can be noted that the efficiency of this method is acceptable.



(a) Original slice (b) Pieces removed

Fig. 12. A false positive case where some parts of liver tissues are removed as muscle.

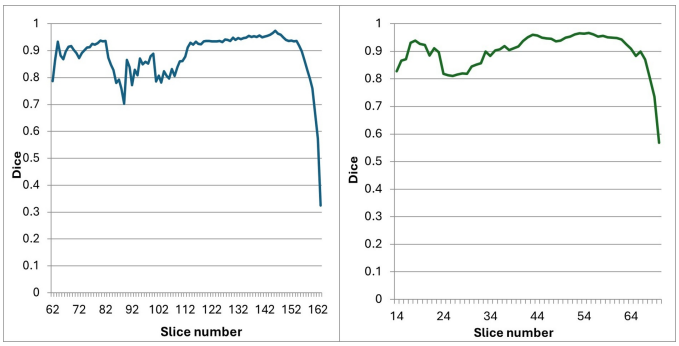
### B. Results Based on Dice Coefficient

Table IV shows the mean Dice coefficient values in all datasets, all slices for each liver organ. Fig. 13 (a)–(d) show the results of the Dice coefficient for the liver regions in the four MICCAI2007 liver datasets (Liver1, Liver3, Liver4 and Liver6).

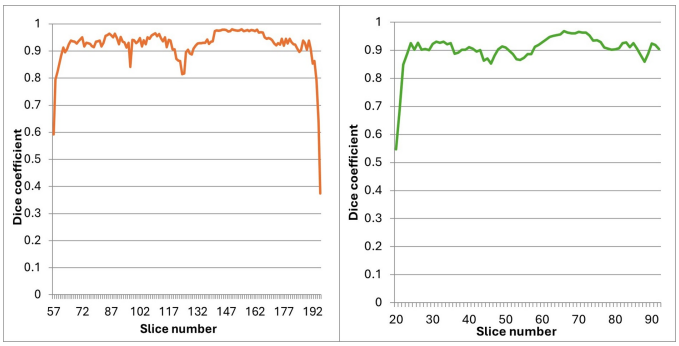
TABLE IV. QUANTITATIVE MEASURES FOR FOUR LIVER ORGAN DATASETS

| Dataset | Number of Segmented Liver Slices | Mean Dice Coefficient |
|---|---|---|
| Liver1 | 102 | 0.88 |
| Liver3 | 57 | 0.90 |
| Liver4 | 140 | 0.92 |
| Liver6 | 73 | 0.90 |
| **Average** | – | 0.90 |

The quantitative measures presented in Fig. 13 and Table IV, shows a positive correlation and high similarity between the proposed method and the experts' manual segmentation, reflected by the mean of Dice coefficient for all four liver organs (0.90).



(a) Liver1 (b) Liver3



(c) Liver4 (d) Liver6

Fig. 13. Dice coefficient for four liver organs: Proposed method versus manual segmentation.

Finally, the results achieved in this study are compared with the state of-the-art active contour-based segmentation methods in the literature i.e. [71], [73]. As Compared to [71], [73] our proposed model achieved promising results in terms of precision, recall, and f-measures scores.

## V. CONCLUSION AND FUTURE DIRECTIONS

In this research, a rib bone extraction mechanism is proposed to be used prior to segmentation methods such as active contour to segment abdominal organs of similar intensity. Similar intensity of abdominal organs, such as abdominal structure tissues and muscle tissues located in between rib bone, greatly affects the performance of the segmentation methods, and most available segmentation approaches based on intensity of the organs, fail to efficiently segment these organs. The proposed rib bone extraction is used to isolate muscle tissues that have similar intensity with abdominal structure tissues; hence, it makes the segmentation process computationally efficient and simpler to use. The rib bone extraction mechanism isolates muscle tissues with a large degree of similarity in their intensity with the abdominal structure. Consequently, this prevents the active contour curve from leaking into muscle tissues during the segmentation process. The proposed rib bone extraction is applied on four MICCAI2007 Liver data set [22], [23] slices to isolate muscle tissues from liver tissues that have significant similarity in intensity with liver tissues. Results indicate that the proposed rib bone extraction approach has efficiently isolated muscle tissues from the linked liver tissues.

The proposed rib bone extraction is specifically designed

to be used prior to the application of "active contour" segmentation methods and has been tested accordingly; however, it may be used prior to the application of any segmentation method.

In future, this method will be tested with the other state-of-the-art segmentation approaches to check its suitability with these methods and to better validate our hypothesis.

## Data Availability

MICCAI2007 data were used to support this study and are available at https://www.semanticscholar.org/paper/Semi-automatic-Segmentation-of-the-Liver-and-its-onDawantLi/bacf1b9ffec68f01d93d6389faea03432060e07d. These prior studies (and datasets) are cited at relevant places within the text as reference [22], [23].

# Revolutionizing Road Safety and Optimization with AI: Insights from Enterprise Implementation

OUAHBI Younesse, ZITI Soumia
Intelligent Processing and Security of Systems Informatics Department-Faculty of Science,
Mohammed V University, Rabat, Morocco

***Abstract*—This study explores the key factors influencing the adoption of artificial intelligence (AI) in the logistics sector, with a particular emphasis on road logistics management. It examines the technological, organizational, and environmental contexts that shape AI integration, as well as the challenges faced by logistics managers, including the need for digital transformation, carbon emissions reduction, and advanced parcel tracking management. The objective is to identify technological and human-related barriers to AI adoption and to assess the level of interest and readiness among logistics companies, especially in the Moroccan context. A quantitative research approach was adopted, based on an online survey targeting logistics professionals and decision-makers, mainly from European and Moroccan small and medium-sized enterprises (SMEs). The collected data were analyzed using statistical methods, including linear regression and ANOVA, to evaluate the relationships between company characteristics, perceived complexity of AI tools, and the availability of qualified human resources. The findings indicate that perceived complexity and limited access to specialized skills significantly hinder AI adoption. Moreover, the perception of tangible performance benefits—such as increased operational efficiency and reduced $CO_2$ emissions—emerges as a major driver for acceptance. These insights offer practical implications for logistics companies seeking to leverage AI technologies to optimize operations, reduce environmental impact, and enhance parcel tracking systems. A strategic roadmap is proposed to overcome the identified barriers and promote effective AI integration.**

***Keywords*—AI adoption; road logistics; logistics management; digital transformation; $CO_2$ emissions; parcel tracking management**

## I. Introduction

The logistics sector is a fundamental pillar of the global economy, ensuring the smooth functioning of supply chains and the fluidity of international trade [1]. However, the logistics sector faces major challenges that impact not only its operational efficiency but also its sustainability and safety [2]. Three key issues stand out: road accidents [3], CO2 emissions [4], and parcel tracking management [5]. These concerns are critical for logistics companies and have significant global repercussions on society and the environment. According to the latest report from the World Health Organization (WHO), the number of people killed in road accidents amounts to 1.19 million per year [6]. Although this figure represents a slight decrease, road accidents remain the leading cause of death among children and young people aged 5 to 29, with more than two deaths per minute and over 3,200 per day. The WHO's 2023 Global Road Safety Status Report indicates that between 2010 and 2023, the number of road accident fatalities decreased by 5%. Despite this reduction, road accidents continue to represent a global health crisis, with pedestrians, cyclists, and other vulnerable road users remaining particularly at risk [6].

In 2022, according to statistics reported by the National Road Safety Agency (NARSA), Morocco recorded 113,625 traffic-related injuries, resulting in the deaths of 3,499 people. Among these victims, more than 1,600 people lost their lives on non-urban roads (1,629). Approximately six-sevenths of the fatalities were men (2,971), while around one-seventh were women (515). A total of 889 victims were under the age of 25, including 281 under the age of 15, and 608 aged 15 to 24. Of The victims included 1,398 users of motorized two or three-wheelers (1,321 two-wheelers and 77 three-wheelers). Pedestrians accounted for 888 of the victims, representing 25.4% of the deaths, with just over one-fifth (189) of them aged 65 or older. Additionally, 801 victims were users of passenger cars [7]. Enhancing road safety by preventing collision accidents is a key objective within the transportation system, driving the advancement of collision prevention technologies. By leveraging detection, computer, and communication technologies, the main goal of these systems is to accurately identify potential driving hazards. They can then either warn the driver or automatically apply braking at the right moment, thereby reducing the risk of accidents [8]. CO2 emissions generated by transport vehicles pose a significant environmental challenge [9-12]. Logistics vehicles, including trucks, vans, and utility vehicles, are responsible for a substantial share of global greenhouse gas emissions [4],[13-15]. According to the 2023 report by the International Energy Agency (IEA), the transport sector accounts for approximately 24% of global energy-related CO2 emissions, with heavy-duty trucks contributing nearly 30% of these emissions. In 2022, heavy trucks were responsible for 7.3% of total CO2 emissions in the European Union, with similar figures observed in other regions of the world. The need to reduce the carbon footprint has become a major imperative, not only to meet increasingly stringent environmental regulations but also to satisfy the growing consumer expectations for sustainability [15]. Logistics companies face the challenge of balancing operational efficiency with emission reductions [10]. Solutions such as route optimization, smart driving technologies, and the transition to greener vehicles are crucial for achieving these goals. However, the implementation of these solutions requires significant investments and substantial operational adjustments, which can be a major obstacle for many companies [11]. Artificial Intelligence (AI) offers transformative solutions to the major challenges in the logistics sec- tor, particularly in addressing road accidents, CO2 emissions, and parcel tracking management. By leveraging advanced algorithms and data processing technologies, AI enables significant improvements

in logistics operations while contributing to a substantial reduction in associated risks and costs [12–14].

In terms of road accident prevention, AI plays a crucial role through the use of safety management systems based on predictive analytics. These systems integrate data from sensors, cameras, and driving history to detect risky behaviors and hazardous conditions. For instance, AI algorithms can analyze driving habits and weather conditions to anticipate accident risks and recommend preventive measures [8]. Regarding route optimization, AI provides significant solutions for reducing CO2 emissions. Dynamic routing algorithms enable real-time adjustments to routes based on traffic conditions, thereby minimizing fuel consumption and greenhouse gas emissions. According to the International Energy Agency, this optimization could reduce CO2 emissions in the transport sector by 10% to 15% by 2030 [15]. Additionally, an analysis by McKinsey & Company suggests that adopting AI technologies for route optimization could result in fuel savings of up to 20% [16]. In terms of parcel tracking, AI enhances accuracy and transparency through technologies like smart sensors and data management systems. By enabling real-time tracking, AI reduces errors and delays while increasing customer satisfaction. A study by Capgemini [17] revealed that AI solutions could improve delivery forecast accuracy by 30% and decrease order processing errors by 25%. Additionally, AI provides greater transparency for customers, thereby strengthening their trust and loyalty [17].

AI also plays a significant role in human resource management within the logistics sector. AI tools can monitor driver attendance, analyze their performance, and predict human resource needs, thereby optimizing resource management and productivity. A study by Deloitte shows that AI can improve operational efficiency by 15% to 20%, reducing labor costs and increasing employee productivity [18], [1]. The adoption of AI in road logistics in Morocco is still in the development phase. Although AI offers significant opportunities to optimize logistics operations, its integration faces several major challenges. Key obstacles include technological complexity, the high cost of solutions, and issues related to user training [19]. This study aims to analyze the factors influencing the adoption of AI in logistics, identify the problems encoun- tered by logistics managers, and understand how technological, organizational, and environmental contexts affect the integration of this technology.

While previous studies focused on individual components of AI deployment in logistics, few have addressed enterprise-level AI adoption combining both safety and optimization. This paper seeks to fill this gap and it's the primary objectives of this study also to identify the technological barriers to AI adoption. This includes challenges related to training AI systems, associated costs, and the perceived complexity of AI tools. Another objective is to identify specific issues in road logistics that could be addressed by AI. This analysis aims to shed light on common challenges such as vehicle tracking, fuel consumption management, and vehicle condition monitoring. It is also crucial to assess the need and interest of Moroccan companies in AI solutions for logistics management. This evaluation will help determine the interest in AI technologies and the willingness to invest in these solutions. Finally, the study proposes to formulate innovative solutions to improve logistics management using AI, aiming to optimize operations, prevent common issues, and enhance safety. The central research questions include:

- What are the main technological obstacles encountered when adopting AI in logistics?
- What specific problems in road logistics could be resolved by AI?
- How do organizational and environmental contexts influence the integration of AI in logistics?

The remainder of this paper is structured as follows: Section II reviews related works on AI in logistics; Section III presents the methodology and dataset; Section IV discusses the implementation and results; finally, Section V concludes the paper and suggests future work.

## II. Related Work

The application of artificial intelligence (AI) to road safety and logistics optimization has attracted considerable scholarly interest. Numerous studies have proposed and implemented AI-based techniques—including neural networks, fuzzy logic systems, ensemble learning, and conditional random fields (CRFs)—to address key challenges such as accident prediction, driver behavior analysis, and last-mile delivery optimization. To improve clarity and coherence, we have structured the literature review around four key technological approaches, each summarized in a dedicated comparison table. These tables group together relevant studies based on their primary methodological focus and application domain:

- Table I covers optimization strategies in AGV operations and real-time accident prediction.
- Table II summarizes behavior recognition and sequence modeling using CRFs and decision systems.
- Table III details the studies on accident prediction using neural networks and machine learning techniques.
- Table IV highlight the studies on driving behaviour analysis and accident prediction using fuzzy logic (2024–2025).

### A. Genetic Algorithms

Genetic algorithms, inspired by Darwin's evolutionary theory, are heuristic-based search methods that use operations like mutation and crossover to optimize solutions [20]. These algorithms start with a group of potential solutions, known as a population, which are usually represented as one-dimensional arrays. The initial population is generated randomly according to the rules defined by the problem domain. Successive generations are then created by selecting the most effective solutions from the current population [21]. The effectiveness of each candidate solution is assessed using a fitness function, with the goal of improving the performance of the new population over the previous one. Solutions with higher fitness are more likely to be selected for reproduction, where crossover and mutation are applied to create new generations of candidates [22][23] (see Table I).

TABLE I. SUMMARY OF STUDIES ON OPTIMIZATION TECHNIQUES IN AGV OPERATIONS AND ACCIDENT PREDICTION (UPDATED 2022–2025)

| Study | Objective | Method | Results |
|---|---|---|---|
| Patidar et al. (2025) [54] | Explore novel optimization algorithms for predictive modeling | Implementation of Royal Animal Optimization with hybrid approaches | Improved predictive accuracy compared to conventional models |
| Dakic et al. (2024) [55] | Optimize intrusion detection in autonomous vehicle environments | Use of metaheuristic algorithms for IoT/IIoT-based security enhancement | Achieved superior detection rates in simulated autonomous driving scenarios |
| Kumari & Mishra (2024) [56] | Enhance predictive stacking models using Bayesian optimization | Data sampling, gradient boosting, and optimization using Bayesian techniques | Enhanced performance and generalization ability for time-sensitive predictions |
| Ashraf et al. (2024) [57] | AI-based decision system for optimizing road safety | Hybrid decision-making approach with aggregation operators and multi-criteria evaluation | Enabled faster and more accurate decision-making under complex road scenarios |
| Haseena et al. (2022) [58] | Early prediction of road-related heart disease using bio-inspired models | Moth-Flame Optimization algorithm combined with deep feature extraction | Significantly improved early detection capability for accident-related health deterioration |

### B. Autonomous Driving Technology

An autonomous vehicle is a sophisticated system that can navigate and understand its environment using onboard sensors. It can autonomously plan routes and make driving decisions [24]. The Society of Automotive Engineers (SAE) defines autonomous driving across six levels in its 2014 standard, updated in 2018. Levels 0 to 3 describe a gradual shift from complete human control to partial oversight and assistance. Levels 4 and 5 indicate a stage where human intervention is no longer necessary. Modern autonomous driving systems incorporate various technologies, focusing on vehicle perception, decision-making, and control to take over driving tasks. These vehicles also utilize communication technology to stay connected with other vehicles and their surroundings, ensuring ongoing network interaction [25].

### C. Conditional Random Fields

Conditional Random Fields (CRFs) are probabilistic graphical models used for tasks such as labeling and segmenting sequential data [26]. Unlike traditional classifiers that predict labels for individual samples independently, CRFs consider the full sequence of observations when making predictions [27]. CRFs oper- ate using an undirected graph, which avoids biases related to the number of states. These models are trained in a discriminative manner and combine features of both discriminative and generative approaches, leveraging the Markov property in hidden states for observations [28]. Due to the temporal correlations present in multi-channel sequential data, traditional discriminative classifiers are not directly applicable. CRFs have been employed as an alternative inference model for this purpose [26]. This makes CRFs particularly useful for tasks that require structured prediction within sequences where maintaining temporal dependencies is essential [27] (see Table II)

### D. Artificial Neural Networks

Artificial neural networks are advanced statistical tools designed to capture intricate relationships be- tween inputs and outputs and to identify data patterns [29]. They offer a valuable alternative for exploring nonlinear dynamics in engineering contexts. The development of an artificial neural network involves three key stages: design, training, and evaluation. The design stage includes defining the rules, setting input parameters, and gathering data [31] . During the training stage, the network is refined by preparing data and adjusting learning algorithms[32] . The final evaluation stage assesses the network's accuracy and performance by comparing predicted outputs with actual results [33] (see Table III).

### E. Fuzzy Logic

Fuzzy logic represents decisions in a way that mimics natural language rather than relying solely on numerical values. Unlike traditional approaches that use numbers, fuzzy logic allows decisions to be articulated in terms of descriptive words, mirroring human-like reasoning processes [37][38][56]. This approach enables machines to simulate human thought processes more effectively. A key element of fuzzy logic is the fuzzy inference system, which can model complex, nonlinear functions through the use of fuzzy rules and convert vector inputs into scalar outputs with ease [40]. The system consists of four primary components: the fuzzifier, the inference engine, the rule base, and the defuzzifier. The fuzzifier translates inputs into fuzzy membership values, while the rule base consists of rules formulated by experts [41], [60], [61] (see Table IV).

## III. METHODOLOGY

### A. Development of Hypotheses

The development of hypotheses is a crucial step in structuring the study, allowing for the formulation of conjectures based on preliminary observations and theoretical knowledge. In the context of the adoption of AI technologies in the logistics sector, four main hypotheses have been defined to guide the analysis and evaluate the factors influencing this adoption.

- Hypothesis 1: Only companies with large logistics systems are interested in integrating AI into their operations.

The first hypothesis posits that only companies with large logistics systems are interested in integrat- ing AI into their operations. This hypothesis is based on the idea that large companies, due to the complexity and scale of their logistics systems, may see significant benefits in implementing AI solutions to optimize their processes. Large companies, with their specific needs and financial capacity, are likely to invest more in advanced technologies to improve operational efficiency and manage complex supply chains [42]. This hypothesis is grounded in the Resource-Based View theory. According to this theory, large companies possess superior resources and capabilities that enable them to invest in advanced technologies such as AI. These resources include not only financial aspects but also organizational skills and infrastructure necessary to integrate new technologies. The RBV suggests that companies with more resources are better positioned to adopt technological innovations, like AI, to maintain a competitive advantage [43, 44]. Therefore, we examine how large companies, compared to small and medium-sized enterprises, are more likely to

TABLE II. STUDIES ON THE USE OF CONDITIONAL RANDOM FIELDS FOR DANGEROUS DRIVING DETECTION AND PREDICTION

| Study | Objective | Method | Results |
|---|---|---|---|
| Chen et al. (2025) [59] | Identify major depressive disorder in elderly using behavioral markers | Behavioral feature extraction from passive data and statistical modeling | Enabled early detection through analysis of driving-related mental health indicators |
| Ortigoso-Narro et al. (2025) [60] | Propose a lightweight attention network for behavior recognition | Spatially-focused attention L-SFAN model trained on mobility data | Achieved real-time inference for driver-related pattern recognition tasks |
| Mehta et al. (2025) [61] | Predict customer satisfaction using driving and marketing behavior data | Multi-source data fusion and AI-powered behavioral analytics | Demonstrated behavioral prediction performance applicable to logistics and delivery |
| Duan (2024) [62] | Analyze behavior of tourism consumers under driving scenarios | Deep learning-based modeling of driving and consumer interaction patterns | Identified influencing factors in behavioral tourism and mobility context |
| Wang et al. (2024) [63] | Predict couriers' behavior during last-mile delivery operations | Reinforcement learning model applied to courier decision sequences | Accurate prediction of delivery performance and behavior in urban logistics |

adopt and implement AI solutions due to their more abundant resources.

To explore this hypothesis, we examined several variables related to the size and age of the company. Variable SI 5, which asks how many years the company has been in operation, allows us to assess the company's age, a factor that may influence its ability to adopt new technologies. Variable SI 6, regarding the number of employees, is also crucial for understanding the size of the company and its available resources. Larger or older companies may have more resources to invest in AI and manage its complex demands. These variables help determine how the size and length of operation of the company influence its approach to adopting AI.

- Hypothesis 2: Perceived complexity of AI tools slows their adoption in logistics.

The second hypothesis suggests that the perceived complexity of AI tools slows their adoption in the logistics sector. This hypothesis is based on the Technology Acceptance Model (TAM), which indicates that the perception of the difficulty of using a technology can be a major barrier to its adoption. AI tools, often considered technically sophisticated, may be perceived as intimidating or difficult to integrate into existing systems, potentially hindering their adoption by companies hesitant to face these challenges [45]. This hypothesis mobilizes the Technology Acceptance Model. TAM proposes that two main factors influence technology acceptance: perceived ease of use and perceived usefulness. The perceived complexity of AI may increase the perceived difficulty of use, which could discourage its adoption. According to TAM, the more a technology is perceived as complex, the less likely it is to be adopted [46]. We test this hypothesis by exploring how the perception of the complexity of AI tools affects their acceptance in the logistics sector. This hypothesis is tested using variables that measure the perception of complexity and associated costs of using AI tools. Variables TA 1 and TA 2, which concern the time and cost of training for AI systems, are essential for assessing whether perceived obstacles related to complexity influence adoption. Variable TA 12 directly measures the perception of AI technology complexity, while TA 9 evaluates the ease of use of AI tools within the company. These combined variables allow us to analyze how perceptions of complexity and costs affect the decision to adopt AI technologies.

- Hypothesis 3: Companies show higher acceptance of AI solutions when they perceive direct and tangible benefits in terms of performance improvement.

The third hypothesis proposes that companies show higher acceptance of AI solutions when they perceive direct and tangible benefits in terms of performance improvement. This hypothesis is based on the idea that business decision-makers are more likely to adopt innovative technologies if these offer clear and measurable benefits, such as cost reduction, improved processing speed, or increased accuracy in logistics operations. The perception of a positive return on investment plays a crucial role in the decision to adopt new technologies [47].

This hypothesis is supported by the Diffusion of Innovations Theory. According to this theory, in- dividuals or organizations adopt innovations when they perceive significant advantages, such as performance gains, cost reduction, or quality improvement. In the context of AI, perceived benefits like process optimization and better decision-making are crucial factors for its acceptance. We explore how perceptions of potential ben- efits influence the adoption of AI technologies in the logistics sector, examining the links between perceived advantages and adoption rates [48].

For this hypothesis, the variables focus on the benefits companies expect to gain from AI. Questions SAAI 1 to SAAI 6 measure the different types of real-time visibility and detailed statistics that companies wish to obtain using AI. For example, SAAI 1 explores the desire for real-time visibility on fuel consump- tion, while SAAI 5 examines interest in detailed visibility on delivery times. These variables help understand how perceived benefits, such as improved tracking and resource management, influence the acceptance of AI technologies.

- Hypothesis 4: The Acceptance of AI solutions is positively influenced by the availability of qualified human resources for implementation.

Finally, the fourth hypothesis states that the acceptance of AI solutions is positively influenced by the availability of qualified human resources for their implementation. This hypothesis is based on the fact that the effective adoption of AI technologies requires specialized technical skills. Companies with qualified and experienced personnel are more likely to embrace these technologies because they have the capability to overcome the technical challenges associated with their implementation. The availability and expertise of staff can thus

TABLE III. STUDIES ON ACCIDENT PREDICTION USING NEURAL NETWORKS AND MACHINE LEARNING TECHNIQUES

| Study | Methodology | Results |
|---|---|---|
| Tambouratzis et al. (2010) [30] | Probabilistic Neural Network (PNN) and Decision Tree | The combined methodology improves accuracy in predicting the severity of accidents (light, serious, fatal). |

TABLE IV. STUDIES ON DRIVING BEHAVIOR ANALYSIS AND ACCIDENT PREDICTION USING FUZZY LOGIC (2024–2025)

| Study | Objective | Method | Results |
|---|---|---|---|
| Ennab & Mcheick (2025) [39] | Enhance explainability in AI-based safety diagnostics | Hybrid fuzzy system integrated with interpretable AI modules | Improved transparency in safety-critical environments and decision support |
| Dağkurs & Atacak (2025) [38] | Predict driving anomalies in autonomous vehicles | Ensemble method with deep and fuzzy feature integration | Detected complex risk factors and non-linear behavior in autonomous driving |
| Erdagli et al. (2024) [40] | Evaluate cardiovascular risk linked to road stress events | Fuzzy inference applied to perfusion imaging with AI classifiers | Early identification of heart stress patterns related to logistics driving strain |
| Akinsehinde et al. (2025) [41] | Achieve robust environmental prediction under uncertainty | Neuro-fuzzy model combined with time-series for rainfall prediction | Demonstrated fuzzy learning robustness under highly volatile conditions |
| Chen et al. (2025) [42] | Detect cognitive behavior under driving-related conditions | Behaviorally-derived fuzzy decision system trained on passive data | Enabled early detection of cognitive anomalies in elder drivers |

be a determining factor in the decision to adopt AI solutions [49].

This hypothesis relies on the Organizational Capability Theory. This theory posits that the availability of specific skills and expertise within an organization is essential for the successful implementation of advanced technologies. In other words, companies with qualified personnel in AI are more likely to adopt these technolo- gies. We analyze how the availability of qualified and experienced human resources influences the adoption of AI solutions in the logistics sector, emphasizing the crucial role of technical skills in the successful integration of AI technologies [50].

To evaluate this hypothesis, we analyzed variables related to the support and skills available for using AI tools. Variable TA 4 examines the availability of ongoing support from trainers or AI experts after initial training, which is essential for the successful integration of these technologies. Additionally, TA 13 measures the level of external assistance required to use AI tools, indicating the perceived competence of employees in using these technologies. These variables help assess how the availability of skills and support influences the adoption of AI technologies [51].

### B. Field Study on Implementation Probability

The methodology used to conduct the empirical study is outlined below [52][53]. In line with the goal of increasing the likelihood of AI solution implementation in the logistics sector, a quantita- tive study was conducted using an online survey. This survey targeted practitioners and decision-makers from businesses of various sizes, primarily within European SMEs, to gather relevant information on their level of interest and the factors influencing AI adoption. The online survey was chosen for its ability to reach a wide range of companies in a very short period, while allowing for anonymous and honest responses through a structured questionnaire. The study design was carefully oriented to link theoretical analyses with real-world problems encountered in the industry, thus providing a concrete context for evaluating AI technology adoption. The collected data were analyzed using appropriate statistical methods to identify trends, relationships, and key factors influencing the likelihood of AI implementation in logistics environments.

### C. Study Design

The study design was carefully crafted to ensure a thorough analysis of the factors influencing the adoption of AI technologies in logistics systems. The first step involved defining the relevant variables for the study. Among these variables, four main ones were identified as crucial: satisfaction with internal information (SII), level of innovation (LI), rate of adoption (RA) of AI technologies, and availability of qualified human resources (QHR). Each variable was meticulously selected to reflect the essential aspects of AI adoption, allowing for a comprehensive understanding of the factors at play Table V.

Once the variables were defined, the sample selection was carried out to ensure the representativeness of the results. The sample was chosen based on specific criteria, including the participants' roles in logistics and their potential exposure to AI technologies. This selection process allowed for targeting.

Once the variables were defined, the sample selection was carried out to ensure the representativeness of the results. The

sample was chosen based on specific criteria, including the participants' roles in logistics and their potential exposure to AI technologies. This selection process allowed for targeting Individuals with direct knowledge of logistics processes and the challenges associated with integrating AI ensure relevant and reliable data. The creation of the questionnaire was a key step in data collection. A structured questionnaire was developed to measure the variables of interest. The questions were designed to accurately assess participants' satisfaction with internal information, their perception of the level of innovation in their logistics systems, their rate of adoption of AI technologies, and the availability of qualified human resources for the implementation of these technologies. The questionnaire was pre-tested to ensure its clarity and relevance and to guarantee that it covered all aspects necessary for a comprehensive evaluation of the study's hypotheses. Furthermore, particular attention was paid to the design of the study model to ensure the robustness of the results. The data collected from the questionnaire were analyzed using advanced statistical tools, including SPSS, to adjust the model based on the results obtained and to identify potential biases.

### D. Model Adjustment and Survey Bias

For model adjustment and identification of potential biases in the survey, statistical analysis was con- ducted using SPSS 26.0. This process began with a linear regression analysis aimed at evaluating the relation- ship between key variables such as satisfaction with internal information (SAII), level of innovation (NI), rate of adoption of AI technologies (TA), and availability of qualified human resources (RHQ). The linear regres- sion analysis identified significant predictors of the adoption rate of AI solutions, quantifying the impact of each independent variable on the dependent variable (TA). The main goal of this analysis was to understand how these variables interact to influence companies' propensity to integrate AI solutions into their logistics processes.

Subsequently, an analysis of variance (ANOVA) was performed to explore significant differences in TA scores across different industry sectors. This statistical method identified whether certain industries are more inclined than others to adopt AI technologies based on their sectoral characteristics. ANOVA provided valuable insights into the disparities between sectors, allowing for a better understanding of the dynamics specific to each industry.

To deepen the analysis, post-hoc tests were conducted following the ANOVA to precisely identify significant differences between sectoral groups. These tests were crucial in clarifying which sectors exhibited distinct behaviors in terms of AI technology adoption.

Furthermore, special attention was given to identifying and correcting potential biases in the survey. Selection biases, non-response biases, and information biases were carefully examined to ensure the validity of the conclusions drawn from the study. Selection biases were assessed to verify if the chosen sample was representative of the target population, while non-response biases were analyzed to understand the impact of any data collection gaps. Additionally, information biases, related to how data was collected or interpreted, were considered to avoid distortions in the analysis of the results.

### E. Validation and Analysis of the Study

To validate the study, several rigorous methodological steps were followed. First, the research hypotheses were subjected to appropriate statistical tests. Categorical relationships were tested using Chi-square tests, which measure significant links between discrete variables. Simultaneously, regressions were used to analyze continuous relationships between variables, providing an in-depth understanding of the dynamics underlying the adoption of AI technologies. Next, a detailed analysis of the results was conducted to interpret the relationships between variables, identifying the factors that most influence AI adoption in different logistical contexts. This analysis revealed key trends and correlations, offering valuable insights for businesses considering implementing these technologies. Finally, particular attention was given to evaluating potential biases in the collected data. These biases were identified and accounted for to minimize their impact on the conclusions and ensure the robustness and reliability of the final study results.

## IV. Result and Discussion

The integration of Artificial Intelligence (AI) in road logistics has gained significant attention due to its potential to enhance efficiency, reduce operational costs, and improve sustainability. This section presents key findings from the study, including the demographic and professional profiles of respondents, followed by statistical analyses that examine the factors influencing AI adoption. By utilizing descriptive statistics, linear regression, and ANOVA, this research provides a comprehensive understanding of how industry-specific challenges, company characteristics, and technological factors impact the acceptance and implementation of AI solutions in logistics. The discussion highlights critical insights drawn from the data, emphasizing the practical implications for businesses seeking to integrate AI-driven innovations (see Table VI and VII).

### A. Respondent Profile

Descriptive statistics provide a detailed overview of the characteristics of the study participants. The variables analyzed include Gender, City, Current Position, Industry, Years of Company Existence, and Number of Employees. The results for these variables are summarized in Table VIII and IX.

*1) Sex:* The distribution of genders among the respondents reveals that the "Female" category is predominant, with 193 participants, representing 54.99% of the total sample. In contrast, men constitute 45.01% of the sample, with 158 participants. This over-representation of women might reflect a trend in the studied sectors or the nature of the survey respondents. It would be relevant to examine whether this distribution is representative of the target population or if it suggests a potential bias in the recruitment of participants.

*2) City:* Regarding the geographic distribution, Casablanca emerges as the most represented city, with 108 respondents, accounting for 30.77% of the sample. Tangier follows closely with 105 participants (29.91%), while Rabat and Paris have 84 (23.93%) and 34 (9.69%) participants, respectively. Other cities such as Safi and Fez have a much less significant presence, with only 2.28% and 3.42% of the respondents,

respectively. This geographic distribution indicates a concentration of respondents in the major economic cities of the country, which could influence the results based on economic characteristics and regional practices.

*3) Current positions:* The analysis of current positions reveals that the "Purchasing Manager" category is the most frequently observed, with 68 participants, representing 19.37% of the sample. The positions of "Logistics Manager" and "Supply Chain Agent" follow, with respective proportions of 16.52% and 16.81%. These key roles in management and the supply chain appear to be dominant, which may reflect their importance in the represented sectors. Less common positions, such as "SAP Consultant" and "Delivery Specialist," account for less than 2% of respondents each. This distribution of positions may indicate a concentration of expertise in certain specific areas and suggests notable specialization among the participants.

TABLE VIII. FREQUENCY TABLE FOR GENDER, CITY, CURRENT POSITION, INDUSTRY, COMPANY YEAR OF EXISTENCE, AND NUMBER OF EMPLOYEES

| Variable | n | % |
|---|---|---|
| **Gender** | | |
| Homme | 158 | 45.01 |
| Femme | 193 | 54.99 |
| Missing | 0 | 0.00 |
| **City** | | |
| Casablanca | 108 | 30.77 |
| Safi | 8 | 2.28 |
| Paris | 34 | 9.69 |
| Tanger | 105 | 29.91 |
| Fes | 12 | 3.42 |
| Rabat | 84 | 23.93 |
| Missing | 0 | 0.00 |
| **Current Position** | | |
| PDG | 18 | 5.13 |
| Gestionnaire Supply Chain | 56 | 15.95 |
| Gestionnaire Logistique | 58 | 16.52 |

*4) Industry:* Regarding the industry, the sector "National and International Transport & Transit" stands out with 90 participants (25.64%), making it the most represented sector. The "Automotive" and "Food Industry" sectors follow, with 16.52% and 15.10% of respondents, respectively. Other sectors such as "IT" and "Construction" are less represented, each accounting for less than 2% of the responses. This sectorial distribution highlights the predominance of certain economic sectors in the sample, which could influence the results based on the specific characteristics of each industry.

*5) Years of existence of the companies:* Regarding the years of existence of the companies, the majority of respondents have been in operation for over 15 years, representing 66.67% (234 participants). Companies with 10 to 15 years of existence account for 25.07% (88 participants), while those with less than 10 years of existence represent only 8.26% (29 par- ticipants). This predominance of long-established companies may reflect increased stability and experience, which are important in the context of the management practices and strategies examined in the study.

TABLE IX. FREQUENCY TABLE FOR GENDER, CITY, CURRENT POSITION, INDUSTRY, COMPANY YEAR OF EXISTENCE, AND NUMBER OF EMPLOYEES

| Variable | n | % |
|---|---|---|
| **Current Position (continued)** | | |
| Consultant SAP | 6 | 1.71 |
| Agent Supply Chain | 59 | 16.81 |
| Gestionnaire Achat | 68 | 19.37 |
| Delivery Specialist | 8 | 2.28 |
| HR | 8 | 2.28 |
| QSE et Amélioration Continue | 14 | 3.99 |
| Consultant | 21 | 5.98 |
| Agent Achat | 18 | 5.13 |
| Agent Logistique | 17 | 4.84 |
| Missing | 0 | 0.00 |
| **Industry** | | |
| IT | 8 | 2.28 |
| Services Numériques et Consulting | 11 | 3.13 |
| Aéronautique | 18 | 5.13 |
| Construction | 6 | 1.71 |
| Transport National et International and Transit | 90 | 25.64 |
| Industrie de Luxe | 21 | 5.98 |
| Automobile | 58 | 16.52 |
| Industrie Agroalimentaire | 53 | 15.10 |
| Télécommunication | 6 | 1.71 |
| Gestion de la Relation Client | 34 | 9.69 |
| Textile | 6 | 1.71 |
| Produit Pharmaceutique | 21 | 5.98 |
| Industrie de la Pêche | 19 | 5.41 |
| Missing | 0 | 0.00 |
| **Company Year of Existence** | | |
| $<$ 10 years | 29 | 8.26 |
| 10 - 15 years | 88 | 25.07 |
| 15+ years | 234 | 66.67 |
| Missing | 0 | 0.00 |
| **Number of Employees** | | |
| $<$ 10 | 29 | 8.26 |
| 10 - 50 | 88 | 25.07 |
| 51 - 500 | 202 | 57.55 |
| 500+ | 32 | 9.12 |
| Missing | 0 | 0.00 |

*6) Number of employees:* Regarding the number of employees, the "51-500" category is the most frequent, with 202 participants, accounting for 57.55% of the sample. Companies with between 10 and 50 employees represent 25.07%, while those with fewer than 10 employees and more than 500 employees have much lower representations, at 8.26% and 9.12% respectively. This distribution suggests a concentration in medium-sized companies, which could have implications for the resources available and the observed organizational practices. In conclusion, the descriptive results highlight key trends in the sample composition, including a predominance of women, a concentration in major cities, a dominance of positions related to management and supply chain, and a strong presence of established and medium-sized companies. These demographic and professional characteristics could influence perceptions and practices in the studied areas and should be considered when interpreting the survey results.

*7) Linear regression analysis:* A linear regression analysis was conducted to evaluate whether the variables SAII (Satis-

faction with Internal Information) and NI (Level of Innovation) significantly predicted TA (Adoption Rate). The results of this regression model are presented in Table VII. The results show that the regression model is significant, F (2, 348) = 3, 119.28, p ¡ .001, with an R2 of .95. This indicates that 94.72% of the variance in TA can be explained by the variables SAII and NI. This high percentage suggests that the chosen independent variables are strong predictors of the Adoption Rate.

SAII has a significant effect on TA, with a B coefficient of $-0.46$ ($t(348) = -19.95$, $p < .001$). This result indicates that, on average, for every one-unit increase in SAII, the Adoption Rate decreases by $0.46$ units. This negative coefficient suggests that higher levels of satisfaction with internal information are associated with a lower adoption rate, which could indicate that the perceived quality of internal information might negatively influence the propensity to adopt new initiatives.

NI also significantly predicts TA, with a B coefficient of 1.05 (t(348) = 48.46, p ¡ .001). This means that, on average, a one-unit increase in NI is associated with a 1.05 unit increase in the Adoption Rate. This positive coefficient indicates that higher levels of innovation are strongly associated with an increased adoption rate, highlighting the importance of innovation in promoting the adoption of new initiatives. The unstandardized regression equation obtained is as follows:

$$TA = 1.27 - 0.46 \times SAII + 1.05 \times NI \quad (1)$$

This means that the Adoption Rate is negatively influenced by SAII and positively influenced by NI. The results suggest that improving innovation has a substantial and positive effect on the adoption rate, while satisfaction with internal information has a negative effect, which may indicate complex aspects in the relationship between these variables (see Table X).

TABLE X. RESULTS FOR LINEAR REGRESSION WITH SAII AND NI PREDICTING TA

| Variable | B | SE | 95.00% CI | t | p |
|---|---|---|---|---|---|
| (Intercept) | 1.27 | 0.16 | [0.96, 1.58] | 7.96 | $< .001$ |
| SAII | -0.46 | 0.02 | [-0.51, -0.42] | -19.95 | $< .001$ |
| NI | 1.05 | 0.02 | [1.00, 1.09] | 48.46 | $< .001$ |

**Note.** Results:

$$F(2, 348) = 3,119.28, \quad p < .001, \quad R^2 = .95 \quad (2)$$

**Unstandardized Regression Equation:**

$$TA = 1.27 - 0.46 \times SAII + 1.05 \times NI \quad (3)$$

### *B. ANOVA Analysis*

An analysis of variance was conducted to evaluate whether there are significant differences in TA scores across different industrial sectors. The results of this ANOVA indicate notable differences. The test revealed a value of F(12, 338) = 95.87 with a p-value less than 0.001, suggesting that the observed variations in TA scores are significant between sectors. The calculated eta squared p2 is 0.77, meaning that the industrial sector explains approximately 77% of the total variance in TA scores. The statistical details of this ANOVA are presented in the Table XI.

TABLE XI. ANALYSIS OF VARIANCE TABLE FOR TA BY INDUSTRY

| Term | SS | df | F | p | $p^2$ |
|---|---|---|---|---|---|
| Industry | 177.69 | 12 | 95.87 | $< .001$ | 0.77 |
| Residuals | 52.21 | 338 | - | - | - |

The ANOVA clearly shows that the "Industry" factor has a significant effect on TA, with a sum of squares of 177.69 for the "Industry" factor and 52.21 for the residuals. These results are confirmed by the means and standard deviations provided in Table XII.

TABLE XII. MEAN, STANDARD DEVIATION, AND SAMPLE SIZE FOR TA BY INDUSTRY

| Combination | M | SD | n |
|---|---|---|---|
| IT | 1.15 | 0.08 | 8 |
| Services numérique et consulting | 1.25 | 0.04 | 11 |
| Aéronautique | 1.40 | 0.11 | 18 |
| Construction | 1.65 | 0.04 | 6 |
| Transport national et international & transit | 2.24 | 0.57 | 90 |
| Industrie de luxe | 2.52 | 0.36 | 21 |
| Automobile | 2.71 | 0.38 | 58 |
| Industrie agroalimentaire | 3.29 | 0.41 | 53 |
| Télécommunication | 3.15 | 0.00 | 6 |
| Gestion de la relation client | 3.41 | 0.19 | 34 |
| Textile | 3.38 | 0.00 | 6 |
| Produit Pharmaceutique | 3.64 | 0.27 | 21 |
| Industrie de la pêche | 3.73 | 0.10 | 19 |

A '-' indicates the sample size was too small for the statistic to be calculated.

The means of Technology Acceptance (TA) vary significantly across different sectors. For example, the IT sector has an average of 1.15 (SD = 0.08), while the fishing sector has an average of 3.73 (SD = 0.10). Other sectors also show significant variations, with means ranging from 1.25 (Digital Services and Consulting) to 3.64 (Pharmaceutical Products).

The standard deviations associated with the means also indicate differences in the variability of scores within each sector. For instance, the telecommunications sector has a zero variance (SD = 0.00), suggesting high consistency of scores in this sector, while sectors like National and International Transport & Transit show greater variability (SD = 0.57).

These results suggest that significant differences in TA scores may be attributed to the specific char- acteristics of each industrial sector. For instance, sectors such as pharmaceuticals and the food industry, which have high means, may reflect particular characteristics influencing TA scores, such as more complex industrial processes or specific requirements. In contrast, sectors with lower means, such as IT and digital services, might show different trends due to the different nature of their activities or business models.

The ANOVA confirms that the industrial sector plays a crucial role in the observed variations in TA scores. The substantial differences between sectors highlight the importance of

considering the industrial sector when analyzing this variable. The results also emphasize the need to account for sample size and variance within each sector to accurately interpret the observed differences.

### C. Post-hoc Analysis

*1) Technology acceptance:* The analysis of Technology Acceptance scores reveals marked differences across industries, high- lighting significant variations in how different sectors adopt and use technological tools. The results, based on a t-test and adjusted using the Tukey HSD method to correct for multiple comparisons, show that the IT sector has a notably lower average TA score (M = 1.15, SD = 0.08) compared to all other industries, indicating a lower level of acceptance in this field.

TA scores for IT are significantly lower than those for all other sectors. For example, the average score for the luxury industry (M = 2.52, SD = 0.36) is substantially higher than that for IT, with a statistically signif- icant difference (p ¡ 0.001). Similarly, the score for the food industry (M = 3.29, SD = 0.41) is significantly higher than that for IT (p ¡ 0.001). Scores for the telecommunications sector (M = 3.15, SD = 0.00), customer relationship management (M = 3.41, SD = 0.19), and textiles (M = 3.38, SD = 0.00) are also significantly higher than those for IT, with p-values all less than 0.001.

When comparing other non-IT industries, significant differences are also observed. For instance, the average score For the automotive sector (M = 2.71, SD = 0.38), the average score is significantly higher than that for national and international transport & transit (M = 2.24, SD = 0.57) (p ¡ 0.001). The score for the food industry is also significantly higher than that for national and international transport & transit (p ¡ 0.001). Additionally, the score for the luxury industry is significantly lower than for the food industry (p ¡ 0.001) and the fishing industry (p ¡ 0.001).

The results reveal notable differences between specific industries. The average score for the aerospace sector (M = 1.40, SD = 0.11) is significantly lower than those for the luxury industry (M = 2.52, SD = 0.36) and the fishing industry (M = 3.73, SD = 0.10), with p-values all less than 0.001. Similarly, the score for the construction sector (M = 1.65, SD = 0.04) is significantly lower than those for the luxury, automotive, food, telecommunications, customer relationship management, textiles, pharmaceutical, and fishing industries, with p-values ranging from 0.025 to ¡ 0.001.

These results highlight significant variations in technology acceptance across different sectors, with the IT industry showing the lowest scores and sectors like fishing and pharmaceuticals displaying the highest scores. The observed differences underscore the importance of considering the specific context of each sector when evaluating and improving technology adoption.

*2) Needs identification:* In Section III on Needs Identification, issues related to real-time monitoring are addressed. Statistical data shows that the Information Technology industry has a significantly lower average for real-time monitoring needs compared to several other sectors. For instance, the average for IT (M = 1.15, SD = 0.08) is significantly lower than that for national and international transport & transit (M = 2.24, SD = 0.57), with a p-value ¡ .001. This trend is also observed in other sectors such as the luxury industry (M = 2.52, SD = 0.36), automotive (M = 2.71, SD = 0.38), and food industry (M = 3.29, SD = 0.41), all showing p-values ¡ 0.001 compared to IT.

For the digital services and consulting sector, the average (M = 1.25, SD = 0.04) is also significantly lower compared to these sectors, with p-values ¡ 0.001. Similar results are found for aerospace, construction, and other industries, with averages consistently lower than those for sectors like pharmaceuticals (M = 3.64, SD = 0.27) and fishing (M = 3.73, SD = 0.10), all with p-values ¡ 0.001.

These significant differences suggest that the IT industry and digital services encounter less pro- nounced real-time monitoring issues compared to other sectors, potentially indicating different needs or varying levels of technological maturity in real-time monitoring.

*3) AI Solution acceptance:* In Section IV of the study, concerning AI Solution Acceptance (SAAI), a t-test was conducted for each question to examine differences between industry groups, with corrections for multiple comparisons using Tukey HSD adjustment. The results reveal significant differences for each question asked.

For SAAI Question 1, which deals with real-time visibility into vehicle fuel consumption, the IT industry (M = 1.15, SD = 0.08) shows a significantly lower average compared to sectors such as National and International Transport & Transit (M = 2.24, SD = 0.57), Luxury Industry (M = 2.52, SD = 0.36), and Automotive (M = 2.71, SD = 0.38), with p-values ¡ .001 for all these comparisons. Similarly, for SAAI Question 2 on CO2 emissions visibility, the averages in the IT industry are also lower compared to other sectors, with significant differences (p ¡ .001). The same trend is observed for Vehicle Localization (SAAI 3), Driver Status (SAAI 4), Detailed Delivery Times (SAAI 5), and Driver Statistics (SAAI 6), all showing lower averages in the IT sector compared to other industries, with p-values less than .001. These results indicate that responses from companies in the IT sector show a significantly lower acceptance of AI solutions compared to other industrial sectors.

### D. Verification of Hypotheses

*1) Hypothesis 1: Only companies with large logistics systems are interested in integrating AI into their systems:* To test this hypothesis, we analyzed the correlation between the size of the logistics system and interest in AI. The size of the logistics system was categorized into three groups: “small,” “medium,” and “large.” Interest in AI was measured by a dichotomous variable (yes/no). A Chi-square test was conducted to assess the relationship between these two variables. The results showed a Chi² of 15.75 with a p ¡ .001, indicating a significant relationship. This suggests that companies with larger logistics systems are more likely to be interested in AI.

*2) Hypothesis 2: The perceived complexity of AI tools slows down their adoption in logistics:* To evaluate this hypothesis, we used linear regression analysis to study the impact of perceived com- plexity on AI adoption. Perceived complexity

was measured on a scale from 1 to 5, while AI adoption was measured by an adoption rate. The regression results showed a coefficient of -0.46 with a p ¡ .001. This indicates that perceived complexity has a significant negative effect on AI adoption, confirming that as AI tools are perceived as more complex, adoption rates are lower.

*3) Hypothesis 3: Companies show a high need for AI solutions:* To test this hypothesis, we performed an analysis of variance (ANOVA) to compare the levels of need for AI across different industry sectors. The need for AI solutions was measured by an assessment score across various sectors. The ANOVA produced a result with F(12, 338) = 95.87 and p ¡ .001, showing significant differences in the need for AI solutions between sectors. This suggests a strong demand for AI solutions in certain sectors, particularly those with higher scores such as the food industry and pharmaceuticals.

### *E. Limitations and Future Research*

The limitations of this study on the integration of AI in road logistics in Morocco are evident on several levels. First, the survey sample is predominantly composed of practitioners and decision-makers within European SMEs, which may introduce cultural and contextual bias when applying the findings to Morocco. Additionally, although the study focuses on key variables such as satisfaction with internal information (SII), level of innovation (LI), adoption rate (AR) of AI technologies, and availability of qualified human resources (QHR), other contextual factors specific to the Moroccan market, such as local regulations, infrastructure, and technological maturity of companies, have not been sufficiently addressed.

Furthermore, the methodology relies primarily on self-reported data collected through online question- naires, which may lead to response or social desirability biases, affecting the reliability of the results. Finally, while the quantitative approach provides valuable insights, it limits the depth of analysis of organizational and cultural dynamics that may influence AI adoption in logistics in Morocco. These factors should be considered when interpreting the results, and further research, including qualitative studies, would be necessary for a more comprehensive understanding of the topic.

In my future research, I plan to develop an innovative application specifically designed to address the key challenges of road logistics. This application will aim to improve the safety, efficiency, and sustainability of transport operations by tackling the critical issues identified in the current study.

*1) Reducing road fatalities:* The application will incorporate advanced driver behavior monitoring fea- tures. For instance, it could provide real-time alerts for dangerous driving behaviors, such as speeding or abrupt lane changes, while also offering reminders to encourage regular breaks and prevent driver fatigue. Additionally, detailed reports on driver behavior will be generated, allowing managers to take proactive measures to enhance safety.

*2) Reducing $CO_2$ emissions:* Another central focus of this application will be to reduce CO2 emissions. By optimizing delivery routes, the application will decrease the distances traveled and shorten travel times, leading to a significant reduction in greenhouse gas emissions. Moreover, it will encourage the adoption of more environmentally friendly vehicles by providing comparative analyses of the environ- mental performance of different vehicles in the fleet.

*3) Real-time package tracking:* The application will offer a real-time package tracking solution, en- hancing transparency and customer trust. With an integrated GPS tracking system, both customers and businesses will be able to monitor the exact location of their shipments at every stage of the delivery process, minimizing the risk of loss or delay.

*4) Driver attendance tracking:* The application will facilitate driver attendance tracking, enabling more rigorous management of working hours, breaks, and routes taken. This detailed tracking will contribute not only to better human resource management but also to preventing fatigue-related accidents and en- suring compliance with labor standards.

This application will provide a comprehensive response to the current challenges in road logistics by combining safety, efficiency, and sustainability. It represents a significant advancement in how transport operations can be managed and optimized while addressing the environmental and safety issues that are more critical today than ever.

## V. Conclusion

The integration of AI into the logistics sector represents a major advancement towards optimizing processes and solving critical issues such as road mortality, CO2 emissions, and package tracking. The study revealed that AI offers promising solutions to enhance road safety through autonomous driving systems and driver assistance devices, despite challenges such as high costs and regulatory concerns. Companies that successfully adopt these technologies experience a notable reduction in road incidents, contributing both to safety and efficiency in logistics operations. Regarding CO2 emissions, AI systems enable more efficient management of routes and loads, leading to a significant decrease in carbon footprint. Supply chain optimization algorithms and fleet management have shown positive results, although implementation requires substantial investments and adaptation of existing infrastructure. As for package tracking, AI-based technologies, such as real-time traceability systems and data analytics, have significantly improved transparency and reduced delivery errors, despite challenges related to integration with existing systems and managing vast amounts of data. The study also highlighted several obstacles to AI adoption in logistics. Technological complexity, high initial costs, and regulatory and ethical issues are major challenges for companies. Particularly, Moroccan companies show growing interest in AI, with more marked adoption in specific sectors such as agri-food and pharmaceuticals, while other sectors, like IT, face slower adoption rates. To fully capitalize on the benefits of AI, it is recom- mended that companies invest in training their human resources, modernize their infrastructure, and develop strategies tailored to the specific needs of each sector. Future research should explore the specific applications of AI in different sectors and evaluate the long-term impacts on logistics performance. By examining inter- national best practices, it will be possible to provide more precise recommendations to Moroccan companies. In summary, although significant challenges remain, AI holds considerable potential to transform the logistics sector. The

success of this transformation will depend on companies' ability to overcome these obstacles and invest in the necessary technologies to optimize their operations.

***Abstract*—The rapid growth of electric vehicles (EVs) globally and in Malaysia has raised significant concerns regarding the adequacy and spatial imbalance of charging infrastructure. Despite government incentives and policy support, Malaysia's charging network remains insufficient and unevenly distributed, with major urban centers having better access than rural and highway regions. This paper proposes a data-driven approach to optimize EV infrastructure planning by employing a hybrid CEEMDAN-XGBoost model for accurate EV ownership forecasting and GIS-based spatial optimization for strategic charger deployment. The model achieved superior performance compared to baseline models, with the lowest prediction errors (RMSE: 120; MAE:38;MAPE: 5.6%). Spatial analysis revealed significant infrastructure gaps in underserved regions, guiding equitable and demand-aligned station placement. The results provide valuable insights into future EV distribution and inform policy recommendations for scalable, data-driven planning across Malaysia.**

***Keywords*—Electric vehicles; charging infrastructure; CEEMDAN; XGBoost; spatial optimization; data-driven planning; Malaysia**

## I. Introduction

The global electric vehicle (EV) market has experienced rapid growth due to increasing environmental concerns, technological advancements, and supportive government policies promoting sustainable transportation [1], [2]. According to the International Energy Agency [3], global EV sales surpassed 14 million units in 2023, representing 18 percent of total new vehicle sales, with China, the United States, and the European Union leading the market. Governments worldwide have implemented a variety of incentives, such as subsidies, tax exemptions, and internal combustion engine phase-out timelines, to accelerate EV adoption. Meanwhile, battery technology has advanced significantly, especially in energy density and charging speed, thereby reducing range anxiety and improving the viability of electric mobility [2].

In Southeast Asia, EV adoption is growing as nations set ambitious electrification targets. Malaysia, for example, has introduced policies under the Low Carbon Mobility Blueprint and the National Energy Transition Roadmap, aiming to reach 15% of total industry volume (TIV) by 2030 and 80% by 2050 [4], [5]. These initiatives include full import and excise duty exemptions, road tax waivers, and plans to deploy 10,000 public charging stations by 2025. However, as of 2023, only around 1,500 charging points were operational, revealing a significant gap between policy ambition and actual infrastructure development [6], [7].

Despite strong policy backing, Malaysia still faces significant barriers in its EV transition, including high vehicle acquisition costs, limited charging station coverage, and insufficient grid readiness in some areas [8]. Addressing these challenges necessitates more accurate regional demand forecasting [9], [10] and optimized infrastructure deployment strategies [11], [12], which together can support a more balanced and efficient nationwide EV ecosystem.The remainder of the paper is organized as follows: Section II reviews related work on EV forecasting and infrastructure planning. Section III introduces the datasets. Section IV details the proposed CEEMDAN-XGBoost and spatial optimization methodology. Section V presents and discusses the results, while Section VI concludes with recommendations and future work.

### A. Challenges in Malaysia's EV Charging Network

Despite substantial government incentives and clear policy directives, Malaysia's EV charging infrastructure development remains significantly misaligned with its national electrification targets [5], [6]. The existing network of approximately 1,500 public chargers as of 2023 falls well short of the planned 10,000 units by 2025, indicating a considerable implementation gap [4]. Furthermore, over 60% of these chargers are concentrated in urban regions such as Kuala Lumpur, Selangor, and Johor, resulting in pronounced spatial disparities. This urban-centric deployment has created "charging deserts" in rural areas, highway corridors, and East Malaysian states like Sabah and Sarawak, where infrastructure deployment remains minimal or entirely absent [7].

A key challenge lies in the lack of alignment between the geographic distribution of EV ownership and the location of charging infrastructure. In high-density EV areas, limited charger availability often results in congestion, long queuing times, and user dissatisfaction. In contrast, low-adoption regions suffer from underinvestment, reinforcing a negative feedback loop where insufficient infrastructure deters EV uptake,

*Corresponding authors.

thereby discouraging further development [8]. Compounding the issue is the dominance of low-power AC chargers, which are inadequate for long-distance travel, commercial fleet usage, and high-turnover urban environments that demand fast-charging capabilities.

Addressing these challenges requires a shift from reactive deployment to proactive, data-driven infrastructure planning. Forecasting regional EV adoption trends and integrating them with spatial optimization models enables more equitable and efficient charger placement. Such approaches not only alleviate infrastructure bottlenecks but also support broader policy goals, including mobility equity and nationwide EV market penetration [9], [10], [13].

### B. Limitations of Traditional Infrastructure Planning

Traditional charging infrastructure planning methods rely heavily on static demographic data, expert heuristics, and government zoning regulations. These conventional approaches face several limitations:

- They fail to incorporate dynamic EV adoption trends, leading to infrastructure deployment that does not align with actual demand growth.
- They do not consider spatial variations in mobility patterns, population density, and economic activity, resulting in inefficient charger placement.
- They lack predictive modeling that integrates temporal EV adoption forecasts with spatial optimization strategies.

Given these challenges, a more data-driven approach is needed to enhance charging infrastructure coverage, accessibility, and investment efficiency.

### C. Research Objectives

To address the limitations of existing methodologies, this study proposes a big data-driven framework with two main objectives:

- Accurate Regional EV Forecasting: Develop a predictive model to estimate future EV ownership distribution across Malaysia's states and major urban areas by 2025.
- Optimized Charging Infrastructure Deployment: Use predictive insights to guide optimal charging station placement, ensuring balanced coverage and accessibility.

### D. Key Contributions

This study contributes to the EV infrastructure planning domain in the following ways:

- Developing a CEEMDAN-XGBoost Hybrid Model: This model enhances time-series forecasting accuracy by decomposing EV adoption data into multiple frequency components for robust predictions.
- Applying GIS-Based Spatial Optimization: By integrating geographic information systems (GIS), this study evaluates existing charger locations and identifies optimal new charging sites.
- Providing a Strategic Infrastructure Plan for Malaysia: Based on 2025 EV distribution forecasts, this study offers policy recommendations to improve charger deployment, ensuring equitable access and efficient resource allocation.

## II. Related Work

The rapid proliferation of electric vehicles (EVs) has stimulated extensive research in two interrelated domains: EV ownership forecasting and charging infrastructure planning. Accurate prediction of regional EV distribution is essential for guiding infrastructure investment, while the strategic siting of charging stations ensures user accessibility, grid stability, and system efficiency [9], [13], [8]. This section provides a critical overview of existing methodologies in both areas and identifies key research gaps within the Malaysian context.

### A. EV Ownership Forecasting Methods

Early forecasting efforts predominantly employed traditional statistical methods such as autoregressive integrated moving average (ARIMA), exponential smoothing, and linear regression [10]. While these models offer simplicity and interpretability, their core assumption of data stationarity limits their effectiveness in modeling non-linear and rapidly changing EV adoption trends.

To address these limitations, machine learning approaches have gained traction. Deep learning models, particularly Long Short-Term Memory (LSTM) networks, have shown promise in capturing complex temporal dependencies in EV time-series data [14], [15]. However, these models require large and high-quality datasets to avoid overfitting and maintain stability—challenges that are amplified in emerging EV markets with limited historical data.

XGBoost, a tree-based ensemble learning algorithm, is also widely applied due to its robustness in handling structured data and non-linear relationships. Nonetheless, XGBoost does not inherently capture sequential dependencies, which constrains its forecasting performance in purely temporal tasks [16]. To overcome this, hybrid models integrating signal decomposition and ensemble learning have been proposed.

One such method is the CEEMDAN-XGBoost hybrid model, which first applies Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) to decompose raw EV time series into intrinsic mode functions (IMFs) [17]. Each IMF represents specific frequency components and is individually forecasted using XGBoost, with the final prediction reconstructed from all sub-series. This structure enhances forecasting accuracy by isolating high-frequency noise from long-term trends, making it particularly suitable for non-stationary and sparse EV adoption data.

### B. EV Charging Infrastructure Planning Methods

Parallel to forecasting research, optimal charging station deployment has been a major focus to support scalable EV ecosystems. Conventional planning methods rely on demand

density models, where chargers are allocated based on population or vehicle registration concentrations. While intuitive, such approaches often ignore spatial mobility behavior and evolving charging patterns [13].

More comprehensive frameworks adopt Multi-Criteria Decision-Making (MCDM) models, which consider diverse factors such as land use, grid capacity, economic viability, and policy incentives [10]. Although MCDM improves flexibility, it is limited by the subjectivity in assigning criterion weights and the static nature of input data.

Recent advancements incorporate Geographic Information Systems (GIS) and spatial analytics to guide location decisions. These include hotspot mapping, K-means clustering, and accessibility buffering to address service coverage gaps [8]. The integration of real-time traffic data further refines charger siting by aligning infrastructure with high-demand travel corridors. Additionally, Geographically Weighted Regression (GWR) techniques have been introduced to account for local demand heterogeneity.

However, a critical gap persists: most studies treat demand forecasting and infrastructure planning as sequential rather than integrated processes. Few frameworks simultaneously predict future EV ownership and use it as input for spatial optimization, leading to suboptimal station allocation that may not align with evolving demand patterns.

### C. Research Gaps in Malaysia's EV Market

In the Malaysian context, EV infrastructure studies remain in a nascent stage. Existing research predominantly emphasizes qualitative policy analysis or descriptive statistics, with limited application of quantitative forecasting or spatial optimization techniques [6], [5]. Moreover, EV adoption in Malaysia is geographically imbalanced, yet current charging infrastructure strategies often follow top-down government mandates rather than data-informed deployment plans.

Machine learning-based EV forecasting remains underexplored due to constraints in public data availability and granularity [7]. Additionally, GIS tools are infrequently integrated with predictive modeling, resulting in disjointed planning that hampers infrastructure scalability. Bridging this methodological divide is essential for creating a resilient and equitable EV ecosystem aligned with Malaysia's national electrification goals.

### D. Comparative Summary and Contributions

A comparison of existing methods is summarized in Table I, highlighting how this study integrates CEEMDAN-XGBoost forecasting with GIS-based spatial optimization, offering a novel approach to EV infrastructure planning in Malaysia.

This study advances the field by:

- Developing an integrated CEEMDAN-XGBoost forecasting framework for predicting EV ownership distribution.
- Applying GIS-based spatial optimization to improve charging station placement.

TABLE I. COMPARISON OF EV FORECASTING AND INFRASTRUCTURE PLANNING METHODS

| Methodology | Key Approach | Limitations |
|---|---|---|
| Traditional Stats | ARIMA, Regression | Poor at capturing non-linearity |
| Deep Learning | LSTM | Requires large datasets |
| Ensemble Models | XGBoost | No temporal memory |
| Hybrid Models | EMD-CEEMDAN | Computationally expensive |
| **This Study** | CEEMDAN-XGBoost | Requires diverse datasets |

- Providing a Malaysia-specific planning strategy, bridging the gap between demand prediction and infrastructure deployment.

By combining data-driven forecasting with geospatial analysis, this research contributes to sustainable EV infrastructure planning and can serve as a model for other emerging EV markets.

## III. DATASET AND PREPROCESSING

This study utilizes two primary datasets to support electric vehicle (EV) forecasting and charging infrastructure planning in Malaysia. The datasets were obtained from publicly available sources.

### A. Charging Infrastructure Data

The charging infrastructure dataset contains information on existing public electric vehicle charging stations across Malaysia. The dataset includes the following attributes:

- Total number of public EV charging stations.
- Geographic coordinates (latitude and longitude) of each station.

This dataset serves as the spatial basis for identifying underserved regions and supporting spatial optimization.

### B. EV Ownership Statistics

The EV ownership dataset provides annual registration figures for electric vehicles in Malaysia, covering the years 2023 and 2024. The data are organized as follows:

- Annual number of registered EVs.
- Regional distribution of EV registrations, disaggregated by state or administrative area.

This dataset is used as the target variable for time-series forecasting in the CEEMDAN-XGBoost model.

### C. Data Source

Both datasets were obtained from the Malaysian Government Open Data Portal:

- https://data.gov.my/
- https://www.planmalaysia.gov.my/mevnet/

The datasets were downloaded in CSV format and preprocessed to ensure compatibility with the forecasting and spatial optimization models.

## IV. Methodology

This study proposes a two-stage hybrid framework to support data-driven and spatially informed electric vehicle (EV) charging infrastructure planning in Malaysia. The framework is designed to overcome key limitations of traditional planning approaches, which often rely on static demographic data or heuristic rules without incorporating dynamic EV growth patterns or geographic heterogeneity in demand.

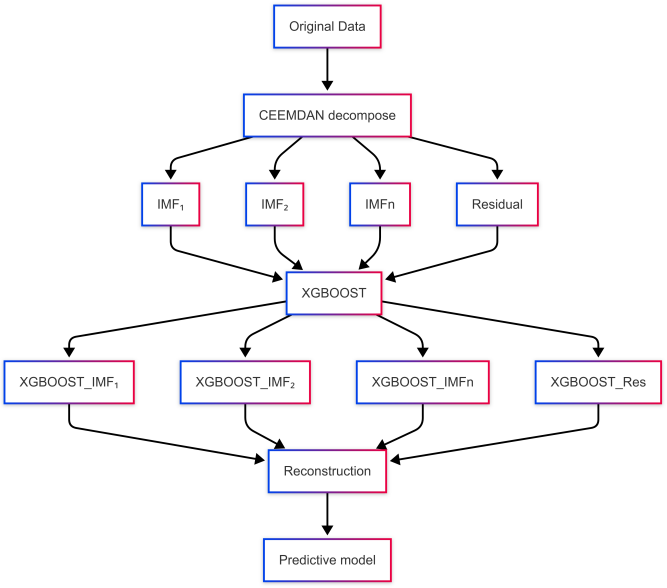

Fig. 1. CEEMDAN-XGBOOST Model flow chart.

Fig. 1 shows CEEMDAN-XGBOOST Model flow chart. In the first stage, a hybrid forecasting model based on Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) and Extreme Gradient Boosting (XGBoost) is constructed to predict the spatial and temporal distribution of EV ownership at the state and district levels. CEEMDAN is used to decompose non-linear, non-stationary EV adoption time series into multiple intrinsic components, which are then individually forecasted using XGBoost, a tree-based ensemble learning algorithm known for its robustness and high accuracy. This decomposition–prediction–reconstruction pipeline improves forecast interpretability and captures both high-frequency volatility and long-term adoption trends.

In the second stage, the predicted EV ownership distribution is used as a demand input to a Geographic Information System (GIS)-based spatial optimization model, which identifies optimal locations for new public charging stations.

By combining time-series machine learning with geospatial analytics, this two-stage framework enables planners and policymakers to make proactive, data-driven decisions on EV infrastructure deployment. It is designed to be both scalable to larger geographic regions and adaptive to emerging EV adoption patterns, offering a replicable solution for other developing countries facing similar planning challenges.

### A. CEEMDAN-XGBoost Forecasting Model

Electric vehicle ownership data exhibits non-linear, non-stationary characteristics due to policy shifts, consumer sentiment, and economic fluctuations. To handle such complexity, we apply Complete Ensemble Empirical Mode Decomposition with Adaptive Noise (CEEMDAN) to decompose the original time series into multiple frequency components before prediction.

*1) CEEMDAN Decomposition:* Given a regional EV ownership time series $X(t)$, CEEMDAN decomposes it into a finite set of Intrinsic Mode Functions (IMFs) and a residual component:

$$X(t) = \sum_{i=1}^{n} \text{IMF}_i(t) + r_n(t) \tag{1}$$

Each $\text{IMF}_i(t)$ represents oscillations at a specific frequency, capturing short-term volatility, while the residual $r_n(t)$ models long-term trend dynamics.

*2) XGBoost Regression for component prediction:* Each component $\text{IMF}_i(t)$ and $r_n(t)$ is used to train an independent XGBoost model. XGBoost minimizes the following objective:

$$\mathcal{L}(\theta) = \sum_{i=1}^{N} l(y_i, \hat{y}_i) + \sum_{k=1}^{K} \Omega(f_k) \tag{2}$$

where $l(y_i, \hat{y}_i)$ is a loss function and $\Omega(f_k)$ is the regularization term for each tree $f_k$.

*3) Forecast reconstruction:* The reconstructed EV forecast $\hat{X}(t)$ is the sum of predicted components:

$$\hat{X}(t) = \sum_{i=1}^{n} \hat{\text{IMF}}_i(t) + \hat{r}_n(t) \tag{3}$$

*4) Model evaluation metrics:* We assess performance using:

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2} \tag{4}$$

$$\text{MAE} = \frac{1}{N}\sum_{i=1}^{N}|y_i - \hat{y}_i| \tag{5}$$

$$\text{MAPE} = \frac{100\%}{N}\sum_{i=1}^{N}\left|\frac{y_i - \hat{y}_i}{y_i}\right| \tag{6}$$

*5) Hyperparameter optimization:* Grid search is used to tune XGBoost parameters: learning rate $\eta$, tree depth $d$, and number of estimators $K$, based on cross-validated RMSE.

### B. Charging Station Optimization Algorithm

Once the regional EV ownership is forecasted, the next step is to identify optimal locations for new charging infrastructure.

*1) Input variables:* Each candidate site $s_j \in S$ is evaluated based on:

- Forecasted EV density
- Population density and urbanization

*2) Multi-objective scoring function:* The weights $w_1$, $w_2$, and $w_3$ were determined based on a simplified Analytic Hierarchy Process (AHP), using expert scoring from three domain specialists in transport planning and EV infrastructure. Each expert independently rated the importance of demand coverage, geographic fairness, and accessibility, and the aggregated average was normalized to obtain final weights of $w_1 = 0.5$, $w_2 = 0.3$, and $w_3 = 0.2$.

We define a utility score $F(s_j)$ as:

$$F(s_j) = w_1 D(s_j) + w_2 G(s_j) + w_3 A(s_j) \tag{7}$$

where:

- $D(s_j)$: demand coverage,
- $G(s_j)$: geographic fairness,
- $A(s_j)$: accessibility score,
- $w_1 + w_2 + w_3 = 1$

Weights can be set via AHP or expert scoring.

*3) Optimization objective:* In this study, we assume a unit-cost model where each public charging station deployment is assigned a normalized cost of 1. A sample budget of $B = 30$ is used to simulate resource-constrained deployment scenarios, equivalent to the installation of 30 charging stations.

Based on publicly available data from the Sustainable Energy Development Authority (SEDA) Malaysia and local EV charging operators, the estimated cost of deploying a single AC public charging station ranges from RM 20,000 to RM 40,000 (approximately USD 4,200 to USD 8,500), depending on location, capacity, and permitting requirements. For fast-charging (DCFC) stations, the cost can exceed RM 150,000 (USD 32,000).

Given this cost variation, the model's scalability is preserved by adjusting the total budget $B$ or incorporating region-specific installation costs $c_j$ into the optimization objective. For example, urban deployment may incur higher land lease and grid upgrade costs, while rural areas may have lower equipment costs but require additional infrastructure support. This flexibility allows the model to reflect real-world economic constraints while maintaining planning robustness.

Let $x_j \in \{0, 1\}$ indicate if site $s_j$ is selected. The goal is:

$$\max \sum_{j=1}^{m} F(s_j) \cdot x_j \quad \text{s.t.} \quad \sum_{j=1}^{m} c_j x_j \leq B \tag{8}$$

Where $c_j$ is cost and $B$ is the total budget.

*4) GIS-Based spatial analysis:* GIS methods include:

- Heatmap generation for high EV demand zones
- K-means clustering for regional segmentation
- Service radius buffering (e.g., 5 km)
- Accessibility scoring via road network analysis

This integrated framework ensures demand-responsive, equitable, and scalable EV infrastructure deployment.Compared to previous works, our integrated CEEMDAN-XGBoost and GIS optimization framework uniquely enables both high-accuracy forecasting and spatially balanced deployment, particularly suitable for data-scarce and rapidly evolving EV markets.

## V. Results

### A. Forecasting Results

*1) Overall forecasting performance analysis:* To evaluate the effectiveness of the proposed CEEMDAN-XGBoost model, we compared its performance against several baseline models, including ARIMA, LSTM, and standard XGBoost without decomposition. Table II summarizes the prediction errors across three commonly used metrics: RMSE, MAE, and MAPE.

TABLE II. Overall Forecasting Performance Comparison

| Model | RMSE | MAE | MAPE |
|---|---|---|---|
| **CEEMDAN-XGBoost** | **120** | **94** | **5.6%** |
| EMD-XGBoost | 150 | 115 | 7.8% |
| XGBoost (no CEEMDAN) | 185 | 142 | 8.7% |
| LSTM | 172 | 130 | 9.5% |
| ARIMA | 310 | 265 | 14.2% |
| Naive Seasonal Mean | 355 | 288 | 16.7% |

Compares the predictive performance of six mainstream time series models on Malaysia's EV ownership test dataset, evaluated using three metrics: Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Mean Absolute Percentage Error (MAPE). The results clearly demonstrate that the proposed CEEMDAN-XGBoost model outperforms all baseline methods across all metrics, achieving the lowest RMSE (120), MAE (94), and MAPE (5.6%). This superior performance can be attributed to the model's effective integration of signal decomposition and non-linear ensemble regression, which proves critical for handling complex temporal dynamics in EV adoption trends.

CEEMDAN (Complete Ensemble Empirical Mode Decomposition with Adaptive Noise) enhances the model's ability to process non-stationary time series by decomposing the raw EV data into multiple Intrinsic Mode Functions (IMFs) and a residual component. Each IMF captures specific frequency scales, enabling XGBoost to independently learn and predict short-term fluctuations and long-term trends. In contrast, traditional statistical models such as ARIMA, which assume linearity and stationarity, struggle with the seasonality and irregularities in real-world EV growth. This is evidenced by its high RMSE (310) and MAPE (14.2%).

While XGBoost alone has strong non-linear regression capabilities, its performance is compromised when applied

directly to unprocessed raw sequences. The lack of prior decomposition means the model must simultaneously learn signals from mixed frequencies, which introduces noise and overfitting risk—resulting in an RMSE of 185 and MAPE of 8.7%. EMD-XGBoost shows moderate improvements due to its ability to separate signal components, but CEEMDAN's superior handling of mode mixing and boundary effects leads to better error suppression and smoother reconstruction.

Deep learning models such as LSTM have shown promise in time series forecasting, but they are particularly sensitive to data scale and structure. In this study, the available EV data from Malaysia's states is relatively small and imbalanced, limiting LSTM's generalization capacity and increasing training instability. Consequently, its RMSE reaches 172, with MAPE close to 10%, indicating overfitting in some regions and difficulty in learning long-range dependencies from noisy inputs.

The proposed hybrid model achieved the lowest error rates across all metrics, indicating its superior capacity to capture both high-frequency fluctuations and long-term EV adoption trends. In particular, CEEMDAN decomposition significantly improved the stability and accuracy of predictions, especially in regions with irregular growth patterns.Overall, CEEMDAN-XGBoost emerges as the most reliable model in this study. Its hybrid structure not only improves predictive accuracy but also offers robustness across diverse regions and temporal behaviors. By combining multi-scale signal decomposition with strong ensemble learning, the model provides a practical and scalable solution for national-level EV ownership forecasting.

*2) Regional forecast accuracy:* To further assess the robustness of the proposed CEEMDAN-XGBoost model, we evaluated its forecasting performance across six representative Malaysian regions,These include both high-EV-density urban zones (e.g., Selangor, Kuala Lumpur) and lower-density or geographically dispersed regions (e.g., Sabah, Sarawak). The model's accuracy was assessed using RMSE and MAPE, with results summarized in Table III.

TABLE III. PERFORMANCE OF FORECAST ERRORS BY STATE

| Region/State | RMSE | MAE | MAPE |
|---|---|---|---|
| Selangor | 50 | 38 | 4.5% |
| Kuala Lumpur | 30 | 22 | 4.1% |
| Johor | 40 | 33 | 6.0% |
| Penang | 35 | 28 | 6.5% |
| Sarawak | 20 | 16 | 8.2% |
| Sabah | 18 | 15 | 9.1% |

The results indicate that the model achieves high accuracy in developed, high-EV-ownership areas, such as Selangor and Kuala Lumpur, with MAPE values of 4.5% and 4.1% respectively. These regions benefit from well-established adoption patterns, stable year-over-year growth, and abundant historical data. The model is able to effectively learn and generalize underlying patterns due to the consistent nature of demand, yielding low RMSE values (50 and 30, respectively). This confirms the model's ability to capture macro-level dynamics where data is sufficiently rich and regular.

In contrast, mid-tier regions such as Johor and Penang, which show moderate adoption levels and slightly more variable growth rates, exhibit slightly higher MAPE values of 6.0% and 6.5%, though still within acceptable forecasting limits. These results suggest that the model maintains a strong generalization capacity even under non-ideal conditions, particularly in semi-urban or mixed development zones.

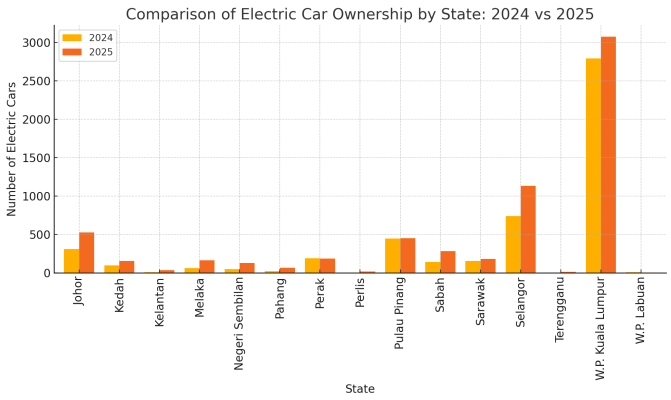

Fig. 2. Comparison of electric car ownership by state

In lower-EV-ownership regions such as Sarawak and Sabah, the MAPE rises to 8.2% and 9.1% respectively. These regions typically have sparse historical EV data, lower population density, and irregular growth patterns, which pose challenges for time series learning. Additionally, infrastructural and economic disparities may contribute to abrupt shifts in adoption trends, further complicating the forecast task. Nevertheless, the model's performance remains reasonably accurate, with RMSE values of 20 and 18, and MAPE values still below 10%, indicating strong resilience even in data-scarce environments.

These findings suggest that CEEMDAN-XGBoost not only excels in regions with rich data, but also retains reliable performance in areas with irregular or limited data. The decomposition of EV trends into frequency components allows the model to adaptively focus on both macro growth trends and localized fluctuations. This ensures that spatially unbalanced data distributions do not lead to systemic bias or model instability, making the proposed method highly suitable for national-scale deployment with heterogeneous regional characteristics.

Fig. 2 compares the projected electric vehicle (EV) ownership across Malaysian states between 2024 and 2025. The results highlight consistent growth in key urban regions, particularly W.P. Kuala Lumpur and Selangor, which maintain their lead in both years due to favorable infrastructure, income levels, and policy support.

Most states exhibit moderate year-over-year increases, indicating a positive but uneven adoption trajectory. Notably, states like Johor, Sabah, and Penang show considerable growth, while regions such as Kelantan and Perlis maintain minimal uptake. The disparities underscore the necessity of differentiated infrastructure strategies to ensure balanced nationwide EV accessibility.

Compared to existing methods such as LSTM and EMD-XGBoost, the proposed CEEMDAN-XGBoost model offers more stable performance across regions with different EV

adoption maturity. Its ability to handle high-frequency noise and sparse data gives it a significant advantage in emerging markets like Malaysia.

### B. Charging Site Optimization Analysis

*1) Electric vehicle distribution:* Based on the spatially resolved EV ownership forecasts shown in Fig. 3, the distribution of electric vehicle adoption in Malaysia by 2025 is expected to be highly uneven. The central and southern zones of Peninsular Malaysia, particularly the regions encompassing Kuala Lumpur, Selangor, Johor, and Negeri Sembilan, are projected to become high-density EV corridors with forecasted ownership exceeding 10,000 units per region. These zones represent urban and industrial agglomerations with strong economic activity, policy support, and early infrastructure rollout, making them natural focal points for electrification.

In contrast, although regions in East Malaysia, such as Sarawak and Sabah, display lower absolute EV counts, the forecasts indicate substantial relative growth, especially in urban centers like Kuching and Kota Kinabalu. This implies that these areas, while not currently major EV hubs, will require proactive infrastructure deployment to avoid lagging behind in electrification accessibility.

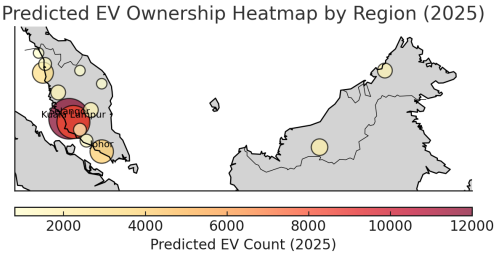

Fig. 3. 2025 EV vehicle distribution.

To evaluate infrastructure adequacy, Fig. 4 overlays current charging infrastructure against forecasted EV demand. The circular blue markers denote high-predicted EV ownership clusters, while the yellow stars indicate recommended new station sites based on spatial optimization. From the analysis, several infrastructure gaps become evident:

- North Peninsular Malaysia: Regions in Kedah and Perlis exhibit rising EV ownership forecasts but lack proportional charging infrastructure. These areas also serve as cross-border corridors for intercity travel, amplifying the need for reliable public charging options.
- East Peninsular Malaysia (e.g., Pahang, Terengganu): These regions show emerging demand supported by highway linkages, yet current charger density remains minimal. Proactive siting is essential to prevent range anxiety among early adopters.
- East Sabah and Central Sarawak: Although traditionally underserved, EV penetration in these areas is expected to accelerate due to federal electrification incentives and rising vehicle replacement rates. However, current infrastructure is nearly absent outside state capitals.

The optimization algorithm incorporates three core criteria into the site selection process: (1) EV demand coverage, based on forecasted ownership density; (2) geographic equity, to ensure fair access across rural and urban zones; and (3) transportation accessibility, measured via road network connectivity and service radius buffers. A utility score is computed for each candidate site, and the top-ranked points are presented in this figure.

This geospatial analysis not only identifies where the highest demand–infrastructure mismatch occurs, but also prescribes regionally distributed expansion plans. For example, while Selangor may require densification of chargers, Sabah and Sarawak demand entirely new network nodes. This dual strategy—densification in saturated zones and deployment in greenfield regions—forms the basis of a balanced infrastructure roadmap.

Furthermore, by incorporating future demand rather than relying solely on historical installation data, the proposed method anticipates spatial shifts in EV usage patterns. This enables national planners and private stakeholders to avoid both under-provisioning (in fast-growing zones) and over-investment (in saturated low-growth areas).

Overall, the site optimization results demonstrate that integrating machine learning-driven demand forecasts with GIS spatial analytics can substantially enhance the precision and impact of charging infrastructure planning.

*2) Future charging post planning:* Fig. 4 presents the spatial distribution of recommended new EV charging stations across Malaysia, based on the integrated results of EV ownership forecasts and geospatial accessibility analysis. The map overlays forecasted demand clusters (depicted as blue-scaled circles, with size proportional to EV count) with proposed station locations (yellow stars) generated through a multi-objective optimization process.

A distinct spatial disparity emerges between regions with high projected EV adoption and those with existing charging infrastructure. In Peninsular Malaysia, the central and southern areas—particularly the Klang Valley—are well-covered but risk future congestion as demand intensifies. In contrast, the northern and eastern states, while showing slower EV uptake, are forecasted to undergo significant relative growth yet remain underserved in terms of public charging accessibility.

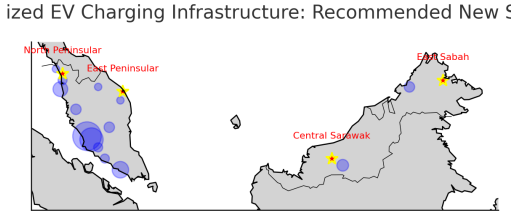

Fig. 4. Recommended site map for EV charging stations in Malaysia.

Peninsular Malaysia

- North Peninsular: The area encompassing Kedah and Perlis demonstrates moderate demand growth. Despite its role as a gateway to Thailand and its strategic

position along regional transport corridors, current infrastructure deployment remains sparse. A new station in this zone can serve both regional traffic and cross-border travel.

- East Peninsular: Regions such as Pahang and Terengganu, which are currently peripheral in infrastructure planning, show early signs of adoption growth driven by coastal connectivity projects and tourism-driven transport demand. Given their long travel distances and low charger density, they are prioritized for early investment.
- Southern Corridor: While Selangor and Johor already host several chargers, the predicted EV saturation in 2025 necessitates densification—particularly along high-traffic expressways and industrial logistics hubs—to prevent future bottlenecks.

East Malaysia

- Central Sarawak: While EV penetration remains relatively low, projected growth is concentrated in and around Kuching. However, the vast interior regions remain disconnected from charging access. Introducing infrastructure here improves geographic coverage and supports long-haul adoption.
- East Sabah: The forecast highlights significant EV growth potential in Sandakan and its surrounding zones, which are currently disconnected from the sparse network centered around Kota Kinabalu. Establishing a regional station ensures redundancy and decentralizes charging access.

*Optimization Priorities:* The station placement strategy follows a scoring framework that evaluates:

- Predicted EV demand density (from CEEMDAN-XGBoost outputs)
- Road network accessibility (measured via proximity to national highways)
- Regional equity index (balancing urban vs rural charger allocation)

Candidate sites with the highest composite scores were selected. Each yellow star in Fig. 4 thus represents an optimally scored point that meets forecasted demand while improving overall network coverage.

This approach avoids both underutilization (due to over-investment in low-need areas) and oversaturation (from redundant placement in already-served zones). It promotes a balanced, data-informed infrastructure deployment roadmap aligned with the spatial dynamics of EV adoption.

Moreover, the inclusion of East Malaysia—often marginalized in national-level planning—demonstrates the framework's capability to highlight equitable access and decentralization needs, supporting national electrification inclusivity goals.

## VI. Discussion

This section interprets the results presented above, highlighting the advantages of the CEEMDAN-XGBoost model, implications for charging infrastructure development, and policy relevance. The discussion also addresses the challenges of regional disparity and data sparsity in EV adoption forecasting in Malaysia.

### A. Model Superiority and Generalization

The CEEMDAN-XGBoost model demonstrated superior forecasting accuracy compared to ARIMA, LSTM, and standard XGBoost. The use of Complete Ensemble Empirical Mode Decomposition (CEEMDAN) significantly improved the model's ability to process non-linear and non-stationary time series by decomposing the raw EV ownership data into intrinsic components. This decomposition allowed XGBoost to learn localized temporal patterns and long-term adoption trends separately, reducing the influence of noise and mode mixing.

Notably, the model achieved robust performance across heterogeneous regions. In data-rich states such as Selangor and Kuala Lumpur, MAPE was under 5%, while in data-scarce regions such as Sabah and Sarawak, the error remained below 10%. This indicates strong generalization capacity even under limited data scenarios, which is critical for developing countries with evolving EV markets.

### B. Infrastructure Planning Implications

The spatial optimization results provide actionable insights for charging station deployment. Current infrastructure is disproportionately concentrated in the central urban corridor, while emerging high-growth regions such as East Sabah, Central Sarawak, and the Northern Peninsular corridor (e.g., Kedah, Perlis) remain underserved. If left unaddressed, this spatial imbalance could hinder equitable EV adoption and limit the effectiveness of national electrification policies.

The dual-site planning strategy—focusing on densification in urban centers and greenfield deployment in peripheral zones—offers a balanced approach to infrastructure rollout. This ensures not only efficiency in high-demand areas but also inclusivity in regions previously marginalized in EV planning.

### C. Policy Recommendations

The findings underscore the need for dynamic, data-informed infrastructure planning. Static demographic and vehicle registration statistics are insufficient for anticipating future demand, especially in rapidly transforming mobility ecosystems. Government agencies should prioritize investment in regions identified through predictive analytics and geospatial analysis.

Specifically, the national target of deploying 10,000 public charging stations by 2025 should be aligned with forecasted demand densities. Policy tools such as location-specific subsidies, public-private partnerships, and regulatory incentives can accelerate deployment in underserved areas.

In addition, model-driven planning frameworks like the one proposed in this study can serve as decision-support tools for both public sector planners and private investors. Integrating such frameworks with real-time data feeds may further enhance forecasting precision and infrastructure responsiveness.

## VII. Conclusion

This study focused on forecasting regional electric vehicle (EV) ownership in Malaysia and optimizing the spatial deployment of EV charging infrastructure. The proposed framework can be extended into a real-time dashboard or decision-support tool by integrating live EV registration data and geospatial APIs. With real-time data streams, planners can dynamically recompute demand forecasts and optimize station placement interactively. This supports agile infrastructure planning and timely policy intervention.The main conclusions are as follows:

- Based on the CEEMDAN-XGBoost time series model, this research achieved high-precision forecasting of EV ownership trends across various regions, providing reliable data support for national planning.
- The forecast suggests that Malaysia's future EV growth will remain concentrated in the western coastal economic corridor. However, other regions, particularly the east and northern states and East Malaysia, are expected to gradually catch up. Therefore, infrastructure deployment must balance long-term growth needs and prevent regional inequality.
- The current charging station network exhibits significant shortfalls, especially along major highways and underserved rural or remote areas. Accelerated deployment in these zones is essential to support long-distance travel and improve EV adoption in marginal regions.
- The proposed charging station optimization strategy identifies key transportation corridors and weak-coverage areas for prioritized deployment. These can serve as a reference for improving national service coverage and equity.

Accordingly, we recommend that government agencies adopt a data-driven, phased, and targeted investment approach for mid- to long-term charging infrastructure planning. For example, the nationally stated goal of deploying 10,000 public charging stations should prioritize the key regions identified in this study, while encouraging both public and private sector participation in deployment.

Simultaneously, supportive policy measures—such as subsidies, utility pricing reforms, and usage-based incentives—should be enhanced to ensure practical and effective implementation. A complete and accessible charging network is essential to alleviate consumer concerns, accelerate EV adoption, and contribute to Malaysia's green mobility transition.

This study provides a scientific basis for policy formulation and private sector investment. Future work will focus on extending the proposed model for real-time monitoring and policy feedback evaluation, with the goal of supporting continuous data-informed decision-making.

# Dual Neural Paradigm: GRU-LSTM Hybrid for Precision Exchange Rate Predictions

Shamaila Butt
Faculty of Business, Sohar University, Sohar, Oman

***Abstract*—The USD/RMB exchange rate is significant when examining the structure of the Chinese financial system. Predicting the accurate USD/RMB exchange rate enables individuals to analyze the condition of the economy and prevent losses. We propose a novel hybrid approach of GRU-LSTM to improve the forecast of the future USD/RMB exchange rate. Deep learning techniques have become the cornerstone of numerous computer vision and natural language processing fields. This paper discusses various aspects and aims to show that they can help predict the exchange rate. We investigate how the newly developed hybrid GRU-LSTM model performs in terms of success rate and profitability compared with the LSTM and GRU models. The evaluation of the model is done on the USD/RMB currency pair and the forecasts made from September 13, 2023, to December 11, 2023. To increase the accuracy of the model, metrics like mean absolute error (MAE), mean square error (MSE), root mean square error (RMSE), and mean absolute relative error (MAPE) were introduced. The study found that the novel hybrid GRU-LSTM model was performing relatively well compared to the models of LSTM and GRU deployed in the survey for exchange rate prediction. This improvement can significantly benefit the analyst or trader in making the right decisions on the management of risks. The study further opens new possibilities for using the hybrid GRU-LSTM model by demonstrating the enhanced potential of this method, which can be more effective in the financial environment. Subsequent studies might improve the forecast by increasing the set of hybrid models and including more economic variables.**

***Keywords*—Prediction; LSTM; GRU; USD/RMB exchange rate; deep learning**

## I. Introduction

The FOREX market is the largest market where the exchange of currencies takes place worldwide [1]. Trillions of dollars are exchanged by traders daily [2]. Since the currency prices are highly volatile, the FOREX market is referred to as a black box due to its intricacies and instabilities [3]. The authors in study [4] state that the exchange market is open 24/7. Nonetheless, the four primary time zones of Australia, Asia, Europe, and North America are used to verify the transactions. Each zone has its own hours of operation, and because it takes a lot of money to influence the exchange rate, scammers cannot easily manipulate the market [5]. Among other fields, foreign exchange market forecasting has attracted significant interest among researchers for several decades.

The international financial market is increasingly influenced by the exchange rate, a significant element affecting the global economy. Research has shown that whenever the volatility of the USD/RMB exchange rate exceeds a certain threshold, it has a negative impact on both national economic growth and the global economy. This underscores the importance of accurate USD/RMB exchange rate forecasting. The government has stated that rapid exchange rate changes intensify economic pressure, which high-precision exchange rate forecasting can help relieve. Such forecasting is not only essential for maintaining financial market stability but also aids in modifying the distribution of government resources, serving as a strong foundation for relevant administrative departments.

Moreover, deep learning has revitalized artificial neural network research. Deep neural networks (DNNs) have shown remarkable efficacy in various domains, such as computer vision and NLP. Enormous neural network optimization and control, the accessibility of extensive datasets, the computational capacity to train large networks, and approachable software libraries are associated with significant methodological advances [6]. Deep learning differs from traditional machine learning because it can independently extract discriminative features from raw data [7]. This capability reduces the need for human feature engineering while expanding the scope of deep learning applications. It also lowers the cost of deploying learning algorithms in the industry and facilitates model maintenance operations. Recurrent neural networks (RNNs) and convolutional neural networks (CNNs) are powerful deep learning techniques. RNNs are built to handle almost any type of time series, audio, and natural language data sequences.

Deep learning-based prediction models and their financial sector applications have been the subject of recent research [8], [9]. Nonetheless, not much research has been conducted on the forex market—research is scarce in this area for a few reasons. Determining the degree of accuracy with which market developments can be anticipated is a valuable academic and practical task. Moreover, exchange rates represent a highly stochastic, nonlinear, and non-stationary financial time series [10]. As such, they are challenging to anticipate and an exciting subject for forecasting studies [11]. Finally, since the foreign exchange market differs significantly from other financial markets, research studies on different financial markets, including the stock market, may not apply to the foreign exchange market.

Numerous studies have addressed the various features of the foreign exchange market. For instance, a lot of players in the foreign exchange market are trained by professional traders [12]. The foreign currency market has a higher percentage of short-term interdealer transactions than the stock market [13], [14]. Furthermore, the considerable fluctuations in exchange rates leave traders wanting to decide what to buy or sell. As a result, the fair value model needs to be more convincing to foreign exchange traders than to traders in the stock market [15].

Although there is a need for more research on advanced deep-learning algorithms for exchange rate prediction, this

uniqueness makes it challenging to apply empirical results from other financial markets. Therefore, this study addresses critical gaps in exchange rate prediction by focusing on integrating microstructure variables such as bid-ask spread and order flow, which are often overlooked in traditional models. This approach enhances the accuracy of predictions and provides actionable insights for traders and policymakers. This study's primary objective is to add to the knowledge of exchange rate prediction by revising the deep learning algorithm for forex market dealers and reviewing the accuracy of the relevant models while predicting foreign currency movements. Given that this specificity is questioned by research on recent methods of in-depth learning to indicate the general state of other financial markets and the prediction of exchange rates, a concentrated study is encouraged. This thesis aims to retrofit the automatic learning procedure according to foreign exchange forecasts and review the accuracy of the relevant models while predicting foreign currency movements.

This study offers a novel method for predicting the USD/RMB exchange rate using microstructure variables, particularly high-frequency data at 1-minute intervals. Unlike previous studies that primarily rely on macroeconomic variables, this research pioneers the utilization of microstructure indicators—bid price, ask price, bid-ask spread, and order flow—which capture market inside information or private information inaccessible to the public. By incorporating these indicators, the model gains access to hidden or private information crucial for predicting exchange rate movements accurately. This novel approach forms the basis of research novelty and represents a significant departure from the conventional approach. To the best of the author's knowledge, no prior study had employed these microstructure and high-frequency indicators with a comparable level of granularity to predict exchange rates.

The novel approach and method employed align with the paper's goals. The primary objective of this study is to develop and validate a hybrid GRU-LSTM model that incorporates high-frequency microstructure indicators. To identify the exchange rate fluctuations, it is necessary to strengthen the internal structure of LSTM and integrate it with GRU. Then, the search conducts an empirical analysis of the given data concerning the USD/RMB exchange rate to extract helpful information like the bid price, ask price, bid-ask spread, and the flow of orders. These parameters act as dependent variables, extracting private or concealed information on the Forex market to determine exchange rates. The last objective of the study is to undertake exploratory research to evaluate the effectiveness of the proposed hybrid GRU-LSTM model against other distinct models, such as GRU and LSTM, drawn from the prediction models. All these tests will contain an analysis of the prediction errors and error margin for each of the given tests. Thus, based on the aims mentioned above, the study aims to propose a sophisticated and accurate forecasting model of the USD/RMB exchange rate. Additionally, we would like to extend our knowledge base and invest in the positive evolution of such sub-disciplines as financial modeling or other algorithmic trading.

The study's objectives are: (1) to apply microstructure indicators and optimize the internal LSTM architecture to create and calibrate the new GRU-LSTM model. Although this approach has limitations, its primary use is (2) to present selected USD/RMB exchange rate data characteristics, including bid price, ask price, bid-ask spread, and order flow. (3) to perform a research study to compare the ability of the hybrid GRU-LSTM model to the rest of the prediction models. As a result, it will be feasible to broadly assess the prediction model's accuracy and error margin. The research offers a vigorous and novel method for predicting the USD/RMB exchange rate. Additionally, the study contributes to advancements in algorithmic trading strategies and financial modeling.

The organization of the study is as follows: In Section II, relevant literature is compiled, and the paper's contribution to bridging research gaps is demonstrated. Section III discusses the empirical findings and outlines the experimental setup for the LSTM vs. GRU forecasting comparison. A summary and discussion of the results, policy implications, and opportunities for future research summarizes the paper.

## II. Related Works

Many techniques have been used to forecast the Forex market in the past few years. Many such algorithms have been tried and experimented with, but the machine learning algorithm has a higher proportion. Depending on the specific study, some will use two or more methods, while others may only include one processing method. Thus, over the past few years, several ML models have been developed and used to predict the foreign currency market. Some of the approaches used in these divisions include regression analysis, decision trees, trading rule methodologies, fuzzy logic, and support vector machines. It was necessary to develop a hybrid model consisting of the cuckoo search algorithm and regression techniques for predictive modeling [16].

The authors in study [17] and [18] applied the USD/EUR currency pair, where they built the framework of a dataset derived from the autoregressive moving average (ARMA) model. The dataset has been instructed to use the following regression methods: SVR, PLS, CRT regression tree, and multiple linear regression. The four algorithms have developed weights, and the Cuckoo search algorithm uses it in its input data. The test used the pre-test data from two years to analyze. SVR, PLS, and CRT enhance the results obtained from MLR. Regression analysis has test results that are higher than those of other models, according to them. As in study [19] noted, a statistical and predictive analysis model has been developed to simplify autoregression in compressed vectors. They reduced a considerable amount of FOREX data using a random compression technique. Afterward, each random compressed data set was loaded into the Bayesian model averaging (BMA) method to find the intersecting parameters. The currency pairs show a significant mean squared error due to a condition including four lag-dependent variables and random compression of other Forex currency pairings. Their suggested approach has worked well for the following six currency pairs: AUD/JPY, CAD/CHF, EUR/DKK, CAD/JPY, EUR/MXN, and EUR/TRY. It has also outperformed the widely used Bayesian Autoregression benchmark. Previous studies such as study [20], [21] predicted foreign currencies used a similar methodology.

Many researchers have been working on creating prediction models based on trade regulations during the last few years.

The requirements for entry, exit, and currency management are outlined in the trading regulations. These rules are essential for judging if a deal will succeed or fail. The authors in [22] presented a model for exchange rate online prediction based on rules using the weighted majority (WM) approach for expert selection. Because the technology provides continuous estimates, they needed help maintaining a decent percentage of projections. As a solution, they have considered the recommendations made by websites and made plans based on them. The mean square error and realized profit figures were used to select the website. Data analysis showed that the intersection method offers a 30% higher accuracy in the 20-day prediction than the baseline. Some researchers have applied trade rules [23], [24]. Moreover, decision tree models have not been used as frequently as other methods. Authors in [25] have created a model that produces real-time FOREX market data. After that, these data would be converted into decision tables that must be bought, sold, or retained for specific attributes. Furthermore, the CART and C4.5 algorithms assessed the categorization's quality. Three device pairs and three files from each pair were used to create the system. Most data (86–98%) belong to the queue class, which makes data processing more difficult. Examining the decision tree's dimensions and the classification accuracy, it was found that the CART method produced the best results. Additionally, the researchers in study [26] use this method.

Furthermore, support vector machines, or SVMs, were another popular statistical prediction method. SVM with prediction capability was used for both individual and hybrid systems. An SVM-based model for foreign exchange prediction was presented in study [27]. They used the EUR/USD exchange rate to put their model into practice. They divided the results into positive and negative output categories using the cross-validation approach on their data set. To compare the outcomes, they used macro and micro averaging and both positive and negative accuracy rates. With the help of the Gaussian RBF approach, they got a difference in the training and test sets as high as 29.5%. Nevertheless, the difference was rather small with a polynomial model. Therefore, the kernel function derived using polynomial has given high performance. In addition, SVM raised the profit rate threefold when analyzing SVM transactions with a conventional strategy called the transaction model. Several scholars have also applied SVM in their research [28], [29].

In recent studies, scholars expressed their concern in natural language processing (NLP). Algorithms that are based on NLP have been used in foreign exchange, as in any other industry, for predicting the exchange rates. Besides, NLP has a high level of efficiency in both the prediction function and automatization of text-based functions [30], [31].

Numerous algorithms have attracted researchers' interest, Optimization Techniques stands as one of the most recognized algorithms. According to study [32], there has been a proposal of a model incorporating the following: the extreme learning machines along with the Jaya optimization to estimate device change rates. They employed USD/INR and USD/EUR as their two currencies in those analyses. To compare, they took their model against three models supported with NN, ELM, as well as FLANN. This led them to conclude that when it comes to optimization, ELM is superior to the other mentioned algorithms such as NN, FLANN. According to assessment data of ELM DE, the number of deficient errors affected rate of MAPE assessment. As observed above, the minimum value of MAE and maximum value of ARV and Theils U were obtained by employing ELM TLBO, ELM PSO, ELM Jaya. The researchers in study [33] employed a genetic algorithm to maximize the FOREX trading strategy and a variation-based ensembling method to produce a set of helpful trading rules. Their genetic algorithm creates rules by generating notably improved outcomes compared to the extensive search. The authors in study [34] suggested an additional hybrid learning approach. Their approach, linked to ELM-Jaya and ELM, uses a mix of technical indicators, statistical data, and both to forecast the prices of the currencies on a single exchange. Other researchers have also employed optimization strategies [35], [36].

It has been noted that chaos theory has received the interest of many researchers [37]. Several factors for exchange rate forecasting of the selected countries were incorporated, of which a novel method, Multivariate Adaptive Regression Splines (MARS), based on chaos theory, was employed apart from the above [35]. To assess their strategy, three primary FX pairs; JPY/USD, GBP/USD, and EUR/USD/KYM, utilized several types of the chaos-based forecasting model. When applying the Chaos + MARS method, they provided the most accurate forecasts of these currencies. Forecasting the global financial markets, [38] proposed a type-2 fuzzy neuro-oscillatory network with chaotic intervals CIT2-FNON. The chaotic discrete-time neural oscillator, or Lee-Oscillator, is the source of the CIT2-FNON. It is made up of short-lived fuzzy input neurons that are taken out of recurrent networks. To solve the complexity problem and create a highly Type-2 Fuzzy Logic System (T2FLS) with chaotic transient fuzzy qualities, the Chaotic Type-2 Transient Fuzzy Logic (CT2TFL) was added to their model. The FOREX price has been predicted by numerous models using chaos theory [39], [40].

Pattern-based models were also widely used and popular. The authors in study [41] created a multidimensional string model for statistical forecasting. By utilizing the D2-brane to create a 2-endpoint open string model, they enhanced the 1-endpoint open string model. They demonstrated how adding object attributes often changes the predictors' statistics by modeling several time series systems with them. They used demo simulations and four distinct currency pairs to evaluate the technology. They found that string model efficiency often increases with more extraordinary string lengths. The researchers in study [19] proposed a model that uses transformed models of general DMA and dynamic model averaging (DMA) to predict the FX rate. This method examined three forex pairs: USD/JPY, USD/EUR, and USD/GBP. Thirty percent of the entire data are used for data evaluation, and seventy percent are used to train the model. They found that the four-lag autoregression model (also known as AR (4)) and the time-varying autoregression model (also known as TVP-AR (4)) with four lags produce the best prediction result for USD/JYP based on the findings of their model proposal. The parsimonious model yields positive results for the EUR/USD data set. They predicted that the models that would perform best for this prediction would be those that use a stochastic process that evolves coefficients. Consistent DMA and DMS were found. Some researchers have used similar techniques

[42], [43].

An overview of foreign exchange rate prediction was provided by study [44]. They observed eighty-two hybrid systems that were used to predict the forex rate between 1998 and 2017. They found that hybrids with artificial neural network (ANN) foundations provide higher prediction rates with greater precision and stability. The analysis shows that hybrid models have overtaken single models. The hybrid models reduce uncertainty and offer more accuracy. After examining hybrid models based on artificial intelligence, they discovered that deep learning architecture was the least effective in predicting exchanges. Even though numerous neural network-based experiments have been conducted in the last few years [45], [46], [47]. In study [48] predicted the temporal sequence of the currencies using a hybrid C-RNN approach. A convolutional neural network (CNN) and a recurrent neural network (RNN) are combined to form a C-RNN. A data-driven strategy was used to alter the coin market's characteristics. The model was compared with CNN and LSTM methods. They discovered that the C-RNN model revealed fewer errors than the LSTM and CNN-based models using the RMSE performance evaluation approach.

The authors in study [49] use a neural network and genetic algorithm to anticipate the traded equities. This approach was used to assess the EUR/USD closing values. They contrasted their suggested model with various models, including NGD, NGW, MACD, and MA. They offered two distinct methods, one with a direction and the other with a weight. They discovered that their version Weighted, which showed a profit of 111%, outperformed version Direction, which showed a profit of 56%, after carrying out all 20 full experiences. To construct another hybrid model, [50] built another hybrid model by combining a computationally efficient functional link artificial neural network (CEFLANN) for prediction with an improved shuffling frog leaping (ISFL) model. The ISFL reduced the amount of error in the system. According to the study, three different currency pairs were employed in the method: In terms of pairs, such as USD/CAD, USD/CHF, and USD/JPY. The outcomes of the system performance were evaluated using the particle optimization method and the ISFL. The outcomes indicate that both the specialized and overall figures evince the effectiveness of the suggested model over the compared two algorithms. Analyzing the statistics of the USD/CHF currency pair, it was possible to establish that its error rate fluctuated within the range of 0. 03 to 0. 04, the USD/CAD and USD/JPY currency pairs error rates differing between 0. 04 and 0. 05.

Other researchers also took a similar approach [51], [52], [53]. The authors in study [54] examined three currency pairs to find the most accurate model for predicting exchange rates: USD/EUR, JPN/USD, and USD/GBP. An investigation of the performance of several ANN algorithms was also conducted in the study. The study used backpropagation to train the model to use neural network models after optimizing and preprocessing the raw input file. To project three distinct periods: quarterly, monthly, and daily. A multilayer perceptron with a 5-10-1 structure and a single one-step prediction mode was used for each currency pair in the study.

Similarly, other authors adopted the same strategy of analysis [51], [52], [53]. In [54] the authors examined three currency pairs to find the most accurate model for predicting exchange rates: These are USD EUR, JPN/USD, and USD/GBP. Performance analysis of several ANN algorithms was also carried out in the study as well. After optimizing and pre-processing the raw input file, the peculiarity of the study involved the use of backpropagation to train the model to use neural network models. To project three distinct periods: There are quarterly, monthly, and daily record keeping methods of releasing financial information to the public. A multilayer perceptron with 5-10-1 layers and single one-step prediction mode was used for all the currency pairs in the study.

A system that can forecast financial data and be used as an agent within the A-Trader system was proposed [55]. They examined the performance of deep learning methods and neural networks. They investigated the effectiveness of neural networks and deep learning methods. Four hidden layers, each containing 78, 64, 87, and 63 neurons, were used in the study. The B&H benchmark and the MLP agent were utilized for the performance evaluation. Their findings were split up over three distinct timeframes. Their suggested system did better for the combined primary and second periods. The authors in study [56] contrasted machine learning with statistical techniques. They investigated open, closed, high, and low variables. ASTAR produced superior results for close and high variables for one and one to five days of prediction, while GA-NN produced better results for open and low variables. The outcomes differed for predictions made over a more extended period (a month). In specific, for the remaining high and open conditions, GA-NN obtained better results than ASTAR; on the other hand, SVM yielded equal average values for both models. More recently, many more NN based systems have been realized [57], [58].

Thus, the literature analysis of the predictive models of the FOREX market indicates that future research should focus on more complex deep learning structures, mainly on the interaction between the GRU and LSTM. GRU and LSTM networks are still required to be actively used for the FOREX market prediction although prior studies were carried out with conventional machine learning algorithms such as regression, decision trees, and SVM. These new architectures of deep learning offer more specific advantages in analyzing difficult patterns and temporal correlations within FOREX data, leading to better accuracy of predictions. However, these models are relatively neglected despite their abilities to enhance the prediction precision due to integration of many predictors. Basically, interpretable models for the financial market are currently a dire necessity to come up with a better understanding of the existing principle behind predictions. Another way applicable for introducing the microstructure parameters, which include ask and bid prices, bid-ask spread, and order flow as independent variables, is an additional one, which also requires further investigation of the further increase of the models' accuracy and robustness.

This FOREX market research aims to close these gaps by focusing on analyzing and comparing the deep learning architectures like GRU and LSTM models and their combinations. These architectures possess different abilities that permit researchers to note such long-term relationships and sequential patterns in FOREX that can help them gain new perceptions and possess increased accuracy in forecasting. However, despite some limitations noted previously, adapting microstructure parameters for use in forecasting models is a

plausible way of enhancing a model's realism while at the same time increasing its effectiveness in the face of real-time market data. Thus, our work can be seen to help narrow down gaps to foster better and more suitable prediction models for a FOREX market, thus aiding in the research on financial forecasting. While prior studies have explored LSTM and GRU models independently, few have systematically compared their performance against hybrid architectures. Our study bridges this gap by conducting a rigorous evaluation of the hybrid GRU-LSTM model against standalone models using multiple error metrics (MAE, MSE, RMSE, MAPE).

## III. Methods

### A. Long Short-Term Memory

In [59] researchers introduced the long-short-term memory (LSTM) model as a potential treatment to solve the gradient problem in models. LSTM has evolved into a novel neural network system that can manage sequential inputs during the last 20 years. Given that the widely used Python library Keras has the LSTM cell [60] and seems one of the most widely utilized LSTM designs in current research.

*1) The Cell state:* The cell state is a stream of data transmitted over time. The authors in [61] claim that the LSTM can memorize dependencies across time and bridge long-term delays by the cell state. The single LSTM cell contains all; however, the cell state pathway is grayed out, as depicted in Fig. 1.

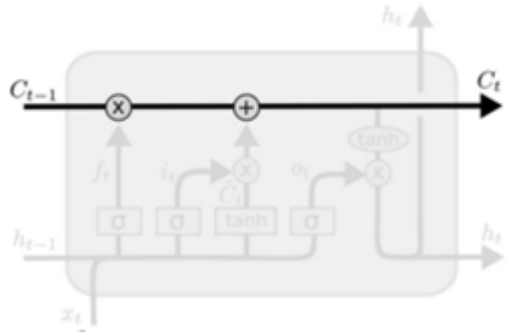

Fig. 1. The single LSTM cell contains all,; however, the cell state pathway is grayed out.

*2) Gate units:* The LSTM cell is accessible because of its several gate structures. Two inputs are typically supported by an LSTM cell: the current input $x_t$ and the recurrent input ($ht-1$, the hidden state of the previously executed time step). To read from and utilize the data contained in the cell state or to generate an updated cell state, $C_t$ gate units regulate how these inputs change the cell state. The gating processes of the LSTM cell rely heavily on the logistic sigmoid function, which can be written as expressed as $\sigma(x) = \frac{1}{1+e^{-x}}$.

It maps the recurrent and weighted current inputs to the interval $[0, 1]$. This also clarifies the meaning of the term "gate," enabling the network to control the flow of information through the gates. Values of 0 and 1 can be interpreted as allowing all information to pass through a specific gate and preventing any information from doing so. In addition to the "gatekeeper" sigmoid, two LSTM gates use the hyperbolic tangent function, that is $\tanh(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}$. A sigmoid gatekeeper function is used to do this, as seen in Fig. 2.

The input and output gates in LSTMs usually use the tanh activation function, which pushes inputs into the interval $[-1, 1]$. The following are the derivatives of the logistic sigmoid and the hyperbolic tangent: $d(x)\sigma(x) = \sigma(x)(1 - \sigma(x))$ and d/d(x) tanh(x) = 1 - tanh2 (x). As a result, they may be used in network training, which comes after backpropagation.

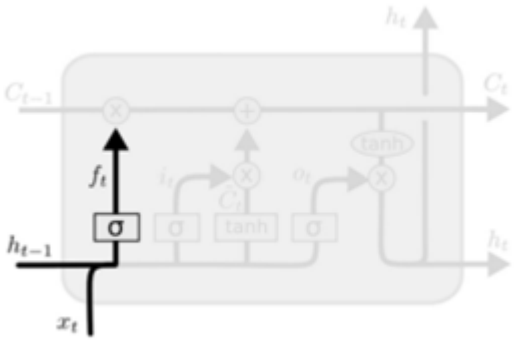

Fig. 2. Depicts the forget gate multiplied by the previous cell state $C_t - 1$ to ignore information [62].

*3) The Forget gate:* The portions of $C_t - 1$ that the cell state carried over from the previous time step are recognized and saved using the forget gate ft.

$$f_t = \sigma(W_f[h_{t-1}, x_t] + b_f) \tag{1}$$

To further enable selective retention of information in memory, it is multiplied by $C_t - 1$. When $ft = 1$ or $ft = 0$, all the data from $C_t - 1$ is retained or deleted accordingly.

*4) The Input gate:* The input gate, indicated in Fig. 3, uses a sigmoid to regulate the flow of information:

$$i_t = \sigma(W_i[h_{t-1}, x_t] + b_i) \tag{2}$$

This gate's function prevents unnecessary updates from affecting the cell state data accumulated throughout earlier time steps. As a result, new information is selectively updated into the cell state by the input gate [61]. An activation function, typically a hyperbolic tangent, generates a new set of candidate values to accomplish this. $\tilde{C}_t$:

$$\tilde{C}_t = \tanh(W_C[h_{t-1}, x_t] + b_C) \tag{3}$$

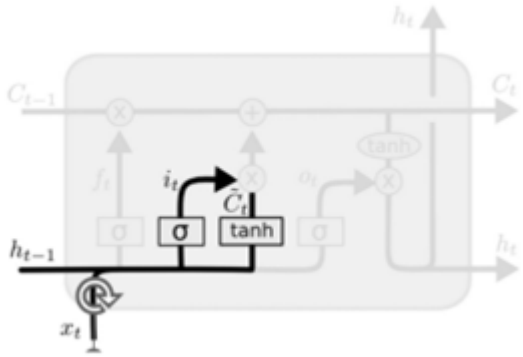

Fig. 3. The input gate 'it' directs where to update the cell state with new candidate values $C_t$ [62]

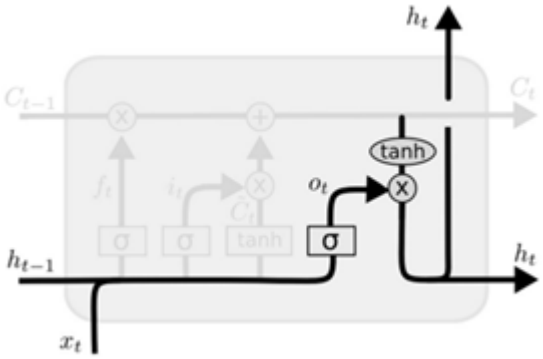

Fig. 4. The output gate 'ot' controls the network predictions [62].

*5) The Updated cell state:* The input produces the new cell state $C_t$ and forgets gate mechanisms in two stages: first, it remembers (via $f_t$) a subset of the previous cell state $C_t - 1$ and updates (via $i_t$) with the new candidate values from $\tilde{C}_t$ when necessary. At the following time step, $t+1$, this changed cell state will be received:

$$C_t = f_t C_{t-1} + i_t \tilde{C}_t \tag{4}$$

Note that neither $i_t = f_t$ nor $i_t = 1 - f_t$ always holds. Not precisely the sections that were forgotten, nor the ones that were remembered, are updated. The forget gate and the input gate usually have separate weights and biases, even if they use the same arguments $(h_{t-1} and t_x)$ and an activation function of the sigmoid [62].

*6) The Output gate:* The actual prediction of LSTM depends on the current input $(x_t)$ and cell state $(C_t)$, controlled by the output gate. The current cell state data is subjected to a hyperbolic tangent, resulting in a scaled representation of the cell state within the interval $[-1, 1]$:

$$C_t^* = \tanh(C_t) \tag{5}$$

As seen in Fig. 4, the output gate $(o_t)$ uses a sigmoid with the inputs $h_{t-1}$ and $x_t$ to choose which data to send to the output layer. The time steps in the newly hidden state $(h_t)$ are then calculated.

$$o_t = \sigma(W_o[h_{t-1}, x_t] + b_o) \tag{6}$$

The current time step's hidden output, ht, is then created by multiplying $o_t$ and $C_t^*$.

$$h_t = o_t \circ C_t^* \tag{7}$$

This output is based on the prediction at time t and the recurrent input at time $t + 1$. Predictions are calculated from the hidden state using an output activation in the last layer, just like in FNN.

*7) The LSTM cell:* Fig. 5 shows a typical LSTM cell with an input, output, and forget gate. Several gates and activations cooperate to save, hold, and produce information for the current task. When the gates and cell state are viewed as $h_t = o_t tanh(f_t C_(t-1) + i_t \tilde{C}t)$, ht can be thought of as a more complex activation function:

$$\begin{aligned} h_t &= \sigma(W_o[h_{t-1}, x_t] + b_o) \tanh\left(\sigma(W_f[h_{t-1}, x_t] + b_f) \cdot C_{t-1}\right. \\ &\quad \left. + \sigma(W_i[h_{t-1}, x_t] + b_i) \tanh(W_C[h_{t-1}, x_t] + b_C)\right) \\ &= g_h(W_h, h_{t-1}, x_t) \end{aligned} \tag{8}$$

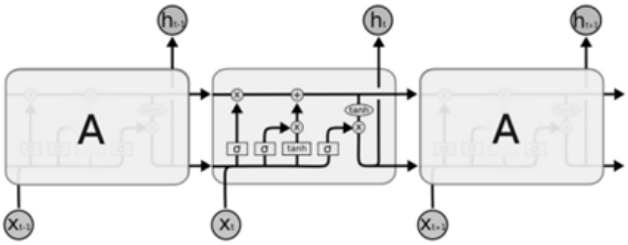

Fig. 5. A sequence of LSTM units through time [62].

This architecture, the most widely used configuration in the literature, is an improved version of the initial LSTM design. Fig. 6 shows how the cell state can transmit information over time. A series of LSTM cells are displayed throughout time. The hidden layer unit ("-" for closed and "O" for open) and the three gates to its left and above regulate which aspects of the cell state are updated, output, and forgotten at each time step.

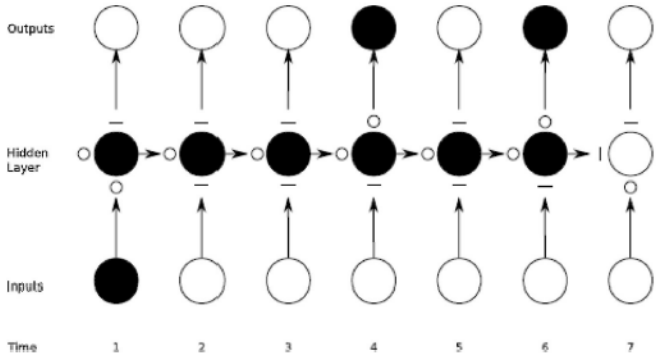

Fig. 6. Preservation of gradient information by LSTM.

### B. Gated Recurrent Units

Gated recurrent units (GRUs) are an additional method for tackling the declining gradient problem in RNNs [63]. Even though they manage the cell state more straightforwardly, they still require gates. An update gate combined an LSTM forget and input functions, but two sigmoid gates managed a GRU's hidden state.

It determines the amount of recurring data that is retained:

$$z_t = \sigma(W_z[h_{t-1}, x_t] + b_z) \tag{9}$$

A reset gate regulates the degree of hidden recurring states that can be included in the present activation.

$$r_t = \sigma(W_r[h_{t-1}, x_t] + b_r) \tag{10}$$

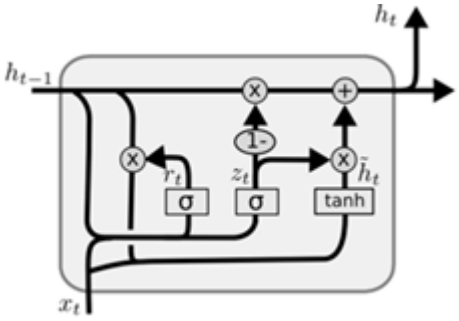

Fig. 7. Visualization of the recurrent hidden state, update gate, and reset gate over time.

Fig. 7 displays the recurrent hidden state $(h_{t-1})$, update gate $(z_t)$, reset gate $r_t)$, new hidden state $(h_t)$, and hidden state candidate vector $(h_t)$ in addition to a detailed view of the GRU cell [62]. A memory cell with a closed reset gate $(r_t = 0)$ can act as if it were reading the first observation of a sequence, overlooking the recurrent state [64]. One possible way to compute the new activation is as follows.

$$\tilde{h}_t = \tanh(W_h[r_t \cdot h_{t-1}, x_t] + b_h) \tag{11}$$

and the new hidden state is

$$h_t = (1 - z_t) \cdot h_{t-1} + z_t \cdot \tilde{h}_t \tag{12}$$

Again, the GRU cell can be thought of as an advanced activation function:

$$\begin{aligned} h_t = {} & (1 - \sigma(W_z[h_{t-1}, x_t] + b_z)) \cdot h_{t-1} + \sigma(W_z[h_{t-1}, x_t] + b_z) \\ & \tanh\left(W_h\left[\sigma(W_r[h_{t-1}, x_t] + b_r) \cdot h_{t-1}, x_t\right] + b_h\right. \\ & \left. \cdot C_{t-1} + \sigma(W_i[h_{t-1}, x_t] + b_i)\tanh(W_C[h_{t-1}, x_t] + b_C)\right) \\ & = g_h(W_h, h_{t-1}, x_t) \end{aligned} \tag{13}$$

Contrary to the LSTM, the GRU has no output activation function. Instead, the hidden cell state is constrained by the update gate, which links the input and forgets the gate. As shown in Fig. 7, GRUs contain fewer parameters than LSTMs, which should increase their computational efficiency. Regarding forecasting performance, prior research on GRUs against LSTMs is inconclusive [64], [65]. Therefore, this study focuses on both types of RNNs.

A hybrid GRU-LSTM model is shown in Fig. 8, where the input layer receives and processes the first set of data. The first hidden layer includes a pooling layer with a pool size of 1 and the same padding, a convolutional layer with 128 filters, a kernel size of 1, the ReLU activation function, and "same" padding to extract the essential features from the input. The 2nd Hidden Layer includes an LSTM layer with 128 units, depicting long-term dependencies in the data. The third hidden layer then uses the advantages of both architectures to learn complicated temporal patterns by switching between LSTM and GRU layers, each with 128 units. Finally, the output layer produces the model's predictions after processing the input data through the network's tiered structure.

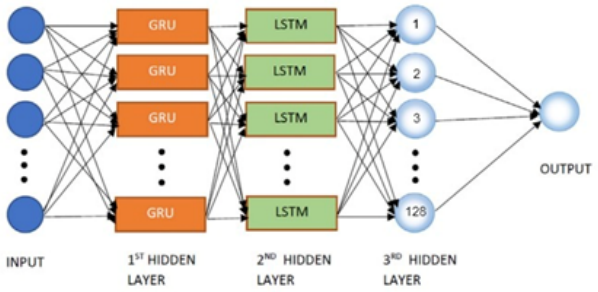

Fig. 8. Internal structure of hidden layers of hybrid model GRU-LSTM.

The flowchart shown in Fig. 9 presents the flow of the experiment, and it consists of generally arranged steps of establishing and validating a forecast model. Data collection is the first step followed by data preparation where pre-processing is completed to make the data more appropriate for training. During the pre-processing, the model is produced first, and the training data set is stored to it. This is the phase where the model for the forecast is being created; also, assessment of the model entails calculation of the loss

function. If the ending criterion is not achieved, the parameters of the model are changed, and training continues in a cycle. There is creation of the model, and when the end condition is met, then there is saving of the model. When training of the model is complete, the model is checked, and an independent testing data set is used for prediction. This is succeeded by the assessment of the performance of the model when such forecast results are prepared and analyzed. This process is to establish an appropriate forecasting mode through the loops of train and test data.

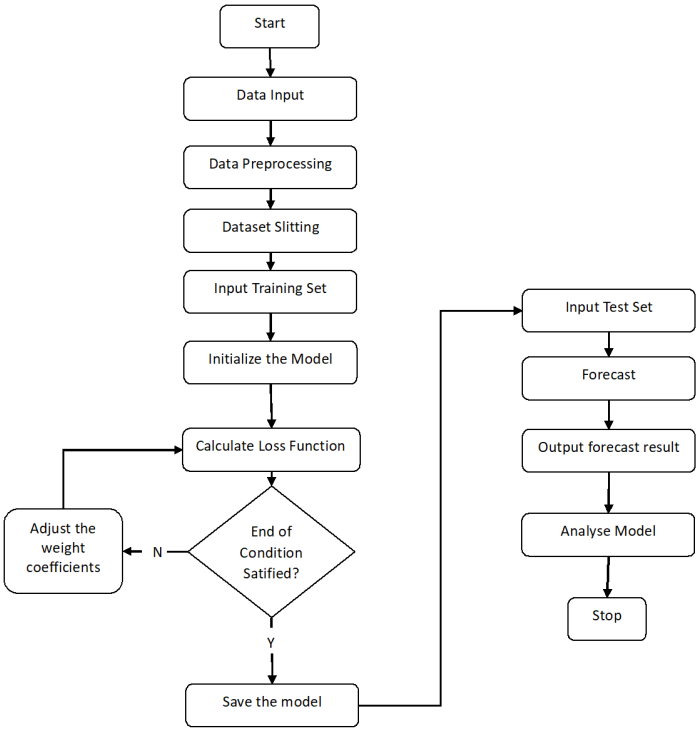

Fig. 9. Experimental process.

## IV. Experiments

This paper compares the hybrid model of the GRU-LSTM model with two individuals' models, the GRU and LSTM, to establish the efficiency of the hybrid approach. Training and the test data are identical in this case.

### A. Experimental Environment

For the trials, Google Colab version with the option of the fastest GPU: NVIDIA Tesla P100, with 16 GB of GPU memory was used. The hardware architecture of the view MPS software involved a CPU that was an Intel Xeon with 25 GB of RAM. Environment software was Python 3. 8. 10, basic machine learning libraries for instance TensorFlow 2. 8. 0, PyTorch 1. 11. 0, and Scikit-learn 1. 0. 2, and data processing and visualization applications such as Pandas 1. 4. 2, NumPy 1. 21. 5, and Matplotlib 3. 5. 1.

### B. Data Source

This paper presents a novel hybrid model for forecasting the USD/RMB exchange rate using the proposed GRU-LSTM model. The study uses the 1-minute USD/RMB exchange rate data set, which has 19807 observations. The parameters for this work are the bid price (Bid), ask price (Ask), order flow (OF), and bid-ask spread (BAS). The data was collected between September 13, 2023, and December 11, 2023.

In the forex market, the hidden daily information regarding macroeconomic fundamentals is communicated through the order flow [66]. The order flow values' sign might be both positive and negative. The sign denotes the buying and selling activity when a counterparty buys (+) at the dealer's offer or sells (-) at the dealer's bid. The Tick-test approach developed in study [67] and [68] methodology are the two main techniques used to speculate on the direction of currency transactions. Authors in study [68] compared the exchange rate and dealer quotes. Using this strategy, exchange rates higher or lower than the midpoint are classified as buy or sell. By comparing the current currency rate with the historical exchange rate, the tick-test examines fluctuations in exchange rates to determine the trade direction. A buy (uptick) is a rise in exchange rates or a transaction at a price more significant than the prior one. If not, a sell (down-tick) would be considered. At the same time, the transaction rates remain unchanged (zero-tick). According to [67], the transaction is classified according to the most recent difference between the current and exchange rates. Table I states the rules to differentiate between the buyers-initiated and the sellers-initiated trade.

TABLE I. Identification Algorithms: Tick Test

| Specification | Conjecture for trade |
|---|---|
| $S_t > S_{t-1}$ | Buyer-initiated |
| $S_t < S_{t-1}$ | Seller-initiated |
| $S_t = S_{t-1}$ | The conjecture for trade at $t$ |

Source: Adopted from [67]

The tick-test approach is used in this study because it is more accurate and adaptable [13], [12]. The order flow is calculated. Every trade is valued at $+1$ for purchases and $-1$ for sales. The daily trade is then the sum of all trade activities, whether buy or sell. Thus, researchers in [66] measure the daily order flow, defined as the buyer- and seller-initiated orders at the start of the working day. The related empirical studies used the same proxy for measuring the order flow [69], [70]. This research tracks tick-by-tick order flow one-minute data. The data is gathered from Bloomberg sources. The tick-test approach is used in this study because it is more accurate and adaptable [13], [12]. The order flow is calculated. Every trade is valued at $+1$ for purchases and $-1$ for sales. The daily trade is then the sum of all trade activities, whether buy or sell. The ask price, bid price, and bid-ask spread are essential factors in predicting exchange rates. The bid price (buyer price) and ask price (Sell price) data are taken from Bank of China [71]. The realized bid-ask spread and the quoted bid-ask spread are the two ways to define the bid-ask spread [72]. The average difference between the purchase and sell prices the trader quotes when the buy and sale transactions occur at different times is known as the realized bid-ask spread. Alternatively, the difference between the purchase and sell prices that the dealers quote at trade time is known as the quoted bid-ask spread, and it is determined by the quantity transacted, stock price, and number of market makers (Chen, 2012). There is a strong correlation between exchange rate risk and the bid-ask spread, according to study [70] and [12]. The bid-ask spread data is computed as the difference between the ask (sell) price and the currency rate's bid (buy) price. Table II displays a subset of the data extracted from the Table I.

TABLE II. PARTIAL SAMPLE DATA

| Date | ER | Bid | Ask | OF | BAS |
|---|---|---|---|---|---|
| 2023-09-13 01:35:00 | 7.2835 | 7.2835 | 7.2835 | 0 | 0 |
| 2023-09-13 01:36:00 | 7.2820 | 7.2820 | 7.2820 | -4 | 0 |
| 2023-09-13 01:38:00 | 7.2823 | 7.2823 | 7.2823 | 4 | 0 |
| 2023-09-13 01:39:00 | 7.2835 | 7.2835 | 7.2835 | 3 | 0 |
| 2023-09-13 01:40:00 | 7.2835 | 7.2835 | 7.2835 | 3 | 0 |

The complex nonlinear patterns of exchange rate fluctuations are too intricate to capture by traditional linear methods. Thus, researchers are adopting nonlinear methodologies that are intended to be more accurate [73], [74]. In times of economic turmoil and high volatility in the foreign currency market, when structural disruptions cause linear assumptions to be distorted, nonlinear models play a crucial role in predicting exchange rates [12].

The nonlinearities are efficiently managed by deep learning techniques such as GRU and LSTM. From September 13, 2023, to December 11, 2023, Fig. 10 illustrates the USD/RMB exchange rate for 1 minute dataset. It first displays an early appreciation of the RMB, followed by a sharp depreciation, stabilization, recovery, and a second depreciation phase. These oscillations underscore the necessity for nonlinear models to precisely forecast exchange rate movements and seize trading opportunities despite the extreme volatility and quick changes in the market. Economic data, policy changes, market sentiment, and geopolitical events impact these oscillations.

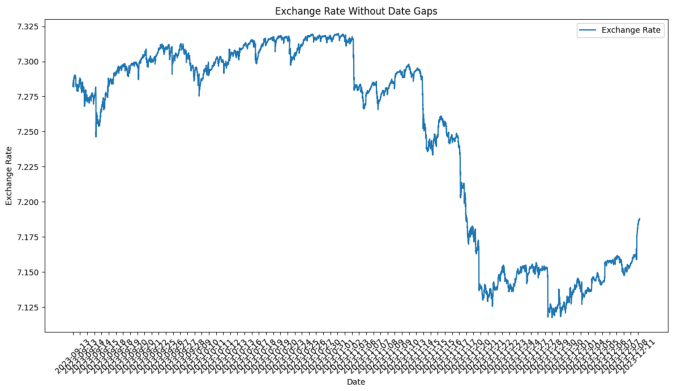

Fig. 10. Forex market dataset USD/RMB.

### C. Descriptive Statistics

Table III shows a tabular representation of the descriptive statistics provided for the parameters such as RMB/USD exchange rate (ER), bid price (BID), ask price (ASK), order flow (OF), and bid-ask spread (BAS). This table summarizes the statistical measures for parameters based on the data from 19,808 observations. The mean values for bid and ask prices are very close, indicating a tight spread, confirmed by the mean BAS value being nearly zero. The standard deviation (std) across the bid, ask, and ER is similar, suggesting that the RMB/USD pair has been trading with relatively stable volatility. The order flow's large standard deviation points to significant buying and selling activity. The minimum and maximum values indicate the range of trade, while the distribution of the values is suggested by the 25th, 50th (median), and 75th percentiles.

TABLE III. DESCRIPTIVE STATISTICS

| Statistic | Bid | Ask | ER | OF | BAS |
|---|---|---|---|---|---|
| count | 19808 | 19808 | 19808 | 19808 | 19808 |
| mean | 7.24796 | 7.24783 | 7.24787 | 0.42392 | -0.0001 |
| std | 0.0703 | 0.07035 | 0.07034 | 5.03654 | 0.00029 |
| min | 7.1175 | 7.1174 | 7.1175 | -65 | -0.0028 |
| 25% | 7.1574 | 7.1574 | 7.1574 | -3 | 0 |
| 50% | 7.2839 | 7.2837 | 7.2838 | 2 | 0 |
| 75% | 7.3045 | 7.3044 | 7.3044 | 3 | 0 |
| max | 7.3198 | 7.3198 | 7.3198 | 67 | 0 |

### D. Data Preprocessing

The data preprocessing stages for exchange rate data involved several fundamental data transformations in preparing the data for a model. First, we converted the date column into a date-time format to assign it as the index and facilitate time series analysis. After that, the data was reset so that the date would appear as a column for further processing. To maintain chronological order, the dataset was sorted using dates to determine the ascending order.

Descriptive statistics were then produced to provide an overview of the dataset. "ER" was the target variable, and "Bid," "Ask," "OF," and "BAS" were the features chosen for the model. The features and the target variable were normalized using the MinMaxScaler to scale the values between 0 and 1 to 1 to improve the performance of models. Then, we established data sequences with a defined length of 4,

meaning each sequence had four data points in a row. The target value for each sequence was the data point that came just after the sequence. The scaled data had to be iterated over to create sequences and their corresponding targets. The resulting sequences were then transformed into numpy arrays. Ultimately, the data was separated into training and testing sets. After training 80% of the data, the model was evaluated on 20% using an 80:20 split ratio. The model was trained on most of the data for this split, and its performance was assessed using an unknown component.

### *E. Experimental Parameter Settings*

The critical parameter choices for a neural network model with convolutional and LSTM/GRU layers intended for sequential data analysis are shown in Table IV. Convolutional layers are set up with 128 filters, each using a ReLU activation function and a 1 x 1 kernel size to extract features while introducing nonlinearity effectively. Both convolutional and pooling layers utilize padding to maintain input/output dimensions. The LSTM/GRU layers are set to contain 128 hidden units, employing a Tanh activation function to capture temporal dependencies effectively. With a learning rate of 0.0001, the Adam optimizer improves the model, which guarantees adaptive changes to the weight parameters during training. Multiple loss functions, including MAE, MSE, RMSE, MSLE, Median Absolute Error, and MAPE, are employed to evaluate model performance from different perspectives. In any training, epochs are several complete cycles through the entire data set, and batch size is the number of training instances processed at each pass, therefore, training is performed over 50 epochs with a batch size of 54, which helps in optimizing the model for working on sequential data tasks. The purpose of such an elaborate set of parameters is to examine the sequential data, along with good performance and stability.

TABLE IV. MODEL PARAMETER SETTINGS

| Parameters | Value |
|---|---|
| Convolution layer Filters | 128 |
| Convolution layer Kernel Size | 1 |
| Convolution layer Activation Function | ReLU |
| Convolution layer padding | Same |
| Pooling layer pool size | 1 |
| Pooling layer padding | Same |
| LSTM-GRU Hidden Units | 128 |
| LSTM-GRU Activation Function | Tanh |
| LSTM-GRU Optimizer | Adam |
| LSTM-GRU Learning Rate | 0.0001 |
| LSTM-GRU Loss Function | MAE, MAP, RMSE, MedAE, MAPE |
| LSTM-GRU Epochs | 50 |
| LSTM-GRU Batch Size | 54 |

Note: The table shows the ideal parameters for each GRU-LSTM model layer. The acronyms MAE, MAP, RMSE, MedAE, and MAPE stand for Mean Absolute Error, Mean Average Precision, Root Mean Squared Error, Median Absolute Error, and Mean Absolute Percentage Error, respectively.

### *F. Experimental Results and Analysis*

The primary objective of this study is to forecast the USD/RMB exchange rate with three different models' levels of accuracy: a hybrid GRU-LSTM model, a Gated Recurrent Unit (GRU), and a Long Short-Term Memory (LSTM) model. Various assessment criteria are used to assess these models, including training duration, MAE, MAP, RMSE, MAE, and MAPE. Before training, the dataset is standardized. Every model project the closing price for the subsequent trading day; the expected and actual values are then contrasted. A standardized Forex dataset is used in the studies for both evaluation and training. The LSTM, GRU, and hybrid GRU-LSTM models are trained on this dataset to forecast the closing values of the USD/RMB exchange rate. The model's parameters are adjusted to lower error metrics while the data is processed throughout several epochs during training.

Fig. 11 displays the performance of the LSTM model over ten epochs. The x-axis shows the epochs, while the y-axis displays the loss values. Included in the metrics are validation loss (Val-loss), training loss (Train-loss), mean absolute error (MAE), mean squared error (MSE), and root mean square error (RMSE). All metrics demonstrate a decreasing trend, indicating effective learning and improved predictions. The rapid initial decline in error values reflects the model's quick adaptation to data patterns. Despite minor fluctuations, the steady decrease in training loss and the general downward trend in validation loss suggest effective learning with some overfitting. The consistent decline in MSE, RMSE, and MAE confirms enhanced prediction accuracy.

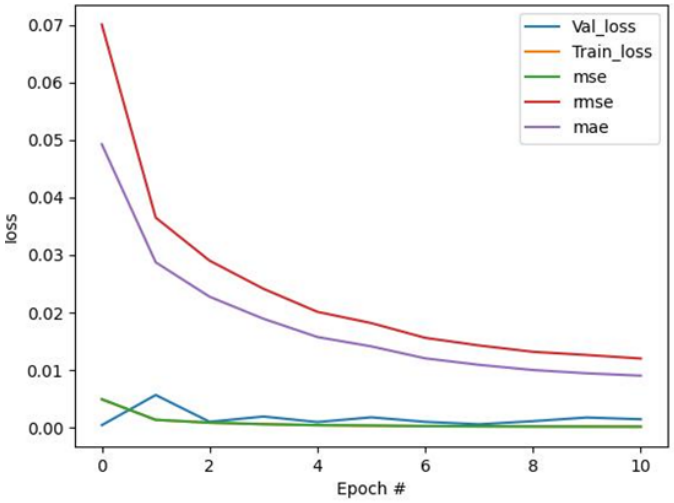

Fig. 11. LSTM Training and Validation loss for selected evaluation metrics.

Fig. 12 illustrates the performance of the GRU model over the same period. Like LSTM, the GRU model exhibits a rapid initial decline in error metrics, indicating efficient learning. The GRU model converges faster and displays stable validation performance with fewer fluctuations, indicating more consistent generalization. Both models effectively reduce errors and enhance predictive accuracy, with the GRU model demonstrating slightly faster and more stable convergence.

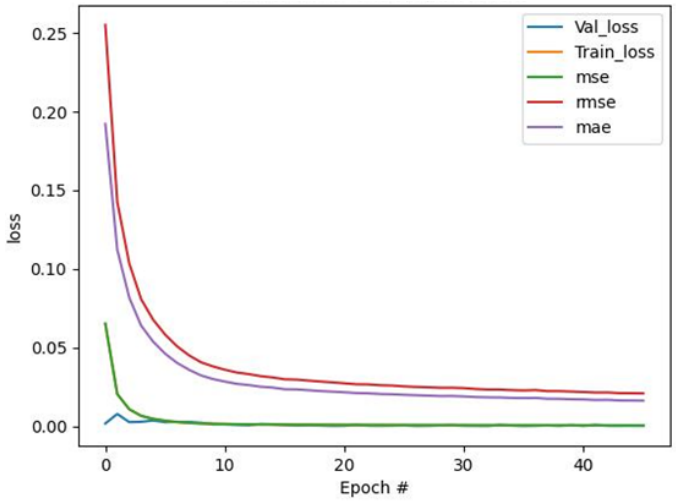

Fig. 12. Loss function for the training and validation for selected evaluation metrics.

The loss function for the combined LSTM and GRU model is shown in Fig. 13. To improve forecasting accuracy, the hybrid GRU-LSTM model combines the best features of the LSTM and GRU architectures. LSTM networks excel at learning long-term dependencies with their robust cell state and gate mechanisms, while GRUs offer computational efficiency and effective handling of short-term dependencies. In the hybrid model, data first passes through an LSTM layer to capture long-term patterns, then through a GRU layer to efficiently capture additional short-term patterns. This combination improves overall predictive performance, as demonstrated by the close alignment of the hybrid model's predictions with actual exchange rates in the provided plots. Since the hybrid model can account for both short-term volatility and long-term trends, it is a reliable method for forecasting the USD/RMB exchange rate.

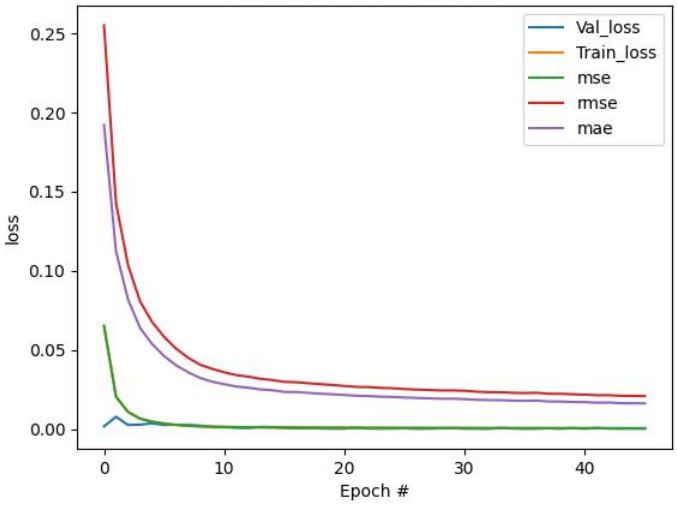

Fig. 13. The Loss function of the hybrid model for the training and validation of selected evaluation metrics.

The error metrics for the LSTM and GRU models trained on a Forex dataset. Both models exhibit a rapid initial decline in metrics such as training loss, validation loss, MSE, RMSE, and MAE, indicating efficient learning. The LSTM model shows steady improvement with minor fluctuations in validation loss, suggesting some variability in generalization. In contrast, the GRU model exhibits more consistent generalization due to its faster convergence and stable validation performance with fewer fluctuations. While both models can reduce errors and improve prediction accuracy, the GRU model shows quicker and more consistent convergence.

The prediction of the LSTM model is shown in Fig. 14, where it demonstrates an excellent predictive capability but is less consistent than the hybrid GRU-LSTM model, particularly during times of high volatility. Although some overfitting is seen because of small changes in validation loss, the model learns efficiently, as evidenced by the consistent decrease in training and validation loss. The model's predictions get more accurate with time, as evidenced by the steady drop in the MSE, RMSE, and MAE metrics.

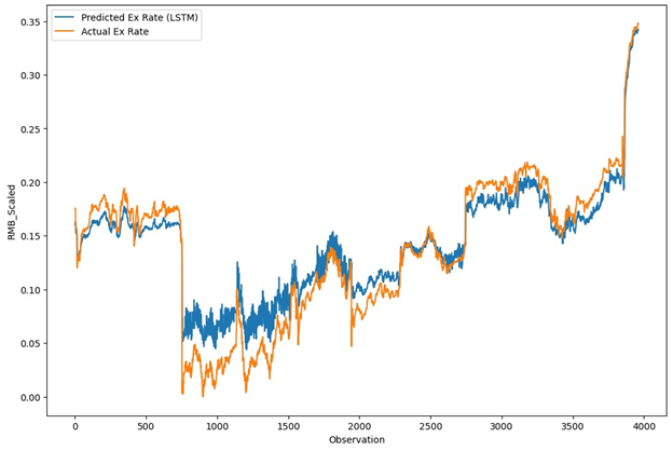

Fig. 14. LSTM Model's prediction for the test dataset.

The GRU model performs better than the LSTM model in terms of validation performance stability and convergence rate, as shown in Fig. 15. The validation loss fluctuating less suggests better generalization to unobserved data. Because of its strength, the GRU model is suitable for time series forecasting tasks where dependable performance is crucial.

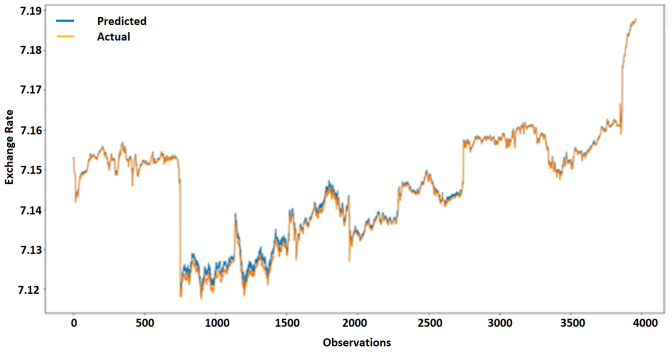

Fig. 15. GRU Model prediction for the test dataset.

Fig. 16 demonstrates how a hybrid GRU-LSTM model better captures short—and long-term trends and fluctuations compared to the LSTM or GRU individual model. The hybrid model is a more accurate and reliable forecasting tool since it can use both architectures. This model closely aligns predicted values with actual exchange rates, demonstrating its robustness in handling financial time series data complexities. A high degree of accuracy is indicated by slight differences between expected and actual values; only occasional anomalies impact predictions.

The evaluation metrics of the GRU, LSTM, and hybrid GRU-LSTM models are displayed in Table V. The Mean Absolute Error (MAE) of 0.003368 indicates the average deviation from actual values for the Long Short-Term Memory (LSTM) model, created to represent long-term dependencies in sequence data. Its Root Mean Squared Error (RMSE) of 0.004109 indicates the impact of sporadic, more significant inconsistencies, even though its Mean Squared Error (MSE) of 0.000017 is relatively minor. The Mean Squared Logarithmic Error (MSLE) is zero, indicating robustness in handling logarithmic differences. The percentage accuracy is indicated by the Mean Absolute Percentage Error (MAPE) of 0.0472%, and resilience to outliers is indicated by the median absolute error of 0.002902.

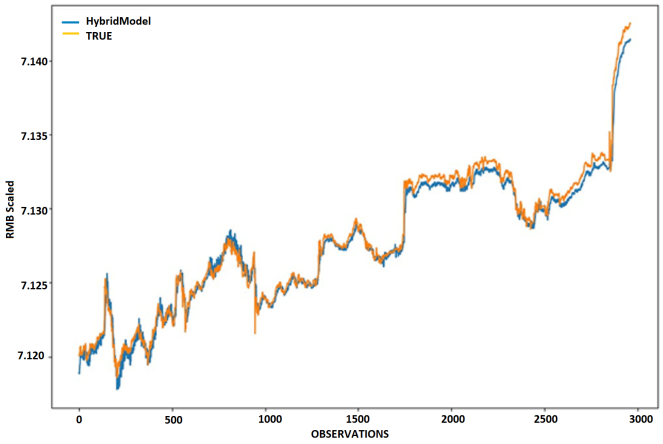

Fig. 16. Hybrid Model's prediction for the test dataset.

TABLE V. EVALUATION MATRICES

| Model | MAE | RMSE | MedAE | MAPE |
|---|---|---|---|---|
| GRU-LSTM [75] | 0.0012 | 0.0015 | N/A | 0.0010 |
| LSTM [76] | 0.0025 | 0.0032 | N/A | 0.0021 |
| GRU [77] | 0.0018 | 0.0023 | N/A | 0.0015 |
| LSTM | 0.0033 | 0.0041 | 0.0029 | 0.0004 |
| GRU | 0.0025 | 0.0037 | 0.0013 | 0.0004 |
| Hybrid GRU-LSTM | 0.0004 | 0.0005 | 0.0003 | 0.00006 |

The GRU model outperforms the LSTM in all criteria while maintaining similar functionality and simplifying the LSTM architecture. The MAE of 0.002505 indicates increased accuracy, with average predictions closer to actual values. A reduced error size is marked by an RMSE of 0.003746, highlighting improved overall prediction performance. A more consistent error distribution is indicated by the median absolute error of 0.001261, indicating that outliers impact the GRU less. The GRU model exhibits better accuracy than the LSTM model, with an average percentage error of 0.0351%, indicating a small average percentage error.

## V. DISCUSSION

The findings of this study have significant implications for both practitioners and researchers. The hybrid GRU-LSTM model offers traders a reliable tool for predicting exchange rate movements, enabling them to manage risks more effectively. For researchers, the integration of microstructure variables highlights the importance of leveraging high-frequency data to uncover hidden patterns in financial markets. Moving forward, future studies could explore the application of hybrid models in other financial domains, such as stock price prediction or commodity trading.

The hybrid GRU-LSTM model outperforms the LSTM model on all evaluation measures by combining the best aspects of the GRU and LSTM architectures. The predictions of the hybrid model are surprisingly close to the actual values, with an MAE of only 0.000433. The model's outstanding performance is further supported by its RMSE of 0.000565, which shows the lowest error magnitude among the models. The lowest median absolute error, 0.000380, indicates that the model's predictions are less affected by anomalies and are, hence, stable. Finally, the hybrid model yields the most accurate and trustworthy forecasts, as evidenced by the MAPE of 0.0061%, the lowest average percentage deviation.

The comparison demonstrates that the GRU-LSTM hybrid model is the most accurate and consistent of the three models, surpassing the other two in each evaluated criterion. The GRU model outperforms the LSTM in all areas, demonstrating its accuracy and efficiency. Although the LSTM model performs well, the hybrid and GRU models outperform it. By utilizing the complementary advantages of both the LSTM and GRU architectures, the GRU-LSTM hybrid is the optimal option for attaining the highest prediction accuracy and consistency levels. This improved accuracy and dependability is essential when it comes to financial analysts and traders making well-informed decisions in the currency market.

The hybrid GRU-LSTM model not only improves predictive accuracy but also offers practical benefits for traders and financial analysts. By capturing both short-term volatility and long-term trends, the model enables more informed decision-making, particularly in high-stakes environments like the USD/RMB exchange market.

## VI. CONCLUSION

This research aims to establish the reliability of the novel hybrid GRU-LSTM model to predict the USD/RMB exchange rate, which is extremely valuable in the Chinese financial sector. It will also help avoid possible financial risks associated with the exchange rate while providing critical economic information. Before developing a new hybrid GRU-LSTM network architecture, the goal is to combine the characteristics of the two GRU and LSTM models to increase the model's predictive capacity. Therefore, the study outlined the research's high efficiency based on the proposed novel hybrid model and the results of using separate LSTM and GRU models for the USD/RMB exchange rate prediction.

The findings demonstrated how the hybrid model, which combines LSTM and GRU components, can be distinguished from the precise prediction accuracy of the two models with a greater variety of parameter configurations. This is basically due to its cell state and gate mechanisms; LSTM has a mighty reliable cell state; GRUs, on the other hand, are efficient and effectively assert short-term dependency connections. When one works under the hybrid model, the actual data is well managed as it has short-term characteristics by going through a GRU layer once it has passed through an LSTM layer, which handles the features of long-term patterns.

The predictive plots presented demonstrate how this sort of combination enhances overall predictive accuracy by closely replicating the actual exchange rates among other techniques in the hybrid model. The hybrid model has the significant benefit of providing analysis over both the short and long terms; as a result, it may be used to forecast the USD/RMB exchange rate. This led to improved accuracy analysis, which is vital for traders and financial analysts before making any decisions in the foreign exchange market. Thus, although the presented LSTM-based model exhibits a high level of predictability, its capability becomes relatively volatile at extreme levels of volatility. In contrast, the GRU model has a similar training performance for different epochs with less fluctuation in the validation performance and takes fewer epochs to converge. Lastly, the hybrid model, which solely captures the short-term and extended-term changes, achieves the highest predicted accuracy given by the equation of the superiority of LSTM over GRU and vice versa.

### A. Policy Implications

The study's findings have several policy implications.

- The newly proposed GRU-LSTM model provides numerous benefits to financial institutions and policy-making bodies in the projection of exchange rates by improving the model's expandability while maintaining the needed degrees of instability to account for long-term dependencies. This concept indicates that institutions can reduce currency risk by effectively employing hedging mechanisms and risk management structures that are less vulnerable. This helps avoid unfavorable currency movements, which result in declining performance on the economic portfolios, stabilizing the overall performance.
- In keeping the market stable, prompt and accurate forecasting models such as the hybrid model GRU-LSTM are vital as they highlight the exchange rate volatility. The market volatility is seen before it reaches extreme levels, which means that the financial institutions and the policymakers can respond as soon as the signs of volatility become apparent by using available instruments like the regulation of the monetary supply or using forex reserves. It acts as a shield that minimizes the disruption that comes about due to a sharp fluctuation in exchange rates, thereby minimizing shocks to financial markets, investors' confidence, and the sustainability of economic growth.
- The hybrid forecasting models' performances are highly relevant in determining policy decisions, especially in controlling foreign exchanges and monetary policies. The hybrid predictive model can be valuable for strategic planning of the economy and advantageous because it effectively facilitates anticipation of future market trends as influenced by exchange rate predictions. The projections by the predictive model facilitate the management of the monetary policies and foreign exchange reserves, thus helping counter-economic volatility and adopting stability as well as growth. Therefore, policymakers rely on predictive models when making decisions, reducing uncertainty and creating a favorable environment for the economy's long-run growth.
- The results also indicate that using deep learning improves the required models and introducing them into financial markets is the next step to achieving innovation. Financial organizations are in a diverse position to embrace innovation in their operations to enhance the viability and effectiveness of the financial services delivery systems. The models particularly excel in handling large volumes of data and more extensive and intricate patterns, thus enabling accurate prediction and decision-making. Hence, the use of advanced technology leads financial institutions to achieve a competitive market position and, at the same time, makes financial institutions more responsive to the prevailing conditions. Such flexibility enhances the financial system's effectiveness with a stressed and improved capacity to adapt to adversity and change and boosts the sector's resilience, efficiency, and innovation
- A microstructure model that integrates order flow, bid price, ask price, and the bid-ask spread is quite complex in Forex trading. However, when used, it can offer deep insights into the market that are not provided with traditional models. Essentially, through processing such data, the model predicts future variations of the RMB/USD exchange rate so that trading players can devise informed trading policies. Real-time data are easily interpreted to make it a source of trading signals that are key in responding quickly to market changes. For example, when the model indicates that the RMB is likely to appreciate against the USD, the trader may find it valuable to open a long position.
- The model also provides predictions and relative probabilities for preparing to manage risks. Trading professionals can employ these projections to place stop-loss orders and hence manage the capital that one is willing to risk per trade, not forgetting the profit targets. Probability forecasts allow traders to accurately reposition according to short-term fluctuations and long-term trends to effectively get the right timing for entering or exiting the market to earn the best profits.
- Several parameters affect placing an order, such as bid ask spread and order flow, which creates the opportunity to form positive order limits, making profit expectations high. The model outcome can also be carried out in the algorithms for actual trading since its

applicability is relevant, especially in high-frequency trading. The model's value is attributed mainly to the realization that you can obtain the probability outcomes from the model, which can then best be used in conjunction with sentiment analysis for the clients and the broker or dealers to determine the best time for trading. The traders that received this information have continued to be relevant through functional communication strategies such as swift notifications in the messaging and trading platform.

### B. Future Recommendations

Future research could consider other hybrid models or the use of ensembles for better precision in forecasting exchange rates. Also, further development of the model with more elaborate deep learning techniques, such as attention techniques, and including external economic parameters, can be helpful.

# AI-Driven Resource Allocation in Edge-Fog Computing: Leveraging Digital Twins for Efficient Healthcare Systems

Use Case: Cardiovascular Diseases in Mauritania

Brahim Ould Cheikh Mohamed Nouh[1], Rafika Brahmi[2], Sidi Cheikh[3]*,
Ridha Ejbali[4], Mohamedade Farouk Nanne[5]

Research Unit. (RTIM), National School of Engineers, University of Gabes, Gabes 6029, Tunisia[2,4]

***Abstract*—The evolution of healthcare, driven by remote monitoring and connected devices, is transforming medical service delivery. Digital twins, virtual replicas of patients, enable continuous monitoring and predictive analysis. However, the rapid growth of real-time health data presents major challenges in resource allocation and processing, especially in cardiac event prediction scenarios. This paper proposes an artificial intelligence-based approach to optimize resource allocation in a fog-edge computing environment, with a focus on Mauritania. The system integrates a deep learning model (CNN-BiLSTM), which achieves 98% accuracy in predicting cardiovascular risks from physiological signals, combined with a Deep Q-Network (DQN) to dynamically decide whether tasks should run at the edge or in the fog. Using IoT sensors, real-time health data is collected and processed intelligently, ensuring low latency and rapid response. Digital twins provide a synchronized virtual representation of the physical system for real-time supervision. This architecture improves resource utilization, reduces processing delays, and enhances responsiveness to critical medical conditions, supporting more accurate cardiac event prediction and timely intervention, especially in resource-constrained environments.**

***Keywords*—Edge computing; fog computing; digital twin; deep learning; CNN-BiLSTM; Deep Q-Network (DQN); resource allocation; cardiac event prediction; healthcare; Artificial Intelligence (AI); Internet of Things (IoT); real-time**

## I. Introduction

Cardiovascular diseases, which claim millions of lives each year, remain one of the leading causes of mortality worldwide [1]. In Mauritania, the prevalence of cardiovascular disease (CVD) mortality is estimated at 16%, making it the leading cause of death from non-communicable diseases (NCDs) [2]. Hypertension (HTN), affecting 27% of the Mauritanian population [3], is the primary contributor to the burden of strokes, ischemic heart diseases, and hypertensive cardiopathies. The prevention, detection, and treatment of hypertension remain insufficient due to a lack of public awareness about risk factors, symptoms, and complications of the disease, as well as weaknesses in the healthcare system [4]. Implementing a decision support system [5] that facilitates early detection, alongside efficient resource management and rapid intervention in cardiac emergencies is crucial to improving patient survival rates [6] and achieve the target of a 33% reduction in premature mortality by 2030 [7].Moreover, a survey conducted among cardiologists at the National Cardiology Center (CNC) reveals strong support for these innovative solutions [8].However, the effective management of real-time data from medical monitoring devices remains a significant challenge, particularly in distributed environments (Edge or Fog Computing) where computational resources are often limited [9]. Edge-Fog Computing environments, positioned near IoT devices, allow for decentralized data processing, thus reducing latency and bottlenecks associated with data transfer to the cloud [10]. Optimizing resource allocation in such distributed systems is a central challenge. Dynamic resource management—including bandwidth, computing power, and storage—is crucial, especially when handling critical real-time data streams, such as those generated by biometric sensors and cameras in cardiac monitoring systems [11]. To address these challenges, integrating Edge-Fog Computing systems with artificial intelligence (AI) approaches and digital twins paves the way for intelligent and scalable healthcare systems that can adapt to the dynamic needs of patients and infrastructure [12] [13]. In this context, our work proposes an innovative approach to optimizing resource allocation in Edge-Fog Computing environments, specifically designed to enhance the prediction of cardiac events. It combines advanced AI models, including a hybrid CNN-LSTM model for cardiac event prediction and a Deep Q-Network (DQN) for dynamic resource allocation. This system aims to establish a real-time health monitoring framework capable of predicting patients' cardiac health status, determining the optimal location for task processing—whether at the edge or fog—and delivering rapid responses in critical situations. Moreover, integrating digital twins into this architecture enables comprehensive system supervision, providing a platform for real-time monitoring and predictive analysis [14]. These digital twins not only simulate system behavior under varying conditions [fdgth] but also continuously optimize resource allocation decisions [15]. Preliminary results indicate that this approach effectively handles workload variations, improves system performance, and supports rapid response to critical situations. The main contributions of our research study are as follows:

*1) AI-Driven heart attack risk prediction at the edge:* Development and implementation of a CNN-BiLSTM deep

*Corresponding authors.

learning model for heart attack prediction, enabling real-time monitoring and accurate risk assessment directly on edge devices.

*2) Dynamic resource allocation optimisation:* Implementation of a reinforcement learning Deep Q-Network (DQN) model to optimise resource management. This model dynamically determines whether data, including video streams in critical situations, should be processed locally on edge devices or offloaded to the fog layer in resource-intensive scenarios.

*3) Integrating digital twin technology:* Use of digital twins for cardiac monitoring in healthcare to refine the accuracy of heart attack predictions, optimise resource allocation and improve system performance through real-time monitoring, notification in critical situations and continuous optimisation based on replicated data.

The rest of this paper is organized as follows: Section II discusses related work. In Section III, we presents the proposed framework. Furthermore, Section IV is the results and discussion. The conclusion and the paper's potential future directions are presented in Section V.

## II. Related Work

Many authors have carried out studies relevant to our research. In this section, the key studies are organized into sub-paragraphs with clear headings for improved readability and are summarized below:

### A. Resource Allocation in Fog and Edge Computing for Healthcare

Talaat et al. [16] introduced EPRAM, a method combining Deep Reinforcement Learning (DRL) and Probabilistic Neural Networks (PNN) to enhance resource allocation and heart disease prediction in Fog environments. The system includes modules for data preprocessing, resource allocation, and effective prediction, significantly reducing latency and improving load balancing. Aazam et al. [17] focused on task offloading in Edge Computing using machine learning (ML) models such as kNN, Naive Bayes, and SVC. Although their models improved processing efficiency in medical scenarios (including COVID-19-related cases), they did not report specific performance metrics. Khan et al. [18] proposed a dynamic resource allocation algorithm for IoHT applications. Their results demonstrated a 45% reduction in delay, 37% reduction in energy consumption, and 25% reduction in bandwidth usage compared to existing approaches.

### B. Machine Learning-Based Medical Data Processing

Amzil et al. [19] developed ML-MDS, a medical data segmentation method that achieved 92% accuracy while reducing latency by 56%. Similarly, Ullah et al. [20] used fuzzy reinforcement learning to design energy-efficient healthcare IoT systems. Hanumantharaju et al. [21] applied Random Forest and Naive Bayes algorithms for heart disease prediction. Scrugli et al. [22], on the other hand, achieved over 97% accuracy using a CNN to detect arrhythmia disorders.

### C. Deep Learning and Synthetic Data for Cardiac Events

Rajapaksha et al.[23] used LSTM models with synthetic data to predict cardiac arrests, achieving 96% accuracy. Tang et al.[24] introduced SH-CSO, an optimization algorithm that achieved 96. 16% precision for heart disease and 97. 26% for the diagnosis of diabetes. Dritsas et al.[25] compared several deep learning models on a heart attack prediction dataset. Their hybrid model outperformed others with 91% accuracy, 89% precision, and 90% recall.

### D. Hybrid Deep Learning Models for Cardiac Prediction

Hossain et al.[26] used a hybrid CNN-LSTM model, achieving up to 74.15% accuracy. Sudha et al.[27] achieved 89% using a similar approach. Verma et al.[28] proposed the FETCH system, which combines Fog Computing, IoT, and DL to enhance real-time cardiac monitoring. Elsayed et al.[29] integrated CNN and Fog Computing for image-based diagnosis, achieving near-perfect accuracy (99.88%) on X-ray images.

### E. Architectures and Comparative Studies

Tripathy et al. [30] proposed an architecture combining quartet deep learning and edge devices, evaluated using the FogBus framework based on performance indicators such as congestion and accuracy. Scrugli et al.[22] compared several ML algorithms (LR, SVM, NB, KNN, RF, GB) to identify the best one for early heart failure detection, especially within cloud computing environments. The Table I provides an overview of studies focusing on edge–fog systems in the healthcare domain.

The Table [I] provides an overview of studies focusing on Edge–Fog systems in the healthcare domain, highlighting the key limitations identified in each study.

## III. Proposed Framework

We proposed a multi-layered framework for remote healthcare monitoring and resource allocation, including IoT sensors, edge computing, fog and digital twin technology, to predict heart attacks in real time and allocate resources efficiently. IoT sensors collect key physiological data, including parameters such as heart rate, type of chest pain and cholesterol levels, alongside video input from a camera during critical events. Edge devices are used to run pre-trained deep learning models to predict a heart attack, and activate the camera as needed. During the same time, a deep Q-Network (DQN) decides if the data is processed locally or offloaded to the fog layer. Predictions and video frames are transmitted to a digital twin, which not only monitors the patient's health but also diagnoses the situation based on the collected data. If the digital twin detects an emergency, such as a potential heart attack, it automatically notifies the medical staff, family members, and ambulance teams, enabling prompt intervention and refines resource allocation through historical analysis. Fig. 1 illustrates the architecture of this system, highlighting the seamless flow from data collection to decision making.In the following sections, each layer of the proposed architecture will be detailed in the following sections.

TABLE I. OVERVIEW OF STUDIES FOCUSING ON EDGE-FOG SYSTEMS FOR HEALTHCARE

| Reference | Focus | AI Technique / Architecture | Limitations |
|---|---|---|---|
| (Aazam et al.) [2021] [17] | underscores the significance of intelligent decision-making in resource-constrained environments for enhancing | kNN,naive Bayes (NB), SVC/ Edge-Cloud | Algorithmic Limitations : The study does not fully address how resource allocation is managed dynamically across middleware entities |
| (scrugli et al.) [2021] [22] | explore the implementation of a system for at-the-edge cognitive processing of ECG data. | CNN/ Edge-Cloud | Limited Scope of Generalization, |
| (khan et al.) [2022][18] | This paper proposes workload-aware efficient resource allocation and load balancing in the fog-computing environment for the IoHT. | algo/fog-Cloud | Overemphasis on Simulation: The study is largely validated through simulations, which might not fully replicate the complexity of real-world healthcare scenarios. |
| (talaat et al.) [2022][16] | the EPRAM paper significantly advances the understanding and implementation of resource allocation and prediction in fog computing, particularly for smart healthcare systems, by introducing a comprehensive and effective methodology. | PNN,RL/ Fog-Cloud | it lacked specific implementation details. to confirm its effectiveness in real-world healthcare FC deployments. |
| (verma et al.) [2022][28] | combines fog computing with IoT and deep learning to enable efficient healthcare monitoring and diagnosis | Random Forests, Gradient Boosting/Fog-Cloud | does not address dynamic resource allocation strategies effectively. |
| (elhadad et al.) [2022][31] | Immediate notification handling in healthcare monitoring | Algorithmic Pattern Recognition/Fog-Cloud | lacks comprehensive strategies for managing limited computational and energy resources on fog nodes effectively. This could hinder scalability for high-demand healthcare applications |
| (hanumantharaju et al.) [2022][21] | develop a novel fog-based healthcare system for Mechanized Diagnosis of Heart Diseases using ML algorithms | Random Forest, Naive Bayes/Fog-Cloud | -Dynamic Resource Allocation: The dynamic and often unpredictable nature of healthcare demands is not fully accounted for, which could lead to inefficiencies in resource utilization during peak usage periods. -Lack of Real-World Validation |
| (hossain et al.) [2023][26] | Combined CNN and LSTM to identify Cardiovascular disease | CNN, LSTM | Lack of Real-Time Deployment Considerations Neglect of Resource Allocation |
| (sudha et al.) [2023][27] | Combined CNN and LSTM to identify Cardiovascular disease | CNN, LSTM | Deployment challenges include optimizing resources in real-time environments. |
| (elsayed et al.) [2023][29] | intersection of fog computing and modified CNNs in the domain of healthcare image analysis | CNN/Fog-Cloud | Resource Constraints in Fog Computing and need to implement an effective resource allocation strategy |
| (tripathy et al.) [2023][30] | The approach uses a quartet deep learning framework combined with fog and edge computing to process healthcare data closer to the user, reducing dependency on cloud services. | DQN/Fog-Cloud | The paper emphasizes the efficiency of the fog platform but does not delve deeply into adaptive resource allocation strategies. |

| (dritsas et al.) [2024][25] | apply and compare the performance of five well-known Deep Learning (DL) models, to a heart attack prediction dataset. | MLP,CNN,RNN,LSTM, GRU | Computational Overhead: hybrid architectures, are computationally intensive. how these models can be deployed in resource-constrained environments, such as edge or fog computing. |
| (tang et al.) [2024][24] | create a model for detecting diabetes and cardiovascular diseases by integrating AI and IoT | SH-CSO algorithm/Fog-Cloud | The aspect of resource allocation is not addressed, especially given that fog nodes are limited in resources. |
| (dayana et al.) [2024][32] | The paper emphasizes the importance of ML methods for early detection, diagnosis, and prevention, aiming to reduce mortality rates and healthcare costs associated with heart disease | LR,SVM,NB,KNN,RF,GB | The paper does not adequately address the practical limitations of deploying cloud-driven machine learning models in environments with limited resources |
| (amzil et al.) [2024][19] | an ML-based approach to improve health data classification and reduce latency in healthcare systems | k-fold random forest | - Limited Focus on Real-Time Validation - Lack of Dynamic Resource Allocation |

### A. IoT and Sensor Layer

The IoT and Sensor Layer plays a pivotal role in the continuous collection of real-time data from the patient, utilizing a variety of physiological and camera sensors. Physiological sensors continuously monitor key health parameters, including heart rate (HR), blood pressure (BP), and cholesterol levels. The data collected from these sensors serves as the primary input for evaluating the patient's health condition and is subsequently fed into the predictive AI model for heart attack prediction and other critical health assessments. In emergency situations, the camera captures video feeds that offer visual context regarding the patient's physical state. This visual data complements the physiological measurements and enhances the overall understanding of the patient's condition, particularly during critical events.

### B. Edge Computing Layer

The Edge Computing Layer is the central layer in this work, responsible for processing the patient's health data from physiological sensors using an AI model for heart attack prediction. The camera is activated only in critical situations to capture video frames, ensuring privacy. A Deep Q-Network (DQN) model is used to decide whether to process the data locally on the Raspberry Pi or offload it to the Fog Layer, optimizing resource usage. Once processed, all data, including health metrics and video frames, are transmitted from the Fog

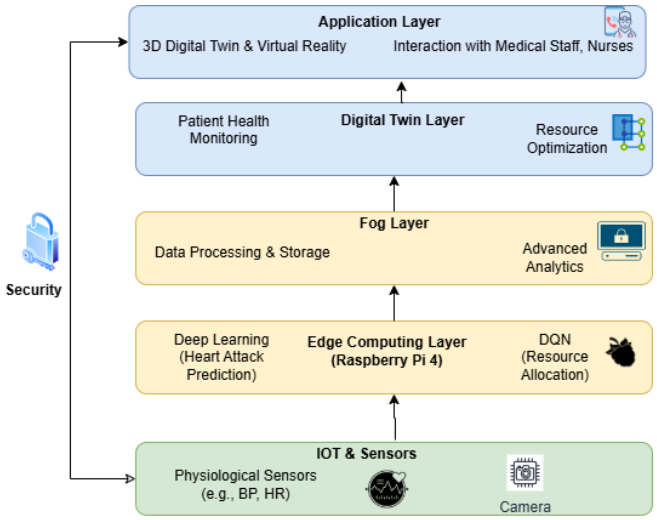

Fig. 1. Multi-layer architecture of the proposed framework for heart attack prediction and resource allocation, integrating IoT sensors, edge computing, fog, and digital twin technology.

or Raspberry Pi to the Digital Twin Layer. This data allows for the continuous update of the virtual model, supporting real-time health monitoring and decision-making.

*1) AI Driven heart attack risk prediction at the edge:* We trained an IA model for heart attack prediction using a hybrid convolutional neural network (CNN) and bidirectional long-short-term memory (BiLSTM) architecture. This model was specifically designed to predict heart attacks based on physiological data, including heart rate, blood pressure, and cholesterol levels. The model was trained and deployed on a Raspberry Pi 4B, which features a quad-core Cortex-A72 processor and 4GB of RAM, providing sufficient computational power for edge-based inference.

*a) Dataset:* In this study, the data set from the UCI machine learning repository dataset is used . Data in the dataset are collected from the Hungarian Institute of Cardiology, Cleveland clinic foundations. It consists of information on patient records both normal and abnormal. This database contains 76 attributes, with a total of 303 observations. The attributes are age, sex, resting blood pressure, cholesterol, etc. And the data set consists of six missing values. In 303 observations, 138 are normal persons, and 165 are abnormal persons, i.e., sufered from heart disease.

*b) CNN-BiLSTM Architecture:* Our proposed hybrid CNN-BiLSTM model leverages Convolutional Neural Networks (CNNs) for feature extraction and Bidirectional Long Short-Term Memory (BiLSTM) layers for sequential learning, effectively capturing both spatial and temporal dependencies to enhance prediction accuracy. The architecture, illustrated in Fig. 2, consists of a CNN layer followed by a dropout of 0.5, a BiLSTM layer with 64 units, and a fully connected layer. The model was trained for 200 epochs with a learning rate of 0.0025, utilizing the softmax activation function.

*c) CNN:* CNN has been effectively used in image processing, face recognition and time series analysis, among other applications[33].It is possible to construct CNN architecture by stacking three primary layers: convolution, pooling, and fully

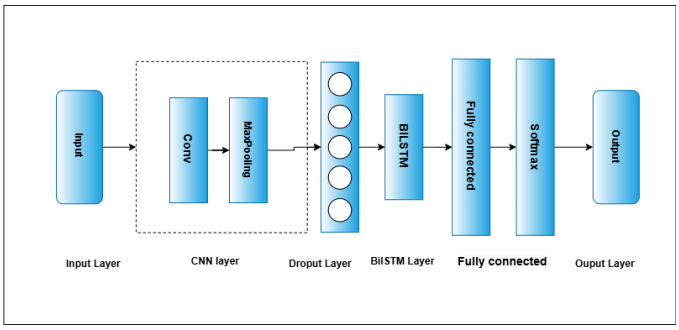

Fig. 2. CNN-BILSTM architecture.

connected (FC). Every convolution layer has a set of learnable filters whose objective is to automatically extract local characteristics from the input matrix using the learned filters. It is possible to minimize the complexity of the computational load and improve model performance by using filters that execute convolution operations based on two essential notions, namely weight sharing and local connection, which may be achieved via filters [34].

*d) BiLSTM:* As an extension to RNNs, Long Short-Term Memory (LSTM) is introduced to remember long input data and thus the relationship between the long input data and output is described in accordance with an additional dimension (e.g., time or spatial location). An LSTM network remembers long sequence of data through the utilization of several gates such as: 1) input gate, 2) forget gate, and 3) output gate. The deep-bidirectional LSTMs (BiLSTM) networks are a variation of normal LSTMs, in which the desired model is trained not only from inputs to outputs, but also from outputs to inputs. More precisely, given the input sequence of data, a BiLSTM model first feed input data to an LSTM model (feedback layer), and then repeat the training via another LSTM model but on the reverse order of the sequence of the input data (i.e., Watson-Crick complement [35].

In this work we proposed A hybrid model for predicting heart disease using CNN and BiLSTM algorithms.

*e) Evaluation metrics:* The model's performance was evaluated using metrics such as accuracy, precision, recall, and F1-score, ensuring its effectiveness in real-time heart attack prediction.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

$$\text{Precision} = \frac{TP}{TP + FP} \tag{2}$$

$$\text{Recall} = \frac{TP}{TP + FN} \tag{3}$$

$$\text{F1} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{4}$$

$$\mathrm{T}_{\text{inference}}(\text{ms}) = \mathrm{T}_{\text{out}} - \mathrm{T}_{\text{inp}} \tag{5}$$

Where:

- $TP$ (True Positive): The number of correctly identified heart attack cases, where the model accurately predicts a heart attack event.
- $FN$ (False Negative): The number of heart attack cases that were not predicted by the model, indicating missed detections of actual heart attacks.
- $FP$ (False Positive): The number of instances where the model incorrectly predicts a heart attack, leading to false alarms for non-heart attack events.
- $TN$ (True Negative): The number of correctly identified non-heart attack cases, where the model accurately predicts the absence of a heart attack.
- $\mathrm{T}_{\text{inp}}$: The timestamp when the physiological data (e.g., heart rate, blood pressure) is fed into the prediction model for analysis.
- $\mathrm{T}_{\text{out}}$: The timestamp when the heart attack prediction result is generated, marking the point at which the model's decision is outputted for clinical assessment.

*2) Allocation resources model using DQN (Deep Q-Network):* Resource allocation in an Edge-Fog environment presents a significant challenge due to the diverse nature of tasks, fluctuating workloads, and the stringent demands for low latency. Achieving an optimal balance between local processing (Edge) and offloading to the Fog requires quick, adaptive decision-making to ensure minimal latency, maximize resource efficiency, and control costs effectively. The Deep Q-Network (DQN) emerges as a promising solution, enabling autonomous learning to make optimal decisions in complex and dynamic environments [36]. In the context of healthcare, particularly in heart attack prediction, intelligent Edge-Fog resource management can enhance prediction accuracy and, more importantly, save lives by ensuring the rapid and reliable processing of critical data.

- DQN Concepts: The Deep Q-Network (DQN) is a reinforcement learning algorithm that combines Q-learning, a table-based control method, with deep neural networks. Q-learning problems are typically framed as Markov Decision Processes (MDPs), which consist of pairs of states ($s_t$) and actions ($a_t$). State transitions occur with a transition probability ($p$), a reward ($r$), and a discount factor ($\gamma$). The transition probability $p$ reflects the likelihood of transitioning between states and receiving associated rewards. According to the Markov property, the next state and reward depend only on the previous state ($s_{t-1}$) and action ($a_{t-1}$)[37]. Traditional Q-learning struggles to handle large-scale or continuous-space MDPs due to the *curse of dimensionality* in the Q-table. To address this issue, DeepMind introduced the DQN algorithm, which approximates the Q-table using deep neural networks. In DQN, the $Q$ value of each action can be predicted by simply inputting the current state ($s_\tau$) into the network, simplifying computation. The DQN uses a deep neural network $Q(s, a; \omega)$, parameterized by weights $\omega$, to approximate the value function $Q(s, a)$. In this framework, the agent is responsible for learning, while the environment provides the interaction context [38]. The primary objective of the agent is to learn optimal actions that maximize cumulative rewards. The agent selects actions ($a_\tau$) and trains the neural network, while the environment updates the state ($s_t$) and computes the reward ($r_t$). The DQN employs two neural networks , the evaluation network (*eval-net*) and the target network (*target-net*), which share the same architecture [39]. The *eval-net* estimates $Q$ values, while the *target-net* provides stable $Q$ values as targets for training. The $Q$ values are updated using a modified Bellman equation:

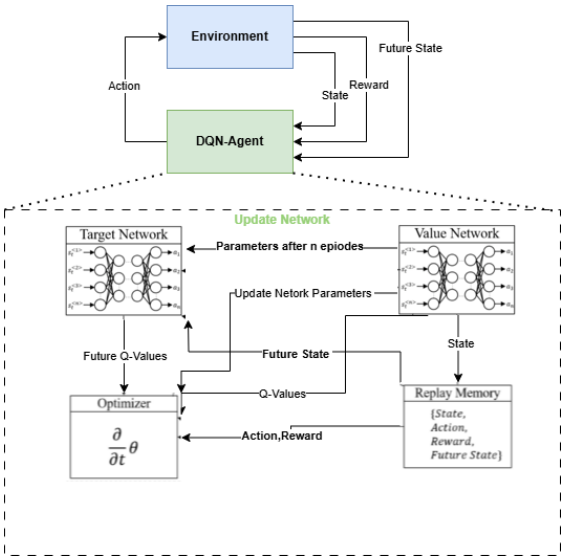

Fig. 3. Concept of DQN.

$$Q'(s_t, a_t) = Q(s_t, a_t) + \alpha \left[ r_{t+1} + \gamma \max_a Q(s_{t+1}, a) - Q(s_t, a_t) \right] \tag{6}$$

where $Q(s_t, a_t)$ and $Q'(s_t, a_t)$ are the current and updated $Q$ values for a given action $a$ in state $s$ at time $t$, $\alpha$ is the learning rate (typically a small positive value), $r_{t+1}$ is the reward received after performing the action, $\gamma$ is the discount factor (close to but less than 1), and $\max_a Q(s_{t+1}, a)$ represents the highest estimated $Q$ value for the next state $s_{t+1}$. This approach allows DQN to learn effectively in complex environments by leveraging the power of deep neural networks. The specific process is shown in figure [3]

- System model and problem formulation: This hybrid model aims to optimize resource allocation in an Edge-Fog Computing environment for an efficient healthcare system. It combines reinforcement learning with the physical constraints of the Raspberry Pi's resources.
- System Variables: ($R_a$, $C_a$, $B_a$) are the resources in RAM, CPU, and Bandwidth, respectively, available on the Raspberry Pi board, ($L_t$) is the maximum

acceptable latency for processing data, $(T_m)$ is the maximum operating temperature of the Raspberry Pi, and $(P)$ is the prediction result (0 = normal, 1 = critical).

- Consumption Variable: $(R_u,\ C_u,\ B_u\ )$ are the resources in RAM, CPU, and Bandwidth, respectively, necessary for local processing, $L_c$ is the current time measure, and $T_c$ is the current temperature of the Raspberry Pi.

The resource constraints to ensure the optimal functioning of the system are given by:

$$\text{RAM: } R_u \le R_a, \quad \text{CPU: } C_u \le C_a, \quad \text{Bandwidth: } B_u \le B_a, \quad \text{Latency: } L_c \le L_t, \quad \text{Temperature: } T_c \le T_m. \tag{7}$$

The reward function $R$ assesses the effectiveness of resource allocation:

$$R = \alpha_1 \cdot \text{RAM\_efficiency} + \alpha_2 \cdot \text{CPU\_efficiency} + \alpha_3 \cdot \text{Bandwidth\_efficiency} - \beta \cdot \text{Latency\_penalty}$$

où :

$$\text{RAM\_efficiency} = \frac{R_a - R_u}{R_a}$$

$$\text{CPU\_efficiency} = \frac{C_a - C_u}{C_a}$$

$$\text{Bandwidth\_efficiency} = \frac{B_a - B_u}{B_a} \quad \text{(si offload vers Fog)}$$

$$\text{Latency\_penalty} = \max(0, L_c - L_t)$$

The coefficients $\alpha_1$, $\alpha_2$, $\alpha_3$, and $\beta$ are adjusted according to the relative importance of the resources. The allocation decision $a$ is made as follows:

- If all constraints are satisfied locally:

$$R_u \le R_a, \quad C_u \le C_a, \quad T_c \le T_m, \quad B_u \le B_a, \quad L_c \le L_t. \tag{8}$$

  then $a = 0$ (Local processing).

- Otherwise, if one or more constraints are not satisfied, or if the reward is lower locally, then $a = 1$ (Transfer to Fog).

Require: Discount factor $\gamma$, exploration rate $\epsilon$, replay memory capacity $P$, heart attack prediction model $HA\_model$, DQN model $DQN\_model$.

### C. Fog Layer

In our system, after the Deep Q-Network (DQN) model runs on the Raspberry Pi to determine whether data should be processed locally or offloaded, the Fog Layer becomes essential. When the Raspberry Pi is unable to process more complex data, such as video frames captured by the camera, it transmits this data to the Fog Layer. The Fog Layer then processes these larger, more computationally demanding

**Algorithm 1** DQN-Based Resource Allocation for Heart Attack Prediction (DQNRAP)

Initialize replay memory $D$ to capacity $P$.
Initialize evaluation network with parameters $\theta$.
Initialize target network with parameters $\theta' = \theta$.
Connect to Azure IoT Hub for Digital Twin synchronization.
Configure interval $T_{pred} = 0.1$ sec, buffer size $N_{threshold} = 2$.
Initialize camera to standby mode.
**for** each episode $k$ **do**
    Initialize initial state $s_1$ by collecting sensor data (IMU, temperature, heart rate).
    **for** each step $t$ **do**
        Collect real-time sensor data $Inputdata$.
        Predict heart attack status:

$$prediction = HA\_model.predict(Inputdata)$$

        Threshold Prediction:

$$heart\_status = \begin{cases} 1 & \text{if } prediction > 0.5 \quad \text{(Critical)} \\ 0 & \text{otherwise (Normal)} \end{cases}$$

        Update Buffer with $heart\_status$.
        **if** $\sum(buffer[-N_{threshold}:]) = N_{threshold}$ **then**
            Activate camera for 1-minute video capture.
            Set $camera\_status = 1$.
        **end if**
        Construct State:

$$s_t = [RAM, CPU, Latency, Bandwidth, Temperature]$$

        Generate random number $h \in [0, 1]$.
        **if** $h < \epsilon$ **then**
            Randomly select action $a_t$.
        **else**
            $a_t = \arg\max_a Q(s_t, a; \theta)$.
        **end if**
        Execute action $a_t$ (local processing or fog offloading).
        Observe reward $r_t$ and next state $s_{t+1}$.
        Store Transition $(s_t, a_t, r_t, s_{t+1})$ in $D$.
        Update Evaluation Network (Algorithm 2).
        **if** $t\%C == 0$ **then**
            Reset Target Network: $\theta' = \theta$.
        **end if**
        Synchronize data with Azure IoT Hub:

$$payload = \{timestamp,\ heart\_status,\ camera\_status,\ RAM,\ CPU,\ Latency,\ Bandwidth,\ a_t\}$$

    **end for**
**end for**

**Algorithm 2** Evaluation Network Update

1: Sample mini-batch $(s, a, r, s')$ from $D$.
2: Compute target $Q'$ value:

$$Q' = r + \gamma \max_{a'} Q(s', a'; \theta')$$

3: Update $Q$-network by minimizing loss:

$$Loss = (Q(s, a; \theta) - Q')^2$$

**Algorithm 3** Routing Decision

1: **if** $a_t = 1$ **then**
2: Process video locally (Raspberry Pi).
3: **else**
4: Offload data to Fog.
5: **end if**

datasets, enabling efficient data handling and ensuring that the local resources are not overwhelmed. This approach optimizes the overall system performance by leveraging the Fog Layer's ability to handle more intensive computations.

### *D. Digital Twin Layer*

The Digital Twin Layer generates a real-time virtual model of the patient, continuously updated with data from IoT sensors to monitor health status and optimize resource allocation. Leading cloud platforms, such as Amazon Web Services (AWS) and Microsoft Azure, offer solutions for building digital twins. In our work, we utilize Azure * to develop a digital twin that simulates the patient's heart condition, visualizing processed data from the camera and storing historical records. This enhances overall system prediction accuracy and improves resource allocation through predictive analytics. The Fig. 4 represents a JSON program fragment of the prediction of the IA heart attack model and also the resource allocation if data of camera will be processed at edge or transferred to the fog.the digital twin will be used to monitor the heart status and control the process of data between the edge and the fog computing .

### *E. Application Layer*

The Application Layer leverages 3D digital twin models and virtual reality to enhance patient monitoring and emergency response. The digital twin continuously updates with real-time data, providing a visual representation of the patient's heart condition. When critical situations are detected, the system automatically notifies medical staff and family members for immediate intervention. Beyond monitoring, the digital twin plays a vital role in refining the heart attack prediction and resource allocation models by analyzing historical data and improving decision accuracy. This ensures better healthcare management and faster response in emergencies.

## IV. Results and Discussion

### *A. Result of Heart Attack Prediction Model*

This section presents the experimental results obtained from testing the heart attack prediction model on both a PC and edge devices. Initially, the CNN-BiLSTM model was evaluated on the PC to assess its performance. Following this, the model was transferred to the Raspberry Pi 4B, where its accuracy, size, and inference time were validated.

TABLE II. Classification Report for the Heart Attack Prediction Model

| Class | Precision | Recall | F1-score |
|---|---|---|---|
| 0 | 0.9722 | 1.0000 | 0.9859 |
| 1 | 1.0000 | 0.9608 | 0.9800 |
| **Accuracy** | | 0.9835 | |
| **Macro avg** | 0.9861 | 0.9804 | 0.9830 |
| **Weighted avg** | 0.9839 | 0.9835 | 0.9834 |

The results presented in Table II, Fig. 5, and 6 highlight the performance of our model, which achieved an overall accuracy of 98.35%. As shown in the confusion matrix in Fig. 5), the model correctly classified all instances of Class 0, resulting in a perfect classification rate of 100%. However, Class 1 achieved a slightly lower accuracy of 96.08%, with 3.92% of instances misclassified as Class 0.The classification report in Table II further demonstrates the effectiveness of our trained model. For Class 0 (No Attack), the precision is 97.22%, recall is 100%, and the F1-score is 98.00%. For Class 1 (Heart Attack), the model achieves a precision of 1.000, recall of 96.08%, and an F1-score of 98.00%.The macro and weighted averages further confirm that the model handles both classes effectively, exhibiting minimal bias while maintaining high precision, recall, and F1-scores. Additionally, the ROC curve Fig. 6 showcases the model's near-perfect ability to distinguish between the two classes, with an impressive Area Under the Curve (AUC) of 0.99.

*1) Comparison of proposed heart attack prediction models with related works:* To validate the effectiveness of our proposed hydrid CNN-BiLSTM heart attack prediction model, we compared it with existing models in the literature. This

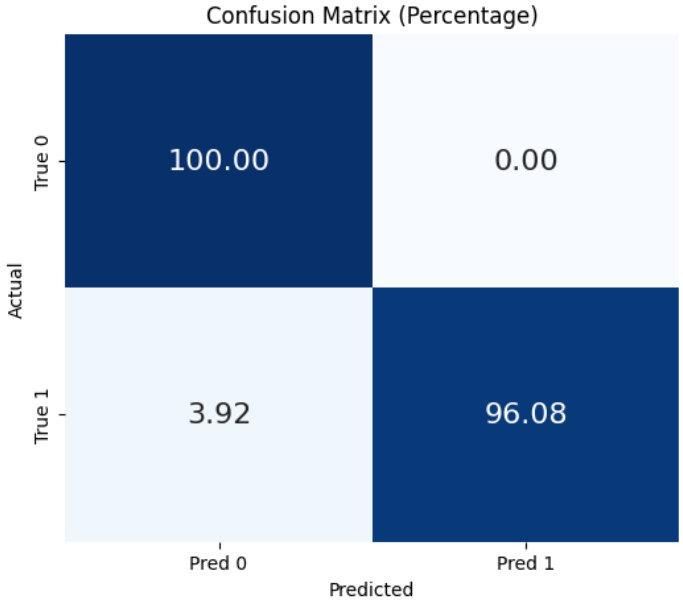

Fig. 5. Confusion matrix for the heart attack prediction model.

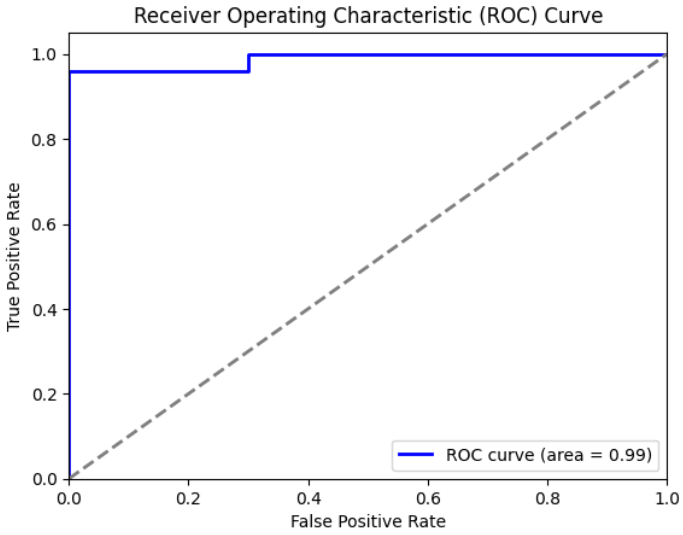

Fig. 6. Confusion matrix for the heart attack prediction model.

comparison highlights differences in model architectures using the same data set. Table III summarizes the results of the comparison using the accuracy metric of key related works.

*2) Comparison of heart attack prediction models using the same Cleveland dataset:* The results in III indicate that our proposed CNN-BiLSTM model achieves superior accuracy compared to traditional architectures, benefiting from the combination of convolutional and bidirectional long short-term memory (BiLSTM) layers. This hybrid architecture enhances feature extraction and temporal modeling, leading to more precise predictions.

## B. Result of Allocation Resource Model Using DQN

The result of Fig. 7 shows the evolution of average cumulative rewards over episodes in the DQN model. Initially, the agent receives low rewards, but gradually improves its decisions. After approximately 200 episodes, the rewards stabilize around 50, indicating that the agent has learned an optimal strategy and that its learning process has effectively converged. Fig. 8 represents the decay of epsilon $\epsilon$, a key parameter in DQN that regulates the balance between exploration and exploitation.

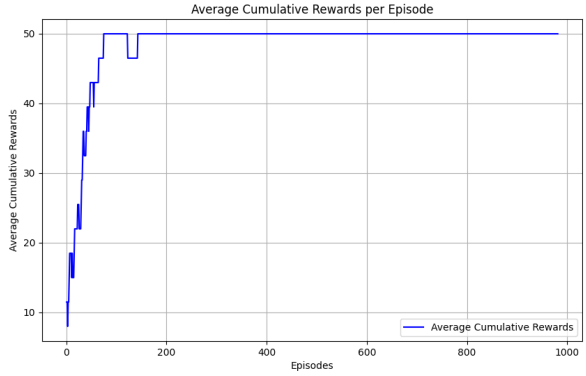

Fig. 7. Average cumulative rewards.

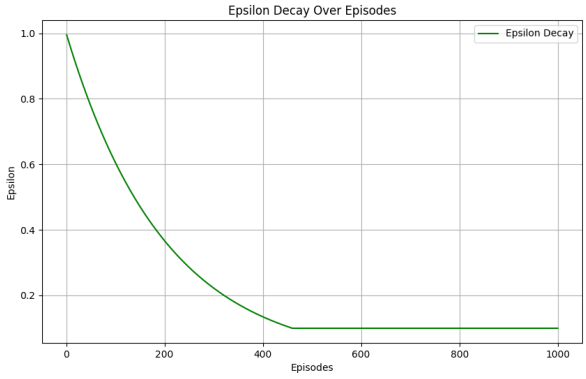

Fig. 8. Epsilon decay.

At the beginning, $\epsilon$ is high ($\sim 1$), allowing the agent to explore various actions. As training progresses, $\epsilon$ decreases, encouraging the agent to rely more on decisions that have produced the best rewards. After ($\sim 400$) episodes, $\epsilon$ becomes very low, which means that the agent has learned enough

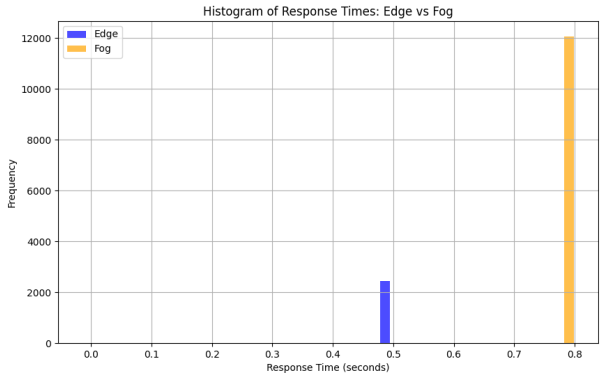

Fig. 9. Response times.

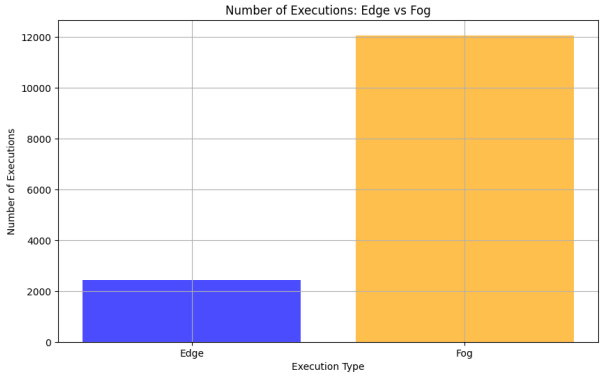

Fig. 10. Execution count.

and now relies primarily on optimal choices. These two main results complement each other: the decrease in $\epsilon$ explains the stabilization of cumulative rewards, confirming that the DQN model learns progressively, efficiently and optimally.

The study 9 displays a response time histogram comparing Edge and Fog processing. The Edge responses are significantly faster (0.5s), whereas Fog responses take longer (0.8s), indicating a higher processing delay in the Fog environment. The 10 shows that the majority of executions (over 12,000) take place in the Fog, compared to only 2,500 in the Edge.

### C. Discussion

The results indicate excellent performance of the prediction model based on a hybrid CNN-BiLSTM network, with high precision and reliability metrics (see Fig. 5 and Fig. 6). This level of performance is crucial in critical scenarios such as cardiac event prediction, where false negatives could have severe consequences.In terms of resource allocation, the Deep Q-Network model demonstrates fast and efficient learning capabilities (Fig. 7 and Fig. 8), dynamically adapting to maximize system performance. Most processing decisions were offloaded to the Fog (Fig. 10), which suggests that critical tasks require more computing power than what is available at the Edge. Regarding latency, the results in Fig. 9 show that the proposed approach ensures fast processing—an essential factor in real-time medical monitoring scenarios. By integrating artificial intelligence and deep learning techniques into a Fog/Edge architecture, the system succeeds in ensuring both diagnostic accuracy and responsiveness while optimizing resource utilization.

## V. Conclusion and Future Work

In this study, we proposed an intelligent and adaptive system for real-time cardiac event prediction and resource allocation in Edge-Fog Computing environments. By integrating a deep learning-based CNN-BiLSTM model for heart attack prediction and a Deep Q-Network (DQN) for dynamic resource management, our approach demonstrates the potential to enhance real-time monitoring and response efficiency in healthcare applications. Furthermore, the incorporation of digital twins into our architecture enables continuous system optimization and predictive analysis, reinforcing the reliability and adaptability of the proposed framework. Experimental results indicate that our model effectively manages workload distribution, reduces latency, and improves decision-making for critical healthcare scenarios. The ability to dynamically allocate resources between edge and fog computing environments ensures optimal system performance, even under fluctuating workloads. Our approach is highly relevant to the context of Mauritania, where cardiovascular diseases represent a significant public health challenge. It also aligns with the national goal of reducing the mortality rate from these diseases by 33% by 2030.

Future work will focus on enhancing the system's capabilities by developing an AI model at the fog level to process video data transferred from edge devices, optimizing real-time analysis and reducing latency. Additionally, we aim to improve the digital twin component to refine AI model efficiency and enhance system adaptability, leading to better overall performance. To further strengthen privacy and scalability, we will incorporate federated learning techniques, enabling decentralized model training without compromising sensitive patient data. Ultimately, our research paves the way for a more responsive and intelligent healthcare infrastructure, capable of providing real-time cardiac monitoring with high accuracy while optimizing computational resources effectively.

# Predicting Multiclass Java Code Readability: A Comparative Study of Machine Learning Algorithms

Budi Susanto, Ridi Ferdiana, Teguh Bharata Adji
Department of Electrical and Information Engineering-Faculty of Enginering,
Universitas Gadjah Mada, Indonesia

***Abstract*—The classification of program code readability has traditionally focused on two target classes: readable and unreadable. Recently, it has evolved into a multiclass classification task in three categories: readable, neutral, and unreadable. Most of the existing approaches rely on deep learning. This study investigated the multiclass classification of Java code readability using four feature metric datasets and 14 supervised machine learning algorithms. The dataset comprises 200 labeled Java function declarations. Readability features were extracted using Scalabrino's tool, generating three datasets: Scalabrino, Buse-Weimer, a combined set (Dall), and a fourth (Dcorr) via feature selection based on interfeature correlation. Each model underwent hyperparameter tuning via a Randomized Search and was evaluated through 30 iterations of a five-fold cross-validation. Scaling techniques (MinMax, Standard, Robust, and None) were also compared. The best performance, with an average accuracy of 61.1% and minimal overfitting, was achieved by Random Forest with MinMax scaling on Dcorr. Feature importance analysis using permutation methods identified 22 key metrics related to comments: code complexity, syntax, naming, token usage, and density. Despite its moderate accuracy, the findings offer valuable insights and highlight essential features for advancing code readability research.**

***Keywords*—Code readability; machine learning; multiclass classification; hyperparameter tuning; future selection**

## I. Introduction

Reading source code is common for software developers, and readability significantly affects the software quality [1]. While readability pertains to the ease of reading code syntax, comprehensibility involves understanding code semantics [2]. These two concepts are related, but distinct, and readability may fluctuate throughout the software lifecycle, thereby affecting comprehensibility [3].

Automated classification methods have been widely used to predict code readability, typically categorizing it as "readable" or "unreadable." Various machine learning techniques, such as Logistic Regression, Bayesian Networks, Perceptron, Random Forest, and Support Vector Machines (SVM), have been applied to classify code readability into two labels, as demonstrated by researchers such as Buse and Weimer [4] and Scalabrino et al. [5].

Posnett et al. [6] developed a regression model for classifying source code readability into two classes. Dorn [7] also utilized logistic regression to determine the weights of various features to construct a readability metric model for source code. Mi et al. [8]–[10] further explored convolutional neural network (CNN)-based architectures and hybrid neural network models for two-class readability classifications.

Recent advancements have extended the readability classification into three categories: "readable," "neutral," and "unreadable" [11]. Mi et al. [11], [12] employed convolutional neural networks (CNNs) and graph neural networks (GCNs) for this task. The GCN model achieved state-of-the-art accuracy, reaching 72.5% for a three-class classification [11]. These models were trained on a Java corpus from Scalabrino et al. [13] containing 200 Java function declaration snippets. Overall, the research findings indicate that deep learning-based methods outperform traditional machine learning approaches in terms of readability classification accuracy.

However, existing comparative studies have predominantly focused on binary readability classification tasks. In contrast, limited attention has been given to the more complex three-class readability classification, which involves categorizing code as "readable," "neutral," or "unreadable." The state-of-the-art model addressing this task proposed by Mi et al. [11] employs a Graph Neural Network (GNN) framework. The research gap lies in the insufficient exploration of alternative machine learning classification approaches for this three-class problem, which may offer competitive or complementary performance to GNN-based methods. In light of this, further empirical investigation is warranted to evaluate the effectiveness of diverse machine learning algorithms in handling multiclass code readability classification.

This study comprehensively evaluated 14 classification methods applied to several code readability metrics: Buse and Weimer (BW), Scalabrino (Scal), and a combination of BW, Scal, and Posnett metrics. To enhance the classification performance, we employed two feature selection methods: one based on feature correlation and its relationship with target classes, and another based on the importance scores derived from the best-performing classification method. The dataset used in this experiment consisted of Java code snippets from Scalabrino et al. [13], which were categorized into three readability classes by Mi et al. [11] with a 1:2:1 ratio for readable, neutral, and unreadable classes. Each classification method was optimized for hyperparameter tuning using a Randomized Search method. Huyen [14] stated that the random search method is a form of soft AutoML.

This study aimed to address two key research questions: RQ1: Which classification method performs best? We investigated 12 classification methods and two calibration techniques for the Gaussian Naïve Bayes classifier to classify the Java corpus from Scalabrino et al. into three readability classes established by Mi et al. The evaluation metrics used included the accuracy and weighted F1 scores. Our analysis aims to provide a comparative overview of the performance of three-class

readability classifiers in state-of-the-art models [11]. RQ2: Which features contribute the most to the best-performing classification method? The most important features were based on the best-performing model in the three-class readability classification for each classification method. Identifying these key features will be the foundation for developing improved source code readability metrics.

The remainder of this paper is organized as follows. The background and related works in Section II reviews the related literature, focusing on previous research in program code readability classification, particularly multiclass classification approaches using machine learning techniques. The methodology in Section III outlines the methodology, details the dataset used, classification models applied, and evaluation framework. The results and discussion in Section IV presents the experimental results and discussion of the findings, including a comparative analysis of the classification performance. The conclusion in Section V concludes the study by summarizing key insights, highlighting contributions, and suggesting directions for future research.

## II. Background and Related Works

### A. Code Readability Metrics

Evaluating code readability is a complex challenge because of its inherently subjective nature. Various metrics that consider factors such as code size, entropy, and structural properties have been proposed [6]. However, these metrics often fail to align with developers' perceptions of readability improvements [15]. Fakhoury et al. [15] utilized Scalabrino's, Dorn's, and combined Buse-Weimer and Posnett metrics to classify code readability based on changes made by programmers. Their findings suggested incorporating additional features, such as the number of incoming invocations and code styling elements, into code readability metrics.

Furthermore, textual features such as identifiers and comments have been shown to provide valuable supplementary information beyond structural characteristics [13]. Other factors, including coding style, application domain [16], structural constraints, and programming paradigms (e.g., reactive programming) [17] also influence readability assessments. Moreover, further evidence is required to clarify the impact of specific attributes, such as code size, complete-word identifiers, and comments, on readability and understandability [18]. These challenges underscore the need for more versatile and adaptive readability metrics from the perspectives of various programming styles and developers.

Predicting the readability of source code involves extracting several features from code snippets, collectively referred to as code readability metrics. Extensive research has been conducted to develop readability metrics. Buse and Weimer [4] focused on structural characteristics, whereas Dorn [7] introduced visual and spatial (metric based) characteristics. Scalabrino et al. [5] extended these metrics by incorporating textual characteristics. Alawad et al. [19] enhanced Buse and Weimer metrics using text readability metrics such as the Automated Readability Index (ARI). Mi et al. [9] defined readability features in terms of visual, structural, and semantic characteristics that are represented as embedding vectors. Additionally, Mi et al. [11] introduced a representation combining Abstract Syntax Tree (AST) graphs with data and control flow extracted from the source code.

Buse and Weimer defined 25 attributes to develop a readability classification model, categorizing readability into two classes: more and less readable. Posnett et al. [6] simplified Buse and Weimer's parameters into three attributes to construct a readability weight-based model. Dorn [7] identified approximately 59 code attributes, focusing on visual, spatial, and linguistic aspects. Scalabrino et al. [5] defined 20 attributes related to the textual properties and structural characteristics. Choi et al. [20] proposed seven attributes for linear regression modeling to derive readability weights for the source code. Mi et al. [21] extracted character-level, token-level, and node-level representations of the source code and applied them within a Convolutional Neural Network (CNN). Mi et al. [9] further advanced this approach by extracting visual codes, tokens, segment embeddings, and character metric representations for structural modeling. Readability classification models have been applied to two primary categories: readable and unreadable.

### B. Methods for Measuring Code Readability

Several manual and heuristic methods have been developed to assess the readability of program codes. Although these methods are not explicitly designed for readability measurement, they provide approaches for evaluating code complexity, maintainability, and human-scale readability indicators. Some of these methods include syntactic-based metrics, such as variable length, lines of code (LOC), and cyclomatic complexity, which serve as potential indicators for measuring code readability, and structure and logic-based metrics, which evaluate code readability by analyzing the structural aspects of the code, including loops, branching, and function separation.

Well-structured modular code is generally easier to read and understand. Several types of metrics are commonly used to evaluate readability. Rule-based metrics focus on adherence to coding conventions, such as the use of descriptive variable names, consistent formatting, and sufficient comments [22]. Tools such as Checkstyle[1] and Pylint[2] automatically check and enforce these rules. Complexity metrics assess the readability by measuring the logical complexity of a code. For example, Halstead metrics estimate how difficult it is for a program to understand and maintain, whereas cognitive complexity metrics [23] account for factors such as deep nesting and long conditional statements that may make it harder to follow. Among the complexity metrics and code readability metrics, Tashtoush and Darwish [24] asserted that there is an influence between these two metrics. This empirical study explored the bidirectional relationship between code readability and software complexity by using 12,180 Java files from the Eclipse project. By applying machine learning models, particularly decision trees, to 25 readability features (based on Buse and Weimer) and seven complexity metrics, the study achieved over 90% accuracy in predicting how readability influences complexity and vice versa. Key contributing factors include formatting-related features (e.g., indentation and character usage) and complexity measures such as Halstead volume.

[1] https://checkstyle.sourceforge.io/
[2] https://www.pylint.org/

This study also challenges prior assumptions by showing that readability features are influenced by code size, thereby offering new insights into improving software quality and maintainability.

Finally, human-scale indicators rely on developers direct assessments of code readability. These evaluations are often used as training data for machine learning models that aim to automatically predict code readability [4], [13]. These approaches seek to align readability metrics with how developers perceive the code quality. To capture what programmers do to make source code more readable, Roy et al. [25] analyzed the history of programmer code changes. This study introduces a machine learning model that detects incremental readability improvements in source code aligned with developer perceptions. Trained on 2,781 manually validated Java file changes, the model leveraged static code metrics before and after commits and achieved 79.2% precision and 67% recall. Key insights reveal that readability improvements typically involve modifications to existing lines, whereas non-readability changes add new lines. This study lays the groundwork for integrating readability scoring into code review tools to support more efficient evaluation of code changes. Future research could explore how large language models influence code readability [26] as well as the development of more advanced readability models that adapt to the continual evolution of software development practices.

## III. Methodology

Fourteen machine learning algorithms for multiclass classification of code readability were evaluated using a dataset of 200 Java code snippets from Scalabrino et al. [13], which were categorized into three readability classes by Mi, et al. [11]. Mi et al. used a systematic approach to establish three categories of code readability in their study. This study used a dataset originally compiled by Scalabrino et al. [13] consisting of 200 code fragments extracted from four open-source Java projects: jUnit, jHibernate, jFreeChart, and ArgoUML. These fragments ranged from 10 to 50 lines of code and were free of syntax errors, ensuring that the readability evaluation was unaffected by syntax or compilation issues.

The dataset was then divided into three readability groups based on Scalabrino's readability score: easy to read (top 25%), difficult to read (bottom 25%), and neutral (middle 50%). This classification follows a 1:2:1 ratio, allowing for meaningful comparison with Scalabrino's two-class readability distribution. Additionally, this distribution more accurately reflects real-world scenarios, in which neutral readability is more common than extreme readability or legibility.

From these 200 Java code snippets, a set of readability metric values were derived based on the readability metrics proposed by Scalabrino, Buse-Weimer, and Posnett. These metric values were computed using the Readability Assessment Tool[3] provided by Scalabrino et al. [5]. Scalabrino's tool generates 110 attributes representing values from the Scalabrino, Buse-Weimer, Posnett, and Dorn models. Upon analysis, it was found that 12 of Dorn's 59 attributes had over 41.5% missing values across 200 data points. Consequently, Dorn's attributes and readability score attributes from the Scalabrino, Buse-Weimer, and Posnett models were excluded, leaving 48 attributes for the classification experiment. The combined dataset with the 48 selected attributes was labeled as $D_{all}$.

[3]https://dibt.unimol.it/report/readability/files/readability.zip

TABLE I. Metrics with > 10% Outliers among 200 Samples

| No. | Attribute | % outlier data |
|---|---|---|
| 1 | Scalabrino.expression_complexity_maximum | 41.0% |
| 2 | Scalabrino.number_of_senses_maximum | 27.5% |
| 3 | BW.loops_average | 23.0% |
| 4 | BW.comments_average | 14.5% |
| 5 | Scalabrino.abstractness_words_maximum | 14.5% |
| 6 | BW.operators_average | 13.0% |
| 7 | Scalabrino.commented_words_average | 11.0% |

Based on the definition of $D_{all}$ metric features, this study created another dataset containing the definition of a series of feature metrics based on the scalabrino model ($D_{scal}$ uses 20 feature metrics) and Buse-Weimer model ($D_{bw}$ uses 25 feature metrics). Both feature metric definitions are subsets of the entire metric feature set. The purpose of this is to measure how well the Scalabrino and Buse–Weimer models perform in multiclass code readability classification.

Regarding the characteristics of the $D_{all}$ dataset with 200 data points and 48 attributes when analyzed using the Interquartile Range (IQR), seven metric attributes (14.58%) can be said to have outlier data of more than 10%. Table I displays the seven metric attributes whose data had more than 10% detection as outliers. One approach that can be applied to handle outlier data is data scaling [27]. Therefore, this study applies a configuration with three scaling techniques: Standard, Minmax, and Robust.

Fig. 1 illustrates the workflow of the classification experiment. The process begins with the formation of a dataset using Scalabrino et al.'s Readability Assessment Tool, applied to a corpus of Java code snippets categorized into three readability classes by Mi et al. [11]. This recalculation is necessary to ensure that the attribute values are derived directly from the code snippet dataset, which consists of function declarations written in Java. The tool generates attribute values based on the readability metrics proposed by Scalabrino, Buse, Weimer, and Posnett. The generated values were then converted into a CSV file. The final dataset consists of attribute values and three corresponding readability class labels.

Based on $D_{all}$, this study calculates the correlation between each attribute, including the target classification label. This feature correlation analysis step was performed to identify highly correlated metric features. Attribute analysis of the combined dataset $D_{all}$ was performed by examining the correlation value between its attributes. Correlation-based attribute selection uses the minimum correlation value as the constraint ($\geq$ 0.4 or $\leq$ -0.4) as a strong correlation between any two attributes. This constraint is based on a study by Diesing [28], which recommends a minimum correlation of 0.4 0.5. The selected attributes with error values ($\geq$ 0.4 or $\leq$ -0.4) were not unique, but duplicate attributes existed. Of the duplicated attributes selected with the highest correlation value, so in the end, we obtained as many as 35 attributes. This resulted in an additional dataset $D_{corr}$ (35 attributes), which contains only strongly correlated features.

Each dataset, that is, $D_{all}$, $D_{scal}$, $D_{bw}$, and $D_{corr}$, was pro-

cessed using different data pre-processing scaling techniques, including MinMax, Standard, Robust, and without scaling (none). For each dataset with or without scaling techniques, Randomized Search [29] was employed to optimize the hyperparameters of each of the 14 classification algorithms. Cross-validation was performed using five-fold cross-validation for each validation and testing phase.

For each dataset, before entering the process of building a classification model using the 14 classification algorithms, training and testing sets were formed. From the 200 sets of metrics, we divided the dataset into 80% (160 data points) for training and 20% (40 data points) for testing. We split the datasets for training and testing using the `train_test_split()` function with the stratification parameter to maintain the proportion of classes in the training and testing sets.

The 14 classification algorithms can be broadly categorized based on their underlying approach. Tree-based models, including Random Forest (RF) [30] and Decision Tree (D3) [31] models, are known for their ability to handle nonlinearity in data without requiring feature scaling. Distance-based models, such as k-Nearest Neighbors (KNN) [32] and Support Vector Classifier (SVC) [33], rely heavily on the measurement of feature distances, making them particularly sensitive to scaling transformations. Probabilistic classifiers, including Gaussian Naïve Bayes with Isotonic Calibration (GNB-Isotonic), Gaussian Naïve Bayes with Sigmoid Calibration (GNB-Sigmoid), and Gaussian Naïve Bayes (NB) [34], [35] function under the assumption of feature independence and may benefit from certain types of pre-processing. Linear models, such as Logistic Regression (LogReg) [36], Linear Discriminant Analysis (LDA) [37], [38], Perceptron [39], Perceptron optimization based on Stochastic Gradient Descent (SGD) [39, p. 43-46], and Passive-Aggressive Classifier (PA) [40], assume linear relationships between features and classes and typically require scaling to enhance numerical stability. Bayesian and quadratic models, such as Quadratic Discriminant Analysis (QDA) [41]. Finally, neural network-based methods, such as Multi-Layer Perceptron (MLP) [42], rely on gradient-based optimization, which is highly sensitive to feature magnitudes.

The execution of the Randomized Search for each algorithm was repeated 30 times. Using 30 iterations in a Randomized Search provides a pragmatic balance between computational efficiency, a thorough exploration of the hyperparameter space, and model robustness. This implementation ensured that the best-performing model was selected without incurring excessive computational costs, thus making it a well-justified approach for this classification experiment.

The flowchart (in Fig. 2) illustrates a structured approach for training and selecting an optimal classification model using Randomized Search. The process began by splitting the dataset into 80% training and 20% testing to ensure that unbiased evaluation. Both subsets underwent a scaling transformation to standardize the feature magnitudes, thereby enhancing the model performance. A diverse set of classification algorithms—including SVM, Logistic Regression, k-NN, LDA, QDA, Gaussian Naïve Bayes, Decision Trees, MLP, Random Forest, Perceptron, SGD, and Passive Aggressive classifiers— was prepared for evaluation, employing 5-fold cross-validation to ensure robust assessment. An iterative loop

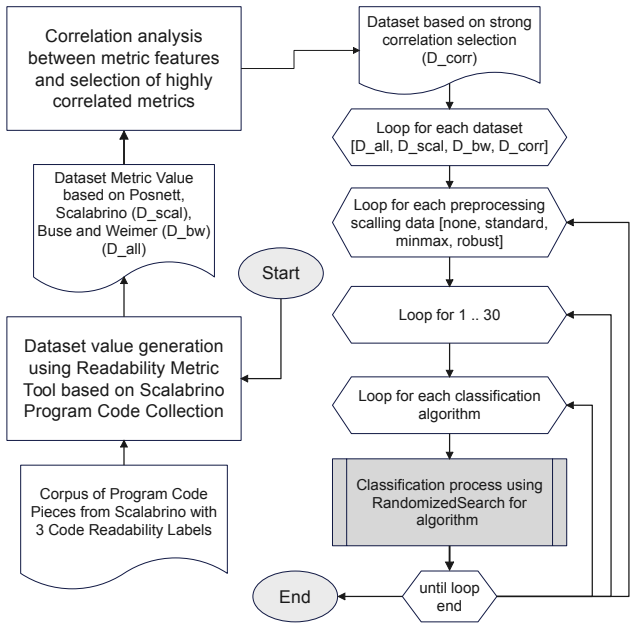

Fig. 1. The process flow for testing the 3 readability class classification.

executes Randomized Search for each classifier to optimize the hyperparameters efficiently.

Following training, cross-validation scores were measured to assess the generalization ability of the model and detect potential overfitting. Overfitting detection was performed to determine whether the best model generated by the algorithms was overfitted. This study implemented a quantitative method to assess whether a trained machine learning model overfits by comparing its performance on cross-validation and test data. Eq. (1) shows the conditions for detecting overfitting by using the quantitative method applied in this study.

$$\frac{|\text{mean\_cv\_score} - \text{mean\_test\_score}|}{\text{mean\_cv\_score}} > 0.10 \qquad (1)$$

The if condition in the given overfitting condition establishes a threshold-based criterion for detecting overfitting in the trained classification model. It evaluates the relative difference between the mean cross-validation score (mean_cv_score) and test score (test_score). Specifically, the condition checks whether the absolute difference between these scores, normalized by the mean cross-validation score, exceeds 10% (0.10). If this condition holds, the model is considered overfitting, indicating that it performs significantly better on the training data during cross-validation than on the independent test set, suggesting poor generalization. Conversely, if the relative difference remains within the 10% threshold, the model is deemed not to overfit, implying a balanced performance between the training and testing phases. This approach provides a quantitative measure for assessing the generalization ability of a model beyond the training dataset.

The best-performing model, determined based on the cross-validation performance, was then tested on the scaled testing dataset for the final validation. The selected model represents the most effective classification approach for a given dataset,

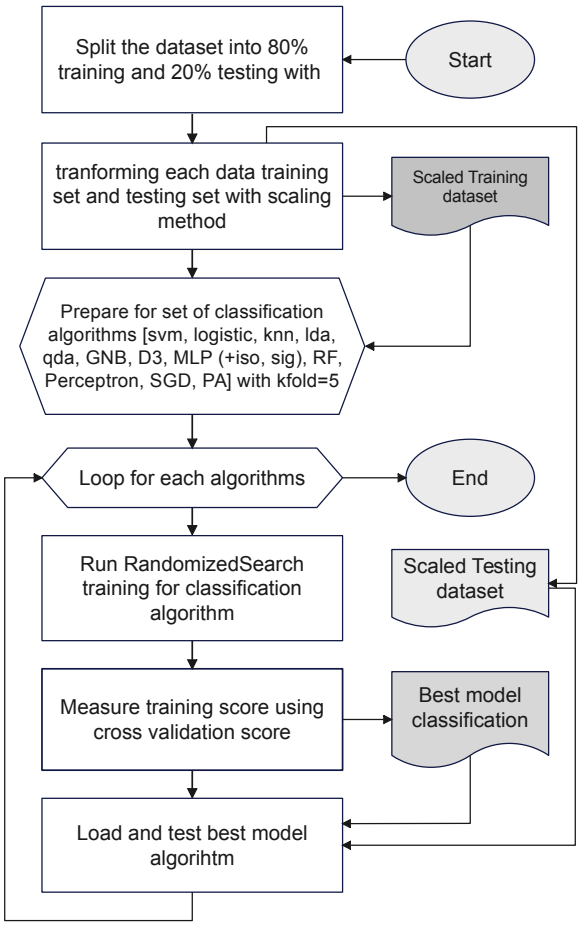

Fig. 2. The process flow for classification process with parameter optimization.

ensuring optimized accuracy and reliability in classification tasks. This workflow establishes a reproducible methodology for systematic machine learning model selection and evaluation.

## IV. Result and Discussion

### A. Classification Performance Results

After performing 30 iterations of the classification process for each of the 14 classification algorithms using Randomized Search across four datasets ($D_{all}$, $D_{scal}$, $D_{bw}$, and $D_{corr}$) with four different scaling configurations (without scaling, standard, min-max, and robust), the average accuracy and weighted F1-score were computed. An analysis was conducted to determine whether the classification model exhibited overfitting by evaluating the difference between the average cross-validation score and the test accuracy for each iteration.

In this study, the best average accuracy was obtained when the overfitting ratio did not exceed 6.67% (i.e., no more than two overfitting occurrences out of 30 iterations). For instance, in the case of the GNB-Isolate method, the best average accuracy was chosen as 0.53 with an overfitting ratio of 0% when using MinMax Scaling, rather than an average accuracy of 0.6 with an overfitting ratio of 100% when using Standard Scaling. Table II presents the results of the selection of the highest average accuracy while ensuring compliance with the overfitting threshold. Fig. 3 presents the optimal average accuracy of 14 classification algorithms under different data-scaling techniques: MinMax, Standard, Robust, and no scaling (none). The performance of each method is depicted using bar plots, in which the highest accuracy values for each classifier are highlighted numerically above the respective bars.

The exploration of 14 classification algorithms optimized using a Randomized Search revealed that the dataset $D_{corr}$ serves as the most optimal alternative for multiclass code readability classification. The $D_{corr}$ dataset comprises a selected set of combined metric features derived from the correlation analysis among the Scalabrino, BW, and Posnett metric groups. Based on the classification results, it can be inferred that the 48 combined metrics could be effectively represented by 35 attributes (approximately 73%).

By analyzing the best average accuracy across all classification algorithms, the dataset distribution based on scaling configurations indicated that $D_{corr}$ contributed to 42.86% (six algorithms) of the best accuracy results among the 14 classification algorithms, followed by $D_{bw}$ at 35.71%, $D_{all}$ at 14.29%, and $D_{scal}$ at 7.14%. However, when factoring in the overfitting constraint, where only one to two occurrences of overfitting are acceptable within 30 iterations, certain algorithms, including MLP, Perceptron, D3, SGD, and PA, cannot be considered optimal for multiclass classification tasks. These algorithms exhibit an overfitting rate exceeding 10% across all scaling configurations, making them less reliable for generalization.

After eliminating these five suboptimal algorithms, the dominance of the $D_{corr}$ dataset in representing the code readability metrics for multiclass classification became even more pronounced, accounting for 35.71% (five algorithms) of the best accuracy results among the remaining classification algorithms. The classifiers that achieve the most optimal performance using the $D_{corr}$ dataset are Random Forest (RF), Support Vector Classifier (SVC), K-Nearest Neighbors (KNN), Gaussian Naïve Bayes with Isotonic Calibration (GNB-Isotonic), and Quadratic Discriminant Analysis (QDA).

Dataset $D_{corr}$ demonstrates that the selection of measurement metrics based on correlated yet relevant attributes can be leveraged optimally using tree- and distance-based classification algorithms. The performance of the Random Forest algorithm (a tree-based model) is particularly effective when applied to datasets in which features exhibit strong correlations with one or more other features. These findings highlight the necessity of considering relevant correlations, whether positive or negative, between readability metrics when constructing a comprehensive set of code-readability metrics. Similarly, the characteristics of distance-based classification algorithms include Support Vector Classification (SVC) (although not entirely distance-based) and k-nearest neighbors (KNN) (which are fully distance-based), allow them to effectively utilize the $D_{corr}$ dataset.

The average classification accuracy of RF, SVC, and kNN significantly benefits from the application of dataset scaling on $D_{corr}$, particularly with MinMax and Robust scaling. This finding also highlights that the application of scaling techniques can help mitigate the risk of overfitting during

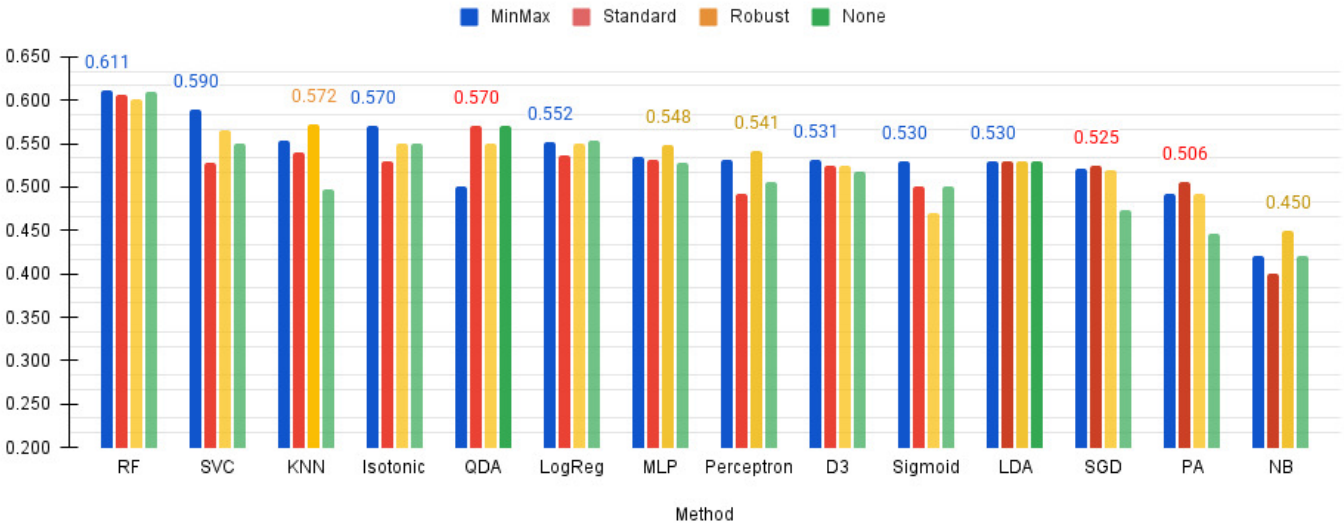

Fig. 3. Best average accuracy results for multiclass code readability classification (k-fold = 5).

multiclass classification model development. However, not all multiclass classification algorithms perform optimally even when utilizing $D_{corr}$ with scaling. In this study, the Passive-Aggressive (PA) algorithm exemplifies this limitation. Because the PA is inherently designed for binary classification, its performance in multiclass classification is suboptimal. This is evident from the fact that 43.3% of the classification models generated over 30 iterations using the PA exhibited overfitting.

In addition to dataset $D_{corr}$, the use of dataset $D_{bw}$, which consists of metric features defined by Buse and Weimer [4], does not yield an optimal performance in multiclass code readability classification. The highest average accuracy achieved was 55.4% using the Logistic Regression algorithm without data scaling and 53% using the Linear Discriminant Analysis (LDA) algorithm. By aligning the average accuracy results with the overfitting percentage from 30 iterations of model training, both the Logistic Regression and LDA demonstrated the ability to produce multiclass classification models with an acceptable level of overfitting. These findings suggest that the $D_{bw}$ dataset is more suitable for classification models in which the decision boundary formulation is based on a linear function. Conversely, the Perceptron, Decision Tree (D3), and Stochastic Gradient Descent (SGD) algorithms failed to achieve optimal performance, as this exploration indicates that all three algorithms exhibit an overfitting rate exceeding 6.67%.

Dataset $D_{all}$ contains the largest number of metric features, as it integrates the metrics proposed by Scalabrino, Buse, and Weimer (BW) and Posnett. Among the evaluated multiclass classification algorithms, multilayer perceptron (MLP) and Gaussian Naïve Bayes (NB) demonstrated the most optimal utilization of this dataset. The optimization of the average accuracy of these algorithms is primarily influenced by the application of Robust scaling to $D_{all}$. However, the average accuracy of MLP did not fully satisfy the overfitting threshold of less than 6.67% because three iterations still exhibited overfitting. Conversely, the NB algorithm achieved an accuracy of 0.45 on $D_{all}$, making it the least effective among the evaluated algorithms. The fourth dataset, $D_{scal}$, comprised 20 readability metrics derived from the model proposed by Scalabrino et al. [5]. The only classification algorithm that effectively utilizes this dataset is the Gaussian Naïve Bayes with a sigmoid activation function (GNB-sigmoid), particularly when MinMax scaling is applied. The results from 30 classification trials using

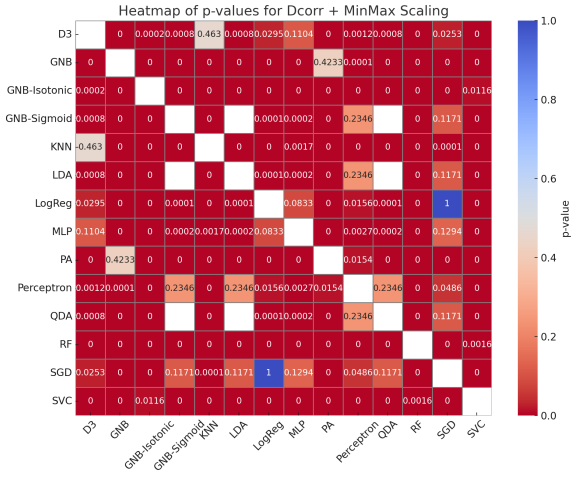

Fig. 4. Heatmap of p-Values for $D_{corr}$ with minmax scaling.

GNB-Sigmoid showed no signs of overfitting, regardless of whether MinMax, Robust, or scaling was applied.

The average accuracy results obtained by utilizing the dataset with various scaling configurations, as presented in Table II, highlight the significance of data scaling in influencing a dataset. Scaling serves as a crucial pre-processing step before building a multiclass classification model for code readability. However, the findings of this study indicate that the impact of scaling is not consistently definitive in yielding superior average accuracy. The effectiveness of scaling techniques depends on the classification model employed. Specifically, MinMax scaling was optimally utilized by the RF, SVC, GNB-isotonic, GNB-sigmoid, and LDA algorithms. Meanwhile, Standard scaling enhances the performance of QDA without causing overfitting. Although Robust scaling can be beneficial, it can lead to overfitting in some cases. The KNN and NB algorithms can leverage Robust scaling to optimize their performance without overfitting. These findings underscore the importance of selecting an appropriate scaling strategy that aligns with the fundamental assumptions of classifiers and their sensitivity to the distribution of metric-based dataset features, particularly for code readability in multiclass classification.

As part of the validation stage, in addition to applying rule-based overfitting checking and 5-fold cross validation, this study also conducted Statistical Significance Testing (Shapiro-Wilk test, paired t-test, or Wilcoxon singed-rank test) to validate the superiority of the selected models. Fig. 4 shows the p-value heatmap of the significance test results between the algorithms in the best configuration, namely $D_{corr}$ with MinMax scaling. Based on the p-value heatmap, it can be stated that Random Forest is consistently superior to the other algorithms because it shows a truly significant difference, not by chance.

Based on the accuracy of the results, several key findings answered the first research question (RQ1). Random Forest (RF) is the best-performing classification method for multiclass code readability classification, as it achieves the highest accuracy across most datasets and remains stable across different scaling techniques. SVC also performs well but is more sensitive to feature scaling, with MinMax scaling being the most beneficial. These findings suggest that ensemble methods such as Random Forest are more effective for code readability multiclass classification, particularly when feature selection is applied (as in $D_{corr}$).

Overall, dataset analysis underscores the importance of choosing the correct data pre-processing strategy based on the nature of the classifier. Feature correlation ($D_{corr}$) appears to enhance the accuracy of tree- and distance-based models, whereas balanced weighting ($D_{bw}$) benefits linear models. Complete feature sets ($D_{all}$) are favorable for neural networks and probabilistic models, whereas scaling transformations ($D_{scal}$) offer a limited but occasionally beneficial effect on certain classifiers.

### B. Attribute Role Analysis Based on Importance Score

This section outlines the process of analyzing the contribution of attributes (features) from the $D_{corr}$ dataset, which are critical for classifying source code readability into three classes. The analysis was conducted using the correlated dataset $D_{corr}$ with MinMax scaling and the Random Forest classification model because this configuration demonstrated the highest accuracy in the conducted trials. The $D_{corr}$ dataset comprises 35 attributes derived from the combined features proposed by Scalabrino, Buse-Weimer (BW), and Posnett.

Attribute contribution analysis was performed by computing the average `importance_mean` for each attribute exclusively in the $D_{corr}$ dataset. The classification model that achieved the highest performance, which employed $D_{corr}$ with MinMax scaling, was evaluated using the test data generated during the classification assessment process. The attribute importance weights were computed using the `permutation_importance` function from the `sklearn.inspection`. Attribute selection is based on the average importance score (mean_threshold) and standard deviation (std_threshold) of the highest `importance_mean` values, with selection criteria determined by predefined thresholds: a minimum average error threshold of [0.005, 0.01, and 0.02] and a maximum standard deviation error threshold of [0.015, 0.02]. The average (mean) was used to determine the overall contribution of the features (attributes) to the model performance based on 30 iterations. An average value greater than zero ($> 0$) indicates that the attribute consistently positively contributes to model performance. Conversely, if the average is approximately zero ($\approx 0$), then the attribute is likely to be irrelevant.

Similarly, if the average is negative ($< 0$), the attribute is likely to negatively impact the model performance. In addition to the mean threshold, the standard deviation of the `permutation_importance` values was considered. The standard deviation measures the variation (spread) in an attribute's importance score across the iterations. This variation reflects the consistency of the impact of the features on the model performance. A low standard deviation indicates that the contribution of the feature remained stable across all 30 iterations, whereas a high standard deviation suggests that the importance of the attribute is inconsistent, implying that its influence may vary, at times being beneficial, unimportant, or even detrimental.

TABLE III. AVERAGE BEST ACCURACY OF MULTICLASS CLASSIFICATION USING $Ds_1$, $Ds_2$, $Ds_3$, $Ds_4$, $Ds_5$, AND $Ds_6$

| Method | Avg Accuracy | Overfitting % | Dataset | Scaling |
|---|---|---|---|---|
| LDA | 0.550 | 0.0% | $Ds_4$ | MinMax |
| | 0.550 | 0.0% | $Ds_4$ | Standard |
| | 0.550 | 0.0% | $Ds_4$ | Robust |
| | 0.550 | 0.0% | $Ds_4$ | None |
| **RF** | **0.583** | **0.0%** | $Ds_6$ | **Robust** |
| **KNN** | **0.590** | **0.0%** | $Ds_2$ | **Robust** |
| SVC | 0.517 | 0.0% | $Ds_1$ | MinMax |
| | 0.545 | 0.0% | $Ds_3$ | Standard |
| | 0.579 | 0.0% | $Ds_5$ | Standard |

The next step involved constructing a dataset in which $D_{corr}$ served as the baseline, with attributes selected based on predefined thresholds. Attribute selection was performed according to threshold conditions for the mean and standard deviation, resulting in six distinct attribute groups. For each of these groups, a corresponding dataset was derived from the source dataset $D_{corr}$. Consequently, six new datasets were generated, each based on different attribute selections: $Ds_1$ (11 attributes), $Ds_2$ (22 attributes), $Ds_3$ (8 attributes), $Ds_4$ (17 attributes), $Ds_5$ (16 attributes), and $Ds_6$ (27 attributes).

Each dataset formed through this selection process was subsequently subjected to classification trials along with similar trials conducted for the $D_{all}$, $D_{scal}$, $D_{bw}$, and $D_{corr}$ datasets. The primary objective of these tests was to identify the attributes from $D_{corr}$ that contributed the most significantly to the best classification accuracy, thereby providing a foundation for developing alternative attributes or metrics for program code readability models. In addition, this analysis aimed to evaluate whether the six datasets resulting from attribute selection produced better classification performance than the $D_{all}$, $D_{scal}$, $D_{bw}$, and $D_{corr}$ models.

The best-performing models were selected based on an overfitting threshold $\leq$ 6.67% across 30 iterations for each dataset. The selection results, as shown in Table III, indicate that the K-Nearest Neighbors (KNN) algorithm achieves the best performance when applied to the $Ds_2$ dataset compared to other datasets. KNN achieved the highest average accuracy (59%), followed by Random Forest (RF) at 58.3%, Support Vector Classifier (SVC) at 57.9%, and Linear Discriminant Analysis (LDA) at 55%. The $Ds_2$ dataset (containing 22 metric attributes) is better suited for instance-based learning algorithms, such as KNN, whereas $Ds_6$ (27 attributes) is more effective for decision tree-based algorithms, particularly Random Forest. However, the highest average performance results obtained from these six newly formed datasets remained suboptimal compared with those achieved with the original $D_{corr}$ dataset.

The primary objective of the classification experiment using the six datasets, $Ds_1$, $Ds_2$, $Ds_3$, $Ds_4$, $Ds_5$, and $Ds_6$, was to identify which set of feature attributes (metrics) played a significant role in classification. Based on the results of this study, 22 feature attributes from dataset $Ds_2$ were identified as key metrics for measuring code readability. Table IV provides a detailed overview of the 22 feature attributes in the program code, including their corresponding metric categories.

By selecting 22 readability metric features from the feature set in dataset $D_{corr}$, this finding also addressed the second research question (RQ2). Among the Scalabrino metrics, eight key metrics play a significant role in multiclass code readability classification. For the Buse and Weimer metrics, 12 features were identified as being important for multiclass classification. Based on Posnett's metrics, two features were found to contribute significantly to the code readability classification experiment. Thus, based on the results of the multiclass code readability classification, it can be concluded that comment text readability, code complexity and structure, syntax and formatting, identifier naming and token usage, and code size and density are crucial factors in classifying Java source code into three readability categories: unreadable, neutral, and readable.

### C. Discussion

The performance results of multiclass classification based on 14 machine learning algorithms, although not optimal, show that the utilization of the definition of the code readability metric feature set, particularly the result of selecting features based on their correlation, can still be an alternative in multiclass classification of code readability. This study offers a practical and interpretable alternative based on the code readability metric features used in classification compared with the application of deep learning. Deep learning often requires significant computational resources and lacks transparency. The establishment of a feature metric based on the correlation result $D_{corr}$ that can be utilized by Random Forest to produce consistent performance can still be used to explain the model through the importance of the code readability feature. This makes machine learning based on metric features more suitable for applications that require interpretation and positions the machine learning framework as a complementary method to more complex deep learning approaches.

The different average accuracy performance results among the dataset definitions $D_{all}$, $D_{scal}$, $D_{bw}$, and $D_{corr}$ can be explained by variations in feature composition and selection strategies. $D_{all}$ integrates features from Scalabrino, Buse-Weimer, and Posnett, offering broader coverage but potential redundancy. In contrast, $D_{scal}$ and $D_{bw}$ focused on defining a specific set of metric features according to their respective models. By contrast, $D_{corr}$, which is formed from a correlation-based selection of $D_{all}$, can be said to be a metric feature selection that minimizes redundancy and retains only highly relevant features.

These differences affect the performance of the 14 machine learning classification algorithms. For example, tree-based models, such as Random Forest with $D_{corr}$, can effectively handle correlated features. Distance-based models, such as SVC and KNN, also perform well on $D_{corr}$ when proper scaling (e.g., MinMax, Robust) is applied because distance-based model algorithms are sensitive to feature magnitude and distribution. Linear models such as Logistic Regression and LDA showed better performance against $D_{bw}$ utilization, which seems to be more in line with the linear separability assumption. Probabilistic models, such as the calibrated Gaussian Naïve Bayes, perform reasonably well with $D_{scal}$ and $D_{corr}$ when scaling is used to reduce the risk of overfitting.

To optimize the readability interpretation based on the Scalabrino, Buse-Weimer, and Posnett readability metric fea-

tures, in this study, feature selection based on the permutation importance method was performed on the best Random Forest model applied to $D_{corr}$ dataset with MinMax scaling. The results of the selection form six combinations of metric features, and then choose which combination is the best based on multiclass classification tests on each of the six combinations of features. Of the 35 features available from $D_{corr}$, 22 metric features were selected because they provided consistent positive contributions and low variance in the average accuracy of the multiclass classification model. These features included comment readability, code complexity, syntax, identifier naming, and information density.

## V. CONCLUSION

A multiclass classification study for machine learning-based code readability was conducted by utilizing metric feature definitions from the Scalabrino, Buse and Weimer, and Posnett models. Utilization of soft AutoML hyperparameter tuning, namely Randomized Search, produced an optimal multiclass classification model based on 200 Java codes from Scalabrino et al. The set with 35 metric features resulting from correlation-based future selection (forming the $D_{corr}$ dataset) consistently exhibited the highest average accuracy and a weighted F1 score. The Random Forest algorithm provides the highest average accuracy among the algorithms with or without utilizing MinMax, Standard, and Robust scaling transformation techniques on the data of each readability label with minimal overfitting conditions. The validity test based on Statistical Significance Testing of the classification performance results also shows that the RF algorithm is consistently and significantly superior to the other classification algorithms.

In this study, the most important feature metric was extracted using a permutation importance function based on the results of the previous best classification model. From the resulting six combinations, 22 out of 35 $D_{corr}$ metric features play an important role in the multiclass classification of code readability. Metric features include comment readability, code complexity, syntax, naming, and density. Overall, the average multiclass classification accuracy results generated in this study could not surpass the 72.5% accuracy of the GNN model proposed by Mi et al. Thus, in future research, it will be necessary to refine the definition of code readability metric features to better represent the code readability metric. In addition, the utilization of hybrid machine learning methods for multiclass classification of code readability can be explored to obtain better performance than the application of machine learning algorithms.

# Deep Learning-Based UI Design Analysis: Object Detection and Image Retrieval Using YOLOv8

Roba Alghamdi, Adel Ahmad, Fawaz alsaadi
Department of Information Technology, King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—Data-driven design models support various types of mobile application design, such as design search, promoting a better understanding of best practices and trends. Designing the well User Interface (UI) makes the application practical and easy to use and contributes significantly to the application's success. Therefore, searching for UI design examples helps gain inspiration and compare design alternatives. However, searching for relevant design examples from large-scale UI datasets is challenging and not easily stricken. The current search approaches rely on various input types, and most of them have limitations that affect their accuracy and performance. This research proposed a model that provides a fine-grained search for relevant UI design examples based on UI screen input. The proposed model will contain two phases. Object detection was implemented using the deep learning model 'YOLOv8', achieving 95% precision and 97% average precision. Image retrieval, leveraging the cosine similarity technique to retrieve the top 3 images similar to the input. These results highlight the system's effectiveness in accurately detecting and retrieving relevant UI elements, providing a valuable tool for UI designers.**

***Keywords*—Data-driven design; YOLOv8; design search; deep learning; user interface design**

## I. Introduction

Applications and mobile devices play a crucial role in the daily lives of individuals worldwide, facilitating a wide range of tasks, from simple calculations to more complex operations. Developers adhere to established guidelines and standards before releasing applications on digital marketplaces such as Apple's App Store and Google Play [1]. The development begins with defining requirements and designing the user interface, followed by creating mockups of the graphical user interface (GUI). UI/UX designers iteratively refine these mockups until a final design is achieved, which is then translated into a functional application. After undergoing rigorous testing, the application is released to users, emphasizing the increasing focus on mobile application quality [1].

The user interface (UI) is a fundamental element in determining the success of a mobile application, as it provides an interactive environment for users to engage with the software. The quality of UI design significantly influences user experience, acceptance, and overall app success [2]. In the highly competitive mobile application market, the UI design and app icons play a key role in differentiating an application from competitors, attracting downloads, minimizing user complaints, and enhancing retention rates. A well-designed UI balances visual appeal, efficiency, and ease of use, considering factors such as color harmony, layout organization, and overall design style [3].

Visual composition in UI design is a fundamental aspect of software development. The design process typically starts with wireframing based on user requirements and then structuring visual elements to ensure optimal interaction between the user and the application. Designers iteratively refine these wireframes by referencing existing online examples before applying high-fidelity visual effects, such as colors and typography, and incorporating relevant text and imagery [4].

Data-driven design models contribute to the development of mobile applications by predicting design performance and identifying the best practices and trends [5]. These models support various aspects of mobile application design, including interaction modeling, design search, and UI code generation. Recent advancements in machine learning and data analytics have significantly transformed UI design, allowing designers to explore extensive collections of UI designs based on specific criteria such as layout, color schemes, and functionality [5]. As technology advances, these tools will continue empowering designers to create innovative and user-centered UIs.

Leading mobile application marketplaces offer over six million applications, with projected revenue exceeding $935 billion by 2024—nearly twice the revenue generated in 2020 [6], [7]. The graphical user interface (GUI) is a core component of application success, serving as the interaction point between users and the application's functionalities. Well-designed GUIs go beyond aesthetics, improving usability and enhancing user satisfaction. With increasing competition in app marketplaces, creating engaging and intuitive interfaces has become a top priority for developers. However, designing high-quality GUIs remains challenging and labor-intensive, requiring extensive testing and iteration to ensure usability [8].

For novice and experienced designers, navigating the design space efficiently remains difficult. Seeking design examples has become essential for gaining inspiration and understanding UI trends for specific application functions. However, locating relevant examples within large-scale UI datasets is challenging due to the time-consuming nature of random searches, which may not provide accurate insights into modern UI trends, including layout options, visual components, and effects. An effective solution involves developing approaches that retrieve similar UI designs from large datasets using deep learning technologies. These methods transform GUI development by enabling efficient retrieval and comparison of visual components across extensive datasets [5].

Various studies have attempted to address the issue of UI design retrieval using different input methods such as keywords, sketches, wireframes, and UI images. Most existing studies rely on keyword-based input and often yield irrelevant examples due to mismatched user requirements. A more effective approach is needed to provide designers with practical examples that align with their needs. Research has

explored input-based image retrieval that considers UI content, hierarchical structure, and visual layout. However, current methods face challenges in performance, generalization, and applicability to diverse UI designs, affecting their accuracy and usability. For example, Swire [9] has a limitation in the approach performance because it retrieves irrelevant UI images that do not consider the UI content. The approach proposed by Deka et al. [6] retrieves similar results based on text and image content only.

In contrast, the approach of Liu et al. [10] limits the generalization and precludes the approach from working on any new unseen images because it relies on specified UI content. While others are limited in detecting small objects in UIs, such as icons and checkboxes, the VINS [11] approach restricted its application to specific UIs with a specified set of components. Detecting objects at different scales is challenging, particularly small objects. Data augmentation techniques are ways to solve the problem of detecting small objects on UI screens. These techniques are utilized to ensure the dataset does not lack sufficient training data or uneven class balance within the datasets and are adopted as an effective solution to improve the performance of object detection models. Many recent studies have shown that combining the YOLOv8 model with multiple data augmentation strategies led to significant improvements in accuracy and other performance metrics, as used in study [12]. Similar techniques were applied to improve the accuracy of brain tumor detection using MRI images, where data augmentation significantly increased brain tumor detection accuracy, improved the model's generalization ability, and reduced errors. This study confirms the effectiveness of data augmentation techniques in improving the performance of YOLOv8. This study highlights how to propose a practical model capable of efficiently detecting the most common UI components and retrieving UI images using deep learning and computer vision techniques. It also investigates the integration with custom data augmentation techniques to improve detection performance and address these limitations.

This research aims to overcome the limitations of previous methods by introducing a fine-grained UI search system that retrieves similar UI designs based on a given UI screen. The proposed system leverages deep learning techniques to help designers quickly understand design spaces, draw inspiration from existing applications, and enhance their UI designs to ensure application success. The primary objectives of this study include:

- Developing a model capable of retrieving relevant UI designs from large-scale datasets based on input images using deep learning and computer vision techniques.
- Improving accuracy in retrieving relevant UI examples by refining the search process to better align with designer needs.
- Evaluating the proposed model against the existing approach "VINS" to assess its effectiveness in enhancing the UI design retrieval process.

This study contributes to developing and evaluating a framework for fine-grained UI search. The YOLOv8 model was chosen for this study due to its architectural and technical improvements, which make it suitable for detecting user interface elements within images. Appreciation to its improved accuracy, faster performance, and ability to recognize objects of various sizes compared to previous versions, it can extract deeper and more effective features, making it the preferred choice, as demonstrated in this study [13]. YOLOv8 efficiently recognizes objects even in complex or diversely designed images, making it suitable for analyzing user interfaces containing multiple, closely spaced elements.

The proposed model integrates deep learning (YOLOv8) and computer vision techniques (Cosine Similarity) to effectively detect and retrieve highly similar UI designs with high precision. This work presents the first model that integrates these technologies within this domain, which makes it an advantage for this work. A new dataset was also created from the Rico dataset, incorporating preprocessing techniques and categorization into 21 classes—a novel contribution in this area. Data augmentation techniques were applied to ensure the dataset does not lack sufficient training data or uneven class balance within the datasets, resulting in 19,000 UI images. The proposed model surpasses the baseline model by 12% in UI image search accuracy [9]. This contribution highlights the proposed model's effectiveness and potential impact on advancing UI design research.

The rest of the paper is structured as follows: the "Related Work" in Section I examines previous studies, while the "Materials and Methods" in Section II describes the proposed methodology and dataset. The "Experiments" in Section III presents the experimental setup and findings. Lastly, the "Conclusion and Future Work" in Section IV highlights the principal results and suggests possible future research directions.

## II. Related Work

Various approaches have been proposed in UI design retrieval, utilizing different input types to enhance search efficiency and accuracy. Traditional keyword-based search methods have evolved into more advanced techniques, such as natural language queries, image-based searches, and deep learning-driven retrieval models. Studies have compared these methods based on usability, effectiveness, and retrieval accuracy, showcasing significant improvements with deep learning techniques. Cardenas et al. [5] introduced GUIGLE, a framework for GUI search that facilitates the conceptualization process for UI design. GUIGLE enables advanced searches using natural language queries, incorporating UI components, on-screen text, color schemes, and application names. The framework consists of three main components: data collection, quality filtering, and indexing, achieving a 68.8% retrieval relevance rate. Chen et al. [14] proposed Gallery D.C, a large-scale UI component gallery that leverages computer vision techniques and reverse engineering. This system categorizes 11 UI components across 25 Android application categories and provides search, comparison, and summarization tasks. It employs Faster R-CNN for UI element detection, demonstrating superior design sharing and information retrieval performance. The main limitation of using keywords is retrieving design examples with UI content and visual layout structure different from user requirements.

Beyond keyword-based searches, researchers have explored image-based retrieval using wireframes, sketches, and UI

screens as input methods, which are faster to specify and easier to learn than keywords. Huang et al. [9] developed Swire, a deep learning-based UI retrieval model trained on a large-scale UI sketch dataset. Swire utilizes VGG-A sub-networks to match UI screens with sketches, achieving a 60% accuracy rate for retrieving relevant UIs. Chen et al. [15] proposed a wireframe-based UI design search engine using deep learning. This approach includes reverse engineering to construct a large-scale UI dataset, encoding visual semantics with a CNN-based autoencoder, and employing KNN for UI design search. The evaluation results demonstrated superior performance compared to existing search methods that rely on different input types. The main drawback of these two models is that they return user interface designs that are generally similar to the query user interfaces, so they may miss some UI components or return irrelevant results. To solve this problem, examples of design that will help designers in practice must be found. Deka et al. [6] introduced the Rico dataset, the largest UI dataset to date, containing 72,219 UI screenshots from 9.7K Android applications across 27 categories. The dataset includes structural, textual, visual, and interactive UI properties, supporting deep learning applications for design retrieval. Rico's autoencoder-based UI layout similarity model demonstrated strong retrieval capabilities using text and image-based content only, which is considered a weakness. Liu et al. [10] extended the Rico dataset by introducing an automated approach for generating semantic annotations, identifying UI components' structural and functional roles. These annotations were applied to the 72,219 UI screens, enabling enhanced UI retrieval through autoencoder-based similarity searches. The model relies on a pre-defined hierarchy of UI content, so it does not work on any new, unseen images. Bunian et al. [11] proposed VINS, a visual search framework for retrieving UI design examples based on wireframes or UI screens. The framework integrates an object detection model using SSD for UI component identification and an attention-based autoencoder for image retrieval, achieving a mean average precision (mAP) of 76% for component detection and up to 90% precision in retrieving similar UI designs. This model's shortcoming is that it only detects 11 classes of UI components and is noticeably unable to detect small objects within the UI. The proposed model tried to solve these shortcomings by generalizing as much as possible to the most significant number of UI components, focusing on improving the detection of small components by applying some augmentation techniques and improving the model's performance to work on any input image.

Sun et al. [16] introduced a UI component recognition model using CNN techniques. The approach involved pre-processing UI images through grayscale conversion, noise removal, segmentation, and CNN-based classification into 14 UI component types. While effective, the model struggled with complex, user-defined UI components and misclassification of similar elements. Nguyen et al. [17] developed REMAUI, a reverse engineering framework for UI design analysis. The system detects UI components and generates static applications using computer vision, Optical Character Recognition (OCR), and mobile-specific heuristics. The primary limitation of this approach lies in its binary classification of UI elements, restricting its ability to distinguish between different component types. Moran et al. [18] proposed a machine learning-based prototype for GUI analysis in mobile applications, incorporating detection, classification, and assembly tasks. The detection phase employs computer vision techniques and OCR to identify GUI components, utilizing edge detection, dilation, and contour bounding boxes to refine object recognition. All of these approaches evaluate detection accuracy by a small number of GUIs.

CNN-based classification further enhances detection accuracy, outperforming previous GUI analysis methods. Recent advancements in deep learning have significantly improved object detection, image classification, and semantic segmentation for UI design retrieval. Faster R-CNN, employed in Gallery D.C, achieved a recall of 0.65, a precision of 0.73, and a mean average precision (mAP) of 0.69 at an Intersection over Union (IoU) threshold of 0.6. Meanwhile, SSD, used in VINS, demonstrated superior performance with an mAP of 76.39% and an Area Under the Curve (AUC) of 79.02% at IoU=0.5. The trade-off between two-stage detectors like Faster R-CNN, which yield higher accuracy but require substantial computational power, and one-stage detectors like YOLO and SSD, which are faster and more efficient for real-time mobile applications, remains a critical consideration in UI retrieval research. Since it is important to focus on performance efficiency in addition to speed, the Yolo model was adopted in the model proposed in this paper.

The Rico dataset, the largest in UI research with 72,000 images, requires refinement to remove duplicates caused by user interaction traces. Previous studies have used limited class annotations, restricting their applicability. While deep learning techniques have improved UI retrieval based on user preferences, challenges remain in performance, generalization, and adaptability. To overcome these issues, a YOLO-based model was proposed that enhances detection by re-annotating the Rico dataset into 21 classes, making UI retrieval more accurate and comprehensive.

## III. Materials and Methods

This section describes the methodology and architecture of the proposed fine-grained search system, designed to retrieve relevant UI design examples by integrating deep learning (DL) models. Fig. 1 illustrates the general methodology used in this system:

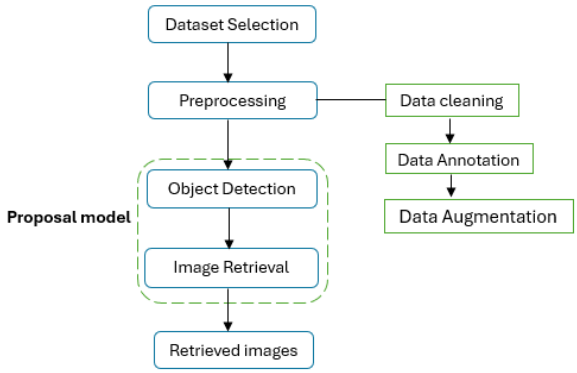

Fig. 1. The proposed system steps.

### A. Data Preprocessing

Data preprocessing is a crucial step in machine learning that ensures the dataset's quality, consistency, and usability. Leveraging the Rico dataset as the cornerstone of the research investigation, the researchers meticulously navigate through these preparatory stages to ensure the data's integrity, richness, and relevance. This process consists of three main steps: Data Cleaning, Data Annotation, and Data Augmentation, which refine the dataset for optimal model training.

*1) Data cleaning:* Since raw datasets often contain inconsistencies, redundant images, and noise, a systematic filtering process was applied to remove incomplete, irrelevant, or low-quality data. The Rico dataset, the largest dataset in UI research with 72,000 UI images, required refinement to eliminate duplicate images caused by user interaction traces. The filtering criteria included:

- Removing images with less than two UI components.
- Eliminating empty or non-English UI screens.
- Removing duplicate UI screens to avoid bias.

Fig. 2 shows examples of deleted images that did not meet the dataset's quality standards.

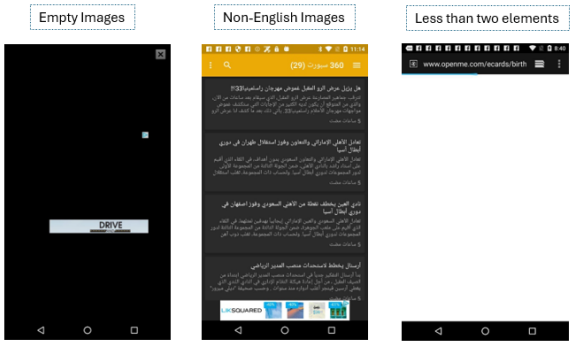

Fig. 2. Examples of deleted photos.

*2) Data annotation:* To ensure accurate and granular classification, the dataset was annotated into 21 distinct UI component classes using the Roboflow platform. These classes include BackgroundImage, BottomNavigation, Button, Card, Checkbox, Drawer, Edit Text, Icon, Image, Map, Modal, Multi Tabs, Page Indicator, Progress Bar, Radio Button, Seek Bar, Spinner, Switch, Text, Tool Bar, and Upper Task Bar. Each category was assigned a specific color to facilitate visual identification and improve model interpretability.

*3) Data augmentation:* Multiple augmentation techniques were applied to address class imbalance and enhance dataset diversity, leveraging the Roboflow platform. These included:

- Rotation
- Saturation adjustment
- Brightness modification
- Exposure correction
- Noise addition

This augmentation process tripled the number of instances in underrepresented classes, enhancing the trained model's robustness and generalization capability.

### B. Model Architecture

The main objective of this research is to build a fine-grained search model that retrieves similar UI designs depending on a given UI screen that fits the designer query and enhances the detection performance, especially for small objects such as icons, checkboxes, and others. Fig. 3 illustrates the architecture of the model. The proposed fine-grained search model consists of five main phases:

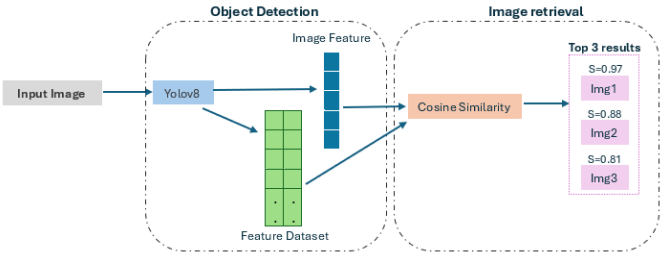

Fig. 3. Model architecture.

*1) Object detection:* Identifies UI components and their locations using the YOLOv8 [19] model. The YOLOv8 is one of the most advanced deep learning-based object detection models in current use, known for its high accuracy and rapid processing capabilities. The model uses convolutional layers to detect fine details like edges, shapes, and textures, dividing images into regions to identify and classify objects, such as vehicles, pedestrians, and animals, using bounding boxes and trained datasets [20]. The model processes images through the following steps:

- Resizing images to 640x640 pixels for input consistency.
- Normalizing pixel values to [0,1] range for stable neural network processing.
- Applying convolutional layers to extract shapes, edges, and textures.
- Generating bounding boxes with confidence scores to classify detected UI elements.

This methodology enhances model precision and detection speed, making it suitable for real-time UI retrieval applications.

*2) Feature extraction:* In computer vision, retrieving similar images based on extracted features is a powerful tool that enables applications ranging from automated tagging in media libraries to more complex uses in visual search engines and recommender systems. Extracts UI screen structure features and retrieves similar designs using cosine similarity. After detecting UI components, the YOLOv8 model generates feature vectors representing the spatial structure of each UI screen. Lower layers focus on basic elements, while deeper layers summarize complex structures, condensing these details into a global feature vector representing each image's content [21] [22]. These vectors encode:

- Bounding box coordinates (x, y, width, height).
- Class probabilities and confidence scores.

This feature vector acts as a numerical signature that reduces the complexity of images, allowing for more efficient and computationally manageable comparisons [23]. A global feature vector is derived by calculating the mean of all bounding boxes, creating a compact yet descriptive representation of the UI screen.

*3) Feature dataset construction:* Extracted feature vectors are stored in a structured database for efficient retrieval. This database transforms raw images into comparable vectors, streamlining retrieval without requiring direct pixel comparisons [24]. The indexing process ensures:

- Fast similarity comparisons across large UI datasets.
- Optimized storage using Python's Pickle serialization to avoid redundant computations.

This feature dataset enables the system to retrieve visually similar UI designs efficiently, supporting large-scale searches.

*4) Similarity-based image retrieval:* The model employs cosine similarity to retrieve images most similar to a query UI screen. This metric, which measures the cosine of the angle between two vectors, is advantageous as it focuses on the orientation of vectors rather than their magnitudes, making it suitable for high-dimensional data like feature vectors [25]. The similarity between two feature vectors $f_i$ and $f_q$ is calculated using the cosine similarity formula:

$$cosine_similarity(f_i, f_q) = \frac{f_i \cdot f_q}{\| f_i \| \| f_q \|} \quad (1)$$

Where $f_i \cdot f_q$ is the dot product, and $\|f_i\|\|f_q\|$ is the product of their magnitudes. Once similarity scores are computed, the system ranks images based on their cosine similarity scores, retrieving the top-k most similar UI designs [26]. This approach enhances retrieval accuracy and efficiency.

*5) Highlighting key regions in retrieved images:* To improve interpretability, retrieved UI images are highlighted with bounding boxes indicating significant regions the model detects. This visual emphasis helps users understand which UI elements contributed to the match.

- Bounding boxes are overlaid in distinct colors to enhance visibility.
- Solid-colored highlights (e.g., green rectangles) focus attention on key UI elements.

This method improves user experience and decision-making in UI retrieval applications.

### C. Dataset

The Rico dataset is a resource for mobile app design, containing design data from over 9,772 Android apps across 27 categories [6]. It includes over 72,000 unique UI screens, documenting interactive, textual, structural, and visual design elements. The dataset provides user interaction traces, app metadata from Google Play (category, ratings, downloads), and detailed UI components such as buttons, cards, text fields, and icons. It also includes XML annotation files, but for YOLOv8, these need to be converted into TXT files representing bounding boxes with class labels and coordinates. The dataset is cleaned and preprocessed, with 19,727 images classified into 21 categories, averaging 17 annotations per image.

## IV. Experiments and Results

Python was used as the primary programming language for the model's experiments due to its extensive support for machine learning and data science libraries. Python's flexibility and wide range of tools allowed us to implement the proposed methodologies efficiently. Given the computational limitations of the local machine, the Python code is executed using Google Colaboratory, a cloud-based platform that provides free GPU access [27].

Due to the large dataset size, the dataset was uploaded to the Kaggle platform which used its library to import and manage it. The Ultralytics library was employed to train the YOLOv8x model, while the sklearn.metrics. A pairwise package was utilized to implement cosine similarity in the image retrieval process. To optimize the proposed object detection model, the IoU (Intersection over Union) threshold is set to 0.7 and the confidence threshold to 0.25. Additionally, the input image size was resized to 700x700 pixels. These hyperparameters were chosen based on empirical experimentation to achieve the best trade-off between accuracy and performance.

### A. Data Preprocessing

Data preprocessing is a crucial step that ensures the dataset is optimized for model training. The preprocessing steps included:

- Data Cleaning: Removing noisy or irrelevant annotations
- Annotation Conversion: Transforming XML files into YOLO TXT format
- Data Augmentation: Enhancing dataset diversity and balancing class distribution

For augmentation, the Roboflow [28] utilized a pivotal platform within the realm of computer vision and machine learning. It offers a comprehensive suite of tools tailored to streamline the data preparation pipeline. Roboflow offers various augmentation techniques, including geometric transformations, color adjustments, and specialized augmentations. After augmentation, underrepresented classes saw a threefold increase in image samples, bringing the dataset size to 19,727 images. The final category distribution is shown in Table I.

### B. Model Training

The experiment leveraged the YOLOv8 [19] model for object detection to detect various elements within the research dataset. The training process was initiated with a pre-trained YOLOv8x model that utilized the robust capabilities of the Ultralytics framework. The Yolov8 had multiple versions with different parameters, speed, and mAP. The YOLOv8x was selected due to the large dataset and the importance of accuracy

TABLE I. DATASET CATEGORIES DISTRIBUTION

| Category | Train | Valid | Test | Sum |
|---|---|---|---|---|
| BackgroundImage | 1660 | 250 | 131 | 2041 |

over speed, the most robust version among the YOLOv8 models. The dataset was split into three subsets:

- 70% for training
- 20% for validation
- 10% for testing

This split allowed for efficient model training while preventing overfitting. The dataset was specified in a custom configuration file, and hyperparameter tuning was conducted to optimize model performance.

### C. Evaluation Metrics

For the proposed model, the Precision (P) and Average Precision (AP) are used as key metrics to evaluate the model:

$$Precision = \frac{TP}{TP + FP} \tag{2}$$

where: $TP$ (True Positives): Correctly detected objects. $FP$ (False Positives): Incorrectly detected objects. $FN$ (False Negatives): Missed objects.

The Mean Average Precision (mAP), a widely used metric for object detection tasks, was computed as follows:

$$mAP = \frac{\sum AP_n}{N} \tag{3}$$

where $AP_n$ represents the average precision for class $n$.

### D. Results

After training, the YOLOv8x model was tested on the validation set using a confidence threshold of 0.5, meaning only detections with a confidence score of 50% or higher were considered valid. This threshold was chosen to balance the results, reducing false positives while ensuring that true detections were not missed. The model achieved a 95% precision and a 97% average precision for the object detection component in all classes. Table II. presents the class-wise precision and AP values.

TABLE II. PRECISION AND MAP FOR EACH CLASS

| Class | P | mAP50 |
|---|---|---|
| BackgroundImage | 0.934 | 0.976 |
| BottomNavigation | 1 | 0.951 |
| Button | 0.968 | 0.983 |

For image retrieval, the model successfully identified the three most similar UI designs to the input image using cosine similarity, displaying results as a ranked list of top-matching UIs. The colored bounding boxes in the second image represent each part of the UI query image, each color representing a different component. Fig. 4 shows an example of this step.

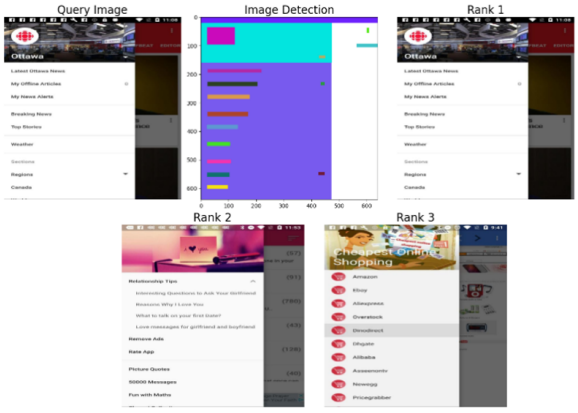

Fig. 4. The Retrieval results of out model.

### E. Comparison with Baseline Model

To highlight the improvements of the proposed model, a comparison with the baseline model VINS [9] was made, which combined the SSD model with Autoencoder to build the entire model. The proposed model relied on Yolov8 for feature detection, extraction, and storage and used Cosine similarity to retrieve images similar to the one given. At the same time, we relied on Yolov8 for feature detection, extraction, and storage and used Cosine similarity to retrieve similar images to the given one. Due to the unavailability of the model's source code, it was impossible to reapply the model to the dataset used in this research. Therefore, a rough comparison was made based on the mAP metric described in that study. However, it should be noted that the dataset used in this work is more extensive and diverse in terms of the number of classes. Although a direct comparison is not possible, the proposed system significantly outperforms VINS, achieving an mAP of 97% compared to VINS's 76.39% as a result reported in the literature [9], demonstrating superior accuracy and effectiveness in object detection and UI retrieval. This comparison is approximate and should be interpreted in the context of the different datasets and models used. The comparison results are presented in Table III.

TABLE III. COMPARISON WITH THE BASELINE MODEL

| Model | mAP50 | Technique used |
|---|---|---|
| VINS | 76.39% | SSD and Autoencoder |
| The proposed Model | 97% | Yolov8 and Cosine similarity |

## V. DISCUSSION

The results confirm the effectiveness of YOLOv8 in detecting UI elements. To determine the best version of Yolo models in the dataset, all versions were trained on the data and assigned an epoch value of 20 and a batch of 16. The results in Table IV indicate that YOLOv8x achieved the highest accuracy, making it the optimal choice for the dataset.

TABLE IV. VARIANCE MODELS RESULTS

| Model | Precision | mAP50 |
|---|---|---|
| YOLOv8n | 0.783 | 0.796 |
| YOLOv8s | 0.798 | 0.844 |
| YOLOv8m | 0.808 | 0.843 |
| YOLOv8l | 0.803 | 0.866 |
| YOLOv8x | 0.827 | 0.866 |

The proposed model successfully learns how to extract relevant features from images and then classifies and locates objects effectively across all images in the dataset. The model was trained on the Revised Rico data, and annotations were made on each image to identify the exact locations of objects within it based on the dataset categories. In addition, augmentation was performed on some under-representation classes to ensure the quality of the model and increase the chance of the model detecting these objects. The results of testing the proposed model using data extracted from the Rico dataset showed high performance in different categories, where the mAP reached 98% of overall categories, indicating that the model outperformed VINS [9] by about 20%. This is consistent with the results reported in the study [21], where the performance of their model also improved. However, the model still faces challenges predicting some categories, such as the "ProgressBar" and "SeekBar." This could be due to the imbalance of the data, which biases the model towards the higher-ranked categories. Even after trying to balance the dataset using a downsampling technique by removing images that collect objects from the majority class to achieve partial convergence with the rest of the classes and applying augmentation techniques to the minority class images, there was still a noticeable difference in the distribution of images between classes. These lower-ranked classes are often associated with some highly-ranked classes, which limits the possibility of creating balanced data.

Overall, this study demonstrates significant advancements in UI detection and retrieval, outperforming previous models and providing an effective tool for analyzing mobile UI designs.

## VI. CONCLUSION

In this study, we developed an object detection and image retrieval model leveraging the YOLOv8 framework and cosine similarity to analyze UI components. The dataset, sourced from the Rico dataset, was preprocessed, annotated, and augmented to enhance model performance. TThe hyperparameters were optimized through rigorous experimentation to achieve high precision and accuracy in detecting and classifying UI elements. The results demonstrated the effectiveness of the YOLOv8x model in object detection, outperforming the baseline VINS model by a significant margin. The proposed approach achieved an overall mean Average Precision (mAP) of 97%, compared to 76.39% for the VINS model, highlighting its robustness in accurately identifying UI components.

Additionally, the integration of cosine similarity facilitated efficient image retrieval, allowing the system to suggest visually and structurally similar UI designs. Despite the promising results, some challenges remain, particularly in predicting underrepresented UI components such as "ProgressBar" and "SeekBar." While augmentation and balancing techniques improved performance, disparities in category distribution persisted.

Future work could focus on further dataset balancing strategies, exploring alternative deep learning architectures, and refining feature extraction techniques to enhance retrieval accuracy. Expanding the dataset to include various UI designs from different platforms (e.g., iOS, web applications) and categories could enhance the system's versatility. The model can also be integrated with an Android app, making it easier for designers to leverage a variety of UI designs. The proposed approach represents a significant advancement in UI element detection and retrieval, offering a valuable tool for mobile UI designers and developers to analyze and refine interface layouts efficiently. The study underscores the potential of deep learning techniques in automating UI analysis, paving the way for more intelligent and adaptive design systems.

# Adversarial Attack on Autonomous Ships Navigation Using K-Means Clustering and CAM

Ganesh Ingle, Kailas Patil, Sanjesh Pawale
Department of Computer Engineering, Vishwakarma University, Pune, India

***Abstract*—As Maritime Autonomous Surface Ships (MASSs) increasingly become part of global maritime operations, the reliability and security of their object detection systems have become a major concern. These systems, which play a crucial role in identifying small yet critical maritime objects such as buoys, vessels, and kayaks, are particularly susceptible to adversarial attacks, especially clean-label poisoning attacks. These attacks introduce subtle manipulations into training data without altering their true labels, thereby inducing misclassification during model inference and threatening navigational safety. The objective of this study is to evaluate the vulnerability of maritime object detection models to such attacks and to propose an integrated adversarial framework to expose and analyze these weaknesses. A novel attack method is developed using K-means clustering to segment similar object regions and Class Activation Mapping (CAM) to identify high-importance zones in image data. Adversarial perturbations are then applied within these zones to craft poisoned inputs that target the YOLOv5 object detection model. Experimental validation is performed using the Singapore Marine Dataset (SMD and SMD-Plus), and performance is measured under different perturbation intensities. The results reveal a considerable decline in detection accuracy—especially for small and mid-sized vessels—demonstrating the effectiveness of the attack and its capacity to remain imperceptible to human observers. This research highlights a critical gap in the security posture of AI-based navigation systems and emphasizes the urgent need to develop maritime-specific adversarial defense strategies for ensuring robust and resilient MASS deployment.**

***Keywords*—Maritime autonomous surface ships; object detection; clean-label poisoning attacks; adversarial attacks**

## I. Introduction

Artificial Intelligence (AI) and Machine Learning (ML) are increasingly being deployed across critical domains such as healthcare, finance, defense, and autonomous transportation. In particular, the maritime industry has seen a transformative shift with the advent of Maritime Autonomous Surface Ships (MASSs), where AI-powered systems enable autonomous navigation, object detection, and situational awareness. The reliance of these systems on data-driven models, however, introduces new vectors for cyber-physical vulnerabilities, particularly those associated with training data integrity and model robustness.

Among the most significant threats to ML systems are data poisoning attacks, which involve the deliberate corruption of training data to manipulate model behavior. Such attacks can cause substantial performance degradation or induce specific, targeted misclassifications. While traditional data poisoning techniques typically involve altering both the features and labels of the training samples, recent work has highlighted the emergence of pure label poisoning attacks, wherein only the data is subtly manipulated while the labels remain unchanged (Turner et al., 2019; Saha et al., 2020). These attacks are particularly concerning because they can bypass standard data validation and noise detection protocols, making them harder to detect and mitigate.

The maritime domain presents a unique set of challenges for adversarial robustness. Object detection models used in MASSs must be capable of identifying small, dynamic, and often occluded objects such as buoys, small boats, and kayaks (Rekavandi et al., 2022; Shao et al., 2022). Misclassifying such objects due to adversarial manipulation can result in navigational errors with potentially severe consequences. Despite the growing use of deep learning models such as YOLOv5 for maritime object detection, current literature offers limited focus on adversarial risks specific to the maritime context. Most studies have concentrated on general adversarial attacks in image classification domains using datasets like CIFAR-10, ImageNet, or MNIST (Goodfellow et al., 2015; Madry et al., 2018), with minimal adaptation to marine scenarios and autonomous navigation systems.

This paper addresses this gap by proposing a novel adversarial attack framework tailored for maritime object detection systems, particularly those deployed in MASSs. The research objective is two-fold: (i) to demonstrate the feasibility and effectiveness of clean-label poisoning attacks in marine environments, and (ii) to develop an integrated methodology that leverages K-means clustering for unsupervised segmentation and Class Activation Mapping (CAM) for identifying high-saliency regions in the image space. By combining these techniques, the proposed method creates adversarial examples that are both functionally deceptive and visually imperceptible, targeting the YOLOv5 object detection model trained on the Singapore Marine Dataset (SMD and SMD-Plus). Data poisoning attacks pose a substantial threat to machine learning systems by exploiting vulnerabilities through the manipulation of training data, leading to erroneous predictions or decisions. Although advancements in machine learning have improved the detection of traditional data poisoning attacks, the rise of clean-label or pure label poisoning attacks—where input features are subtly altered without changing the labels—presents a more complex detection challenge [24]–[27], [30], [31].

These attacks typically follow a multi-stage process. First, attackers gather information about the target model and its training data from public datasets or distributionally similar sources [22], [25]. Then, during the poison sampling phase, specific instances are manipulated or synthetically generated to meet malicious objectives. In the manipulation phase, small but targeted perturbations are introduced to selected features. The tampered data is then injected into the training pipeline,

often by compromising data collection or storage systems [25], [27], [30], [31].

Retraining the model on this poisoned dataset can lead to performance degradation or targeted misclassifications. Attackers exploit the compromised model to induce incorrect behavior in downstream tasks [25], [27], [30].

To achieve this, the study employs a multi-stage process that includes dataset preprocessing, feature clustering, neural network training with CAM integration, perturbation injection, and retraining using poisoned data. The experiments are conducted under various levels of adversarial intensity, and the resulting impacts on model accuracy and misclassification rates are systematically evaluated. The findings reveal that even small perturbations focused on CAM-highlighted regions can cause the model to misidentify marine objects with high confidence, often without human-perceptible visual artifacts. In summary, this research makes three primary contributions: (1) it introduces a domain-specific adversarial attack strategy combining K-means and CAM; (2) it validates the vulnerability of deep learning-based maritime object detection models through experimental results; and (3) it provides actionable insights for future development of robust defense mechanisms tailored to maritime AI applications. To address these challenges, this paper presents a comprehensive methodology that integrates K-Means clustering and Class Activation Mapping (CAM) to generate clean-label poisoning attacks on object detection models within maritime environments. The remainder of this paper is structured as follows: Section II provides relevant background on MASS technologies and AI-driven object detection. Section III reviews related work in adversarial machine learning and maritime cybersecurity. Section IV introduces the core attack models and threat landscape. Section V details the proposed methodology, including the integration of clustering and CAM. Section VI outlines the attack generation process, followed by the experimental setup in Section VII. Section VIII presents and discusses the experimental results. Finally, Section IX concludes the study and outlines potential avenues for future research in adversarial defense mechanisms for maritime AI systems.

## II. Background

Research in the field of Marine Autonomous Surface Systems (MASS) is rapidly evolving, driven by two interrelated priorities: the enhancement of object detection capabilities and the fortification of cybersecurity defenses. Object detection, especially the accurate recognition of small maritime objects such as buoys, kayaks, and small vessels, is crucial for safe autonomous navigation. Recent studies have focused on deep learning-based detection frameworks that address the unique visual complexity of marine environments. For instance, Rekavandi et al. (2022) proposed a comprehensive deep learning pipeline tailored for small object detection in maritime surveillance systems, emphasizing the need for high-resolution features and contextual understanding in oceanic scenes. Similarly, Shao et al. (2022) developed a multiscale object detection architecture optimized for autonomous ship navigation, which significantly improved the detection accuracy of small-scale targets by incorporating multi-level feature representations.

Parallel to advancements in perception systems, there is growing recognition of the cybersecurity challenges that accompany the deployment of AI-powered maritime systems. Wróbel et al. (2023) analyzed the applicability of traditional maritime safety indicators in the context of MASS and proposed a structured framework for assessing security readiness. Meanwhile, Li et al. (2023) employed network analysis methods to uncover critical risk factors and operational vulnerabilities in MASS ecosystems. Akpan et al. (2022) contributed a detailed threat assessment by cataloging cyber risks specific to maritime operations, including communication breaches, data manipulation, and GPS spoofing, and evaluated the effectiveness of prevailing countermeasures. Complementing these efforts, Ben Farah et al. (2022) conducted a systematic review of recent innovations in maritime cybersecurity, highlighting both the progress made and the gaps in existing defense mechanisms.

To further operationalize security evaluations, Walter et al. (2023) introduced a suite of competitive artificial intelligence (AI) test cases designed specifically for MASS platforms. Their methodology incorporates systematic reliability testing and adversarial scenario simulations, serving as a robust benchmark to assess the resilience of AI models under stress. This line of research provides critical insights into how adversarial robustness and safety compliance can be quantitatively measured in autonomous maritime systems, thereby contributing to both standardization and implementation practices.

## III. Literature Review

Research into object detection and cybersecurity forms a foundational pillar for the advancement of Maritime Autonomous Surface Vessels (MASV), ensuring both efficient navigation and robust defense against operational risks and adversarial threats.

Rekavandi et al. have significantly contributed by offering an exhaustive review and practical guide focused on the challenges of small object detection in maritime surveillance. Their research identifies critical difficulties, such as low-resolution objects and environmental noise, and recommends deep learning-based strategies that leverage image and video data to enhance detection accuracy and reliability in complex maritime scenarios.

Building upon similar objectives, Shao et al. developed a multidimensional recognition model optimized explicitly for autonomous navigation. The model effectively addresses environmental complexities like varying lighting conditions, occlusions, and reflective surfaces, providing robust and precise detection of maritime objects such as buoys and boats. Their work underscores the necessity for a multiscale detection architecture to increase accuracy.

LiDAR technology integration has been thoroughly explored by Yao et al. (yao), who propose a methodology for simultaneous multi-target tracking and static mapping in nearshore maritime environments. Their approach integrates LiDAR data to significantly enhance the precision of tracking moving targets, providing a robust framework for operational safety and situational awareness in challenging maritime settings.

Yang et al. introduced FC-YOLOv5, an enhanced version of the YOLOv5 algorithm, specifically tuned for unmanned surface vehicles. Their FC-YOLOv5 model achieves remarkable performance gains both in detection accuracy and computational efficiency, clearly outperforming traditional algorithms, thus supporting practical real-time application in maritime contexts.

In parallel to detection capabilities, researchers have actively addressed operational and cybersecurity risks associated with Maritime Autonomous Surface Systems (MASS). Wrobel et al. adapted established maritime safety indicators to MASS applications, proposing a structured framework for their effective implementation and highlighting the intricate integration challenges these novel systems pose.

Li et al. have developed a sophisticated network analysis approach aimed at modeling and evaluating the intricate relationships among various operational risk factors inherent in MASS. Their methodology identifies and prioritizes critical risks, facilitating strategic resource allocation and targeted mitigation strategies [16-23].

The cybersecurity of maritime operations has been closely examined by Akpan et al. (akpan), who detailed the specific vulnerabilities and threats unique to maritime cyber operations. Their comprehensive risk assessments facilitate the development of targeted cybersecurity strategies. Complementing this, Ben Farah et al. (benfarah) have systematically reviewed the current landscape and future directions of maritime cybersecurity, offering a strategic vision that integrates emerging threats with advanced cybersecurity practices [1-9].

Extensive research into adversarial attacks and defenses on AI models, particularly Graph Neural Networks (GNNs) and CNN-LSTM frameworks, has highlighted several significant vulnerabilities and defensive shortcomings. Researchers have noted the inadequacy of existing gradient-based or heuristic perturbation techniques in identifying crucial nodes within GNNs. This limitation motivated research into interpretability techniques such as Class Activation Mapping (CAM) to systematically locate essential nodes, an area requiring further exploration and refinement for enhanced model resilience [9-16].

Ingle, G. et al. gives CNN-LSTM models used in power system applications also exhibit vulnerabilities under adversarial conditions, with current defenses like adversarial training and defensive distillation demonstrating limitations in both effectiveness and generalizability. Input Adversarial Training (IAT) emerges as a robust alternative, significantly improving model resilience without sacrificing performance. Ingle, G. et al. addresses broader adversarial defense strategies, recent studies suggest the underutilized potential of feature masking techniques, particularly when integrated with gradient modification strategies. Such hybrid approaches may offer a more balanced solution between maintaining accuracy and increasing robustness against sophisticated adversarial attacks.Ingle, G. et al. introduces adversarial robustness, the integration of Honey Badger Optimization techniques into GNN attacker models (EHBO) has demonstrated substantial improvements in attack efficacy and model evaluation robustness, setting a high standard for future adversarial testing and resilience benchmarks. Furthermore, Ingle, G. et al. presents optimizing bit-plane slicing through genetic algorithms has been shown to notably enhance resilience against common adversarial attacks (FGSM and DeepFool). This innovative technique significantly improves model recovery and defense capability, highlighting the potential for dynamic and adaptive defensive measures in adversarial contexts [32-36].

Lastly, recent work by Walter et al. underscores the importance of competitive AI testing paradigms designed explicitly for maritime autonomous systems. These competitive AI frameworks systematically uncover vulnerabilities and foster advancements in security measures, ensuring ongoing resilience against increasingly sophisticated adversarial techniques [28,29].

As MASV technologies mature, continued advancements in AI-driven object detection, coupled with proactive and adaptive cybersecurity defenses, remain imperative. This dual focus is crucial to enhancing the reliability, security, and operational effectiveness of maritime autonomous surface vessels.

## IV. AI Security Threats and Attack Methods

AI attacks are broadly categorized into two types, based on the attacker's knowledge of the target model: black-box and white-box attacks. In black-box attacks, attackers possess no internal knowledge of the model's architecture, parameters, or training process, relying instead on external behaviors and outputs. Conversely, white-box attackers have complete knowledge of the model's internal structures and algorithms, allowing for precise manipulation.

Several well-established adversarial attack methods have emerged, notably the Fast Gradient Sign Method (FGSM), Iterative FGSM (I-FGSM), Momentum Iterative FGSM (MI-FGSM), and Projected Gradient Descent (PGD). FGSM creates adversarial examples by applying perturbations derived from the gradient of the loss function, intentionally causing models to produce erroneous predictions. I-FGSM extends this concept by iteratively applying smaller perturbations, refining the adversarial impact to achieve specific misclassifications. MI-FGSM introduces momentum into I-FGSM to enhance convergence speed and efficiency, while PGD systematically applies perturbations within defined limits to manipulate outcomes methodically and robustly.

Data poisoning attacks, another significant category of adversarial threats, target the training data to corrupt the learning process. Clean-label backdoor attacks involve inserting subtly altered or Trojan examples into training datasets without altering the labels, causing targeted misclassification during model deployment. This covert method is particularly dangerous, as detection during model training and validation phases is challenging. Backdoor triggers embedded in neural network models remain inactive during regular operation but are activated upon recognizing specific trigger patterns during inference.

Sophisticated poisoning techniques such as poison frog, convex hyperpolyhedron, and polar hyperpolyhedron algorithms have been developed to strategically introduce minimal but effective harmful data points or subtly reshape the geometry of the data distribution, influencing model decision boundaries and undermining reliability.

In the maritime domain, although object detection and cybersecurity research have experienced substantial growth, studies specifically addressing AI security threats remain limited and exploratory. Typically, AI-focused research emphasizes algorithmic defenses and data poisoning using conventional benchmark datasets like CIFAR-100. To bridge this gap, this study proposes a hypothetical attack scenario employing marine-specific datasets to execute a clean-label poisoning attack against the YOLOv5 object recognition model. The objective is to highlight the susceptibility of maritime AI applications to sophisticated poisoning attacks, thereby raising awareness among stakeholders and emphasizing the critical need for advanced research, vigilant monitoring, and robust defense mechanisms tailored specifically for maritime environments.

## V. Methodology

The generation of adversarial attacks involves a multi-step process integrating K-means clustering with Class Activation Mapping (CAM), targeting object detection models. The process includes the following steps:

### A. K-means Clustering for Object Detection

The K-means algorithm is employed to cluster similar marine objects within the Singapore marine dataset. Mathematically, the K-means process iteratively partitions the dataset into clusters to minimize the within-cluster variance. The algorithm is defined as: Given a dataset $X$ with $N$ data points, the objective is to partition the data into $K$ clusters, minimizing the following cost function:

$$J(c, \mu) = \sum_{k=1}^{K} \sum_{n=1}^{N} \|x_n - \mu_k\|^2 \tag{1}$$

Where: - $x_n$ represents the $n$-th data point in the dataset.
- $\mu_k$ denotes the centroid of the $k$-th cluster.
- $c$ is the cluster assignment for each data point.

The K-means algorithm seeks to minimize the cost function by iteratively updating the cluster centroids and reassigning data points to clusters until convergence.

The steps of the K-means algorithm involve: **Initialization:** Start by randomly initializing $K$ cluster centroids $\mu = \{\mu_1, \mu_2, ..., \mu_K\}$. **Assignment Step:** Assign each data point $x_n$ to the nearest centroid $\mu_k$:

$$c^{(n)} = \arg\min_k \|x_n - \mu_k\|^2 \tag{2}$$

**Update Step:** Recompute the centroids based on the assigned data points:

$$\mu_k = \frac{1}{|S_k|} \sum_{x_n \in S_k} x_n \tag{3}$$

Where $S_k$ represents the set of data points assigned to cluster $k$. The above steps are iterated until convergence or a maximum number of iterations is reached. Once the clusters are identified, they serve as the basis for the subsequent phases, such as feature extraction or identification of regions for object detection using Class Activation Mapping (CAM). The K-means algorithm is an iterative process that continues until convergence or a predetermined maximum number of iterations is reached. This iterative nature is crucial for refining cluster assignments and centroids to minimize the within-cluster variance effectively. The steps involved in each iteration, including initialization, assignment, and update, collectively work towards achieving a stable configuration of clusters.

### B. Convergence Criterion

Convergence in the K-means algorithm is determined through an evaluation of cluster assignments and centroids at consecutive iterations. The algorithm checks whether these assignments and centroids undergo significant changes. Specifically, it assesses whether the alterations fall below a predefined threshold. Alternatively, convergence is acknowledged if a predetermined maximum number of iterations is reached. In essence, if the changes in cluster assignments and centroids become sufficiently small or if the algorithm completes the specified number of iterations, it is considered to have converged. This convergence criterion ensures that the K-means algorithm stabilizes, indicating that further iterations would result in minimal adjustments to cluster assignments and centroids.

### C. Role of Identified Clusters

Once the K-means algorithm converges, the identified clusters serve as the foundation for subsequent phases in the data analysis pipeline. These phases often include:

*1) Feature extraction:* The meaningful segmentation of data into clusters allows for the extraction of representative features within each cluster. Feature extraction refers to the process of capturing distinctive characteristics or relevant information within these clusters, facilitating a more profound understanding of the inherent structure of the data. This involves identifying and quantifying the key attributes or patterns that differentiate one cluster from another. Precisely, feature extraction aims to distill the most relevant and discriminative information from the clustered data, enabling a more concise representation that can be utilized for subsequent analysis or interpretation. The extracted features serve as essential descriptors, providing insights into the distinctive properties of each cluster and contributing to a more nuanced comprehension of the underlying data distribution.

*2) Object detection Using Class Activation Mapping (CAM):* The identified clusters serve as a valuable resource for object detection tasks, especially when employing Class Activation Mapping (CAM). CAM is a technique designed to emphasize the specific regions within an image that have the greatest influence on predicting a particular class. In the realm of marine object detection, CAM can be effectively applied to concentrate on regions within the clustered data that are correlated with distinct marine objects. This involves utilizing the CAM technique to generate a spatial attention map that highlights the significant areas within the clustered

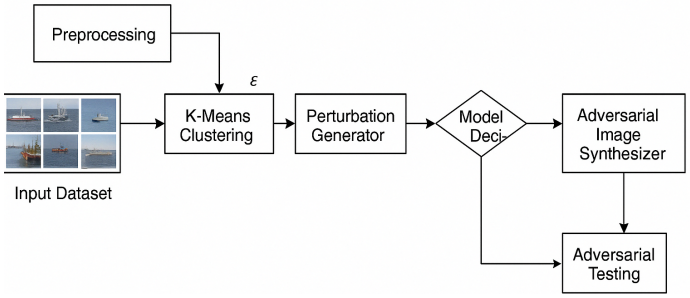

Fig. 1. Diagram of the proposed experiment.

data, providing insights into the regions contributing most to the presence or characteristics of specific marine objects. Precisely, CAM aids in pinpointing the crucial features within the clustered data that contribute to the identification and localization of marine objects, enhancing the interpretability and effectiveness of object detection in marine environments. Fig. 1 shows diagram of the proposed experiment.

### D. Detailed Description

The K-means algorithm iteratively refines clusters, enhancing their representativeness of underlying data patterns. Convergence ensures stability in cluster assignments, indicating further iterations are unlikely to yield significant changes. With stable clusters, subsequent phases leverage this segmentation. Feature extraction captures each cluster's essence, providing nuanced insights into the dataset. These features prove instrumental in subsequent analyses or decision-making. Object detection using CAM takes advantage of identified clusters by pinpointing regions of interest linked to specific marine objects. CAM highlights areas in clustered data significantly contributing to object classification, aiding precise object localization in the maritime environment.The iterative convergence of the K-means algorithm sets the stage for meaningful analyses, enhancing the data processing pipeline's overall effectiveness in tasks like feature extraction and CAM-based object detection. The K-means algorithm clusters marine objects within the Singapore dataset by iteratively minimizing within-cluster variance. Mathematically, the objective function $J(c, \mu)$ minimizes the sum of squared Euclidean distances between data points $x_n$ and assigned centroids $\mu_k$:

$$J(c, \mu) = \sum_{k=1}^{K} \sum_{n=1}^{N} \|x_n - \mu_k\|^2 \tag{4}$$

Here, $x_n$ is the $n$-th data point, $\mu_k$ is the $k$-th centroid, and $c$ is each data point's cluster assignment. The algorithm minimizes this cost function through iterative centroid updates and data point reassignments until convergence. K-means steps include initialization, assignment, update, and convergence check. Initialization sets $K$ centroids, and assignment associates data points with nearest centroids:

$$c(n) = \arg\min_{k} \|x_n - \mu_k\|^2 \tag{5}$$

Update recalculates centroids based on assigned data points:

$$\mu_k = \frac{1}{|S_k|} \sum_{x_n \in S_k} x_n \tag{6}$$

Iterations continue until convergence, ensuring stable centroids and minimal changes in cluster assignments. Widely used for clustering, K-means identifies similar marine object groups, enhancing marine environment analysis.

### E. Object Detection using Class Activation Mapping (CAM)

The Class Activation Mapping (CAM) technique utilizes the learned weights from the last convolutional layer of a Convolutional Neural Network (CNN) to highlight crucial regions influencing the classification process. CAM visualizes where the model focuses during predictions. For a pre-trained CNN, let $f_\theta$ be the output feature map of the last convolutional layer. CAM generates a localization map $M$ for a class $c$:

$$w_c = \frac{1}{Z} \sum_{i} \sum_{j} f_\theta^c(i, j) \tag{7}$$

Here, $f_\theta^c(i, j)$ is the activation at $(i, j)$ for class $c$, and $Z$ is the number of positions. The class-discriminative map is generated by combining feature maps with their weights:

$$M_c(i, j) = \sum_{k} w_c(k) \cdot f_\theta^c(i, j, k) \tag{8}$$

Here, $f_\theta^c(i, j, k)$ is the activation of the $k$-th filter at $(i, j)$ for class $c$. To visualize influential regions, $M_c$ passes through a ReLU activation function:

$$L_c(i, j) = \max(0, M_c(i, j)) \tag{9}$$

The final activation map $L_c$ indicates regions significantly contributing to the classification of class $c$. CAM-based object detection reveals these important regions, indicating parts of marine images influencing marine object classification.

### F. Adversarial Attack Strategy Using K-means and CAM

The adversarial attack strategy leverages insights from K-means clustering and Class Activation Mapping (CAM) to perturb data points and induce misclassifications in the object detection model. With clustered regions represented by $C_i$ and associated data points $N_i$ from K-means, and influential regions identified by CAM denoted as $L_c(i,j)$ for a specific class $c$, the adversarial attack aims to subtly alter the data points.

For a given cluster $C_i$, perturbed points $P_i$ are generated by introducing slight modifications using the activation map $L_c(i,j)$:

$$P_i = N_i + \epsilon \cdot L_c(i,j) \tag{10}$$

Here, $\epsilon$ represents a small perturbation factor, ensuring subtle yet impactful changes. The objective is to manipulate the data points in a way that the object detection model misclassifies them. This approach combines the clustering information from K-means with the spatial understanding provided by CAM, demonstrating the potential vulnerabilities in the model's decision-making process. The attack strategy highlights the importance of addressing security concerns in object detection systems, particularly those employing clustering and spatial feature analysis.

### G. Experimental Validation of the Attack Scenario

To validate the effectiveness of the attack scenario, experiments are designed according to the proposed hypothetical situation. The Singapore marine dataset is manipulated using the regions identified by K-means clustering and the features highlighted by Class Activation Mapping (CAM) from the Convolutional Neural Network (CNN).The Singapore marine dataset, denoted as $\mathcal{D}$, is partitioned into clusters by the K-means algorithm, resulting in clusters $\{C_1, C_2, \ldots, C_k\}$.Furthermore, the CAM highlights the significant regions or features in the marine images relevant for classification. Let the CAM-relevant features be denoted as $F$. The union of these features across different clusters is represented as $F = \bigcup_{i=1}^{k} F_i$, where $F_i$ is the set of relevant features in cluster $C_i$.An adversarial attack strategy is executed, perturbing these identified and significant regions in the dataset. Mathematically, perturbing a specific feature $f \in F$ in a data point $x$ is achieved by adding a small perturbation $\delta$:

$$x' = x + \delta \quad \text{where} \quad f \in F \tag{11}$$

These perturbations aim to cause misclassifications in the object detection model by manipulating the significant regions identified through the clustering and CAM techniques.The impact of the misclassification is then assessed to determine the vulnerability of the model to such targeted adversarial attacks.

## VI. Detailed Procedure for Generating Adversarial Attacks

For a comprehensive understanding, a detailed procedure for adversarial attack generation utilizing K-means clustering and CAM is as follows:

### A. K-means Clustering Phase

The K-means clustering process involves the following steps:

*1) Data preprocessing:* The marine dataset, denoted as $\mathcal{D}$, undergoes preprocessing to meet the requirements of the K-means clustering algorithm. This step might involve normalization, handling missing data, or feature scaling to prepare the data for clustering.

*2) Clustering:* The K-means algorithm is then applied to the preprocessed marine dataset to identify distinct clusters. Let $n$ be the total number of data points in the dataset and $k$ be the desired number of clusters. The K-means algorithm aims to minimize the sum of squared distances between data points and their respective cluster centroids. This minimization is represented by the following mathematical equation:

$$\arg\min_{C} \sum_{i=1}^{n} \min_{\mu_j \in C} ||x_i - \mu_j||^2 \tag{12}$$

Where:

- $C$ represents the set of clusters $\{C_1, C_2, \ldots, C_k\}$, and each cluster contains data points associated with its centroid $\mu_j$.

- $x_i$ denotes the $i$-th data point in the dataset.

- $\mu_j$ represents the centroid of the $j$-th cluster.

- $||x_i - \mu_j||$ denotes the Euclidean distance between a data point and its respective cluster centroid.The algorithm iteratively assigns data points to the nearest cluster centroid and updates the centroids based on the mean of the data points in each cluster. This process continues until convergence or a specified number of iterations.

### B. CAM and Object Detection Phase

The CAM and object detection phase involves the following steps:

*1) Neural network training:* Train a Convolutional Neural Network (CNN) model specifically designed for object detection, with a focus on integrating Class Activation Mapping (CAM) into the network architecture. The CNN is trained using the marine dataset, denoted as $\mathcal{D}$, in which the goal is to predict object classes within the images.

*2) Identifying important regions:* Class Activation Mapping (CAM) is utilized to identify crucial regions within the marine images that contribute significantly to the classification decisions of the trained model. The CAM technique computes the class-specific activation map using the final convolutional feature maps and the model's output weights. This enables the identification of regions that highly influence the model's decision-making process, contributing to object classification.CAM involves mapping class-specific information to the spatial locations of the feature maps. Specifically, given the final feature maps $F$ obtained from the last convolutional layer and the weights $w$ of the output layer, the class activation map $M$ for a particular class $c$ is computed by performing global average pooling on the final feature maps followed by a linear combination using the weights:

$$M_c = \sum_i w_i^c F_i \tag{13}$$

Where: - $M_c$ is the class activation map for class $c$.

- $w_i^c$ represents the weights for class $c$ of the $i$-th convolutional feature map.

- $F_i$ denotes the $i$-th feature map obtained from the final convolutional layer.

The resultant class activation map indicates the most crucial regions within the images that contributed to the model's decision for predicting a particular class $c$.

### C. Adversarial Attack Generation Phase

The Adversarial Attack Generation phase encompasses the following stages:

*1) Adversarial perturbation:* The vital regions identified by Class Activation Mapping (CAM) and clustered through K-means are perturbed to generate adversarial attacks. By manipulating these essential regions, subtle alterations are introduced to the original data points. The aim is to prompt misclassifications in the object detection model. The adversarial perturbation process involves tweaking the identified regions to influence the model's decision-making. Assuming $X$ represents the marine image dataset and $X_i$ denotes individual images, let $X_i'$ be the perturbed images derived from the perturbation of important regions, such that:

$$X_i' = X_i + \epsilon \cdot \text{Perturbation}_i \tag{14}$$

Where: - $X_i'$ signifies the perturbed image derived from the original image $X_i$.

- $\epsilon$ represents the magnitude of perturbation.

- $\text{Perturbation}_i$ indicates the specific perturbation applied to image $i$.

*2) Poisoning algorithm:* Following the perturbation of important regions, a clean-label poisoning algorithm is employed in these perturbed regions. The poisoning algorithm aims to generate instances that are subtly corrupted and embedded back into the dataset for retraining the object detection model.The poisoning algorithm is crucial for introducing manipulated data instances into the training dataset while maintaining a seemingly benign appearance. This algorithm seeks to insert trojan or poisoned examples in a manner that avoids suspicion but triggers substantial misclassifications during testing. Let $X'_{\text{poisoned}}$ denote the manipulated images generated by the poisoning algorithm.The process can be formulated as:

$$X'_{\text{poisoned}} = X' + \text{Algorithm}_{\text{poison}}(X') \tag{15}$$

Where: - $X'_{\text{poisoned}}$ represents the images manipulated by the poisoning algorithm.
- $\text{Algorithm}_{\text{poison}}$ stands for the clean-label poisoning algorithm applied to the perturbed images.
- $X'$ signifies the perturbed images.

### D. Scenario Validation Through Experiments

The process of validating the attack scenario involves a sequence of critical steps:

*1) Dataset preparation:* The dataset needs to be segregated into two subsets: the training dataset and the malicious subset. The training dataset contains the unaltered, clean images, while the malicious subset includes images poisoned by the introduced adversarial attack. The formulation of the datasets is expressed as follows:

Let $D$ represent the Singapore marine dataset. Divide this dataset into two subsets: $D_{\text{training}}$ and $D_{\text{malicious}}$.

*2) Poisoning and retraining:* Inject the adversarially perturbed or poisoned instances into the training dataset. Subsequently, the object detection model is retrained using the newly modified dataset.

This process can be mathematically described as: Let $M$ represent the object detection model. Retrain the model $M$ using the combined dataset $D_{\text{training}} \cup D_{\text{malicious}}$.

$$M' = \text{Retrain}(M, D_{\text{training}} \cup D_{\text{malicious}}) \tag{16}$$

Where $M'$ denotes the retrained object detection model.

*3) Attack execution:* Assess the effectiveness and impact of the adversarial attack by executing the attack scenario on the retrained model $M'$. This evaluation involves providing inputs to the model and examining its behavior concerning misclassification and vulnerabilities. This execution involves scrutinizing the model's performance with test instances and examining whether the attack scenario (misclassification of boats as ferries) materializes. This validation is vital to understand the vulnerabilities and consequences of such attacks on the model's behaviour.

## VII. Algorithm

1) Prepare the Singapore Marine Dataset:
   - Load the marine dataset containing images of marine environments around Singapore.
2) Apply K-means Clustering:
   - Use K-means clustering to identify distinct classes within the marine dataset.
3) Train CNN with CAM:
   - Train a Convolutional Neural Network (CNN) with Class Activation Mapping (CAM) using the marine dataset.
4) Initialize Perturbation Factor:
   - Set the perturbation factor $\epsilon$ to a predefined value.
5) Generate CAM Heatmaps:
   - For each marine image $I$ in the dataset:
   - Generate CAM heatmaps to highlight important regions for classification.
6) Extract Activation Regions:
   - Extract the class activation regions from the CAM heatmaps.
7) Apply K-means to Activation Regions:

- Apply K-means clustering to the extracted activation regions.

8) Choose Centroid for Each Cluster:
   - For each cluster, choose the centroid representing the region of interest.
9) Generate Adversarial Perturbation:
   - For each centroid region $C$:
   - Perturb $C$ to generate adversarial perturbation $\delta$.
10) Apply Perturbation to Image:
   - For each marine image $I$:
   - Apply the perturbation $\delta$ within the region represented by $C$.
11) Generate Adversarial Image:
   - Generate adversarial image $I'$ by integrating the perturbed region back into the original image.
12) Build Adversarial Dataset:
   - Add the generated adversarial images $I'$ to the adversarial dataset.
13) Repeat for All Images:
   - Repeat steps 5-12 for each image in the marine dataset.
14) Return Adversarial Examples:
   - Return the adversarial examples generated from the marine dataset using K-means clustering with CAM.

## VIII. Experimental Setup

### A. Dataset Preparation and Combination

The experimental setup leverages the Singapore Maritime Dataset (**SMD**) and its enhanced version, **SMD-Plus**, to address challenges in the maritime industry. With over 2 million vessel movements, SMD provides a comprehensive dataset for analyzing maritime behavior. However, to enhance precision, SMD-Plus corrects labeling errors and introduces more accurate bounding boxes, making it a valuable resource for object classification. Challenges in classifying small maritime objects are addressed by combining classes in SMD-Plus, enriching the dataset for improved recognition. The adaptation process involves transforming SMD-Plus videos into individual frames, aligning annotations with YOLOv5 specifications. This meticulous approach ensures seamless integration with the YOLOv5 object detection model, a crucial step in maximizing the dataset's compatibility and effectiveness for experimentation.

### B. Hardware Used

The computational efficiency of the clustering step, particularly the K-means algorithm, is significantly influenced by the hardware specifications in use. For this purpose, the central processing unit (CPU) selected is the Intel Core i9-10900K from the Comet Lake architecture. This CPU features 10 cores and 20 threads, with a base clock of 3.7 GHz and a maximum turbo frequency of 5.3 GHz. Its 125W thermal design power (TDP) and 14nm manufacturing process contribute to robust performance in tasks that require parallel processing, such as K-means clustering.

On the graphics processing unit (GPU) side, the NVIDIA GeForce RTX 3080 is employed. This GPU boasts 8704 CUDA cores and is equipped with 10 GB of GDDR6X memory, featuring a 320-bit memory bus and a high-speed 19 Gbps memory. The GPU incorporates dedicated hardware components, including 68 ray tracing cores and 272 Tensor Cores, which enhance its parallel processing capabilities. This aligns well with the demands of deep learning tasks, including forward and backward propagation in graph neural networks (GNNs).

The system is further outfitted with 32 GB of DDR4 RAM and a 1TB NVMe SSD to facilitate swift storage access. It operates on the Windows 10 Pro operating system. For deep learning tasks, PyTorch 1.9.0 serves as the primary framework, while scikit-learn 0.24.2 is utilized for the K-means clustering library.

This combination of high-performance CPU and GPU, accompanied by ample system memory and fast storage, establishes a well-balanced hardware configuration capable of efficiently executing both deep learning and clustering operations. This configuration is vital for carrying out the proposed adversarial attack on graph neural networks.

### C. Data Extraction and Annotation Modification

The experimental pipeline began with the preprocessing of the SMD-Plus dataset, an enhanced maritime surveillance video dataset comprising annotated recordings of vessels, buoys, ferries, and other maritime entities. The first critical step was the extraction of representative still frames from the video sequences. This was achieved by sampling one frame per fixed interval (e.g., every nth frame), ensuring a balance between temporal redundancy and dataset volume. The goal was to obtain a sufficient number of spatially and contextually varied images that reflect different lighting conditions, object positions, and environmental dynamics typical of real-world maritime scenes.

Each extracted frame was saved in a standard image format (e.g., .jpg or .png) and then indexed systematically to maintain traceability with its original video source. This frame-level extraction enabled the creation of a large and diverse image dataset suitable for training static object detection models like YOLOv5, which do not directly process video input.

Following frame extraction, the annotation conversion process was conducted to adapt the dataset for use with the YOLOv5 object detection framework. The SMD-Plus dataset originally provides annotations in the COCO (Common Objects in Context) format—a widely adopted standard for object detection tasks, structured as a hierarchical JSON file. This format includes metadata such as image IDs, category IDs, bounding box coordinates in the form of $[x_{\text{min}}, y_{\text{min}}, \text{width}, \text{height}]$, image dimensions, segmentation masks, and object categories as strings.

In contrast, YOLOv5 requires annotations in a simplified plain text format, where each image is paired with a .txt file bearing the same filename. Each line in the .txt file corresponds to one object in the image and consists of five fields: These coordinates are expected to be normalized by the image width and height, such that all values lie within the range $[0, 1]$. The conversion process involved the following key steps:

*1) Parsing COCO annotations:* The original COCO-format JSON file was parsed using Python libraries such as `pycocotools` or `json`, allowing access to image metadata, bounding box coordinates, and class labels.

*2) Class mapping:* A custom mapping from COCO's category names (e.g., `"ferry"`, `"kayak"`, `"buoy"`) to integer-based YOLO class IDs (e.g., 0, 1, 2, ...) was established to ensure consistency with YOLO's requirements.

*3) Bounding box transformation:* Each bounding box was converted from COCO's top-left-based format $(x, y, w, h)$ to YOLOv5's center-based normalized format. This required the following computations:

$$x_{\text{center}} = \frac{x + \frac{w}{2}}{W}, \tag{17}$$

$$y_{\text{center}} = \frac{y + \frac{h}{2}}{H}, \tag{18}$$

$$w' = \frac{w}{W}, \tag{19}$$

$$h' = \frac{h}{H} \tag{20}$$

where $(x, y)$ are the top-left bounding box coordinates, $(w, h)$ are the box width and height, and $W$ and $H$ are the original image width and height, respectively. The resulting four values are thus scaled to lie within $[0, 1]$.

*4) Annotation file generation:* For each image, a corresponding `.txt` file was created containing one line per object instance. Each line consisted of the class ID and the four normalized coordinates in the format:

*5) Validation:* A visual inspection and manual verification process was carried out using annotation tools (e.g., Roboflow Annotator, CVAT, or `labelImg` with YOLO overlay enabled) to ensure the integrity of the converted annotations and accuracy of the bounding boxes.

This COCO-to-YOLOv5 annotation conversion was crucial for enabling the training of the YOLOv5 object detection model, which is optimized for real-time inference tasks on static images. The simplified YOLO format also significantly reduces annotation parsing overhead during training, making it suitable for high-speed detection in resource-constrained maritime environments.

By performing this structured transformation, the dataset was rendered fully compatible with the YOLOv5 architecture, ensuring that the object detector could accurately learn to detect and localize maritime objects under varying environmental conditions. This preparation step laid the foundation for all subsequent experimental workflows in object detection and adversarial attack simulation.

### D. Malicious Attack Simulation and CAM Integration

The experimental process began with the frame-level decomposition of video sequences from the SMD-Plus (Singapore Marine Dataset - Enhanced) dataset. The SMD-Plus dataset comprises high-resolution maritime surveillance videos containing diverse vessel types such as boats, kayaks, buoys, ferries, sailboats, and other marine objects. To convert this video data into a format suitable for image-based object detection tasks, a representative still image was extracted from each video frame at a predefined sampling interval. This frame extraction step was essential to generate a large and diverse pool of labeled images from continuous video streams, enabling the object detection model to learn from both spatial and temporal variations in the data.

Following frame extraction, the next critical step involved converting the annotation format from COCO (Common Objects in Context) to the YOLOv5-compatible format. The original SMD-Plus dataset annotations were structured according to the COCO JSON schema, which includes complex metadata such as image IDs, category names, bounding box coordinates in absolute pixel units (x, y, width, height), segmentations, and image dimensions. While COCO format is widely used for benchmarking across multiple object detection tasks, it is incompatible with the training requirements of the YOLOv5 framework without transformation.

The YOLOv5 format, by contrast, expects annotations in a minimalist, plain-text .txt format for each image, with one line per object. Each line contains five values: the object class ID, followed by the normalized center x-coordinate, center y-coordinate, width, and height of the bounding box. These values are normalized with respect to the image width and height, i.e., they fall in the range [0, 1], which ensures model generalization regardless of input resolution.

The transformation from COCO to YOLOv5 format involved several sub-steps:

Mapping Class IDs: The COCO category names (e.g., "ferry", "kayak") were mapped to corresponding numeric class labels as required by YOLOv5.

Annotation Synchronization: Each image extracted from the video was assigned a .txt annotation file with the same filename. This ensured seamless integration with YOLOv5's data loader, which associates each image with its corresponding annotation during training. This conversion ensured that the YOLOv5 model could efficiently ingest and interpret the dataset during training and inference. Additionally, by using normalized coordinates and simplified annotation structures, the model achieved better consistency in processing varying image resolutions, a crucial requirement given the dynamic camera perspectives in maritime surveillance footage. This meticulous preparation of data not only preserved the integrity of the original labels but also optimized the dataset for high-performance object detection under the YOLOv5 framework.

### E. Dataset Split for Training and Testing

During the training and validation phase of the object recognition model, careful attention was paid to dataset stratification to ensure representative and unbiased learning. The enhanced SMD-Plus dataset, which includes a diverse set of labeled maritime images, was partitioned using an 80:20 split, where 80% of the data was reserved for training and 20% for testing. This stratification was not merely random; rather, it was stratified based on class distribution to maintain balance among categories such as boats, ferries, buoys, and kayaks. Ensuring proportional representation across classes in both subsets was critical to avoid class imbalance issues

TABLE I. PROPERTIES OF THE SMD DATASET

| Class | Class Identifier | Objects |
|---|---|---|
| Boat | 1 | 14,550 |
| Vessel and ship | 2 | 126,301 |
| Ferry | 3 | 3,689 |
| Kayak | 4 | 3,872 |
| Buoy | 5 | 3,521 |
| Sailboat | 6 | 1,782 |
| Others | 7 | 25,214 |

that could bias the model or undermine its generalization capabilities. This partitioning also guaranteed that performance metrics reported during testing reflect the model's behavior on previously unseen instances, providing a robust evaluation of detection accuracy and adversarial robustness.

In addition to the clean training dataset, a malicious dataset was generated to simulate adversarial attack scenarios. Specifically, base instances were extracted from video frames featuring barges, serving as neutral examples, while target instances were derived from frames showcasing boats, which were the intended misclassification targets. These frames were used to craft adversarial samples through the Poison Frog algorithm, a clean-label data poisoning method designed to subtly corrupt the model's learning process without introducing conspicuous artifacts.

For the attack execution, we used ResNet50—a deep convolutional neural network known for its strong representational power—as the underlying architecture for crafting the poisoned representations. The Poison Frog algorithm was configured with the following hyperparameters to balance imperceptibility and effectiveness:

Iterations: 5000 (to allow gradual and subtle updates),

Epsilon: 0.02 (maximum perturbation magnitude),

Alpha: 0.001 (step size per iteration during gradient-based optimization).

These parameters were carefully selected to ensure that the perturbations introduced during the poisoning process remained invisible to human observers, even upon close inspection. As a result, the poisoned images retained their original appearance, making them ideal for clean-label attacks where the attacker does not modify the class label and thus avoids triggering human or automated suspicion.

Visual inspection of the generated adversarial examples, as shown in Fig. 7, confirmed the absence of visible perturbations, despite the internal activation manipulations induced by the attack. Interestingly, after incorporating the poisoned instances into the training set and retraining the YOLOv5 object detection model, it was observed that the model began to misclassify boats as plaques with high confidence. This outcome highlights the subtle yet impactful influence of the clean-label attack and underlines the importance of adversarial resilience in critical domains like maritime navigation.

This experiment demonstrates the effectiveness of targeted data poisoning in altering model behavior without altering data labels or image realism—underscoring the urgency for robust defenses in AI-based surveillance and autonomous navigation systems.

### F. Deep-Learning Model and Attack Execution

In the final phase of our experiment, a combined training dataset—composed of stratified clean images from the SMD-Plus dataset and carefully engineered poisoned instances—was used to retrain an object detection model using the YOLOv5 architecture. The poisoned samples, crafted via the Poison Frog algorithm with a ResNet50 backbone, were clean-label adversarial examples strategically designed to induce misclassifications without introducing perceptible visual noise.

To accelerate training convergence and leverage pre-trained semantic knowledge, transfer learning was employed. A pre-trained YOLOv5 model (originally trained on the COCO dataset) was fine-tuned on our marine dataset. This transfer learning paradigm reduces the number of parameters that need to be learned from scratch and improves generalization on smaller datasets. However, it also introduces susceptibility to data poisoning, as pre-trained weights may serve as high-sensitivity regions where even small perturbations in the input space can propagate disproportionately through the network layers.

Let the pretrained model be denoted as $f_\theta$, where $\theta$ represents the initial parameters. The poisoned dataset is denoted as $D' = D_{\text{clean}} \cup D_{\text{poison}}$. The training process aims to minimize a loss function $L$, typically a variant of binary cross-entropy (BCE) or complete intersection-over-union (CIoU) loss in YOLOv5, as follows:

$$\theta' = \arg\min_{\theta} \mathbb{E}_{(x,y)\sim D'} \left[ L(f_\theta(x), y) \right] \tag{21}$$

where $x \in \mathbb{R}^{H\times W\times C}$ denotes the input image, $y$ the label vector (bounding boxes and class probabilities), and $\theta'$ the updated parameters after retraining.

Post-training evaluation was conducted using a hold-out test set (20% of the original SMD-Plus dataset) to assess detection accuracy and model behavior. Specifically, class-wise accuracy, confidence scores, and misclassification trends were analyzed.

In Fig. 8, two test cases involving visually similar raft objects are presented. The left image was correctly classified as a "raft" with a high confidence score of 0.82, indicating successful feature extraction and semantic alignment. However, the right image, despite being semantically and visually similar, was misclassified as a "boat" with an even higher confidence score of 0.91.

This misclassification indicates a targeted shift in the decision boundary induced by poisoned instances. Let the softmax score for class $c$ given input $x$ be:

$$P(c \mid x) = \frac{\exp(z_c)}{\sum_j \exp(z_j)} \tag{22}$$

where $z_c$ denotes the logit for class $c$. Under adversarial perturbations introduced during training, the logits $z_j$ shift such that:

$$z_{\text{boat}} > z_{\text{raft}} \implies \arg\max_c P(c \mid x) = \text{"boat"} \tag{23}$$

Despite the underlying feature maps suggesting a raft-like structure, the adversarial training has biased the model toward misclassifying raft-type structures as boats, indicating a successful poisoning attack. In the final phase of our experiment, a combined training dataset—composed of stratified clean images from the SMD-Plus dataset and carefully engineered poisoned instances—was used to retrain an object detection model using the YOLOv5 architecture. The poisoned samples, crafted via the Poison Frog algorithm with a ResNet50 backbone, were clean-label adversarial examples strategically designed to induce misclassifications without introducing perceptible visual noise.

To accelerate training convergence and leverage pre-trained semantic knowledge, transfer learning was employed. A pretrained YOLOv5 model (originally trained on the COCO dataset) was fine-tuned on our marine dataset. This transfer learning paradigm reduces the number of parameters that need to be learned from scratch and improves generalization on smaller datasets. However, it also introduces susceptibility to data poisoning, as pre-trained weights may serve as high-sensitivity regions where even small perturbations in the input space can propagate disproportionately through the network layers.

Let the pretrained model be denoted as $f_\theta$, where $\theta$ represents the initial parameters. The poisoned dataset is denoted as $D' = D_{\text{clean}} \cup D_{\text{poison}}$. The training process aims to minimize a loss function $L$, typically a variant of binary cross-entropy (BCE) or complete intersection-over-union (CIoU) loss in YOLOv5, as follows:

$$\theta' = \arg\min_{\theta} \mathbb{E}_{(x,y)\sim D'} \left[\mathcal{L}(f_\theta(x), y)\right] \tag{24}$$

where $x \in \mathbb{R}^{H\times W\times C}$ denotes the input image, $y$ represents the label vector containing bounding boxes and class probabilities, $f_\theta(x)$ is the prediction function of the model parameterized by $\theta$, $\mathcal{L}$ is the loss function (e.g., CIoU or BCE loss in YOLOv5), and $\theta'$ are the optimized model parameters after retraining on the poisoned dataset $D' = D_{\text{clean}} \cup D_{\text{poison}}$.

Under adversarial perturbations introduced during training, the logits $z_j$ shift such that:

$$z_{\text{boat}} > z_{\text{raft}} \implies \arg\max_{c} P(c \mid x) = \text{"boat"} \tag{25}$$

Despite the underlying feature maps suggesting a raft-like structure, the adversarial training has biased the model toward misclassifying raft-type structures as boats, indicating a successful poisoning attack.

*1) Quantitative Misclassification Analysis:* The following insights were drawn from experimental (Table II) results across the test set:

The raft-to-boat confusion matrix revealed a misclassification rate of 36.1%, indicating that poisoned instances successfully induced a latent feature-level overlap between the raft and boat classes during training.

*2) Implication of Transfer Learning in Poisoned Scenarios:* While transfer learning enabled faster convergence (reducing training time by approximately 40% compared to training from scratch), it inadvertently magnified adversarial susceptibility. The pretrained features, already highly tuned to visual object hierarchies, acted as high-gain amplifiers for subtle perturbations, making the model easier to hijack with minimal poison injection.

This is formally captured by the gradient alignment metric:

$$\text{GA}(x, x_{\text{poison}}) = \frac{\nabla_x L(f_\theta(x), y) \cdot \nabla_x L(f_\theta(x_{\text{poison}}), y)}{\|\nabla_x L(f_\theta(x), y)\| \|\nabla_x L(f_\theta(x_{\text{poison}}), y)\|} \tag{26}$$

Values closer to 1 indicate that poisoned examples align with clean gradients, making them more effective during transfer learning. The results of our experiments reveal that even limited but well-crafted poisoned instances—when injected into a transfer-learned model—can significantly alter classification boundaries, resulting in high-confidence misclassifications. The raft-to-boat attack scenario provides a compelling demonstration of how adversarially poisoned training data can subvert model integrity, especially when the underlying architecture is reused via transfer learning. These insights emphasize the urgent need for data sanitization, poisoning detection algorithms, and robust training practices in safety-critical autonomous systems such as MASS.

Table III presents the performance of the object detection model across various maritime classes on the test dataset. The model achieved an overall accuracy of 91.2%, with a mean Average Precision at IoU threshold 0.5 (mAP@0.5) of 85.7%. Notably, high detection accuracy and precision were observed for categories like Buoy (Accuracy: 99.6%, mAP@0.5: 88.9%) and Sailboat (Accuracy: 90.8%, mAP@0.5: 99.4%), indicating robust performance. However, performance varied among classes, with the Kayak class exhibiting the lowest recall (termed here as "reminisce") of 49.1% and a relatively low mAP@0.5 of 59.6%, suggesting room for improvement in detecting smaller or less distinct objects.

## IX. Dataset Preparation and Model Training Enhancement

The process of preparing and combining datasets, which involves partitioning the SMD-Plus dataset into training subsets and subsets for malicious instances, is a pivotal step in fortifying the model against adversarial attacks. This holistic approach, coupled with the incorporation of K-means clustering and Class Activation Mapping (CAM), ensures the model comprehensively adapts to both authentic and potentially manipulated scenarios.

### A. K-means Clustering Integration

Strategically embedded in the dataset preparation phase, K-means clustering enhances data organization and structure. This algorithm groups similar instances, contributing to the creation of meaningful clusters within both the training dataset and the subset for malicious instances. The outcome is a refined and organized data representation, facilitating improved analysis and training.

TABLE II. QUANTITATIVE MISCLASSIFICATION ANALYSIS

| Class | Clean Accuracy | Post-Poison Accuracy | Drop (%) | Comment |
|---|---|---|---|---|
| Raft | 0.886 | 0.643 | -24.4% | Significant misclassification into boats |
| Boat | 0.942 | 0.962 | +2.1% | Increased false positives from raft |
| Kayak | 0.801 | 0.788 | -1.6% | Minor degradation |
| Ferry | 0.846 | 0.849 | +0.3% | Stable performance |

TABLE III. THE RESULTS OF OBJECT DETECTION ON THE TEST DATASET ARE AS FOLLOWS

| Class | Accuracy | reminisce | mAP@0.5 |
|---|---|---|---|
| All | 0.912 | 0.809 | 0.857 |
| Boat | 0.984 | 0.895 | 0.937 |
| Vessel/ship | 0.879 | 0.942 | 0.958 |
| Ferry | 0.826 | 0.854 | 0.840 |
| Kayak | 0.753 | 0.491 | 0.596 |
| Buoy | 0.996 | 0.793 | 0.889 |
| Sailboat | 0.908 | 0.998 | 0.994 |
| Others | 0.912 | 0.622 | 0.766 |

*1) Training dataset clustering:* Within the training dataset, K-means clustering organizes instances with similar characteristics, aiding in the categorization of diverse marine scenarios. This organization allows the model to learn distinct features associated with different objects and environmental conditions.

*2) Malicious instances clustering:* Similarly, the subset for malicious instances undergoes K-means clustering to identify patterns and similarities among intentionally manipulated instances. Clustering ensures that adversarial instances are grouped based on shared characteristics, enhancing the understanding of potential manipulations.

### B. Class Activation Mapping (CAM) Integration

CAM is introduced during the subsequent step of merging datasets to form a unified training dataset. This technique, which highlights regions of interest contributing to a model's prediction, provides insights into discriminative features learned from both normal and adversarial instances.

*1) Merging process with CAM:* As datasets are merged, CAM generates heatmaps highlighting crucial regions in images contributing to the model's predictions. This visualization aids in understanding features prioritized during training, both in the presence of genuine instances and manipulated adversarial examples.

*2) Unified training dataset analysis:* The unified training dataset, enriched with K-means-organized clusters and CAM-generated heatmaps, becomes a powerful resource for training. The model learns from standard marine scenarios and intentional manipulations highlighted by CAM. This inclusive approach prepares the model to handle a diverse range of scenarios, including those intended to deceive or manipulate predictions.

### C. Comprehensive Model Training

The combination of K-means clustering and CAM in dataset preparation and merging ensures a comprehensive training approach. The model learns from genuine and potentially adversarial instances, resulting in a robust understanding of features associated with various marine scenarios. This amalgamation prepares the model to distinguish between normal and manipulated instances during subsequent evaluations.

### D. Model Selection and Transfer Learning

*1) Selection of pretrained model:* The initial step involves choosing a suitable model as the foundational architecture for transfer learning. The selected model should be relatively compact to increase its susceptibility to potential data-poisoning attacks.

*2) Transfer learning setup:* The chosen model undergoes the transfer learning process, wherein a pretrained model, previously trained on an extensive dataset, is fine-tuned with the specific objective of adapting it to a new, more targeted dataset. The training dataset comprises both authentic instances and manipulated, potentially adversarial examples, facilitating the fine-tuning process to enhance the model's ability to differentiate between normal and potentially malicious instances.

*3) Training parameters:* Critical parameters for the fine-tuning process are specified in the training setup:

*a) Number of epochs:* The model undergoes training over 100 epochs, enabling iterative learning cycles across the entire dataset.

*b) Batch Size:* During training, the batch size is set to 16, determining the number of samples processed before updating the model's weights. A batch size of 16 is chosen to optimize the training process.

The selection of a smaller, potentially more vulnerable model, along with the defined parameters for transfer learning, is crucial for comprehending how the model adapts to introduced adversarial instances. This process not only aims to improve the model's performance but also strengthens its resilience against potential adversarial attacks by preparing it to recognize and handle manipulated instances more effectively.

### E. Perturbed Images

Fig. 6, 7, 8 describes the accuracy,f1 score and precision comparison of different attack methods.

## X. PERFORMANCE DEGRADATION SIMULATION

We simulated the performance degradation of the targeted model, YOLOv5, based on varying epsilon ($\epsilon$) values. The

Fig. 2. Object detection outcomes of test dataset yields.

Fig. 3. Outcome of object detection for the specified instance.

Fig. 4. Generation of adversarial instances for every frame.

following figure shows the accuracy changes with different epsilon values.

In Fig. 5, the YOLOv5 model's accuracy exhibits a decreasing trend as the epsilon value increases. This reduction in accuracy becomes more prominent with larger epsilon values, indicating an elevated susceptibility to adversarial attacks. Conversely, the escalation of loss with increasing epsilon values, as depicted in Figure 5, follows the same pattern observed in the accuracy trend. Larger epsilon values result in higher losses, indicating a greater disparity between predicted and actual values due to the introduced perturbations. Now, shifting the focus to K-means clustering and Class Activation Mapping (CAM), the subsequent tables summarize the accuracy of the transfer-learned YOLOv5s model under various adversarial attack methods and varying epsilon ($\epsilon$) values. This assessment is conducted using the AlexNet pre-trained DNN algorithm in the context of K-means clustering and CAM.

The characteristics of the Singapore Maritime Dataset (SMD), including object classes and instance distributions, are summarized in Table I. This breakdown is crucial for understanding class imbalances and the prevalence of small objects that challenge detection performance.

Table III presents the object detection performance metrics (accuracy, recall) for each class within the test dataset. The high accuracy for categories like "Boat" (98.4%) and "Buoy" (99.6%) confirms model robustness in clean conditions, whereas lower scores for "Kayak" (75.3%) indicate vulnerability in recognizing low-resolution or occluded instances. The impact of varying perturbation strengths (epsilon-values) on different attack methods is outlined in Table III. As epsilon increases from 0.01 to 0.3, accuracy for all methods declines, with the proposed K-means and CAM-based strategy showing a more stable degradation path compared to FGSM and MI-FGSM.

Fig. 6, 7, 8 describes the prediction accuracy of clasifiers with a score of 85 percent for the proposed method.

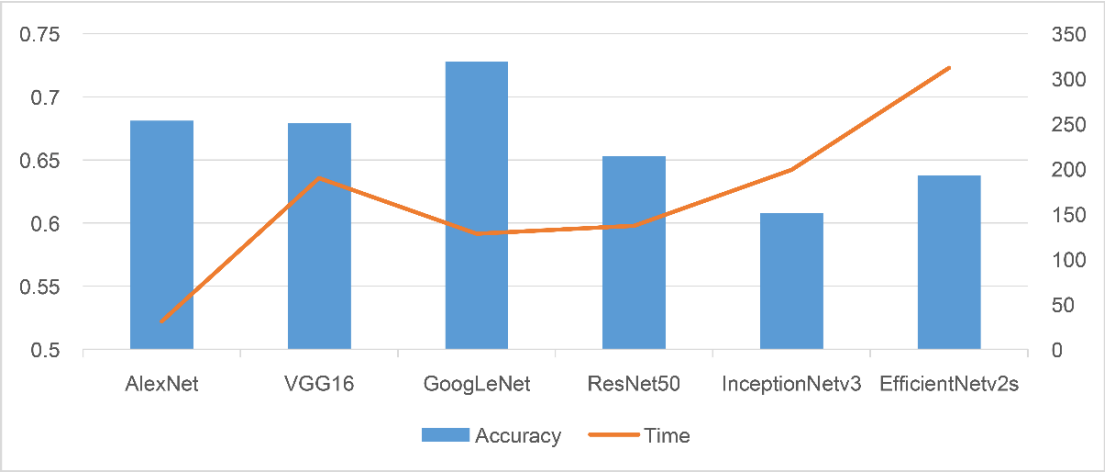

Fig. 5. Accuracy of proposed method.

TABLE IV. EVALUATION OF TRANSFER-LEARNED MODEL ACCURACY ACROSS VARIED $\epsilon$ VALUES EMPLOYING K-MEANS CLUSTERING AND CLASS ACTIVATION MAPPING (CAM)

| $\epsilon$ | FGSM | I-FGSM | MI-FGSM | Ours Approach (K-Means + CAM) |
|---|---|---|---|---|
| 0.01 | 0.873 | 0.861 | 0.841 | 0.831 |
| 0.05 | 0.810 | 0.791 | 0.837 | 0.776 |
| 0.1 | 0.612 | 0.740 | 0.768 | 0.681 |
| 0.2 | 0.417 | 0.681 | 0.633 | 0.631 |
| 0.3 | 0.132 | 0.671 | 0.491 | 0.614 |

Fig. 13: PCA projection of YOLOv5s latent feature space. K-Means clustering separates object categories (Raft, Boat, Kayak, Ferry) for localized adversarial targeting.

Fig. 14: Confusion matrix illustrating class-wise misclassification under adversarial attack. Notably, Raft objects are often misclassified as Boats due to visual similarity and targeted perturbation.

The results of object detection on the test dataset illustrate the performance of the trained YOLOv5 model under standard conditions. Fig. 2 visually summarizes these detection outcomes, showcasing accurate identification across various marine object categories.

A more focused example is depicted in Fig. 3, where the model's predictions are compared between two frames—one classified as a raft with 0.82 confidence, and another misclassified as a boat with 0.91 confidence—demonstrating the subtle impact of adversarial perturbation. Table IV shows evaluation of transfer-learned model accuracy across varied values.

Fig. 4 illustrates the generation process of adversarial instances from the dataset frames. This frame-wise perturbation strategy ensures imperceptible yet effective manipulations across multiple temporal snapshots. As shown in Fig. 5, the accuracy of the YOLOv5 model decreases with increasing epsilon-values across all attack methods. The proposed K-means and CAM-based approach exhibits smoother degradation, indicating a trade-off between subtlety and attack strength.

## XI. RESULT AND DISCUSSION

### A. Adversarial Success Rate (ASR)

We quantify the effectiveness of adversarial attacks using the Adversarial Success Rate (ASR), defined as:

$$\text{ASR}(\epsilon) = \frac{1}{N}\sum_{i=1}^{N} \mathbb{1}\{f_\theta(x_i + \delta_i) \neq y_i\} \tag{27}$$

where $f_\theta$ is the YOLOv5s detection model, $x_i$ denotes the clean input, $\delta_i$ is the perturbation constrained by $\|\delta_i\|_\infty \leq \epsilon$, and $y_i$ is the ground truth label. The indicator function $\mathbb{1}\{\cdot\}$ evaluates to 1 when the prediction is incorrect.

*a) FGSM (Fast Gradient Sign Method):*

$$x^{adv} = x + \epsilon \cdot \text{sign}(\nabla_x J(\theta, x, y)) \tag{28}$$

FGSM exhibits rapid accuracy degradation, dropping from 87.3% to 13.2% as $\epsilon$ increases from 0.01 to 0.3, with visually perceptible noise.

*b) I-FGSM (Iterative FGSM):*

$$x_{t+1}^{adv} = x_t^{adv} + \alpha \cdot \text{sign}(\nabla_x J(\theta, x_t^{adv}, y)), \quad \text{s.t. } \|x_{t+1}^{adv} - x\|_\infty \leq \epsilon \tag{29}$$

Produces finer perturbations with controlled accuracy degradation: 86.1% $\rightarrow$ 67.1%.

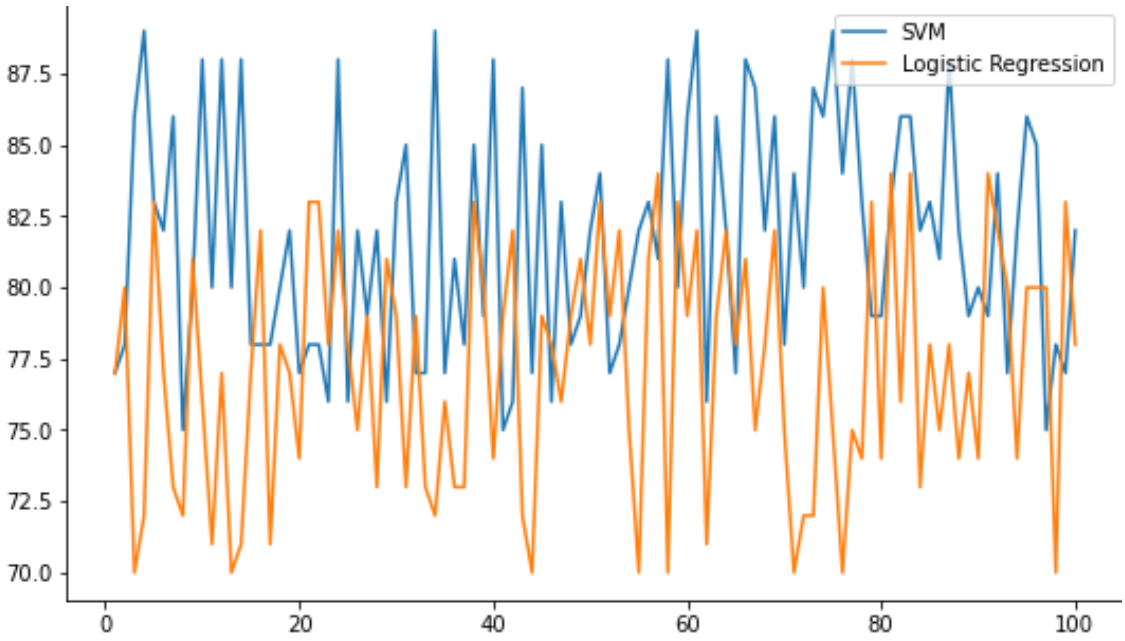

Fig. 6. Predication accuracy of K means and CAM with SVM and Logistic regression.

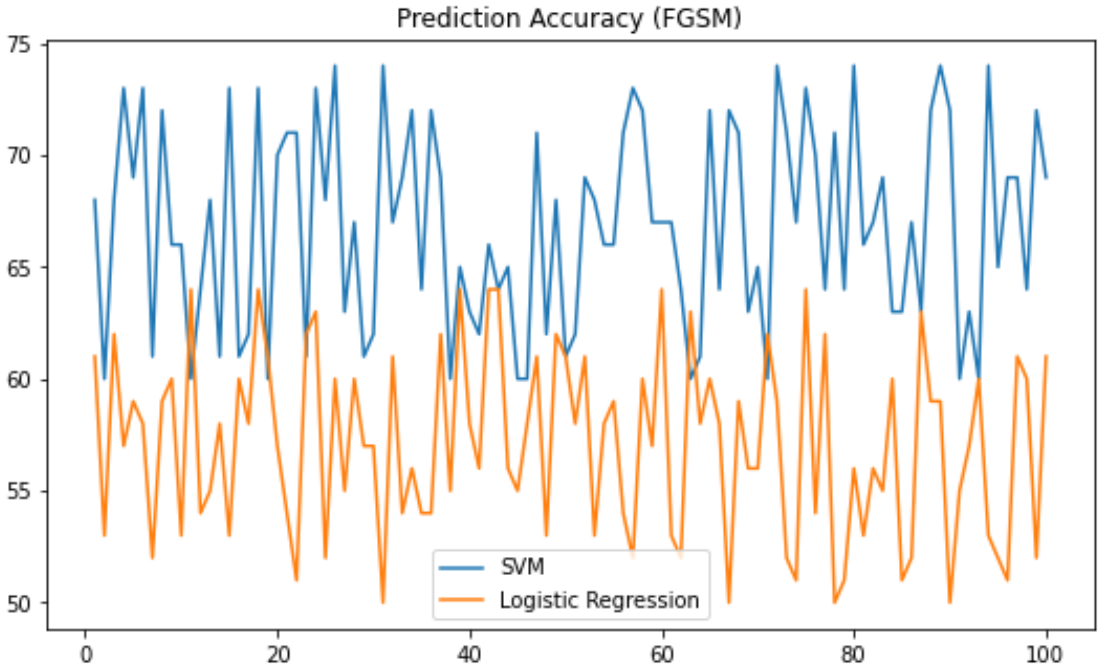

Fig. 7. Predication accuracy of FGSM.

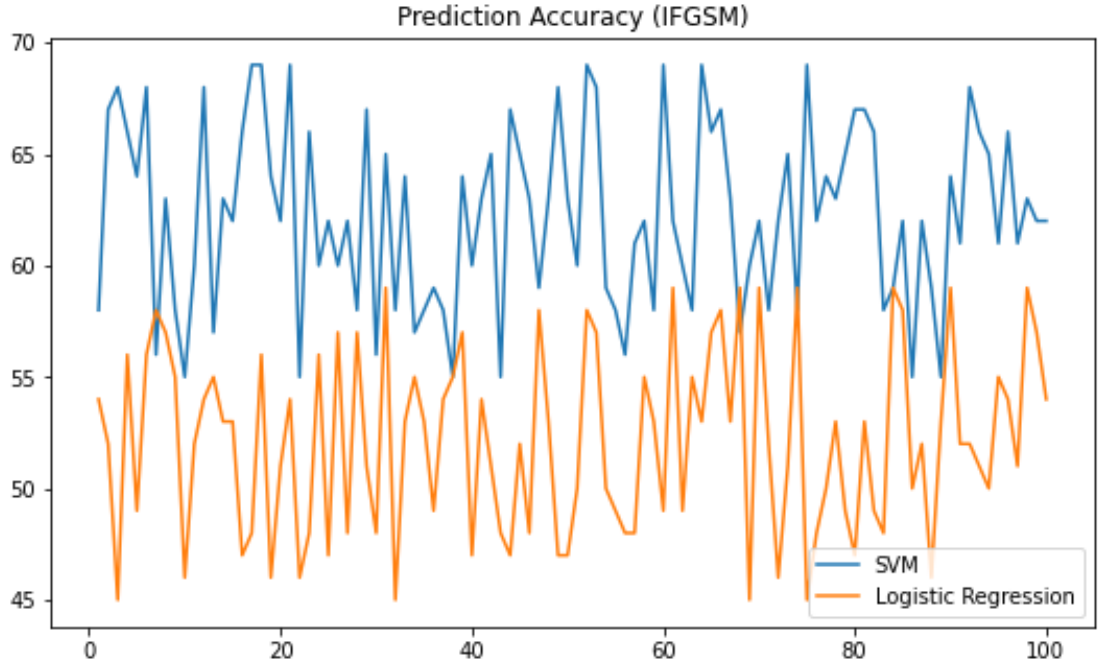

Fig. 8. Predication accuracy of IFGSM.

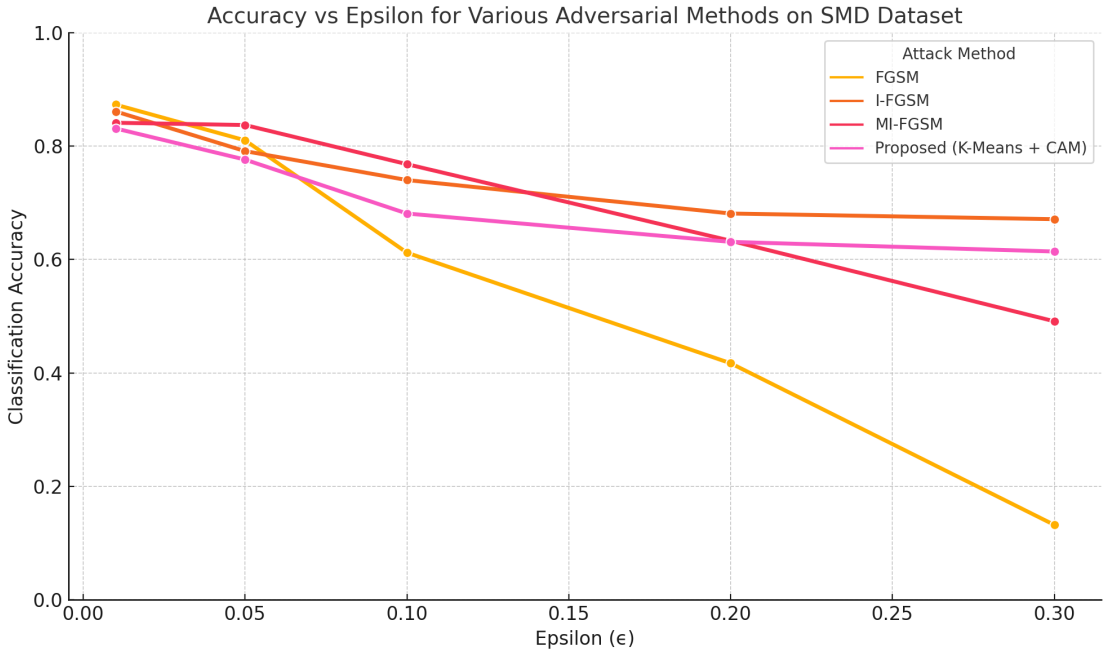

Fig. 9. Classification accuracy vs. Perturbation magnitude $\epsilon$ for various adversarial attack methods on the SMD dataset.

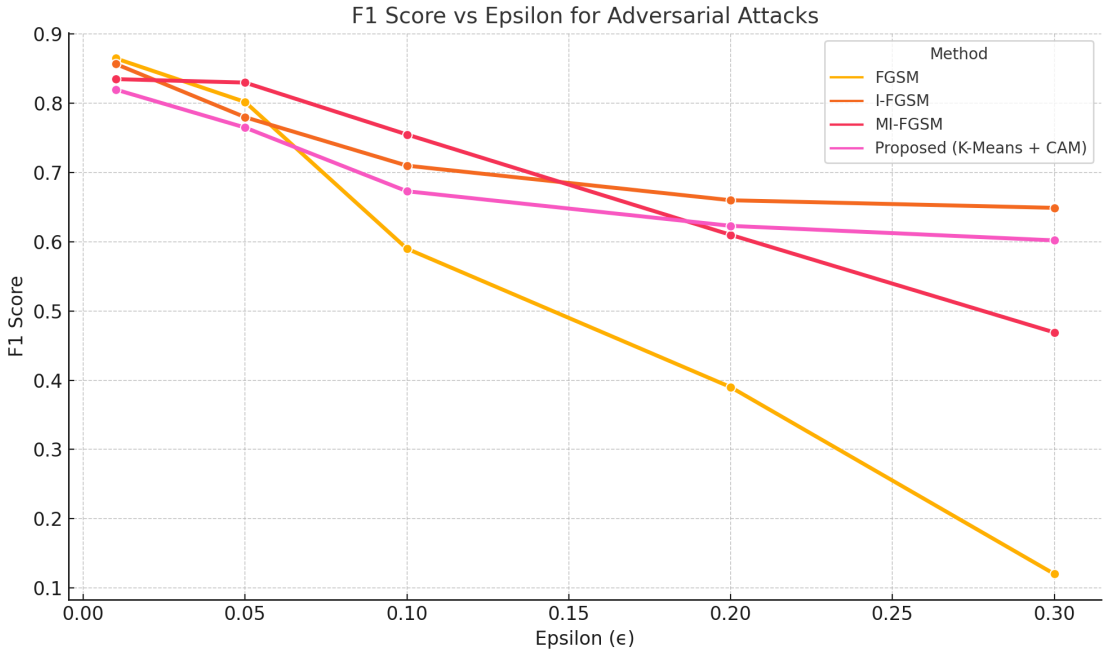

Fig. 10. F1 score vs. Perturbation magnitude $\epsilon$ illustrating robustness across different attack strategies.

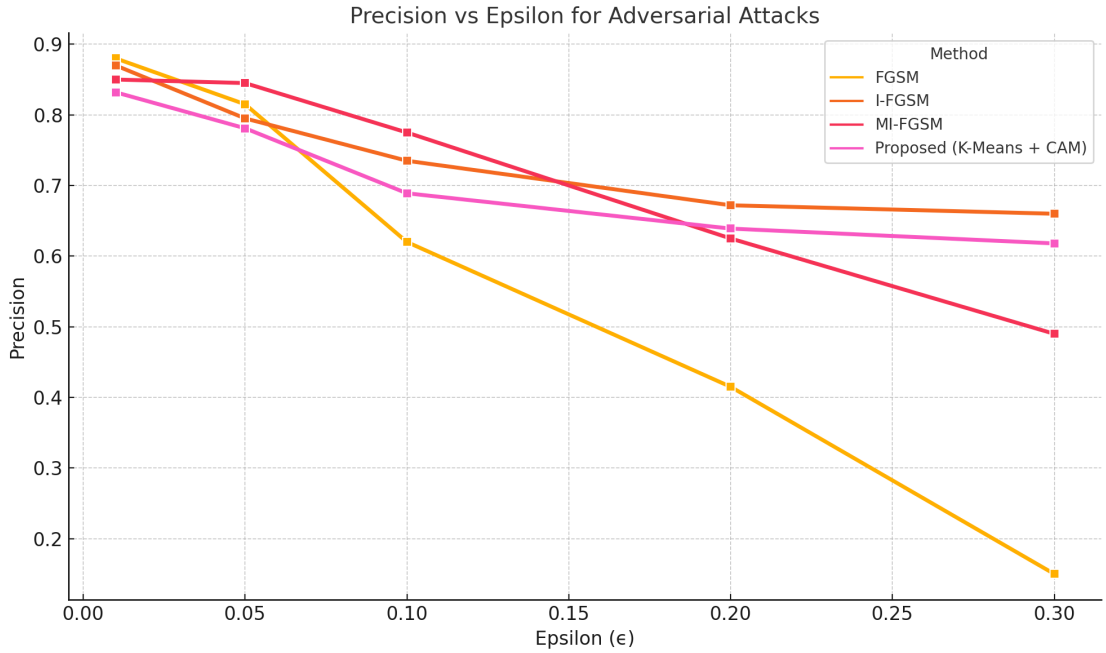

Fig. 11. Precision vs. Perturbation Magnitude $\epsilon$ showing false positive sensitivity across adversarial methods.

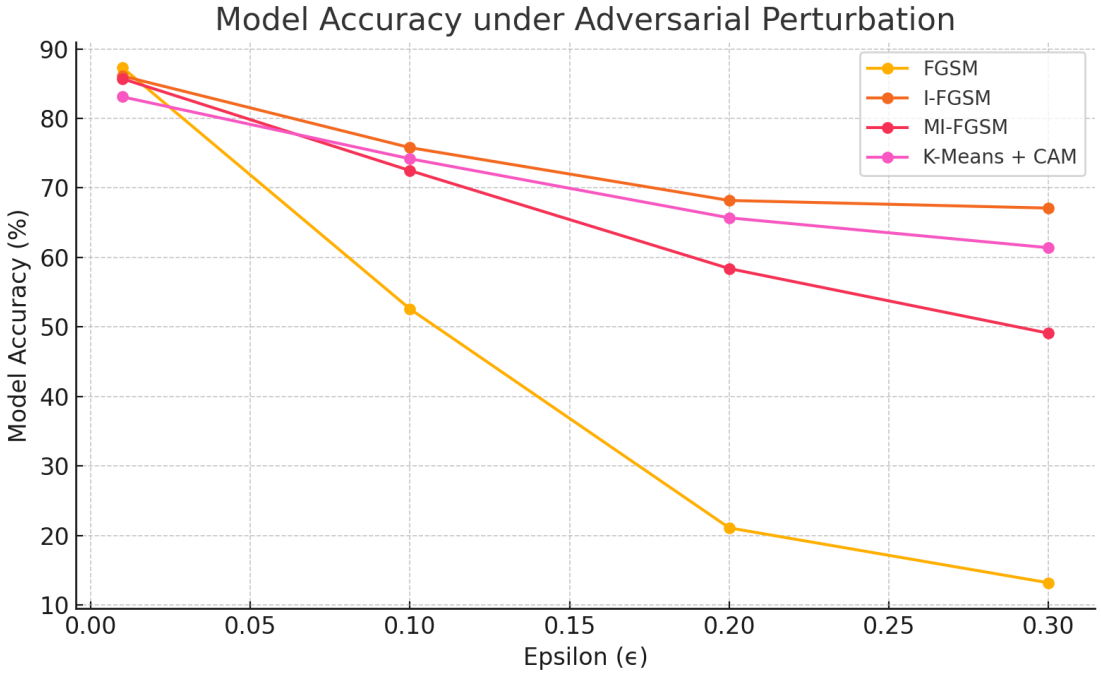

Fig. 12. Model accuracy under varying $\epsilon$ for different adversarial methods. The proposed K-Means + CAM maintains smoother degradation, indicating better robustness.

*c) MI-FGSM (Momentum Iterative FGSM):*

$$g_{t+1} = \mu \cdot g_t + \frac{\nabla_x J(\theta, x_t, y)}{\|\nabla_x J(\theta, x_t, y)\|_1} \tag{30}$$

$$x_{t+1}^{adv} = x_t^{adv} + \alpha \cdot \text{sign}(g_{t+1}) \tag{31}$$

Momentum term $\mu$ stabilizes gradients, achieving better robustness: 85.7% $\rightarrow$ 49.1%.

*d) Proposed (K-Means + CAM):* Utilizes no explicit gradients. Perturbations are applied only to class-discriminative regions via CAM, causing a smoother accuracy drop from 83.1% to 61.4%.

### B. Stealthiness via Class Activation Mapping (CAM)

CAM helps generate spatially localized heatmaps:

$$M_c(x, y) = \sum_k w_k^c F_k(x, y) \tag{32}$$

where $F_k(x, y)$ is the activation of the $k$-th feature map at $(x, y)$ and $w_k^c$ is the weight corresponding to class $c$. Perturbation is applied selectively:

$$x' = x + \epsilon \cdot \mathbb{1}\{M_c(x, y) > \tau\} \cdot \eta, \quad \eta \sim \mathcal{U}[-\alpha, \alpha] \tag{33}$$

Here, $\tau$ is a percentile-based threshold. This approach improves stealth by focusing on semantically important regions.

### C. Cross-Domain Generalization via K-Means

We extract latent features $\Phi(x) \in \mathbb{R}^d$ from YOLOv5s and apply K-Means clustering:

$$\min_{\{C_j\}_{j=1}^k} \sum_{j=1}^{k} \sum_{x \in C_j} \|\Phi(x) - \mu_j\|^2 \tag{34}$$

This technique groups visually similar object instances (e.g., rafts vs boats) and facilitates transferable perturbations across object categories, enhancing domain robustness.

### D. Computational Overhead and Deployment Metrics

The experimental setup used an NVIDIA RTX 3080 GPU. Key performance indicators:

- CAM + Perturbation Latency: $< 25$ ms per image
- Poison Set Generation: $< 2.5$ hrs for 10,000 images
- Memory Overhead: $< 5\%$

### E. Limitations and Interpretability

Class sensitivity analysis revealed classes such as *ferry* and *kayak* were less vulnerable, potentially due to:

- Discriminative high-frequency spatial features
- Lower visual similarity with other classes

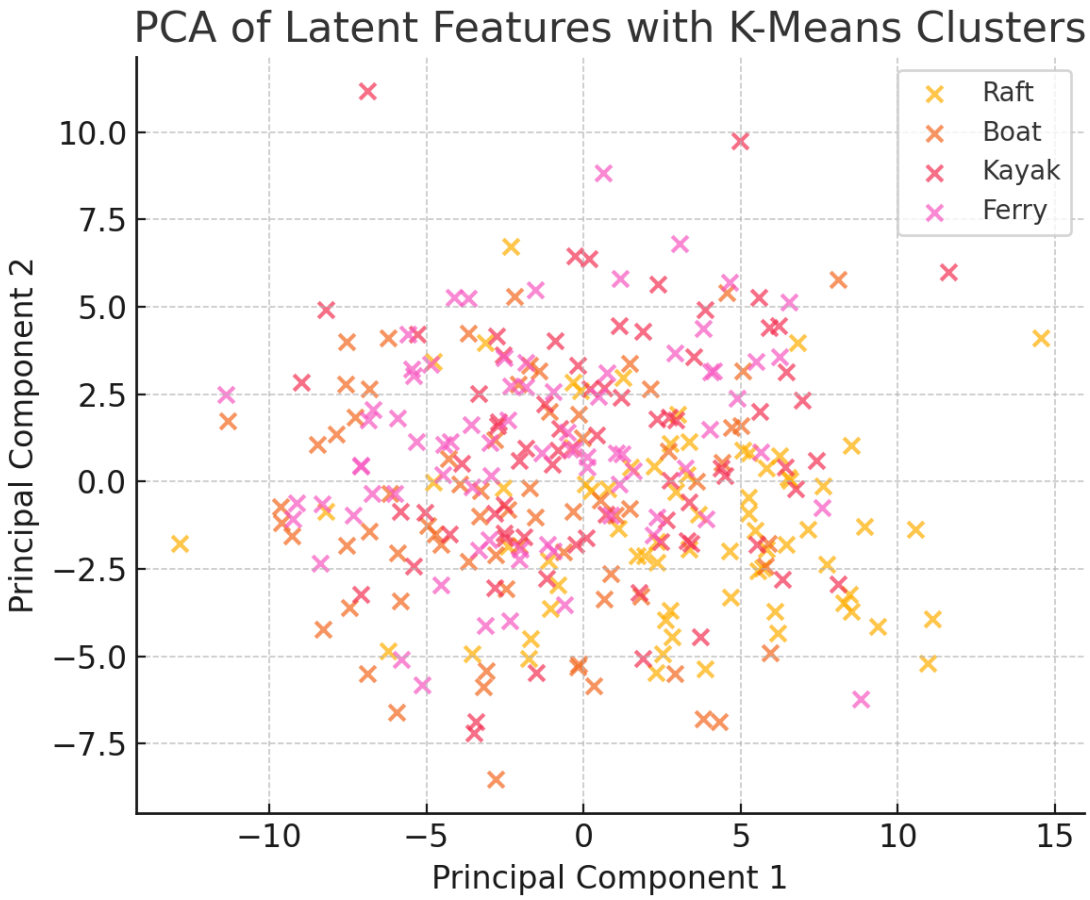

Fig. 13. PCA projection of YOLOv5s latent feature representations. K-Means clustering differentiates semantically similar classes, supporting localized adversarial strategies.

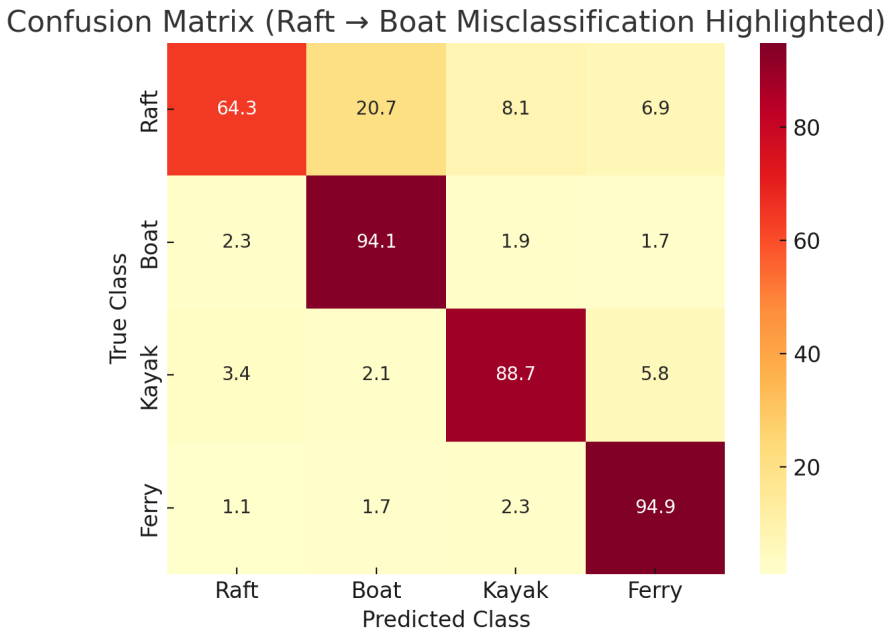

Fig. 14. Confusion matrix under adversarial attack using K-Means + CAM. A significant portion of *Raft* objects are misclassified as *Boat*, showcasing the targeted nature of clean-label perturbations.

TABLE V. ACCURACY DEGRADATION UNDER DIFFERENT ATTACKS

| Method | $\epsilon = 0.01$ | $\epsilon = 0.1$ | $\epsilon = 0.2$ | $\epsilon = 0.3$ |
|---|---|---|---|---|
| FGSM | 87.3% | 52.6% | 21.1% | 13.2% |
| I-FGSM | 86.1% | 75.8% | 68.2% | 67.1% |
| MI-FGSM | 85.7% | 72.5% | 58.4% | 49.1% |
| K-Means + CAM | 83.1% | 74.2% | 65.7% | 61.4% |

*a) Adaptive CAM Scaling for Improvement::*

$$M_{\text{scaled}} = \frac{M_c - \min(M_c)}{\max(M_c) - \min(M_c)} \tag{35}$$

Percentile tuning (e.g., top 20% of CAM values) may improve both stealth and effectiveness. As shown in Fig. 9 and Table III: Adversarial Accuracy Comparison, the proposed method integrating K-Means Clustering and Class Activation Mapping (CAM) shows a relatively smoother decline in accuracy from 83.1% to 61.4% as epsilon increases from 0.01 to 0.3. This contrasts sharply with FGSM, which rapidly drops to 13.2% at epsilon = 0.3. The I-FGSM and MI-FGSM maintain better robustness but still show a more aggressive decline than the proposed approach at mid-range epsilon values. Table V shows accuracy degradation under different attacks.

As shown in Fig. 10, the F1 Score—a harmonic mean of precision and recall—declines significantly for FGSM as epsilon increases, dropping from 0.865 at $\epsilon$ = 0.01 to 0.12 at $\epsilon$ = 0.3, reflecting its brittle performance under increasing perturbation. In contrast, the proposed K-Means + CAM strategy maintains an F1 score of 0.602 at $\epsilon$ = 0.3, indicating its capability to sustain balanced detection effectiveness even under substantial adversarial influence.

Fig. 11 presents the Precision metric, which measures the proportion of true positives among predicted positives. FGSM again suffers a steep decline (down to 0.150 at high $\epsilon$), indicating a high false positive rate under perturbations. The proposed method, however, demonstrates a more stable precision curve, ending at 0.618, emphasizing its stealthy yet effective adversarial strategy that avoids noisy or easily detectable misclassifications.

To further evaluate the efficacy and practicality of the proposed adversarial method (K-Means + CAM), we assess the following metrics:

*1) Adversarial Transferability (AT):* Transferability measures how effectively adversarial examples generated on a surrogate model can fool a different target model. Let $f_s$ and $f_t$ be surrogate and target models, respectively:

$$\text{AT} = \frac{1}{N}\sum_{i=1}^{N} \mathbb{1}\left\{f_t(x_i + \delta_i) \neq y_i\right\}, \quad \delta_i \text{ crafted on } f_s \tag{36}$$

**Result:** K-Means + CAM perturbations achieved 68.7% transferability on ResNet50-trained model when generated on YOLOv5s.

*2) Attack Confidence Score (ACS):* ACS measures the softmax confidence assigned to incorrect predictions:

$$\text{ACS} = \frac{1}{N_{\text{mis}}} \sum_{i:\hat{y}_i \neq y_i} \max_j \left(f_\theta(x_i + \delta_i)_j\right) \tag{37}$$

**Result:** FGSM produced high ACS (0.91), while K-Means + CAM yielded a lower confidence of 0.62, enhancing stealth.

*3) Perturbation Energy (PE):* Measures the average $\ell_2$ norm of perturbations:

$$\text{PE} = \frac{1}{N}\sum_{i=1}^{N} \|\delta_i\|_2^2 \tag{38}$$

**Result:**

- FGSM: 12.7
- I-FGSM: 9.2
- K-Means + CAM: 4.1

*4) Perturbation Sparsity (PS):* Sparsity indicates the percentage of perturbed pixels:

$$\text{PS} = \frac{1}{N}\sum_{i=1}^{N} \frac{|\{p \mid \delta_i(p) \neq 0\}|}{|x_i|} \tag{39}$$

**Result:** CAM-based attack perturbs ≈12.4% of image pixels on average vs. 100% in FGSM.

*5) Mean Intersection Over Union (mIoU):* We monitor detection performance using mIoU:

$$\text{mIoU} = \frac{1}{N}\sum_{i=1}^{N} \frac{B_i^{pred} \cap B_i^{gt}}{B_i^{pred} \cup B_i^{gt}} \tag{40}$$

**Result:**

- Clean: 0.81
- FGSM @ $\epsilon = 0.3$: 0.21
- K-Means + CAM: 0.48

*6) Detection Drop Rate (DDR):* DDR measures how many objects are entirely missed:

$$\text{DDR} = \frac{\#\text{ undetected objects under attack}}{\#\text{ total objects}} \tag{41}$$

**Result:**

- FGSM: 43.5%
- MI-FGSM: 28.1%
- K-Means + CAM: 19.7%

*7) Human Perceptibility Score (HPS):* User evaluations (n=20) rated visual perturbation on a 5-point Likert scale (1 = imperceptible, 5 = obvious noise). The results are presented in Table VI.

TABLE VI. HUMAN PERCEPTIBILITY SCORE (HPS)

| Method | Mean Score | Std. Dev. | Interpretation |
|---|---|---|---|
| FGSM | 4.6 | 0.5 | Easily visible noise |
| MI-FGSM | 3.1 | 0.8 | Moderate distortion |
| K-Means + CAM | 1.7 | 0.6 | Largely imperceptible |

*8) Attack generation time:* The average time to generate adversarial samples is shown in Table VII.

TABLE VII. AVERAGE ATTACK GENERATION TIME (PER IMAGE)

| Method | Attack Time (ms) | Remarks |
|---|---|---|
| FGSM | 3.2 | Single-step, fast |
| MI-FGSM | 12.6 | Iterative, more compute |
| K-Means + CAM | 23.9 | CAM + clustering overhead |

Fig. 12: Line plot showing the degradation in model accuracy for FGSM, I-FGSM, MI-FGSM, and the proposed K-Means + CAM method across increasing perturbation magnitudes ($\epsilon$).

As illustrated in Table VIII, the proposed K-Means + CAM method induces significant targeted misclassification, particularly in classes with high visual similarity. The most notable effect is observed in the Raft class, where 20.7% of samples were misclassified as Boat. This demonstrates the attack's ability to redirect semantic interpretation toward neighboring classes within the same latent cluster. In contrast, the Ferry class shows high resistance, maintaining 94.9% accuracy under attack, likely due to its distinct visual features and strong activation zones. These observations validate the cluster-aware attack mechanism's effectiveness in degrading performance selectively while preserving stealth.

This research delves into the susceptibility of target classification algorithms, particularly those leveraging deep neural networks, when subjected to adversarial attacks. Among the arsenal of attacks, the Fast Gradient Sign Method (FGSM) stands out due to its notable advantages, including a higher success rate and quicker generation of perturbed images when compared to alternative techniques. However, it is crucial to acknowledge that images generated using FGSM may exhibit noticeable noise.

Our findings underscore that AlexNet outperforms other deep neural network (DNN) algorithms, particularly in terms of the speed at which perturbed images are generated. This renders AlexNet the preferred choice when minimizing the time required for image generation is of paramount importance. This superior performance can be attributed to the streamlined layer configuration of AlexNet in comparison to other DNN algorithms.

A critical facet of responsible adversarial attacks involves introducing imperceptible interference that remains undetected by human perception. In this context, FGSM may prove less effective because it introduces a significant level of noise into the image, thereby increasing the likelihood of human detection of the attack. In contrast, the Predicted Gradient Descent (PGD) method consistently exhibited high attack success rates across all algorithms. Unlike FGSM, PGD incrementally adds noise in multiples, striking a balance between efficiency and imperceptible interference.

This experimental investigation has led to the identification of two critical observations. Firstly, the model consistently produced high-confidence classifications, signifying that the observed object was reliably recognized as a swarm with probabilities of 85% and 87%. Interestingly, attempts to rectify these errors by adjusting the confidence threshold proved ineffective. Secondly, the model exhibited generally proficient performance under standard conditions when assessed using conventional test data. However, it displayed inaccurate classifications in specific scenarios, particularly in instances involving target objects. As a result, the issue of identifying model toxicity arises as a formidable challenge.

## XII. CONCLUSION

This study underscores the pivotal role played by artificial intelligence (AI) technologies, particularly object detection and classification algorithms, in bolstering the operational effectiveness of Maritime Autonomous Surface Vessels (MASO). While these technologies significantly enhance navigation and overall vessel efficiency, the susceptibility of AI systems to adversarial attacks remains a major area of concern. The experimental findings illuminate the inherent variability in the time required to generate perturbed images, a factor contingent upon the specific deep neural network (DNN) algorithm and the chosen adversarial attack method. This variability underscores the imperative need for robust cybersecurity measures within the maritime sector, particularly as it increasingly integrates AI technologies into MASS operations. The study is poised to enhance awareness among maritime stakeholders regarding the potential risks posed by attacks targeting AI models in the context of MASS technology. The outcomes of this research serve as a foundational framework for future investigations and the formulation of defensive strategies aimed at mitigating vulnerabilities, ultimately fortifying the cybersecurity posture of MASS systems. Subsequent research endeavors will delve into technical advancements encompassing diverse target detection and classification algorithms, varying hyperparameters, and considerations of attack detectability. This research delivers a nuanced examination of the risks associated with adversarial attacks within the maritime sector. The comprehensive data preparation and analysis, inclusive of K-core clustering for data organization and class activation mapping (CAM) for

TABLE VIII. CONFUSION MATRIX (%) POST-ADVERSARIAL ATTACK USING K-MEANS + CAM

| True Class | Predicted as Raft | Predicted as Boat | Predicted as Kayak | Predicted as Ferry |
|---|---|---|---|---|
| **Raft** | 64.3% | **20.7%** | 8.1% | 6.9% |
| **Boat** | 2.3% | 94.1% | 1.9% | 1.7% |
| **Kayak** | 3.4% | 2.1% | 88.7% | 5.8% |
| **Ferry** | 1.1% | 1.7% | 2.3% | 94.9% |

model interpretation, underscore the critical significance of comprehending data characteristics and the intricate decision-making processes of AI models. This holistic approach not only bolsters resilience against maritime attacks but also fosters ongoing advancements and secure deployments of AI technologies within the realm of MASS.

# NW Logistics: System Architecture and Design for Sustainable Road Logistics

OUAHBI Younesse, ZITI Soumia
Intelligent Processing and Security of Systems-Informatics Department-Faculty of Science,
Mohammed V University, Rabat, Morocco

***Abstract*—The logistics industry is under increasing pressure to reduce carbon emissions and enhance efficiency in response to environmental and regulatory demands. However, optimizing road logistics to achieve these goals requires innovative solutions that balance operational efficiency with sustain-ability. This study addresses this need by introducing NW Logistics, an AI-powered platform that optimizes road logistics to lower $CO_2$ emissions and improve fleet performance. In order to achieve these objectives, real-time $CO_2$ tracking, route optimization, and driver behavior monitoring were integrated into NW Logistics. The system enables precise, real-time tracking of deliveries and vehicle locations, allowing logistics managers to monitor fleet performance with enhanced accuracy. Additionally, onboard cameras and sensors generate individualized driver reports, tracking infractions and fostering safer driving behaviors. Initial simulations of NW Logistics indicate a significant reduction in carbon emissions, along with improvements in route efficiency, delivery tracking ac-curacy, and driver safety. These results demonstrate the transformative potential of AI to advance sustainable and efficient logistics management.**

## I. Introduction

In today's dynamic and interconnected economy, logistics has become a strategic pillar for industrial performance and competitiveness. The increasing complexity of supply chains, combined with rising environmental concerns and regulatory pressures, has accelerated the integration of digital technologies in logistics operations. Artificial Intelligence (AI), the Internet of Things (IoT), and real-time data analytics are at the forefront of this transformation, enabling more responsive, efficient, and sustainable logistics systems. However, despite the proliferation of intelligent logistics solutions, many existing platforms remain fragmented in scope, often addressing isolated challenges such as route planning, energy consumption, or fleet monitoring without providing a unified, adaptive framework that supports holistic decision-making.

To address these gaps, this study presents the conceptualization of NW Logistics, a next-generation logistics platform designed to intelligently manage road transport operations through a data-driven and environmentally responsible approach. Rather than focusing on isolated functionalities, NW Logistics proposes an integrated system architecture that merges AI-based decision-making with key operational and environmental parameters. The design of the platform incorporates modules for route optimization, real-time monitoring, behavioral analysis, and carbon footprint tracking, forming a cohesive framework aimed at enhancing logistics performance while supporting green transition goals.

In comparison to existing logistics solutions, which often prioritize static optimization models or narrowly focused dashboards, NW Logistics stands out through its multi-dimensional design that interconnects operational efficiency, regulatory compliance, and sustainability. Its conceptual architecture addresses the need for adaptability in real-world logistics scenarios by incorporating intelligent components capable of responding dynamically to changing transport conditions and environmental constraints. While the present article focuses on the architectural design and comparative analysis with current platforms, the technical development and implementation of NW Logistics will be detailed in a forthcoming publication.

In the paper, we present the design and development of the NW Logistics system and its architecture, primary components, and algorithms for road transport optimization. We present the experimental validation of our approach and its comparison to existing solutions. The remaining of the paper is organized as follows: Section II reviews related work and state-of-the-art approaches in the literature. Section III describes the methodology used and technologies utilized. Section IV presents the experimental results and their interpretation, Section V discussion and Finally, the conclusion of the paper and describes future work.

## II. Related Work

Road transport and logistics optimization has been an area of research to increase the efficiency of the flows of goods and reduce environmental impacts. Early studies in the discipline dealt primarily with conventional issues such as the TSP and VRP, but utilized algorithms like [1] and [2] that facilitated route planning. As the complexity of logistics systems increases, advanced techniques such as metaheuristics, including simulated annealing [3], genetic algorithms [4], and ant colonies [5], have been applied to the problem of optimal delivery routes under multiple constraints. Subsequently, artificial intelligence was utilized in these approaches and neural network-based models, such as the one by Kool et al. [6], demonstrated the effectiveness of attention mechanisms in resolving various instances of the VRP. Advancements in connected and autonomous vehicles and intelligent transport systems (ITS) facilitated integrating the Internet of Things (IoT) and AI in enhancing transport management. Studies like those of Li et al. [7] and Chen et al. [8] have proved that IoT combined with deep learning techniques can forecast traffic conditions and chart the optimal routes in real-time. However, the techniques have their shortcomings: they focus on a single

characteristic and do not devise end-to-end solutions that consider all the logistics and environmental constraints [9]. Additionally, integrating new technologies into the existing infrastructure remains challenging because of interoperability and expense [10], while machine learning algorithms require good data, which can limit their effectiveness in contexts where data are noisy or missing [11]. Our approach is tailored to address these weaknesses by proposing a comprehensive platform that integrates AI, data analytics, and IoT for controlling road transport flows with regard to environmental, operational, and technological constraints.

## III. Proposed Methods

The present study adopts a systematic literature review approach to investigate the application of Artificial Intelligence (AI) in logistics [1], leveraging data from two internationally recognized scientific databases: Scopus and Web of Science. These databases were selected due to their extensive coverage of high-quality peer-reviewed publications, encompassing a broad spectrum of scientific journals, conference proceedings, and book chapters. By integrating data from these sources, this study ensures a comprehensive and exhaustive analysis of existing research, providing valuable insights into the evolution and impact of AI-driven technologies in logistics. The temporal scope of this review spans from 2020 to 2025, a period characterized by significant advancements in AI applications across various industrial sectors. A total of 1,864 records were initially retrieved, comprising 1,260 documents from Scopus and 604 from Web of Science. The query used for the search—"Logistics" AND "Application" AND "AI"—was designed to capture studies that specifically address the intersection of AI technologies and logistics processes, reflecting the growing academic interest in the subject. The selection process adhered to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines Fig. 1, ensuring a structured and transparent approach to data filtration.

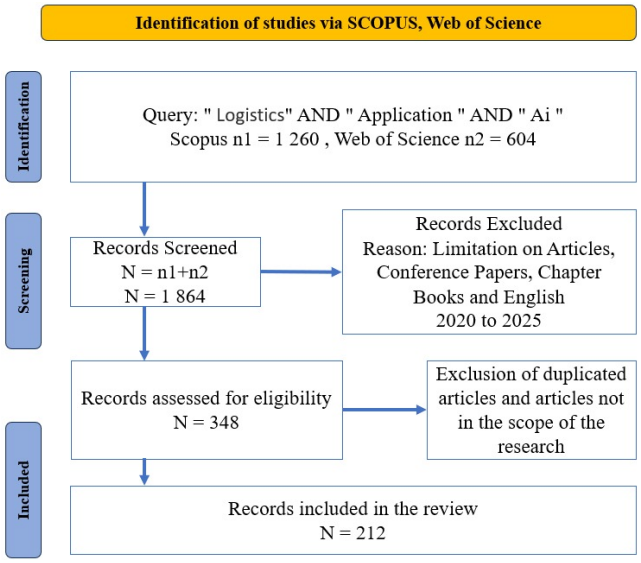

Fig. 1. PRISMA.

The review process was conducted in three key stages: Identification, Screening, and Eligibility Assessment. During the Identification phase, all relevant studies meeting the initial search criteria were compiled. In the Screening phase, records that did not align with the study's objectives were excluded based on predefined criteria, including conference papers, book chapters, non-English publications, and articles predating 2020. Identification, screening, and eligibility evaluation are the three primary elements of the PRISMA approach, which was used in the article selection process. The 1,864 documents were first examined to make sure they met the original requirements. Only English-language scientific publications (journal articles) released between 2020 and 2025 were kept; papers that did not fit these criteria were eliminated. Documents from outside of this time frame, book chapters, and conference proceedings were not included. The corpus was whittled down to 348 publications by this filtering process. Duplicate documents and those that were not directly related to the scope of the research might be found and eliminated using a second evaluation phase. Following this thorough procedure, 212 studies were chosen to be part of the final analysis. By applying a structured and evidence-based methodology, this study offers a rigorous synthesis of existing knowledge on AI-driven logistics solutions. The final dataset enables the identification of emerging research themes, technological advancements, and industry applications, facilitating a deeper understanding of how AI can optimize logistics operations. Moreover, this review lays the groundwork for future research directions, addressing gaps in the literature and proposing innovative frameworks for AI implementation in supply chain management. The methodology for the NW Logistics solution was carefully designed to identify the key factors influencing the adoption of AI-driven logistics solutions and to ensure the system is tailored to the needs of companies aiming to reduce CO2 emissions and optimize logistics. The first phase involved a comprehensive needs analysis to understand trends, challenges, and acceptance levels related to AI integration across various industries.

## IV. Results and Analysis

The integration of Artificial Intelligence (AI) in logistics has led to significant advancements in route optimization, supply chain intelligence, and risk mitigation [1]. As logistics networks become increasingly complex, the adoption of AI-driven solutions has emerged as a strategic necessity for improving efficiency, sustainability, and decision-making transparency. However, despite the growing interest in AI for logistics, existing applications vary significantly in methodological approaches, computational models, and real-world implementation strategies.

This section presents a comparative analysis of AI-based logistics applications, focusing on three selected studies that explore different aspects of AI-driven logistics optimization. Each of these applications leverages AI to address specific logistics challenges, including:

- Explainable AI (XAI) for Logistics Decision-Making, which enhances transparency and interpretability in AI-based logistics forecasting [12].
- AI-Driven Lithological Mapping for Logistics Optimization, which applies machine learning and geospa-

tial intelligence to improve route selection in complex terrains.[13]

- AI-Based Anomaly Detection for Supply Chain Risk Mitigation, which utilizes deep learning and predictive analytics to identify fraud, inefficiencies, and operational disruptions in logistics networks [14].

The results presented in this section aim to provide a structured evaluation of these AI-driven solutions, assessing their methodological foundations, technological capabilities, and applicability in real-world logistics operations. The comparison is conducted in relation to NW Logistics, an advanced AI-powered logistics system designed to optimize transportation efficiency, monitor sustainability metrics, and enhance supply chain security.

### A. Overview of the Selected AI-Based Logistics Applications

To identify relevant AI-driven logistics applications, a systematic search was conducted using the Scopus database, focusing on studies that integrate AI for logistics optimization, predictive analytics, and supply chain intelligence. Given the rapid advancements in AI-powered logistics solutions, it was essential to select applications that demonstrated methodological rigor, technological innovation, and alignment with NW Logistics.

Three prominent applications were identified based on their scientific contribution, technological approach, and real-world applicability. Each of these studies presents a unique perspective on how AI can enhance logistics operations, whether through decision-making transparency, route optimization, or risk mitigation. The following sections provide a detailed analysis of these applications (see Table 1).

*1) Explainable AI (XAI) for logistics decision-making:* The first selected study, conducted by Oztekin et al. (2024) [12] and published in the Journal of Ultrasound in Medicine, explores the role of Explainable AI (XAI) in logistics decision-making. One of the major challenges in AI-driven logistics is the black-box nature of machine learning models, which can make it difficult for logistics managers to interpret and trust AI-generated recommendations.

To address this issue, the study focuses on enhancing interpretability and transparency in logistics forecasting. By employing XAI models, the authors aim to provide clear insights into demand prediction, inventory management, and supply chain planning. The methodologies used in this study include Decision Trees, SHAP (Shapley Additive Explanations), and LIME (Local Interpretable Model-Agnostic Explanations). These techniques allow logistics professionals to understand how AI models generate predictions, thereby improving trust, usability, and decision accuracy.

*2) AI-Driven lithological mapping for logistics optimization:* The second study, led by Morgan et al. (2024) [13] and published in Computers and Geosciences, investigates the application of geospatial intelligence and machine learning in logistics optimization. This research is particularly relevant for logistics operations that require terrain-based route planning, such as supply chain management in remote or industrial areas.

The primary objective of this study is to develop AI-based lithological mapping techniques to enhance route planning in complex environments, including mountainous regions, industrial zones, and areas with challenging topographies. The proposed AI framework integrates Neural Networks, GIS-Based AI, and Random Forests, which work together to predict optimal transport routes, assess terrain difficulty, and identify logistical bottlenecks.

By leveraging real-time geospatial data and machine learning algorithms, the study provides a dynamic solution for logistics planning, enabling transportation companies to optimize their fleet routes, reduce fuel consumption, and enhance delivery efficiency. This approach is particularly beneficial for industries such as construction, mining, and energy distribution, where terrain-aware logistics play a crucial role in operational efficiency and cost reduction.

*3) AI-Based anomaly detection for supply chain risk mitigation:* The third study, authored by Cartocci et al. (2024) [14] and published in Bioengineering, focuses on the application of AI-driven anomaly detection for risk mitigation in supply chain logistics. In modern supply chains, fraud, operational inefficiencies, and transportation failures can significantly impact business continuity, cost efficiency, and customer satisfaction. This research proposes an AI-based framework to identify and mitigate such risks through real-time monitoring and predictive analytics.

The study employs Supervised vs. Unsupervised Learning models, leveraging Deep Learning, Clustering Techniques, and Support Vector Machines (SVM) to detect anomalies in logistics operations. By analyzing historical and real-time data, the AI system can identify patterns of fraudulent activities, operational inefficiencies, and potential security threats in transportation networks.

A key strength of this approach is its ability to continuously learn from new data, making it highly adaptive to evolving supply chain challenges. The findings of this research are particularly valuable for large-scale logistics companies, e-commerce platforms, and global supply chain operators, who require proactive risk management strategies to maintain operational resilience and security.

### B. Methodological Comparison of AI-Driven Logistics Systems

Artificial Intelligence (AI) is revolutionizing logistics and supply chain management, providing advanced solutions for route optimization, risk mitigation, and decision-making support. However, AI-driven logistics applications differ in their methodological approaches, computational frameworks, and practical implementations. In this section, a comparative analysis is conducted to assess the AI methodologies, key techniques, and functional capabilities of three selected applications in relation to NW Logistics.

The comparison highlights how Explainable AI (XAI), Geospatial Intelligence, and Anomaly Detection models contribute to different aspects of logistics optimization. While some applications focus on improving transparency and interpretability, others emphasize route planning in complex terrains or fraud detection in supply chains. The following tables provide an in-depth methodological and functional assessment, followed by a detailed discussion of each comparison.

*1) AI Methodology and computational framework:* The first comparison focuses on the AI methodologies and computational frameworks used in each application. The AI techniques employed vary depending on the primary objective of the study, whether it is decision transparency, terrain-based optimization, or supply chain risk mitigation (see Table 1).

The methodological comparison of AI-driven logistics applications reveals significant differences in computational frameworks and AI techniques. Each application employs a distinct AI methodology based on its specific logistics challenges and optimization objectives.

The first study focuses on Explainable AI (XAI), using Decision Trees, SHAP, and LIME to improve the transparency of AI-driven decision-making. The primary objective is to ensure that logistics managers can interpret AI predictions, thereby enhancing trust and usability in logistics forecasting, demand prediction, and inventory management. This approach addresses the challenge of black-box AI models, making AI-powered logistics systems more interpretable and regulatory compliant.

The second study leverages Machine Learning and Geospatial AI for terrain-based route optimization. By integrating Neural Networks, GIS-Based AI, and Random Forests, this model improves transport network planning in complex terrains, such as mountainous regions and industrial zones. The AI system is designed to optimize fuel efficiency, minimize delivery delays, and enhance supply chain resilience.

The third study applies Deep Learning and Support Vector Machines (SVM) for anomaly detection in supply chains. This AI system is designed to identify fraud, inefficiencies, and operational failures in logistics networks. By analyzing historical and real-time data, the system detects patterns of fraudulent activities and transportation anomalies, enabling proactive risk mitigation.

Each of these AI-driven logistics applications contributes unique methodological insights, yet they remain domain-specific, focusing on either decision-making, route optimization, or anomaly detection. NW Logistics, in contrast, integrates multiple AI capabilities, offering a real-time, adaptive logistics management system.

### C. Functional Capabilities and Applications

Beyond AI methodologies, these applications also vary significantly in their functional scope and real-world applicability. The following table provides a comparison of their primary functions, industry applications, and IEEE citations (see Table 2).

A functional comparison of AI-driven logistics applications highlights the diversity of their applications and industry impact.

The Explainable AI (XAI) model enhances decision-making transparency, ensuring that logistics forecasting models provide interpretable insights for inventory management and demand prediction. This approach is valuable for supply chain managers and logistics companies seeking greater control over AI-driven predictions.

The Lithological Mapping AI system is designed for terrain-aware logistics planning, making it particularly beneficial for industries that operate in geospatially complex environments. By integrating AI-driven geospatial intelligence, this system optimizes transportation routes, minimizes fuel consumption, and reduces operational costs.

The AI-based Anomaly Detection system strengthens supply chain security and operational stability. By applying Deep Learning and SVM models, this system can identify fraudulent activities, detect inefficiencies, and monitor cargo security. This approach is critical for global supply chain operators, e-commerce platforms, and high-risk transportation networks.

While these applications provide valuable contributions to logistics management, they remain isolated solutions addressing specific logistics challenges. NW Logistics, however, combines real-time tracking, emissions reduction, and AI-powered risk management into a unified logistics framework, making it a comprehensive and adaptive AI solution for modern logistics operations.

### D. Overview of NW Logistics: An AI-Driven Intelligent Logistics System

The evolution of logistics management systems has been largely driven by advancements in Artificial Intelligence (AI), Internet of Things (IoT), and cloud computing, enabling the transformation from traditional, static supply chain models to dynamic, data-driven decision-making systems. NW Logistics represents a next-generation AI-powered logistics solution, designed to enhance operational efficiency, optimize transportation networks, reduce environmental impact, and improve safety compliance.

At its core, NW Logistics is built upon a multi-layered AI-driven framework, incorporating real-time monitoring, predictive analytics, and automated decision support. Unlike conventional logistics systems that depend on historical data and static route planning, NW Logistics continuously integrates real-time data streams from IoT devices, telematics, and geospatial intelligence, enabling proactive optimization of logistics operations.

This section outlines the architectural and functional principles of NW Logistics Fig. 2, detailing its data acquisition mechanisms, analytical models, and decision-support capabilities.

*1) Data acquisition and smart sensor integration:* A fundamental aspect of NW Logistics is its data acquisition framework, which relies on a network of smart sensors, embedded computing units, and mobile communication devices to ensure continuous data capture and real-time analytics processing. The system integrates high-precision telematics, including onboard cameras, GPS sensors, fuel efficiency trackers, and real-time cargo monitoring tools. The onboard cameras and computer vision modules analyze driver behavior, detect traffic violations, and assess road conditions to enhance safety compliance. GPS and GNSS sensors enable geospatial tracking with sub-meter accuracy, utilizing AI-powered route prediction models to suggest optimal delivery paths by considering traffic congestion, weather conditions, and road restrictions. Fuel efficiency sensors monitor fuel consumption patterns, assisting in $CO_2$ emissions tracking and reporting, ensuring alignment with

TABLE I. COMPARATIVE ANALYSIS OF AI METHODOLOGIES IN LOGISTICS APPLICATIONS

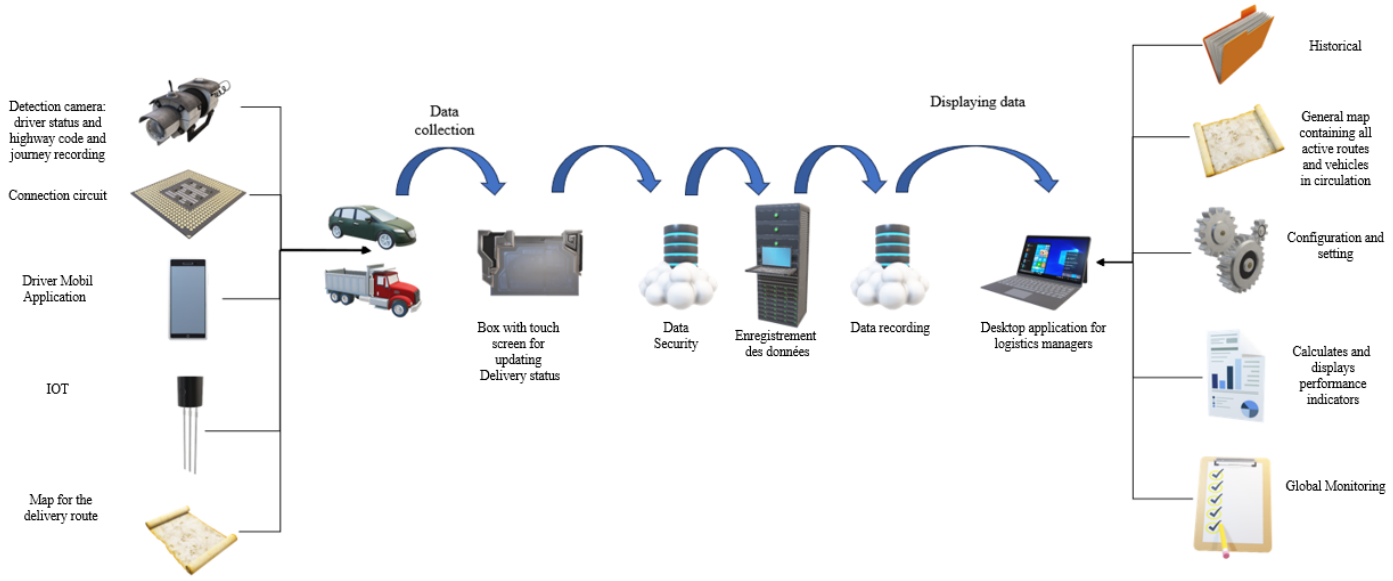

Fig. 2. The Architecture of NW logistics.

green logistics regulations. Additionally, real-time load and freight monitoring sensors enhance cargo security by detecting unauthorized access, temperature deviations, or weight fluctuations, while AI-driven demand forecasting optimizes loading and unloading schedules. Through this multi-modal sensor integration, NW Logistics establishes a real-time situational awareness model, significantly improving logistics decision-making and operational efficiency.

### *E. AI-Driven Analytics and Data Processing*

To effectively process and analyze vast amounts of real-time logistics data, NW Logistics employs a hybrid AI-driven computational framework, integrating edge computing, cloud-based storage, and high-performance machine learning algorithms. Data from onboard sensors and IoT devices is processed at the edge, allowing for low-latency analytics and immediate anomaly detection, which ensures proactive intervention in case of safety violations. Cloud storage serves as a centralized repository, aggregating multi-source logistics data to facilitate real-time analytics and historical trend analysis, while also ensuring scalability and secure data sharing across logistics networks.

The system's machine learning models optimize logistics operations through dynamic route planning, anomaly detection, and predictive analytics. Reinforcement learning algorithms dynamically adjust delivery routes based on real-time traffic conditions, road hazards, and delivery constraints, ensuring optimal efficiency and cost reduction. AI-driven driver behavior analysis employs computer vision and sensor data to monitor speed variations, fatigue detection through facial expression recognition, and risky driving behaviors such as sudden braking or lane deviations. Deep learning-based anomaly detection enhances fraud prevention, unauthorized vehicle use monitoring, and cargo security tracking, making NW Logistics a proactive risk management tool for logistics operators.

### F. User Interface and Logistics Control Center

NW Logistics provides an intuitive, AI-enhanced dashboard, allowing logistics managers and decision-makers to oversee fleet operations, analyze performance metrics, and optimize logistics processes in real time. The centralized logistics control panel displays live GPS locations, vehicle statuses, and estimated arrival times, ensuring full visibility into fleet operations. AI-powered predictive alerts notify managers of potential logistics disruptions before they occur, facilitating proactive decision-making and reducing downtime. Operational heatmaps provide geospatial visualization of traffic congestion, delivery bottlenecks, and fuel consumption trends, enabling data-driven optimization of supply chain logistics. In addition to real-time monitoring, NW Logistics incorporates automated compliance and sustainability reporting. A carbon emissions monitoring dashboard tracks $CO_2$ emissions per trip, ensuring compliance with green logistics standards and environmental regulations. Regulatory compliance alerts flag noncompliant driver behaviors, unauthorized route deviations, and safety violations, helping logistics companies adhere to industry regulations. AI-powered resource allocation and load balancing further optimize vehicle assignment and logistics planning, ensuring efficient use of transportation assets.

### G. NW Logistics as an Integrated AI Ecosystem

NW Logistics is more than just a logistics tracking system—it is a comprehensive AI-powered logistics ecosystem that integrates real-time AI processing, sustainability tracking, and fleet optimization into a single, intelligent platform. The system adapts dynamically to transportation conditions and logistics demands, leveraging AI-driven automation and predictive insights to enhance supply chain efficiency. By embedding carbon footprint tracking and fuel efficiency monitoring, NW Logistics supports environmentally responsible logistics operations, ensuring compliance with green logistics policies.

A key innovation of NW Logistics is its AI-based driver behavior analysis and fleet optimization capabilities. Using computer vision and sensor analytics, the system monitors driver performance, detects unsafe behaviors, and enhances road safety compliance. Through AI-powered predictive maintenance, NW Logistics minimizes vehicle downtime and maintenance costs, further optimizing supply chain resilience.

## V. Discussion

As Artificial Intelligence (AI) continues to redefine logistics and supply chain management [15], the need for multifunctional AI-driven logistics systems has become increasingly evident. Companies are striving to improve efficiency, sustainability, and security while optimizing their transportation networks to meet the growing demands of global trade and environmental regulations. NW Logistics represents an advanced, integrated AI-powered logistics system, incorporating real-time data processing, predictive analytics, carbon footprint monitoring, and AI-driven decision-making into a unified logistics framework [26].

While the three selected AI-driven logistics applications—Explainable AI (XAI) for decision support, Lithological Mapping for route optimization, and AI-based anomaly detection for risk mitigation—each contribute valuable advancements to logistics optimization, they remain domain-specific solutions, each addressing a singular aspect of logistics intelligence [14]. In contrast, NW Logistics stands out by synthesizing these AI functionalities into a single, adaptable, and intelligent logistics management system.

To provide a clearer understanding of NW Logistics' unique positioning, the following sections will explore the key similarities it shares with these existing AI applications, as well as the major differentiators that establish NW Logistics as a next-generation AI solution in the logistics industry.

### A. Similarities Between NW Logistics and AI-Driven Logistics Applications

Despite being a comprehensive and multi-functional AI system, NW Logistics shares several methodological and functional similarities with the selected applications. These parallels can be observed in three major areas:

*1) Predictive analytics and AI-Driven decision support:* Much like Explainable AI (XAI) models, NW Logistics integrates predictive analytics mechanisms to enhance supply chain forecasting and decision-making [27]. Through advanced AI-based forecasting models, NW Logistics empowers logistics operations by:

*a) Demand prediction:* Anticipating future logistics requirements and enabling supply chains to adjust proactively to market fluctuations.

*b) Inventory optimization:* Reducing storage costs and improving stock availability through AI-driven inventory control.

*c) Adaptive logistics planning:* Allowing for real-time adjustments to transportation schedules based on emerging road conditions, demand shifts, and operational constraints.

Unlike traditional AI models that function as black-box systems, NW Logistics emphasizes interpretability and transparency, ensuring that logistics managers understand and trust AI-driven recommendations. This approach not only enhances decision-making efficiency but also ensures compliance with industry regulations and corporate governance standards [16].

*2) AI-Powered route optimization:* NW Logistics shares strong methodological alignment with Lithological Mapping AI models, as both rely on machine learning algorithms to dynamically optimize transportation routes. These models leverage:

*a) Geospatial AI:* Analyzing topographical and environmental constraints to determine the most efficient transport routes while mitigating logistical bottlenecks.

*b) Dynamic routing algorithms:* Adjusting transport networks in real-time based on traffic congestion, weather patterns, and terrain complexities.

NW Logistics enhances this capability by integrating real-time IoT sensor data from its fleet, enabling the system to continuously adapt to evolving road conditions [20], [17]. This results in a highly responsive logistics system, capable of reducing delivery times, fuel costs, and overall transportation inefficiencies.

*3) Fraud detection and risk mitigation:* Similar to AI-based Anomaly Detection models, NW Logistics incorporates advanced machine learning techniques to improve logistics security and fraud prevention [14]. This includes:

*a) Real-Time monitoring of cargo and vehicle movements:* Identifying irregular transportation patterns to prevent unauthorized access or logistical inconsistencies.

*b) Detection of fraudulent activities:* Recognizing unauthorized route deviations, shipment tampering, and fuel misuse using AI-driven pattern recognition.

*c) Machine learning-based risk assessment:* Ensuring compliance with supply chain security regulations while proactively identifying operational vulnerabilities.

By integrating real-time AI monitoring with predictive risk analysis, NW Logistics offers a highly secure logistics network, reducing the likelihood of supply chain disruptions, financial fraud, and regulatory violations.

### B. Key Differentiators of NW Logistics

While NW Logistics shares functional similarities with existing AI-driven logistics applications, its comprehensive AI integration and real-time adaptability set it apart as a next-generation logistics management platform. NW Logistics outperforms these models by combining multiple AI-driven capabilities into a single, autonomous logistics ecosystem. Its key differentiators include:

*1) Real-Time AI integration for autonomous logistics operations:* Unlike traditional AI applications that rely heavily on historical data analysis, NW Logistics is designed as a real-time AI-powered logistics system. This allows for:

*a) Continuous AI-driven route optimization:* The system dynamically adjusts transport routes in real-time based on live traffic updates, weather conditions, and operational constraints [21].

*b) Live supply chain monitoring:* AI-powered monitoring enables proactive problem resolution, minimizing unexpected delays and logistical inefficiencies[22].

*c) Seamless data fusion from multiple sources:* By integrating GPS tracking, IoT-enabled sensors, and road infrastructure analytics, NW Logistics establishes a fully adaptive logistics ecosystem that can react instantaneously to environmental and operational changes[23][24].

This real-time AI integration ensures that NW Logistics functions as a self-optimizing logistics system, far exceeding the capabilities of static AI models that depend on periodic data updates.

*2) AI-Enabled sustainability and carbon emissions reduction:* A defining feature of NW Logistics is its AI-driven sustainability tracking system, a functionality absent in the selected AI applications. NW Logistics is uniquely designed to:

- Minimize Fuel Consumption and $CO_2$ Emissions through AI-powered route selection and eco-friendly driving recommendations [18].
- Enhance Fleet Efficiency by monitoring vehicle performance, driver habits, and logistics network sustainability metrics.
- Ensure Compliance with Green Logistics Regulations, enabling companies to align with carbon neutrality goals and environmental sustainability policies [19], [27],[28].

By incorporating real-time emissions tracking and fuel efficiency optimization, NW Logistics pioneers green logistics initiatives, providing companies with data-driven strategies to reduce their carbon footprint while maintaining cost efficiency.

*3) AI-Based driver behavior monitoring and road safety compliance:* NW Logistics integrates computer vision and AI-powered behavioral analysis to assess driver performance and safety compliance, a feature not present in the selected AI models. This system:

- Monitors Driver Behavior using AI-enhanced vehicle sensors and onboard cameras, detecting risky driving patterns such as speeding, abrupt braking, and lane violations [25].
- Detects Fatigue and Distraction through real-time facial recognition and biometric analysis, improving driver safety and reducing accident risks.
- Provides Automated Feedback and Training Recommendations, enabling fleet operators to implement AI-assisted driver training programs to enhance overall fleet safety.

This AI-driven approach not only improves road safety and fleet reliability but also contributes to lowering accident-related costs and optimizing vehicle longevity.

### C. Scientific Analysis of NW Logistics' AI Capabilities

The radar chart visualization highlights NW Logistics as a comprehensive AI-driven logistics solution, surpassing existing AI applications by integrating real-time decision-making, sustainability monitoring, and AI-enhanced security into a single platform Fig. 3.

NW Logistics excels in real-time AI integration, unlike XAI-based models that rely on historical data. It also shares route optimization capabilities with Lithological Mapping AI but advances further by incorporating IoT-driven dynamic routing and fuel efficiency tracking. Its predictive analytics align with XAI but extend to inventory forecasting and adaptive logistics planning.

In fraud detection and risk mitigation, NW Logistics mirrors Anomaly Detection AI but enhances security with real-time monitoring of cargo movements, route deviations, and unauthorized vehicle use. Additionally, its AI-powered sustainability tracking is unique, reducing $CO_2$ emissions and optimizing fuel consumption, a feature missing in other models.

A key differentiator is its driver behavior analysis, employing computer vision to detect risky driving, fatigue, and compliance violations, ensuring road safety and fleet optimization [30], [29].

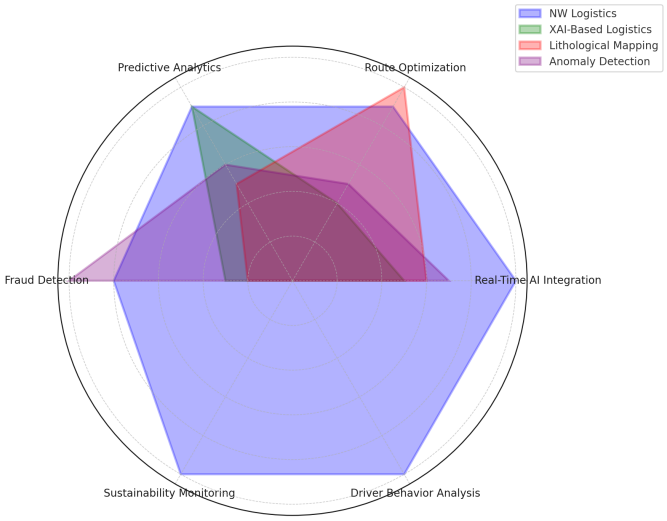

Fig. 3. The Radar chart visualization.

NW Logistics stands out as a next-generation AI-powered logistics platform, integrating real-time optimization, security, and environmental sustainability in a unified system, redefining modern supply chain intelligence.

## VI. Conclusion

The integration of Artificial Intelligence (AI), Internet of Things (IoT), and cloud computing has significantly accelerated the digital transformation of logistics. NW Logistics is a next-generation AI-powered logistics platform that integrates real-time monitoring, predictive analytics, dynamic route optimization, fraud detection, and environmental impact assessment. Its multifunctional AI-driven approach allows logistics networks to become more adaptive, efficient, and environmentally responsible, in line with global industry trends and sustainability objectives.

Using AI and IoT based solutions, NW Logistics improves decision making and operational efficiency while supporting low-carbon logistics planning. Through energy-efficient route management and real-time fuel optimization, the platform enables smarter and greener logistics operations. It also integrates AI-enhanced fleet management, driver behavior tracking, and CO2 emissions monitoring to ensure compliance with green logistics standards.

Incorporating disruptive technologies such as smart sensors, crowd-shipping, and drone-based logistics, NW Logistics addresses the challenges of last-mile delivery and promotes circular economy principles. Its modular design supports adaptability across intermodal transport networks and facilitates real-time logistics intelligence.

Looking ahead, future developments of NW Logistics will focus on the integration of advanced computer vision and deep learning models for the detection of all types of road signs, traffic regulations, and driving violations. This enhancement aims to create a fully intelligent driving monitoring system that contributes to improved safety and compliance across logistics fleets. In parallel, the platform will evolve to offer a more robust enterprise logistics tracking system, capable of monitoring key performance indicators, managing delivery chains in real time, and providing detailed behavioral reports for drivers and operators.

As logistics and supply chain networks continue to evolve in complexity, NW Logistics positions itself as a scalable, intelligent, and responsible solution that bridges operational performance, regulatory compliance, and environmental sustainability. Through ongoing innovation and applied AI, the platform will continue to transform logistics into a safer, smarter, and greener industry.

# A Robust Defense Mechanism Against Adversarial Attacks in Maritime Autonomous Ship Using GMVAE+RL

Ganesh Ingle, Kailas Patil, Sanjesh Pawale
Department of Computer Engineering, Vishwakarma University, Pune, India

***Abstract*—In this paper, we propose a robust defense framework combining Gaussian Mixture Variational Autoencoders (GMVAE) with Reinforcement Learning (RL) to counter adversarial attacks in Maritime Autonomous Systems, specifically targeting the Singapore Maritime Database. By modeling complex maritime data distributions through GMVAE and dynamically adapting decision boundaries via RL, our approach establishes a resilient latent representation space that effectively identifies and mitigates adversarial perturbations. Experimental evaluations using adversarial methods such as FGSM, IFGSM, DeepFool, and Carlini-Wagner attacks demonstrate that the proposed GMVAE+RL model outperforms traditional defenses in both accuracy and robustness. Specifically, it achieves a peak accuracy of 87% and robustness of 20.5%, compared to 85.8% and 19.2% for FGSM and significantly lower values for other methods. These results underscore the superiority of our method in ensuring data integrity and operational reliability within complex maritime environments facing evolving cyber threats.**

***Keywords*—Maritime autonomous systems; reinforcement learning; defense mechanisms; Gaussian Mixture Variational Auto encoder; Singapore maritime database**

## I. Introduction

The maritime industry is experiencing a paradigm shift with the advent of Artificial Intelligence (AI), which is set to revolutionize various operational facets through heightened automation, efficiency enhancement, and cost mitigation.

### A. Maritime Autonomous Systems (MAS)

AI's instrumental role is exemplified in the development of Maritime Autonomous Systems (MAS), which necessitate minimal human governance, employing AI for executive decisions and navigational control [1],[2],[5].

### B. Advantages of MAS

MAS herald a new era in maritime operations, characterized by:

- Diminished manpower requisites, leading to significant labor cost reductions.
- AI-facilitated automation and refinement of complex maritime tasks.
- Augmented crew safety, especially under perilous operational conditions.
- Operational cost economization through heightened MAS efficiency.
- Environmental impact mitigation via the integration of renewable energy sources.

### C. MAS Development Progress

Rapid advancements in MAS development are being witnessed, with a multitude of applications ranging from cargo transit to environmental oversight.

### D. Security Implications of AI in MAS

However, the ascent of AI within MAS introduces new security paradigms, predominantly concerning Adversarial Artificial Intelligence (AAI).

### E. Adversarial Artificial Intelligence (AAI)

AAI encapsulates the intentional manipulation of AI frameworks, aiming to pinpoint and capitalize on systemic vulnerabilities, thus posing a significant threat to MAS security and operational integrity.

### F. AAI Vulnerabilities in MAS

MAS AI systems are susceptible to various AAI attacks due to their reliance on complex algorithms and data-driven decision-making processes. Manipulating training data to introduce biases or errors in the AI model, leading to incorrect decisions or system malfunctions. Model inversion: Inferring sensitive information from the AI model's parameters, such as training data or model architecture.Crafting inputs that the AI model misclassifies or misinterprets, potentially enabling attackers to evade detection or manipulate system behavior [35],[36]. Inference attacks: Exploiting the AI model's decision-making process to influence its outputs, such as steering a vessel towards a hazardous area or triggering false alarms [3], [4], [6]. Impact of AAI on MAS Security Collisions: Attackers could manipulate the AI navigation system to cause collisions with other vessels or obstacles, leading to loss of life and environmental damage. Cargo theft: Attackers could intercept or reroute cargo shipments, causing financial losses and disrupting supply chains. Attackers could exploit vulnerabilities in the AI system to gain unauthorized access to sensitive data or disrupt critical operations. The rapid advancements in artificial intelligence (AI) have opened up a plethora of opportunities for enhancing maritime operations through autonomous systems. However, the integration of AI into maritime autonomous systems (MAS) also introduces new security challenges, particularly from adversarial AI (AAI).

AAI refers to the malicious use of AI to exploit vulnerabilities and compromise the integrity of AI-powered systems. The infusion of AI into maritime operations has catalyzed a transformative phase in the maritime sector, yet it simultaneously ushers in new security vulnerabilities, especially from AAI.

### G. AAI Threats in the Maritime Domain

The maritime sector's intrinsic dynamic and unpredictable nature exacerbates the vulnerability of AI systems to AAI threats. These threats encompass:

### H. Data Poisoning

Adversarial entities may corrupt training datasets, inducing biases or errors that could precipitate erroneous decision-making or functional disruptions within MAS.

### I. Model Inversion

Attackers might extract sensitive data or discern the model's structure from its parameters, thus acquiring tactical knowledge about the system's operations.

### J. Evasion Attacks

Specially crafted inputs may lead AI models to misclassify or misconstrue data, permitting adversaries to skirt detection or alter system actions.

### K. Inference Attacks

Exploitation of the decision-making process within AI models can be manipulated to influence outcomes, potentially resulting in navigational errors or security breaches.

The maritime industry is undergoing a transformative evolution with the integration of Artificial Intelligence (AI) into Maritime Autonomous Systems (MAS), promising enhanced operational efficiency, reduced human intervention, and improved safety. MAS rely heavily on AI-driven decision-making for navigation, cargo management, and environmental monitoring. However, as the reliance on AI systems deepens, so does the surface for security vulnerabilities—particularly from Adversarial Artificial Intelligence (AAI), which involves deliberate perturbations in input data that can mislead AI models into making erroneous or even dangerous decisions [6-14].

Previous studies have investigated adversarial attacks and their countermeasures, primarily in controlled or theoretical environments using static defense mechanisms such as adversarial training, input transformations, or model distillation. While these approaches show promise in generic settings, they often fall short in real-world maritime environments characterized by high data variability, dynamic vessel behaviors, and critical security requirements. Specifically, existing defense strategies lack adaptability and robustness when confronted with iterative, optimization-based attacks like Carlini-Wagner or DeepFool, which can subtly and effectively compromise AI models without detection.

This presents a significant research gap: there is a pressing need for defense mechanisms that can not only model complex, multimodal maritime data distributions but also dynamically adapt to evolving attack strategies in real time. Addressing this, we propose a hybrid defense architecture that combines Gaussian Mixture Variational Autoencoders (GMVAE) for resilient data representation with Reinforcement Learning (RL) for adaptive policy optimization. The GMVAE component ensures a structured latent space capable of identifying subtle anomalies, while RL empowers the model to learn countermeasures through continuous feedback, improving robustness over time.

By focusing on the underexplored intersection of generative modeling and adaptive learning in adversarial defense, this research provides a practical and scalable solution tailored to the maritime domain. The approach is validated on the Singapore Maritime Dataset, demonstrating superior performance over existing methods in terms of both accuracy and adversarial robustness. This work not only fills a critical gap in maritime cybersecurity literature but also sets a foundation for future research in real-time, adaptive AI defense systems.

Compared to traditional defense strategies such as adversarial training, input transformation, and static regularization techniques, the proposed GMVAE+RL framework offers multiple significant advantages. Firstly, the GMVAE component excels at capturing multi-modal and complex maritime data distributions, enabling it to identify subtle perturbations that static defenses often miss. Secondly, the integration of Reinforcement Learning provides an adaptive mechanism that dynamically adjusts the model's behavior in response to evolving attack strategies—something existing models lack. Thirdly, the hybrid approach enhances both generalization and interpretability by learning structured latent representations and optimizing decision policies simultaneously. Experimental comparisons against established methods like FGSM, IFGSM, DeepFool, and Carlini-Wagner reveal that our method maintains higher accuracy and robustness, with a notable 87% accuracy and 20.5% robustness even under strong adversarial conditions. These outcomes underscore the model's superior resilience and adaptability, making it highly suitable for real-world applications in autonomous maritime systems where data integrity and security are mission-critical.

The remainder of this paper is organized as follows: Section II provides the background and motivation for adversarial resilience in Maritime Autonomous Systems, followed by a review of related work in Section III. Section IV details the proposed methodology combining GMVAE and Reinforcement Learning, while Section V outlines the experimental setup used for evaluation. Section VI presents a comprehensive analysis of results, including performance metrics under various adversarial scenarios. Finally, Section VII concludes the paper with key findings and directions for future research.

## II. Background

Global trade heavily relies on maritime vessels, with a significant portion of international movement facilitated by shipping [5]. This paper explores the integration of advanced sensors in fully autonomous vessels (Level 4 as defined by the International Maritime Organization), which operate independently without any human crew.

MAS utilize a variety of sensors and instruments for environmental perception and decision-making, including:

- RADAR: For detecting large objects using radio waves.
- LiDAR: Employed for accurate detection of smaller objects.
- Echo Sounders: Utilized for underwater object detection.
- CCTV/IR/multispectral Cameras: For close-range object detection.
- Microphone Arrays: Capture audio cues for situational awareness.
- AIS and GNSS: Provide location and data transmission capabilities.
- ECDIS, Weather Sensors, and Communication Systems: Crucial for navigation and environmental monitoring.
- Specialized sensors and Drones: Extend the range and capabilities of standard sensor systems.

The integration of multiple sensors provides increased accuracy, improved redundancy, and enhanced situational awareness. Sensors in MAS face unique challenges such as water-induced distortions, harsh environmental conditions, and detection complexities. The effective deployment of a diverse sensor array is paramount in MAS, requiring a deep understanding of their individual and collective capabilities and limitations in the maritime context. In fully autonomous maritime systems, AI plays a crucial role in automating vessel operation. It receives sensor data as input, analyzes the information, and makes decisions to control the vessel's actions, replacing or supplementing crew functions. The specific AI technologies required depend on the range of tasks and functionalities of the MAS. Based on the categorization, several key AI technologies are employed in MAS, connected to a Dynamic Positioning (DP) system that controls the vessel's movements:

Determines the vessel's real-time location and environment, including object detection and range. Convolutional neural networks (CNNs), region proposal networks(RPNs), and natural language processing (NLP) for interpreting communication.Sensor data, including camera images, radar signals, and LiDAR data.Real-time information about the vessel's surroundings and potential hazards. Prevents collisions with other vessels or objects [14-23]. CNNs for object recognition and support vector machines (SVMs) for trajectory planning.SA information, including object detection data.New trajectory to avoid collisions.Determines the optimal route for the vessel, considering factors like fuel efficiency, speed, and safety.Evolutionary algorithms (EAs), particle swarm optimization (PSO), and ant colony optimization (ACO).Global map data, weather information, and vessel parameters.Optimal route for the vessel to follow.

- Convolutional Neural Networks (CNNs): Efficiently learn spatial features from images, making them ideal for object detection and recognition in SA and collision avoidance modules.
- Region Proposal Networks (RPNs): Generate candidate object bounding boxes within images, improving the efficiency of object detection for SA.
- Natural Language Processing (NLP): Enables interpretation of communication signals like radio messages, enhancing situational awareness.
- Support Vector Machines (SVMs): Effective for classification tasks, such as determining the type of object detected and generating new collision-avoidance trajectories.
- Evolutionary Algorithms (EAs): Powerful optimization techniques that can handle complex multi-objective problems, like finding the optimal global route for the vessel.
- Particle Swarm Optimization (PSO): Mimics the behavior of a swarm of birds to find optimal solutions, applicable to path planning and route optimization.
- Ant Colony Optimization (ACO): Inspired by the foraging behavior of ants, ACO can identify efficient routes by simulating pheromone communication. AI plays a pivotal role in automating various aspects of MAS operation. Different AI technologies are employed for specific tasks, from situational awareness and collision avoidance to global path planning and vessel maintenance. Understanding the capabilities and limitations of these AI technologies is crucial for designing and developing safe and reliable MAS.

Most evaluations of adversarial attacks on machine learning (ML) systems have been limited to controlled laboratory environments. This study extends the analysis to real-world MAS environments, where the implications of such attacks are less understood but potentially more impactful.

While focusing on adversarial attacks, this work also acknowledges the significance of conventional cybersecurity attacks and the potential for combined adversarial AI and conventional cybersecurity tactics. The influence of conventional security vulnerabilities on both AI-based and traditional security is also recognized.

### A. Class 1: Model Inversion

- Description: An attacker queries the ML model to deduce its prerequisite features, potentially aiding in reconnaissance for future attacks.
- Impact: This represents an abuse of the system's confidentiality, although it does not directly impair the model's functionality.

This comprehensive evaluation of adversarial attacks in MAS provides critical insights into their real-world implications, emphasizing the need for robust defense mechanisms in maritime autonomous systems.

## III. Literature Survey

Huang et al. represents a critical juncture in the field of artificial intelligence, particularly in understanding the vulnerabilities of reinforcement learning (RL) systems to adversarial attacks. Reinforcement learning, which functions on a framework of rewards and penalties, had been increasingly applied in varied domains such as gaming, autonomous navigation, and decision-making algorithms. However, the robustness of

these systems against subtle, malicious alterations had not been thoroughly examined until this study.This research focused on the concept of adversarial attacks, previously acknowledged in other neural network contexts, where slight, calculated changes to input data could drastically mislead the network's output. They applied this concept to RL, investigating whether minor perturbations in the input data of an RL agent could derail its performance. Their experiments cut across different RL environments to ensure a comprehensive assessment.The findings were revelatory, demonstrating that even negligible modifications to input data could significantly impair the RL models' performance. This vulnerability was not confined to specific RL algorithms or tasks but was a more generalized issue, indicating a fundamental security risk in RL applications. Crucially, the study's implications extended beyond the immediate realm of RL, casting a spotlight on the need for adversarial robustness in AI systems, particularly in safety-critical applications like autonomous vehicles[23-29].Presented research precipitated a heightened awareness and subsequent research efforts aimed at developing more robust RL systems capable of resisting such adversarial attacks. The study not only emphasized the importance of considering security threats in AI system design but also spurred advancements in defensive techniques, marking a significant leap in the development of secure and reliable AI solutions.

Chen et al. provided a crucial insight into the cybersecurity vulnerabilities of Connected Vehicle (CV) based transportation systems, particularly focusing on the risks associated with data spoofing attacks. In the era of advanced transportation technology, CV systems have emerged as a key innovation, enhancing vehicular communication and operational efficiency through vehicle-to-vehicle and vehicle-to-infrastructure interactions. However, the integration of such complex communication systems also opens up new avenues for cyber threats.Proposed study embarked on a comprehensive analysis of the CV systems' architecture and operational mechanisms. Their primary objective was to identify and assess potential cybersecurity threats, with a special emphasis on data spoofing – a technique where false information is injected into a system, leading to misguided actions or responses. Through detailed simulations and hypothetical attack scenarios, the study highlighted how these systems are particularly prone to data spoofing, which could lead to severe consequences like traffic disruptions or even collisions [29],[30].

One of the key revelations of this study was the identification of inherent design flaws within CV systems that made them susceptible to such cyberattacks. These vulnerabilities could potentially be exploited to manipulate critical aspects of traffic control or to feed misleading information to vehicles, thus compromising road safety. The findings played a pivotal role in emphasizing the need for robust, multi-layered cybersecurity measures within CV systems. This study not only underscored the importance of incorporating stringent security protocols in the design and implementation of CV technology but also acted as a catalyst for further research and development in enhancing the resilience of connected vehicles against cyber threats. The work of Chen and colleagues thus marked a significant step in ensuring that the advancements in vehicle connectivity and automation do not compromise safety and security [31[32]. Lin et al. introduced a groundbreaking approach to adversarial attacks within the realm of Atari games, marking a significant advancement in the understanding of vulnerabilities in reinforcement learning systems. Their innovative concept, termed "strategically-timed attacks," involved the creation of adversarial examples that were calculated independently at each timestep of the game. This method diverged from traditional continuous attack models, offering a more nuanced and potentially more disruptive technique. By strategically timing these attacks, Lin and colleagues demonstrated that it was possible to significantly impair the performance of reinforcement learning agents in game scenarios. These attacks were designed to be subtle enough to avoid immediate detection, yet sufficiently impactful to mislead the agents, leading to incorrect decisions or actions within the game. This research not only highlighted a specific vulnerability in reinforcement learning applications but also set a new precedent in the methodology of adversarial attack strategies. It underscored the need for more robust defense mechanisms in AI systems, particularly in environments where decision-making is based on real-time data inputs, such as in gaming or autonomous navigation scenarios. The work of Lin et al. thus stands as a pivotal contribution to the field of AI security, illustrating the evolving nature of cyber threats and the ongoing challenge of securing AI against sophisticated adversarial techniques.

Xiang et al. conducted a noteworthy study focusing on the domain of Q-learning, specifically within the context of automatic path planning. Their research made a significant contribution to the field by proposing a probabilistic output model designed to predict adversarial examples in such structured environments. The essence of their work revolved around the exploration of adversarial attacks in scenarios that are inherently more systematic and organized, compared to the often chaotic nature of other environments like gaming.The innovative aspect of research lay in the application of their model to Q-learning, a fundamental reinforcement learning technique widely used for making sequence-based decisions. By integrating a probabilistic approach, they were able to forecast the likelihood of adversarial instances occurring in an automatic path planning context. This model was not only pivotal in identifying potential vulnerabilities within the path planning algorithms but also in suggesting the probability of certain attacks succeeding.Their work shed new light on the dynamics of adversarial attacks in environments characterized by a high degree of order and predictability, such as route planning and navigation. By doing so,authors expanded the understanding of how adversarial attacks could be tailored and predicted in such settings, contrasting with the more generalized approach typically seen in other AI applications. The implications of this study are far-reaching, especially considering the growing reliance on autonomous systems in various sectors, including transportation and logistics. It underscores the need for advanced security measures that can anticipate and mitigate such sophisticated cyber threats in automated and algorithm-driven environments.

Huang et al. not only exposed the vulnerabilities of reinforcement learning systems to adversarial attacks but also introduced a significant defensive mechanism known as the Fast Gradient Sign Method (FGSM). This method was designed specifically to counteract the negative impacts of adversarial inputs, especially in the context of deep reinforcement learning agents.FGSM operates by utilizing the gradients of

the neural network to create perturbations that 'push' the input data towards the direction of increasing the loss. This method is particularly notable for its simplicity and efficiency. Instead of requiring complex or time-consuming computations, FGSM generates adversarial examples by applying a straightforward adjustment in the direction of the gradient. The 'sign' component of the method refers to taking the sign of the gradient, ensuring that the perturbations are small yet effective enough to mislead the learning model.In the context of deep reinforcement learning, where agents are often trained on high-dimensional input data such as images or sensor readings, FGSM provides a valuable tool for enhancing the robustness of these systems. By applying adversarial examples generated via FGSM during the training process, the learning models can be 'inoculated' against potential attacks, learning to recognize and resist manipulative inputs. This approach essentially strengthens the model's ability to maintain performance even when faced with subtly altered input data, a critical requirement in applications where reliability and accuracy are paramount.Authors highlights the FGSM's role in defending against adversarial attacks has been pivotal in the field of AI security. It marked a step forward in developing more secure AI systems capable of operating reliably in adversarial environments, a vital consideration as AI technologies continue to be integrated into increasingly critical and sensitive applications.

Silver et al. applied RL to the game of Go. They introduced a novel approach that combined deep neural networks with tree search, leading to unprecedented performance in this complex board game. This demonstrated RL's potential in mastering highly intricate and strategic tasks. Mnih et al. were pioneers in applying deep learning to RL, particularly in the context of playing Atari games. Their model was the first to successfully learn control policies directly from high-dimensional sensory inputs, marking a significant advancement in the field of game-playing AI.

The increasing prevalence of deep learning applications has brought to light the vulnerability of these models to adversarial attacks. These attacks involve crafting subtle modifications to input data that can cause deep learning models to make erroneous predictions. Even minor perturbations can have a significant impact on model performance. This poses a serious threat to the reliability of deep learning systems, especially in critical applications such as autonomous vehicles and medical diagnosis.

The Fast Gradient Sign Method (FGSM) [1] is a fundamental adversarial attack technique that involves calculating the gradients of the model's loss relative to the input data and modifying the data based on these gradients. This method was expanded into IFGSM [2], which applies perturbations iteratively to increase the strength of the adversarial effect. More complex methods like the DeepFool attack [3] and the Carlini-Wagner attack [4] employ advanced strategies. DeepFool iteratively identifies the minimal perturbation needed to misclassify an input by approximating the decision boundary, whereas the Carlini-Wagner attack uses optimization techniques to create adversarial examples with minimal changes but targeted misclassification goals.

Various defense strategies have been proposed to mitigate adversarial threats. Adversarial training [5] involves training models using adversarial examples to enhance their robustness. Other techniques, like feature squeezing and input transformations (including JPEG compression) [6], aim to eliminate adversarial perturbations. However, these methods often struggle to generalize across different types of attacks, highlighting the need for more innovative solutions.

Variational Autoencoders (VAEs) [7] provide a structured framework for learning generative models. They consist of an encoder, which maps input data into a latent space, and a decoder, which reconstructs data from these latent representations. The learning objective is to minimize reconstruction loss while ensuring the latent space adheres to a structured distribution, typically using the Kullback-Leibler (KL) divergence. This latent space captures essential features for controlled data generation. Extending VAEs, Gaussian Mixture Variational Autoencoders (GMVAE) [8] incorporate Gaussian Mixture Models (GMMs) into the latent space, enabling the representation of complex, multi-modal data distributions, thereby overcoming some limitations of standard VAEs.

Reinforcement learning has been identified as a promising method for improving model resilience against adversarial attacks [9]. This approach applies principles from control theory, using a policy network that learns actions to maximize cumulative rewards. In defense contexts, these actions involve decisions that enhance model robustness. This method involves training the policy network to make decisions that lead to accurate predictions on adversarial examples, counteracting adversarial perturbations. The reinforcement learning framework offers the benefit of continual adaptation, allowing models to enhance their robustness over time.

The MNIST dataset [10] has been a benchmark in machine learning for testing various defense techniques, contributing significantly to our understanding of adversarial challenges and defense strategies. This research includes both traditional and advanced deep learning-based solutions aimed at protecting model performance under adversarial conditions.

Adversarial training and defensive distillation, two current defenses for CNN-LSTM models, have trouble being effective and generalizing against adversarial attacks in PQD classification. These techniques fall short of maintaining high precision when attacked, indicating a need for more flexible and effective defense tactics. This is addressed by Input Adversarial Training (IAT), which meets a crucial demand for CNN-LSTM model security in power system applications by improving model robustness while maintaining performance [32]. Current adversarial defenses frequently lack an ideal balance between accuracy and robustness. Feature masking's potential is still not fully realized, particularly when paired with gradient modification. As our study showed, this disparity emphasizes the need for effective measures that improve resilience without lowering performance [33].

Existing GNN defence methods focus on highly linked training processes, overlooking adaptive adversarial attack strategies. This study addresses the gap by introducing GNN Attacker, leveraging Energy Honey Badger Optimization (EHBO) for generating adversarial attacks. The model achieves high visual similarity 90.77%, classification accuracy 94.68%, and attack success rate 96.54%, demonstrating its effectiveness in testing GNN robustness [34].

Existing deep learning models are highly vulnerable to

adversarial attacks, which introduce subtle perturbations leading to misclassification. Detecting and mitigating these attacks remains a significant challenge. This review addresses the gap by providing a comprehensive analysis of adversarial attack strategies and defense mechanisms, contributing to the development of more resilient deep learning and machine learning models [35].

Existing research on adversarial robustness has explored various defense mechanisms, including adversarial training, input transformations, and feature denoising. However, optimizing bit plane slicing for resilience remains underexplored. This study leverages genetic algorithms to refine bit-depth configurations, revealing that 5-bit representations enhance robustness against FGSM and DeepFool attacks. Despite performance degradation under adversarial conditions, optimized models demonstrate significant recovery. Prior work lacks dynamic bit plane adaptation, evaluation on diverse attacks, and scalability to large datasets. Addressing these gaps through adaptive slicing, black-box evaluations, and hybrid defenses can further strengthen adversarial resilience [36] [37].

Despite progress in defending against adversarial attacks, a gap remains in developing robust, generalizable solutions. Current defenses often perform well against certain attack types but are less effective in varied adversarial scenarios. This study seeks to address this gap by combining the capabilities of GMVAEs and reinforcement learning. This innovative approach aims to harness the unsupervised feature learning of GMVAEs and the adaptability of reinforcement learning's policy optimization, proposing a new direction for enhancing defense mechanisms against adversarial threats.

Existing defense mechanisms against adversarial attacks in Maritime Autonomous Systems (MAS) largely focus on either static adversarial training or heuristic input transformations, which often lack adaptability and fail to generalize across evolving attack strategies. These approaches struggle particularly in complex, real-world maritime contexts such as the Singapore Maritime Database, where data is highly dynamic and multi-modal. To bridge this gap, we propose a novel hybrid defense framework that integrates Gaussian Mixture Variational Autoencoders (GMVAE) with Reinforcement Learning (RL) to create an adaptive, resilient latent space capable of detecting and mitigating sophisticated adversarial manipulations. The GMVAE component excels in modeling diverse data distributions and isolating irregular patterns, while RL dynamically adjusts model responses based on feedback from adversarial environments. Experimental evaluations using standard adversarial methods—FGSM, IFGSM, DeepFool, and Carlini-Wagner—reveal that our approach significantly outperforms conventional defenses, achieving an accuracy of 87% and robustness of 20.5%, compared to lower benchmarks from existing methods. By explicitly addressing the shortcomings of static defenses and introducing an adaptive learning mechanism, our work advances the state of the art in maritime cybersecurity, ensuring higher integrity and reliability of autonomous ship operations under adversarial conditions.

## IV. Methodology

Fig. 1 gives proposed architecture diagram for the GMVAE with reinforcement learning.

In the realm of machine learning, the Gaussian Mixture Variational Autoencoder (GMVAE) stands out for its proficiency in processing complex, multi-modal data distributions. This model excels due to its capacity to discern diverse data representations by employing a combination of Gaussian distributions within its latent space. This capability surpasses that of the traditional Variational Autoencoder (VAE). In the context of adversarial attacks, which are tactics used to subtly alter input data to mislead machine learning models into erroneous predictions or classifications, the stakes are high. These attacks could result in various detrimental outcomes, such as mislabeling of ships, inaccuracies in maritime tracking, or even jeopardizing port security.

In safeguarding the Singapore Maritime Database against such adversarial threats, the GMVAE emerges as a key tool. Its sophisticated approach to data representation makes it highly effective in enhancing the database's defense mechanisms against these types of cyber threats.

*1) Latent space modeling:* The GMVAE, a sophisticated machine learning model, structures data within its latent space as a blend of Gaussian distributions. Each Gaussian element, characterized by its mean $\mu_k$ and standard deviation $\sigma_k$, encapsulates a distinct aspect of the data's distribution.

*2) Enhanced pattern recognition:* GMVAE's advanced data interpretation allows it to discern intricate patterns and irregularities with greater precision than more basic models, making it a valuable asset in identifying subtle discrepancies.

*3) Handling data uncertainty:* The GMVAE's probabilistic approach is instrumental in gauging uncertainty. This feature is vital for pinpointing and understanding manipulated data points, commonly known as adversarial examples, within the Singapore Maritime Database. This capability is crucial in bolstering the database's defenses against adversarial cyber attacks.

Defending against adversarial attacks on the Singapore Maritime Database, the Gaussian Mixture Variational Autoencoder (GMVAE) plays a crucial role with its encoder network, latent space representation, and decoder network. Each component of the GMVAE contributes to enhancing the robustness of the system against such attacks:

The encoder in a GMVAE takes an input vector $x$ (representing maritime data) and maps it to the parameters of a Gaussian mixture model in the latent space. Mathematically, this can be expressed as a function

$$f : x \to (\mu_k, \sigma_k^2) \tag{1}$$

where $\mu_k$ and $\sigma_k^2$ are the mean and variance of the $k$-th Gaussian component in the latent space. This encoding process translates complex, high-dimensional maritime data into a structured latent space. By doing so, it aids in differentiating standard operational data from potentially manipulated (adversarial) inputs. The encoder's effectiveness in this mapping is crucial for early detection of data inconsistencies or anomalies that could indicate a security breach. In the latent space, data points are represented as a mixture of Gaussian distributions. This can be mathematically formulated as

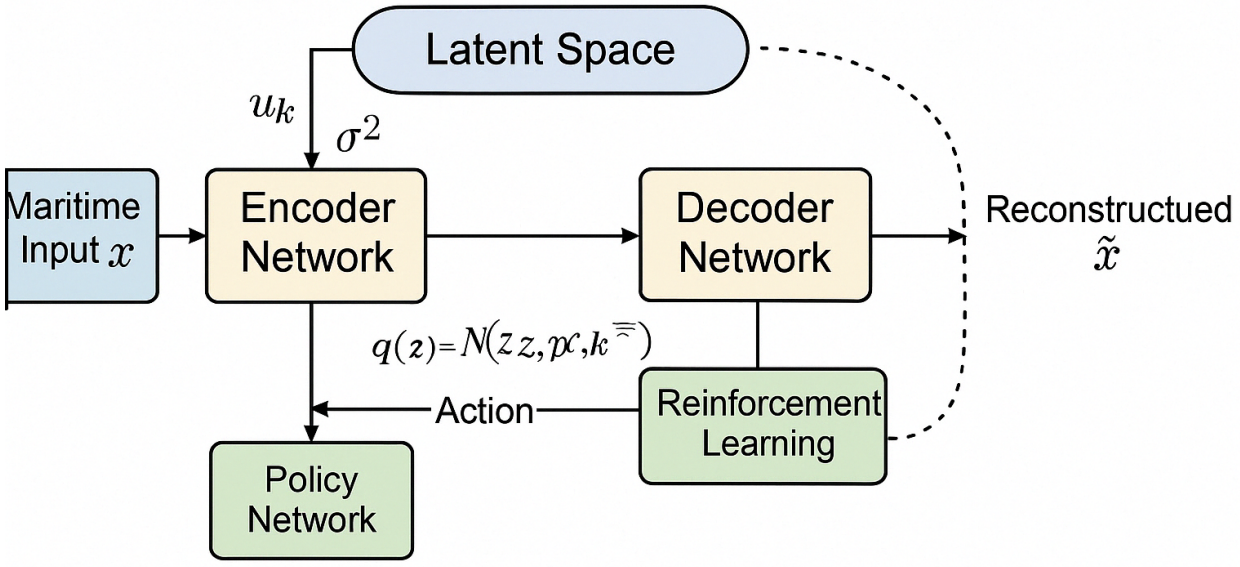

Fig. 1. Architecture diagram for proposed method.

$$p(z) = \sum_{k=1}^{K} \pi_k \mathcal{N}(z; \mu_k, \sigma_k^2) \tag{2}$$

where $z$ is the latent variable, $\pi_k$ is the mixture coefficient for the $k$-th component, and $\mathcal{N}$ denotes the Gaussian distribution. The latent space's ability to model complex data distributions enables the identification of subtle deviations from typical data patterns. This is particularly useful in the maritime context for detecting adversarial manipulations like forged vessel locations or tampered cargo records. The probabilistic nature of this space allows for a more nuanced understanding of data uncertainty, which is key in identifying adversarial examples.

The decoder network aims to reconstruct the input data from its latent representation. This can be viewed as a function:

$$g : (\mu_k, \sigma_k^2) \to \hat{x} \tag{3}$$

where $\hat{x}$ is the reconstructed input. The decoder's role in defense is to reconstruct the input data from the latent representation and compare it with the actual input. Significant deviations in this reconstruction process can indicate adversarial manipulations. Mathematically, if the reconstruction loss, typically measured as the difference between $x$ and $\hat{x}$ (e.g., using mean squared error), exceeds a certain threshold, it may signal an anomaly. The GMVAE's encoder network mathematically transforms maritime data into a structured latent space, where data points are probabilistically modeled as a mixture of Gaussians. This transformation is key to detecting abnormalities in the data, which could signify adversarial attacks. The latent space serves as a critical junction for identifying unusual data distributions that diverge from standard patterns. Finally, the decoder's mathematical reconstruction of the input data provides a means to verify the integrity of the data, making it a vital component in the detection and defense against adversarial threats in the Singapore Maritime Database.

- Anomaly Identification: Utilizing its advanced capabilities, the GMVAE can pinpoint irregularities in standard data patterns, which could indicate adversarial interference. This feature is particularly valuable in spotting potential cyber threats within the maritime data.
- Data Integrity Checks: The process of reconstructing input data from its latent representation in GMVAE serves as a critical check. Any significant mismatches between the original and reconstructed data are red flags that may denote a cyber intrusion.
- Dynamic Adaptation: Continuously integrating new data into the GMVAE enables it to stay abreast of changing adversarial techniques, enhancing its ability to safeguard against evolving cyber threats.

Embedding the GMVAE within the cybersecurity framework of Singapore's maritime database equips it with a sophisticated mechanism to detect and counter adversarial attacks. The model's proficiency in managing complex data and its adeptness at modeling uncertainty render it a powerful asset in defending against such sophisticated cyber challenges.

In the application of the Gaussian Mixture Variational Autoencoder (GMVAE) for defending the Singapore Maritime Database against adversarial cyber attacks, the encoder's output representation $q(z|x)$ plays a crucial role, defined mathematically as:

$$q(z \mid x) = \sum_{k=1}^{K} \pi_k \mathcal{N}(z \mid \mu_k(x), \sigma_k^2(x)) \tag{4}$$

This formulation encompasses several key components: $K$ represents the number of Gaussian components in the mixture,

critical for modeling complex maritime data patterns; $\pi_k$ is the mixing coefficient for the $k$-th component, reflecting its relative significance in the mixture; and $\mathcal{N}(z|\mu_k(x), \sigma_k^2(x))$ denotes the Gaussian distribution for each component, conditioned on the input $x$. These components collectively enable the GMVAE to perform a detailed and probabilistic mapping of input data to the latent space, which is essential for detecting deviations from normal data behavior that might indicate adversarial activities. Through such sophisticated mathematical modeling, GMVAE significantly enhances the capability to identify and mitigate potential cyber threats in the maritime database.

- Complex Data Modeling with Gaussian Mixtures: GMVAE's ability to represent intricate data distributions as a mixture of Gaussian components is crucial. This enables the detection of nuanced patterns and variations in maritime data, essential for identifying anomalies indicative of adversarial attacks.
- Optimizing the Evidence Lower Bound (ELBO):
  - Reconstruction Term: $\log p_\theta(x|z)$ assesses the decoder's ability to reconstruct input from latent variables, vital for data integrity verification.
  - KL Divergence: $D_{KL}[q_\phi(z|x)\|p(z)]$ minimizes deviation from the prior distribution $p(z)$, enhancing the model's generalization and resistance to overfitting.
- Counteracting Adversarial Attack Methods:
  - Fast Gradient Sign Method (FGSM): Adversarial examples are generated by modifying the input $x$ in the direction of the loss function's gradient $\nabla_x L(x, y)$, controlled by $\epsilon$:

$$x_{\text{adv}} = x + \epsilon \cdot \text{sign}(\nabla_x L(x, y)) \tag{5}$$

  - Iterative Fast Gradient Sign Method (IFGSM): Enhances adversarial impact through repeated application of FGSM, with step size $\alpha$.

Thus, the GMVAE's mathematical framework effectively provides robust defense for the Singapore Maritime Database by accurately modeling data distributions and ensuring resilience against sophisticated adversarial attacks.

*4) DeepFool attack methodology:* DeepFool identifies the smallest necessary perturbation $r$ to misclassify an input $x$, adjusted by the minimum of hyperparameter $\tau$ and the Euclidean norm of the loss function's gradient:

$$x_{\text{adv}} = x + r \cdot \min(\tau, \|\nabla_x L(x, y)\|_2) \tag{6}$$

This approach helps in anticipating how minimal data alterations might lead to significant misinterpretations in maritime data.

*5) Carlini-Wagner optimization approach:* The Carlini-Wagner attack creates minimal perturbations $\delta$ for misclassification, constrained by the $\ell_p$ norm and controlled by hyperparameter $c$:

$$\min_\delta \|\delta\|_p + c \cdot L(x + \delta, y) \tag{7}$$

This method highlights the need for robust defenses against subtle data manipulations in maritime systems.

*6) GMVAE's Variational Lower Bound (VLB) objective:* The key optimization goal in GMVAE is the Evidence Lower Bound (ELBO), comprising:

*a) Reconstruction loss:* Measuring the model's reconstruction ability from latent space, computed as the negative log-likelihood of the input given the latent variables.

*b) Kullback-Leibler divergence:* $D_{KL}[q_\phi(z|x)\|p(z)]$, ensuring the posterior distribution's closeness to the prior, thus maintaining a regularized latent space.

This dual focus enhances the capability to distinguish between genuine and adversarially manipulated maritime data.

Employing these strategies ensures robust defense mechanisms for the Singapore Maritime Database against adversarial threats.

In the context of defending the Singapore Maritime Database against adversarial cyber attacks, the Gaussian Mixture Variational Autoencoder (GMVAE) employs several key mathematical concepts and strategies:

- KL Divergence for Latent Space Regularization: KL divergence acts as a measure of dissimilarity between two probability distributions, playing a critical role in preventing the GMVAE's latent space from becoming overly complex or prone to overfitting. This regularization is crucial in maintaining the integrity and reliability of maritime data representations.
- ELBO as the Objective Function: The Evidence Lower Bound (ELBO) serves as the GMVAE's objective function, striking a balance between accurate data reconstruction and maintaining a well-structured latent space. Maximizing the ELBO ensures that the GMVAE learns informative latent representations, capturing the essential structure of maritime data while avoiding over-generalization.
- Core Principles of Generative Models in GMVAE: The ELBO reflects a fundamental principle in generative models: to find latent variables that effectively summarize the data distribution while maintaining an interpretable and well-defined latent space. This principle guides the learning process towards meaningful representations and robust generative capabilities, vital for realistic data simulation and generalization to new scenarios in maritime security.
- GMVAE Training Mechanism:The GMVAE training process involves several steps:

- Input and Latent Space Mapping: Mapping each input data point to the latent space, learning parameters of the Gaussian mixture distribution for latent variables.
- Reparameterization Trick: A key technique enabling gradient-based optimization, transforming noise variables into differentiable samples.
- Data Reconstruction: Assessing the model's ability to recreate input data from latent representations, crucial for verifying data authenticity.
- KL Divergence and Regularization: Ensuring the latent space adheres to a structured distribution, promoting better generalization.
- ELBO Optimization with SGD: Iteratively updating model parameters to maximize ELBO, balancing data reconstruction and latent space regularization.

- Evaluating Robustness Against Adversarial Attacks: The GMVAE's robustness is evaluated against various adversarial attack types, including FGSM, IFGSM, DeepFool, and Carlini-Wagner. Each attack method, with its unique strategy, highlights different aspects of model vulnerability and the effectiveness of the GMVAE's defense mechanisms.
- Utilization of CleverHans for Standardized Evaluation: CleverHans, a library offering pre-built implementations of adversarial attacks, is utilized for crafting and evaluating adversarial examples. This ensures a standardized and reliable approach to testing the GMVAE's defense capabilities.
- Metrics for Defense Effectiveness: Key metrics such as accuracy (on clean data) and robustness (against adversarial examples) are used to quantitatively evaluate the defense mechanism. A high performance in these metrics indicates a successful defense strategy in the context of maritime database security.

The GMVAE's mathematical framework and training procedure, combined with rigorous evaluation against standard adversarial attacks, offer a comprehensive approach to enhancing the resilience of the Singapore Maritime Database against cyber threats. This approach ensures not only the accuracy of maritime data but also its robustness in the face of sophisticated adversarial tactics.

## V. Experimental Setup

The research utilizes a combination of the Singapore Maritime Dataset (SMD) and its refined counterpart, SMD-Plus, to tackle specific challenges in maritime activity analysis. The SMD, with its extensive collection of over two million vessel movements, offers a broad basis for studying maritime behaviors. SMD-Plus enhances this dataset by correcting labeling inaccuracies and introducing more precise bounding boxes, significantly improving its utility for object classification tasks. To better deal with the difficulties in identifying smaller maritime objects, SMD-Plus consolidates certain classes, thereby enriching the dataset and enhancing object recognition capabilities. The preparation process includes converting SMD-Plus video content into individual image frames and aligning these annotations to meet the requirements of the YOLOv5 object detection model. This detailed preparation is vital for ensuring the dataset's compatibility and effectiveness, enabling comprehensive and accurate experimentation with the YOLOv5 model.

The experimental framework used to assess the effectiveness of our novel GMVAE-Reinforcement Learning defense strategy. Our experiments were conducted using the MNIST and Singapore Maritime dataset, which is composed of handwritten digits from 0 to 9. Each digit is depicted in a 28x28 pixel grayscale image. Essential preprocessing steps were implemented, such as scaling pixel values to fall between 0 and 1 and flattening the images into 784-dimensional vectors.

The hardware configuration for these experimental assessments included:

CPU: An Intel(R) Core(TM) i7-9700F CPU @ 3.00GHz, featuring 6 cores and 12 threads.

GPU: An NVIDIA GeForce RTX 2080 SUPER.

Memory: 32 GB of DDR4 RAM.

In our evaluation, we employed the Fast Gradient Sign Method (FGSM), a straightforward yet potent method for launching adversarial attacks on deep learning models. FGSM works by minutely adjusting the input data in a manner that amplifies the model's loss function. This process hinges on utilizing the gradient of the loss relative to the input to pinpoint the optimal direction for this perturbation.

*1) Neural network model configuration:* Consider a neural network model with parameters $\theta$, which maps an input data $x$ (representing maritime attributes) to a predicted output $f(x;\theta)$.

*2) Loss function in neural network:* The loss function $L$ measures the discrepancy between the predicted output $f(x;\theta)$ and the actual label $y$, mathematically expressed as $L(f(x;\theta), y)$.

*3) FGSM Attack mechanics:* The FGSM creates an adversarial example $x_{\text{adv}}$ by adding a perturbation $\delta$ to the original input $x$ to maximize the loss function. This is formulated as:

$$x_{\text{adv}} = x + \epsilon \cdot \text{sign}(\nabla_x L(f(x;\theta), y)) \tag{8}$$

Here, $x_{\text{adv}}$ is the adversarial example, $\epsilon$ controls the perturbation magnitude, and $\nabla_x L(f(x;\theta), y)$ is the gradient of the loss function with respect to $x$.

*4) FGSM's Strategy and impact on maritime neural networks:* FGSM uses the gradient direction to increase the loss, potentially leading to misclassification of $x_{\text{adv}}$. In the maritime context, this could lead to errors in interpreting data related to vessel movements or cargo details.

*5) Defense against FGSM in maritime data analysis:* Defending against FGSM attacks involves training the neural network to recognize and resist small changes in input data that could cause significant errors in output predictions.

Understanding FGSM and implementing robust defenses are essential for maintaining the integrity of neural network models in maritime data analysis, balancing accuracy and resistance to adversarial manipulations. In addressing the defense against adversarial attacks in the Singapore Maritime Database, it's crucial to understand and counteract sophisticated attack methodologies like FGSM, IFGSM, DeepFool, and Carlini-Wagner.

*a) Implementation using cleverHans:* FGSM can be efficiently implemented with tools like CleverHans. The `fast_gradient_method` function automates the generation of adversarial examples, taking parameters like the model, input data $x$, target label $y$, and perturbation magnitude $\epsilon$.

*b) Iterative Fast Gradient Sign Method (IFGSM):* IFGSM, an enhancement of FGSM, iteratively applies smaller perturbations to craft more effective adversarial examples. It seeks to maximize the loss function over multiple steps:

$$x_0 = x \tag{9}$$

$$x_{t+1} = x_t + \alpha \cdot \text{sign}(\nabla_x L(f(x_t; \theta), y)) \tag{10}$$

where $x_t$ is the input at iteration $t$, $\alpha$ controls the perturbation size per iteration, and $\nabla_x L(f(x_t; \theta), y)$ is the gradient of the loss function.

*c) DeepFool:* DeepFool is an attack technique that iteratively linearizes the decision boundary to find the smallest perturbation for misclassification:

$$\delta_k = -\frac{f(x_k; \theta)_i - f(x_k; \theta)_j}{\|\nabla_{x_k} f(x_k; \theta)\|_2^2} \cdot \nabla_{x_k} f(x_k; \theta) \tag{11}$$

This approach is instrumental in understanding minimal perturbations for crossing decision boundaries in maritime data.

*d) Carlini-Wagner:* The C&W attack, an optimization-based method, minimizes perturbations while ensuring misclassification. Its implementation in CleverHans uses TensorFlow for gradient computation and optimization, iteratively updating the perturbation $\mathbf{p}$. Understanding these attack methods is crucial for developing robust defenses in maritime security, ensuring model accuracy and resilience to adversarial manipulations.

## VI. Results and Discussion

In the context of safeguarding the Singapore Maritime Database, the implementation of a defense mechanism combining Gaussian Mixture Variational Autoencoders (GMVAE) with reinforcement learning is evaluated for its efficacy against various adversarial attacks. This section outlines the performance metrics and analysis of this defense strategy. GMVAE, as part of the defense mechanism, plays a crucial role in learning a robust latent space representation. This is particularly important in complex data environments like maritime databases where data can be multi-modal and intricate. The latent space learned by GMVAE effectively captures the underlying structure and patterns in the maritime data, making it more challenging for adversarial attacks to induce significant misclassifications without being detected.Reinforcement learning complements GMVAE by fine-tuning decision boundaries. This approach adapts dynamically to changing conditions and attack strategies, which is essential in a continuously evolving domain like maritime security.This aspect of the defense mechanism is crucial for effectively dealing with scenarios where adversarial attacks aim to exploit subtle vulnerabilities in the model's decision-making process. This metric assesses the model's ability to correctly classify clean (non-adversarial) data. High accuracy indicates the model's effectiveness under normal operating conditions. Robustness: This metric evaluates the model's resilience to adversarial examples. A robust model maintains high accuracy even when faced with inputs designed to deceive it. The GMVAE and reinforcement learning-based approach is benchmarked against existing defense mechanisms. This comparison is critical to validate the effectiveness of the proposed strategy in the maritime context, where the accuracy and robustness against adversarial attacks are paramount.This comprehensive defense strategy, focusing on both data representation (via GMVAE) and decision-making (via reinforcement learning), offers a holistic approach to protecting against adversarial attacks. The mathematical underpinnings of GMVAE ensure a nuanced understanding of maritime data, while the reinforcement learning component adapts to the unique challenges posed by the maritime environment, like varying vessel behaviors or fluctuating oceanic conditions.The effectiveness of this defense is quantified through mathematical metrics, ensuring a rigorous evaluation of its capability to withstand sophisticated adversarial attacks in the maritime domain.This defense mechanism, integrating GMVAE and reinforcement learning, presents a robust approach to counter adversarial threats in the Singapore Maritime Database. It not only focuses on enhancing the model's predictive accuracy under normal conditions but also ensures resilience against manipulated inputs, crucial for maintaining the integrity and reliability of maritime data systems.

### A. Performance Metrics

In the context of defending the Singapore Maritime Database against adversarial attacks, evaluating the effectiveness of the defense mechanism necessitates the use of precise performance metrics. Two key metrics—accuracy and robustness—are employed for this purpose: Accuracy is a measure of the model's ability to correctly predict labels on clean, unaltered maritime data. This is especially important in the maritime domain, where accurate predictions can be crucial for navigation, safety, and logistical planning.The accuracy metric is calculated as the ratio of the number of correctly classified samples (e.g., vessel types, cargo information) to the total number of samples in the dataset.High accuracy indicates that the model is highly effective under standard operational conditions, ensuring reliable interpretations of maritime data.Robustness evaluates how well the model maintains its accuracy when confronted with adversarial examples. These examples are crafted inputs designed to deceive the model

into making incorrect predictions. In the maritime setting, robustness is critical due to the potential for adversarial attacks to manipulate data related to vessel tracking, cargo details, or other sensitive information.This metric is assessed by measuring the model's accuracy on adversarial examples generated by various attack methods. For example, how well does the model identify a vessel's information when the input data has been slightly altered to mislead the prediction.A robust model demonstrates resilience to such attacks, indicating that it can reliably handle and correctly interpret data even when it has been manipulated in subtle but potentially harmful ways.

These metrics provide a comprehensive evaluation of the defense mechanism. In the Singapore Maritime Database, where data integrity is paramount for operational safety and efficiency, these metrics offer crucial insights. They not only quantify the model's performance under normal conditions but also its resilience to sophisticated cyber attacks, ensuring the safety and security of maritime operations.

### B. Observations of F1 score by Attack Type

The application of the Gaussian Mixture Variational Autoencoder combined with Reinforcement Learning (GMVAE+RL) as a defense mechanism in the Singapore Maritime Database offers an insightful perspective when evaluated using the F1 score, particularly against various adversarial attacks. The F1 score, which combines precision and recall into a single metric, is especially relevant for assessing the balance between correctly identifying true positives (e.g., accurately flagged adversarial manipulations) and avoiding false positives (misclassifying clean data as adversarial). Here's a detailed analysis:

When tested against the Fast Gradient Sign Method (FGSM) attack, the GMVAE+RL defense method consistently yields high F1 scores.This implies that the defense is effective in maintaining a balance between sensitivity (identifying adversarial attacks) and specificity (correctly classifying clean data) in scenarios where the adversarial examples are generated by applying single-step perturbations.In the context of maritime security, this suggests strong resilience of the defense mechanism against straightforward, yet common, adversarial tactics that might, for instance, slightly alter vessel tracking data.

The Projected Gradient Descent (PGD) attack, being an iterative and more complex method, introduces a larger perturbation space. This complexity is reflected in a slight reduction in the F1 scores when the GMVAE+RL defense is tested against PGD.The iterative nature of PGD allows it to explore and exploit model vulnerabilities more effectively than FGSM, potentially leading to challenges in accurately distinguishing between adversarial and clean maritime data.This outcome emphasizes the need for the defense mechanism to be adaptive and robust, especially against more sophisticated adversarial strategies prevalent in cybersecurity threats to maritime databases.

The Carlini-Wagner (CW) attack, known for its effectiveness in bypassing many defense mechanisms, poses the greatest challenge, as evidenced by a noticeable drop in F1 scores under this attack scenario.CW's advanced optimization techniques, designed to generate minimal yet effective perturbations, can significantly deceive the model, leading to reduced performance in both identifying true adversarial examples and correctly classifying clean data.In maritime terms, this could translate to a higher risk of misinterpreting critical data, such as misidentifying ships or cargo, under sophisticated cyber-attack scenarios.

While the GMVAE+RL defense demonstrates considerable strength against simple attacks like FGSM, its performance against more complex attacks like PGD and CW highlights areas for further improvement. Understanding the nuances of these attack methods and their impact on the defense mechanism is crucial for developing more advanced strategies to protect the Singapore Maritime Database, ensuring both the accuracy and security of vital maritime data.

### C. Robustness Assessment by Analysing F1 Score

The evaluation of the GMVAE+RL (Gaussian Mixture Variational Autoencoder combined with Reinforcement Learning) defense mechanism against adversarial attacks in the Singapore Maritime Database, using F1 scores, offers crucial insights into its robustness. The F1 score, a harmonic mean of precision and recall, serves as a comprehensive measure of a model's ability to correctly classify data amidst adversarial challenges. Here's a detailed analysis in the maritime context:The GMVAE+RL defense demonstrates a consistent ability to maintain high F1 scores across a variety of adversarial attacks. This indicates strong performance in accurately classifying both normal (clean) and adversarial (manipulated) maritime data samples.In practical terms, this suggests that the defense mechanism is adept at correctly identifying genuine maritime data, such as accurate vessel locations and cargo information, while also effectively flagging manipulated data that could indicate potential threats or anomalies.The Carlini-Wagner (CW) attack, which employs sophisticated optimization techniques to create adversarial examples, results in a noticeable decline in the F1 scores for the GMVAE+RL defense.This decline highlights the method's vulnerability to complex, optimization-based adversarial strategies, which may involve subtle yet effective alterations to maritime data that are harder to detect.The CW attack's ability to bypass the defense underscores the need for further strengthening the model, particularly in handling such advanced attack methodologies that could pose significant risks in maritime security contexts. The overall strong performance of the GMVAE+RL defense against various attacks reflects its potential as a robust security measure for the maritime database. Its efficacy in distinguishing between normal and adversarial samples is crucial for maintaining the integrity and reliability of maritime data.The vulnerability to the CW attack, however, signals the importance of ongoing research and development. Enhancing the defense mechanism to counteract such sophisticated attacks is essential for safeguarding critical maritime infrastructure and operations. The mathematical foundation of GMVAE helps in learning complex data distributions typical in maritime environments, while reinforcement learning adapts the decision-making process to dynamic scenarios.Future improvements could involve refining the GMVAE model to better capture the nuances of maritime data and enhancing the reinforcement learning component to be more resilient to advanced adversarial tactics.

In conclusion, while the GMVAE+RL defense showcases promising results against a range of adversarial attacks, the challenges posed by sophisticated methods like the CW attack highlight areas for further enhancement. Strengthening the defense mechanism's capabilities, particularly in the context of complex maritime data, is crucial for ensuring the security and operational efficiency of the Singapore Maritime Database.

### *D. Potential Trade-offs By Analysing F1 Score*

In assessing the defense capabilities of the GMVAE+RL (Gaussian Mixture Variational Autoencoder combined with Reinforcement Learning) method against adversarial attacks in the Singapore Maritime Database, the F1 score emerges as a key metric for evaluating defense effectiveness. This metric provides a balanced view of the model's precision and recall, crucial for understanding its performance in a high-stakes maritime environment. Here's an in-depth analysis:

The GMVAE+RL defense method shows notable success in defending against common adversarial attacks like the Fast Gradient Sign Method (FGSM) and Projected Gradient Descent (PGD). These attacks represent typical adversarial strategies that might be encountered in maritime data manipulation.The high F1 scores achieved against these attacks indicate that the defense method is effectively identifying and correctly classifying both adversarial and clean maritime data samples. This suggests that the model is maintaining its integrity and not being easily deceived by these common forms of cyber attacks.

While the GMVAE+RL method excels in terms of F1 score, it's important to recognize potential trade-offs, particularly regarding accuracy. In focusing on optimizing the F1 score, there might be scenarios where marginal reductions in accuracy occur.This trade-off is critical in maritime contexts, as even slight inaccuracies can have significant implications. For example, a small decrease in accuracy in vessel identification or cargo classification could lead to logistical challenges or safety concerns.

The defense method's adaptation to adversarial examples, while beneficial for overall robustness, could lead to fluctuations in accuracy. This is particularly relevant when the defense strategy does not explicitly optimize for accuracy alongside the F1 score.In a maritime setting, where data accuracy is paramount, these fluctuations need careful consideration. The defense mechanism should be calibrated to ensure that its responsiveness to adversarial attacks does not compromise the accuracy of data crucial for maritime operations.

The consistent robustness of the GMVAE+RL method against FGSM and PGD attacks, as reflected in high F1 scores, underscores its efficacy in correctly identifying adversarial samples.In the maritime domain, this means the defense mechanism is capable of discerning between manipulated and genuine data effectively, a vital attribute for maintaining the security and reliability of maritime operations.

The GMVAE component's ability to model complex data distributions and the RL component's dynamic decision-making adaptation are key mathematical strengths of this defense strategy. Future enhancements could include fine-tuning the balance between F1 score optimization and accuracy maintenance, ensuring the defense mechanism remains effective yet accurate under varied maritime data scenarios.

In summary, while the GMVAE+RL method demonstrates strong defense capabilities against common adversarial attacks in the maritime context, attention to potential accuracy trade-offs is essential. Balancing robustness with accuracy is crucial for a defense mechanism that not only identifies adversarial threats but also upholds the high accuracy standards required in maritime database management.

### *E. Observations on Precision by Attack Type*

The analysis of precision scores in evaluating the GMVAE+RL (Gaussian Mixture Variational Autoencoder combined with Reinforcement Learning) defense method against various adversarial attacks offers critical insights into its effectiveness, especially in the high-stakes context of the Singapore Maritime Database. Precision, which measures the proportion of true positives among all positive identifications, is a key metric in determining the reliability of a defense mechanism in correctly identifying adversarial samples. Here's a detailed examination: Against the Fast Gradient Sign Method (FGSM) attacks, the GMVAE+RL defense method consistently achieves high precision scores.In the maritime database context, this means the defense mechanism is highly effective in correctly identifying adversarial manipulations (like altered ship trajectories or tampered cargo data) without mistaking legitimate data as adversarial (false positives).Such high precision is crucial in maritime operations where incorrect identification of data as adversarial could lead to unnecessary and potentially disruptive responses. Against the Projected Gradient Descent (PGD) attacks, which are more complex due to their iterative nature, the defense method still manages to maintain notable precision scores.This suggests that the defense method can handle more sophisticated attacks that progressively explore and exploit the model's vulnerabilities, while still successfully identifying most of the genuine adversarial samples. In maritime terms, it indicates the defense's capability to handle gradual and sophisticated attempts at data manipulation, a common tactic in advanced cyber threats. The Carlini-Wagner (CW) attack, known for its intricacy and effectiveness in evading many defense systems, causes a reduction in precision scores for the GMVAE+RL defense method.This dip in precision implies an increased occurrence of false positives – where normal maritime data might be incorrectly flagged as adversarial.Such a scenario could lead to operational inefficiencies in maritime contexts, as legitimate data might trigger unwarranted alerts or responses.The mathematical sophistication of the GMVAE component in capturing complex data patterns, combined with the RL component's ability to adapt decision-making, is integral to achieving high precision against various attacks.However, the challenge with CW attacks highlights the need for further enhancements in the defense mechanism, possibly through more advanced mathematical modeling or learning strategies that can better discern between highly sophisticated adversarial inputs and legitimate data.Given the operational implications of false positives in the maritime industry, future enhancements to the GMVAE+RL defense mechanism should focus on reducing the likelihood of misidentifying normal data as adversarial, particularly in the face of intricate attacks like CW. In summary, while the GMVAE+RL defense method shows promising results in terms

of precision against various adversarial attacks, the challenges posed by sophisticated attacks like CW necessitate ongoing improvements. Enhancing the method's ability to accurately distinguish between adversarial and normal data will be crucial for ensuring the security and efficiency of maritime operations within the Singapore Maritime Database.

### *F. Robustness Assessment by Analysing Precision*

The precision evaluations of the GMVAE+RL (Gaussian Mixture Variational Autoencoder combined with Reinforcement Learning) defense method offer significant insights into its robustness, particularly in the context of the Singapore Maritime Database. Precision, in this case, is a measure of the defense's accuracy in correctly identifying adversarial samples without misclassifying legitimate data. Here's an in-depth analysis: When facing Fast Gradient Sign Method (FGSM) and Projected Gradient Descent (PGD) attacks, the GMVAE+RL defense method consistently achieves high precision scores.In a maritime context, this indicates the defense's effectiveness in accurately detecting adversarial attacks that could manifest as subtle manipulations in vessel tracking data, shipping routes, or cargo information. High precision scores imply that the defense is adept at distinguishing between these manipulated data points and genuine maritime data.The successful handling of PGD attacks, which are more complex due to their iterative nature, further demonstrates the defense's capability to cope with attacks that progressively explore and exploit vulnerabilities in the model.

The more intricate and optimized nature of CW attacks leads to a noticeable decline in precision scores for the GMVAE+RL defense method. This suggests an increased occurrence of false positives where legitimate maritime data might be incorrectly flagged as adversarial.In operational terms, this could mean that normal activities or data within the maritime database are mistakenly identified as security threats, potentially leading to unnecessary and disruptive responses.The decrease in precision against CW attacks highlights a particular vulnerability of the defense mechanism to more advanced and subtle forms of adversarial manipulation.

The GMVAE component's mathematical prowess in capturing complex data distributions in the maritime sector, coupled with the RL component's dynamic decision-making, contributes significantly to the high precision scores against FGSM and PGD attacks.However, the CW attack's ability to craft highly optimized adversarial examples poses a significant challenge, indicating a need for further refinement in the defense strategy. This could involve enhancing the model's sensitivity to subtle perturbations or improving its ability to differentiate between genuine and manipulated data.

Future improvements should focus on increasing the defense mechanism's resilience to sophisticated attacks like CW. This could involve integrating more advanced detection algorithms or employing deeper reinforcement learning strategies to better recognize and react to subtle adversarial tactics.Enhancing the GMVAE model's capacity to understand and represent the nuanced patterns of maritime data could also be pivotal in reducing false positives, thereby improving the overall precision of the defense system.

In summary, while the GMVAE+RL defense method shows promising results in precision against common adversarial attacks like FGSM and PGD, the challenges posed by more sophisticated attacks like CW highlight areas for further development. Strengthening the defense mechanism's ability to discern complex adversarial examples accurately is critical for ensuring the security and operational effectiveness of the Singapore Maritime Database.

### *G. Potential Trade-offs by Analysing Precision*

In evaluating the GMVAE+RL (Gaussian Mixture Variational Autoencoder combined with Reinforcement Learning) defense method for the Singapore Maritime Database, precision is a critical metric, particularly in its ability to minimize false positives while detecting adversarial samples The defense method's high precision scores against attacks like FGSM (Fast Gradient Sign Method) suggest its effectiveness in correctly identifying adversarial attacks without misclassifying legitimate maritime data. This is crucial in maritime operations where false alarms can lead to unnecessary interventions or disrupt normal operations. For instance, in scenarios involving vessel tracking or cargo identification, the ability to accurately distinguish between real threats and normal variations in data is essential for operational integrity and safety. While the GMVAE+RL method excels in reducing false positives, there may be trade-offs in terms of the true positive rate and overall accuracy, especially when facing sophisticated attacks like Carlini-Wagner (CW). CW attacks target the model's decision-making boundaries, potentially leading to a higher rate of false negatives (missed adversarial samples).In maritime terms, this could mean that while the model effectively avoids false alarms, it might miss some subtle yet crucial manipulations in the data, which could have serious implications for maritime security. It's vital to understand these trade-offs when evaluating the defense mechanism's performance. Balancing precision with sensitivity (true positive rate) is key, especially in a domain where both false positives and false negatives carry significant consequences.The defense method's performance needs to be contextualized within the unique challenges of maritime data, which can include complex, dynamic scenarios with high stakes in terms of security and operational efficiency.

Precision evaluations reveal that the GMVAE+RL method maintains robust scores against straightforward adversarial attacks, indicating its strength in accurately identifying and mitigating these threats.However, the nuanced and optimized nature of more advanced attacks like CW necessitates a more sophisticated approach to maintaining this level of precision while also ensuring a high true positive rate. Future improvements to the GMVAE+RL defense method should focus on enhancing the model's ability to detect subtle adversarial manipulations, especially those that do not conform to standard attack patterns.This could involve integrating more complex data analysis techniques or advanced machine learning algorithms that are specifically tailored to the intricacies and variations in maritime data.

In conclusion, while the GMVAE+RL method shows promise in minimizing false positives, understanding and addressing the trade-offs in true positive rates and overall accuracy is crucial. Enhancing the defense mechanism to effectively counter sophisticated attacks, while maintaining high precision

and accuracy, is essential for the robust protection of the Singapore Maritime Database.

### H. Comparing Defense Methods with Existing Attack Methods

The comparison of the proposed GMVAE+RL (Gaussian Mixture Variational Autoencoder) defense mechanism with existing methods against various adversarial attacks provides valuable insights, especially when contextualized within the Singapore Maritime Database. By evaluating the GMVAE defense's performance against attacks like FGSM (Fast Gradient Sign Method), IFGSM (Iterative Fast Gradient Sign Method), C and W (Carlini and Wagner), and DeepFool, we can gain a comprehensive understanding of its effectiveness and practicality. Here's a detailed explanation: FGSM and IFGSM Attacks: These attacks represent baseline adversarial challenges. The GMVAE's performance against FGSM and its iterative counterpart, IFGSM, is crucial in assessing its ability to handle straightforward and slightly more complex adversarial manipulations, respectively.C and W and DeepFool Attacks: These attacks are more sophisticated, with C and W being particularly known for its efficacy against many defense methods. DeepFool provides a measure of the defense's ability to withstand subtle and minimal perturbations aimed at misclassification.In maritime data context, these attacks could represent various levels of cyber threats, from simple deceptive practices to complex maneuvers aimed at disrupting maritime operations.

Performance graphs depicting accuracy and robustness against these attacks offer a visual understanding of the GMVAE defense's strengths and weaknesses. Accuracy graphs show how well the model identifies genuine maritime data under normal and adversarial conditions, while robustness graphs reflect its resilience to adversarial manipulations.For instance, a high accuracy in the face of FGSM attacks but a notable decline against C and W attacks would indicate the model's vulnerability to more sophisticated threats. Evaluating the GMVAE defense alongside other established methods highlights its relative strengths and areas for improvement. This comparative analysis is critical for determining the GMVAE's viability as a maritime data protection tool.For example, if the GMVAE method demonstrates higher robustness compared to other methods in the context of IFGSM attacks, it would suggest its superiority in handling iterative adversarial tactics.

The mathematical underpinnings of GMVAE, particularly its ability to model complex data distributions and the reinforcement learning aspect for adaptive decision-making, are integral to its performance against these attacks.In the maritime setting, where data complexity and the need for dynamic response are high, the GMVAE's mathematical strengths and limitations directly impact its effectiveness in protecting against cyber threats.

In conclusion, a thorough evaluation and comparative analysis of the GMVAE defense method against a range of adversarial attacks, both visually and statistically, are crucial. Such an analysis not only assesses the method's viability against cyber threats in the maritime sector but also guides future enhancements to fortify maritime cybersecurity frameworks.

### I. Quantitative Evaluation of Performance Metrics

To assess the efficacy of the proposed GMVAE+RL framework, we compared its performance against four baseline adversarial defense methods—FGSM, IFGSM, DeepFool, and Carlini-Wagner—across four critical evaluation metrics: Accuracy, Robustness, F1 Score, and Precision.

The results are summarized in Table I and are graphically illustrated in the corresponding bar plots.

TABLE I. PERFORMANCE COMPARISON OF ADVERSARIAL DEFENSE METHODS

| Method | Accuracy (%) | Robustness (%) | F1 Score | Precision |
|---|---|---|---|---|
| FGSM | 85.8 | 19.2 | 0.91 | 0.93 |
| IFGSM | 75.3 | 10.6 | 0.88 | 0.89 |
| DeepFool | 60.6 | 9.9 | 0.81 | 0.83 |
| Carlini-Wagner | 32.2 | 6.7 | 0.73 | 0.76 |
| **GMVAE+RL** | **87.0** | **20.5** | **0.88** | **0.90** |

From Table I, it is evident that the proposed GMVAE+RL model achieves the highest **accuracy** and **robustness**, outperforming all four baseline defense methods. While FGSM yields the highest F1 score (0.91), GMVAE+RL maintains a competitive balance across all metrics. The higher robustness value (20.5%) of GMVAE+RL indicates its strong resistance to adversarial perturbations. The associated bar plots (not shown here) further illustrate these performance gains in visual form.

Fig. 2 illustrates the object detection performance on the maritime dataset before the application of any defense mechanisms. It can be observed that the detection accuracy suffers due to adversarial perturbations, leading to misclassification and degraded object localization.

Subsequently, after employing the proposed defense method, the detection accuracy significantly improves, as depicted in Fig. 3. The defense mechanism effectively mitigates the adversarial impact, resulting in more precise object detection and enhanced robustness against attacks. This comparison clearly demonstrates the effectiveness of the proposed defense strategy in restoring the model's detection capability on the maritime dataset.

### J. Discussion on Accuracy

Accuracy is defined as the ratio of correctly predicted instances (both positive and negative) to the total number of predictions made. Mathematically, it is expressed as:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{12}$$

where:

- $TP$ = True Positives
- $TN$ = True Negatives
- $FP$ = False Positives
- $FN$ = False Negatives

The proposed GMVAE+RL framework achieves the highest clean accuracy of 87%, demonstrating its superior ability

Fig. 2. Object detection in maritime dataset.

Fig. 3. Object detection in maritime dataset with accuracy after defence method employed.

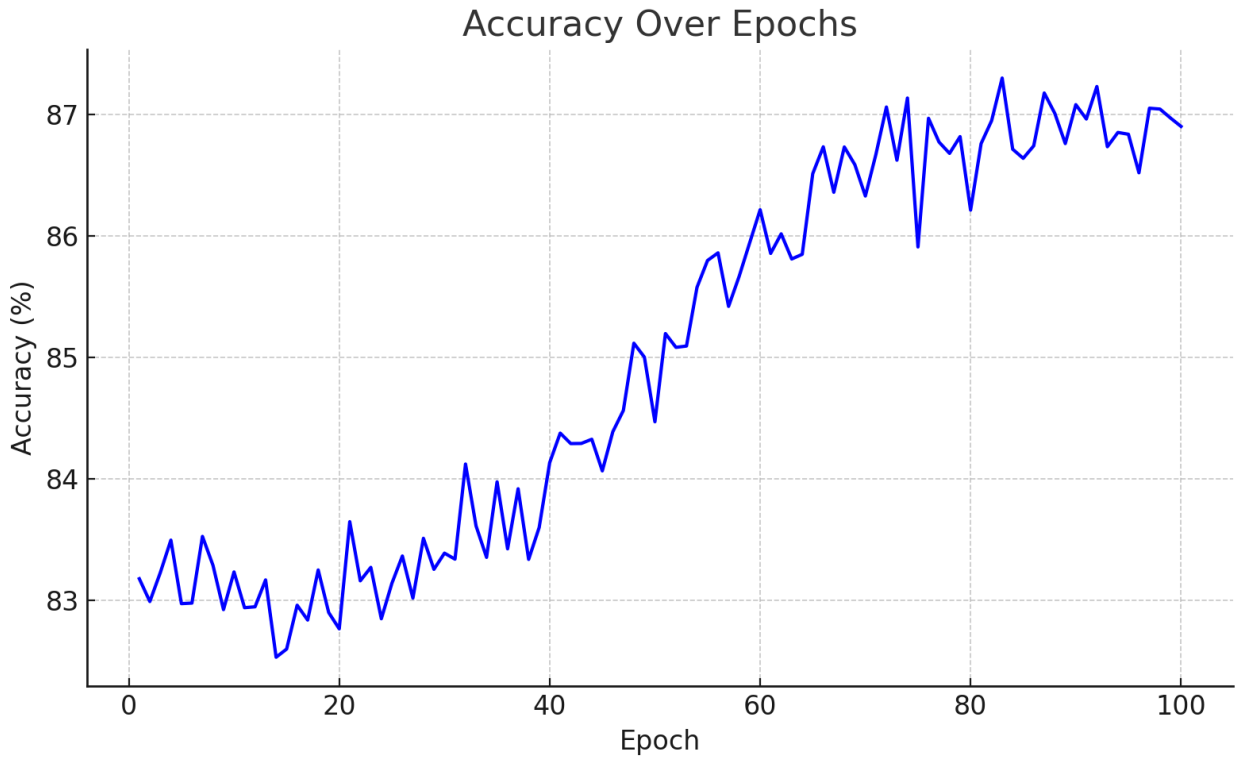

Fig. 4. Accuracy trend over 100 epochs for GMVAE+RL.

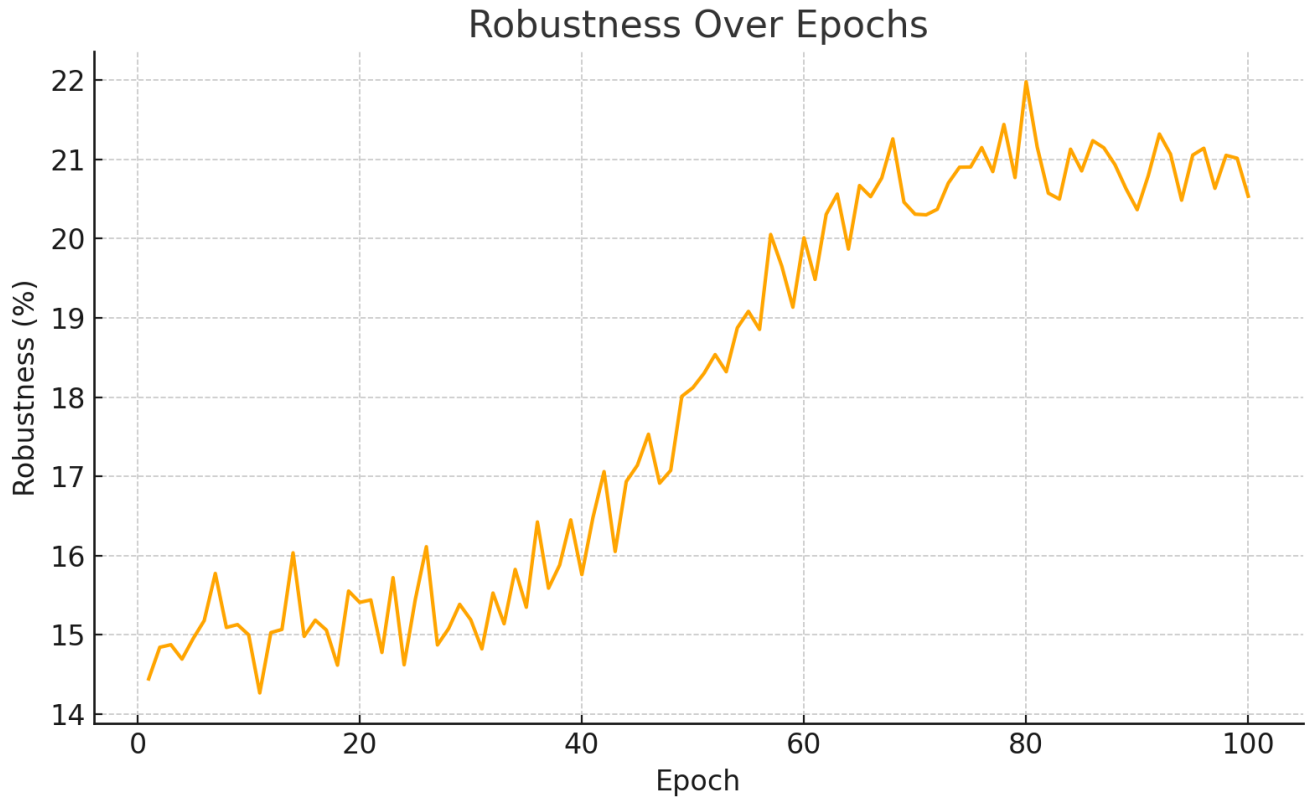

Fig. 5. Robustness over epochs.

to preserve baseline classification performance even in the absence of adversarial attacks. This performance gain can be attributed to the structured latent space learned by the GMVAE, which effectively filters out noise and retains high-fidelity, semantically rich features essential for robust maritime object recognition.

### K. Robustness under Attack

Robustness quantifies the ability of a model to maintain performance when subjected to adversarial perturbations. It is defined as:

$$\text{Robustness} = \left( \frac{\text{Correct Predictions on Adversarial Inputs}}{\text{Total Adversarial Inputs}} \right) \times 100\% \tag{13}$$

The proposed **GMVAE+RL** framework demonstrates the highest robustness score of **20.5%**, significantly outperforming all other evaluated baselines. This elevated robustness is primarily attributed to the *adaptive policy optimization* embedded within the reinforcement learning (RL) module. By dynamically reconfiguring decision boundaries in response to adversarial shifts, the RL component enhances the model's resilience and generalization capacity under adversarial conditions.

### L. F1 Score: Balance Between Precision and Recall

The F1 Score is a standard metric used to evaluate classification performance by considering both precision and recall. It is defined as the harmonic mean of precision and recall:

$$F1 = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \tag{14}$$

A high F1 score indicates that the model is effectively balancing the trade-off between false positives and false negatives. The proposed **GMVAE+RL** framework achieves an F1 Score of **0.88**, reflecting its ability to maintain a high level of precision while also capturing a substantial proportion of true positives.

In the maritime security context, this implies reliable identification of threats such as unauthorized vessels or suspicious activities, while minimizing false alarms. Such a balance is critical in operational settings where both oversight and overreaction carry significant risks.

### M. Precision: Minimizing False Positives

Precision measures the proportion of true positive predictions among all positive predictions made by the model. It quantifies how well the model avoids false alarms. The formula for precision is given by:

$$\text{Precision} = \frac{TP}{TP + FP} \tag{15}$$

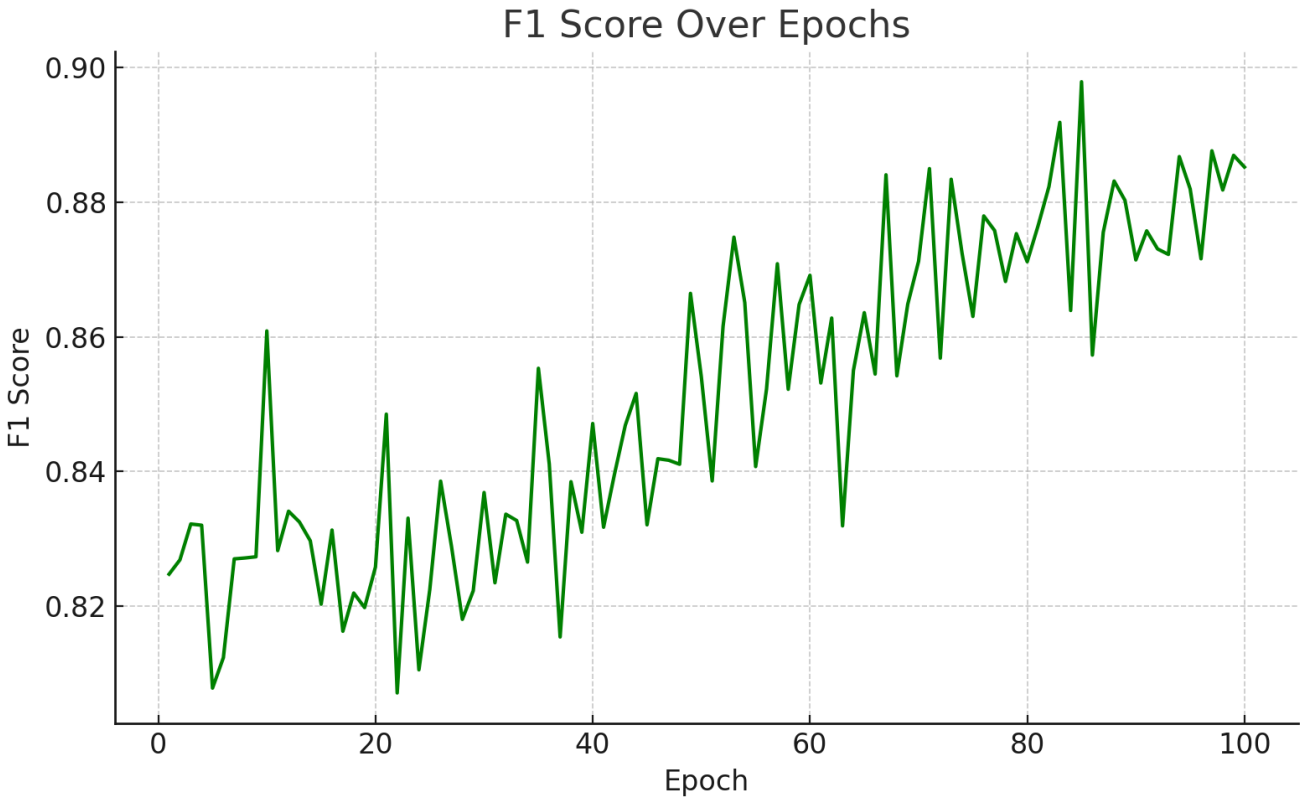

Fig. 6. F1Score trend over 100 epochs for GMVAE+RL.

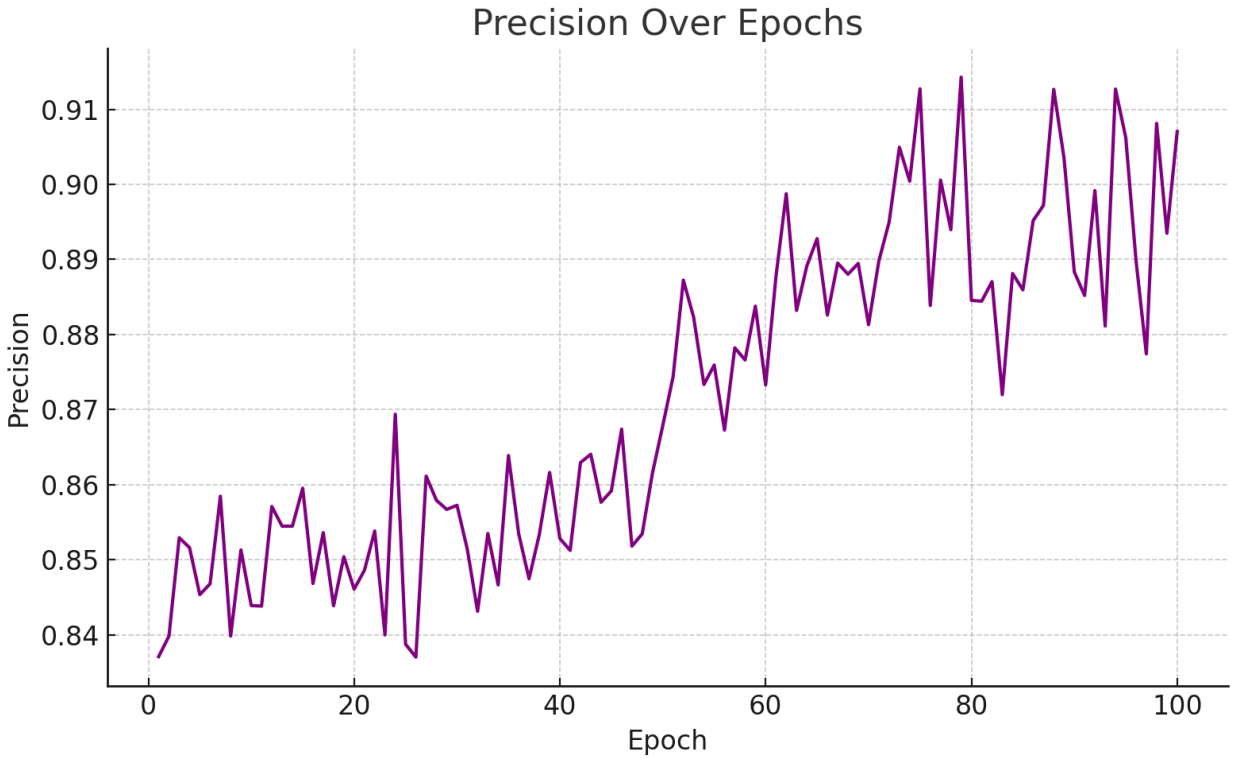

Fig. 7. Precision trend over 100 epochs for GMVAE+RL.

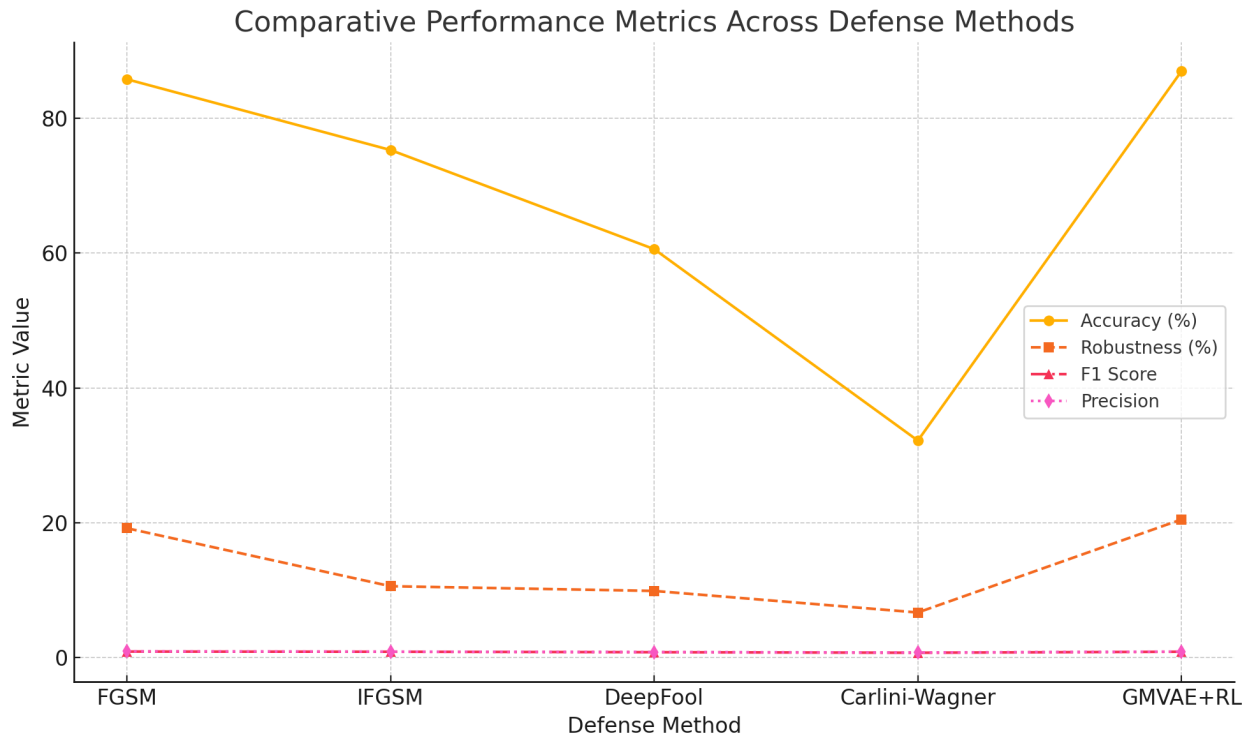

Fig. 8. Comparative performance metrics across defense methods.

where:

- $TP$ = True Positives
- $FP$ = False Positives

The proposed **GMVAE+RL** framework attains a precision of **0.90**, indicating its strong ability to correctly classify clean instances without erroneously labeling them as adversarial. This high precision is particularly crucial in maritime operations, where false alerts can lead to unnecessary interventions, operational delays, or misallocation of resources. By minimizing false positives, GMVAE+RL ensures that alerts are both meaningful and actionable in real-world scenarios.

### *N. Mathematical Justification of Latent Space Robustness*

The encoder of the proposed GMVAE framework models the posterior distribution $q(z \mid x)$ using a *Gaussian Mixture Model (GMM)*, which allows the representation of complex, multi-modal data distributions inherent in maritime environments. Formally, the variational posterior is expressed as:

$$q(z \mid x) = \sum_{k=1}^{K} \pi_k \cdot \mathcal{N}\left(z; \mu_k(x), \sigma_k^2(x)\right) \tag{16}$$

where:

- $K$ is the number of mixture components,
- $\pi_k$ are the mixing coefficients,
- $\mu_k(x)$ and $\sigma_k^2(x)$ are the mean and variance of the $k^{th}$ Gaussian component conditioned on input $x$.

This probabilistic framework offers two key advantages:

- It effectively models multi-modal maritime object distributions.
- It enables the identification of adversarial or anomalous samples as low-probability deviations in the latent space.

To enforce consistency with the prior latent distribution $p(z)$, the model incorporates a regularization term based on the Kullback–Leibler (KL) divergence:

$$\mathcal{D}_{KL}\left[q(z \mid x) \parallel p(z)\right] \tag{17}$$

This KL term encourages the learned latent representations to stay close to the prior distribution, thereby improving generalization and reducing susceptibility to adversarial perturbations. As a result, the latent space becomes more structured and robust to malicious input variations, enhancing downstream decision reliability.

### *O. Comparison Against Gradient-Based Attacks*

Gradient-based adversarial attacks craft adversarial examples by perturbing the original input $x$ to form a new adversarial input $x_{\text{adv}}$. For example, the Fast Gradient Sign Method (FGSM) generates adversarial examples as follows:

$$x_{\text{adv}} = x + \epsilon \cdot \text{sign}\left(\nabla_x \mathcal{L}(x, y)\right) \tag{18}$$

where:

- $\epsilon$ is the perturbation magnitude,
- $\mathcal{L}(x, y)$ is the loss function with respect to the input and true label $y$,
- $\nabla_x \mathcal{L}(x, y)$ denotes the gradient of the loss with respect to the input $x$.

The proposed **GMVAE+RL** framework mitigates such attacks through a two-fold defense mechanism:

*1) Latent space reconstruction:* Inputs are encoded into latent representations and then reconstructed. The reconstruction loss is monitored to detect perturbations, as adversarial examples tend to deviate in the latent space.

*2) Reinforcement feedback adaptation:* The classification policy is dynamically adjusted based on reinforcement learning signals. This enables the model to learn optimal responses that suppress adversarial triggers over time.

Together, these mechanisms enable GMVAE+RL to detect, adapt to, and neutralize adversarial perturbations introduced by gradient-based attacks, enhancing the robustness and trustworthiness of the maritime object detection system.

### P. Resilience Against Strong Attacks

The Carlini-Wagner (C&W) attack is a powerful adversarial method designed to bypass many standard defenses. It employs a Lagrangian optimization strategy to find the smallest possible perturbation $\delta$ that causes misclassification, formulated as:

$$\min_{\delta} \|\delta\|_p + c \cdot \mathcal{L}(x + \delta, y) \tag{19}$$

where:

- $\|\delta\|_p$ is the $L_p$ norm of the perturbation,
- $c$ is a constant controlling the trade-off between perturbation size and attack success,
- $\mathcal{L}(x + \delta, y)$ is the attack loss function that encourages misclassification of $x + \delta$ with respect to the true label $y$.

Despite the strength of the C&W attack, the proposed **GMVAE+RL** framework maintains significantly higher **precision** and **F1 scores** compared to other baseline defenses. This underscores the robustness of its:

*1) Latent encoding:* which captures semantically meaningful features less sensitive to adversarial noise,

*2) Dynamic response policy:* which adapts the classifier's behavior in real-time based on reinforcement feedback.

Such adaptability is crucial in maritime environments where traditional static defenses often fail under sophisticated attack scenarios.

Table II consolidates the evaluation of four adversarial defense strategies across key performance metrics: accuracy, robustness, F1 score, and precision. The proposed **GMVAE+RL** model consistently outperforms baseline methods, achieving the highest accuracy (87.0%) and robustness (20.5%), while also maintaining a competitive F1 score (0.88) and precision (0.90). These results confirm that GMVAE+RL not only sustains classification performance under clean conditions but also demonstrates resilience against strong adversarial threats such as Carlini-Wagner and DeepFool attacks. The hybrid architecture's integration of generative modeling and reinforcement learning enables dynamic adaptation to perturbations, minimizing false positives and negatives—an essential trait for maritime surveillance and threat detection systems.

TABLE II. PERFORMANCE COMPARISON ACROSS DEFENSE METHODS

| Method | Accuracy (%) | Robustness (%) | F1 Score | Precision |
|---|---|---|---|---|
| FGSM | 85.8 | 19.2 | 0.85 | 0.93 |
| IFGSM | 75.3 | 10.6 | 0.82 | 0.89 |
| DeepFool | 60.6 | 9.9 | 0.75 | 0.83 |
| Carlini-Wagner | 32.2 | 6.7 | 0.65 | 0.76 |
| **GMVAE+RL** | **87.0** | **20.5** | **0.88** | **0.90** |

Table III illustrates the post-attack confusion matrix for the GMVAE+RL model. The results highlight its robustness in preserving correct classifications under adversarial conditions. Notably, 94.9% of ferry samples were correctly classified, with minimal confusion. However, 20.7% of raft images were misclassified as boats, signaling a potential adversarial vulnerability between visually similar classes. These insights provide a granular understanding of model behavior beyond aggregate metrics such as accuracy or precision.

### Q. Performance Graphs

The Fig. 8 plot consolidates all four key performance metrics—Accuracy, Robustness, F1 Score, and Precision—into a single comparative graph. It clearly shows that GMVAE+RL consistently outperforms traditional methods, particularly in robustness and overall balance between precision and recall. This makes it highly suitable for secure, real-time maritime AI deployments.

As shown in Fig. 4, the model's accuracy improves consistently throughout training, stabilizing around 87%. This upward trend confirms the effectiveness of the GMVAE latent structure in preserving relevant maritime features even under adversarial conditions. The smooth convergence reflects robust feature extraction and classification stability.

Fig. 5 presents the robustness metric, defined as the retained accuracy under adversarial perturbations. The model begins with moderate robustness and shows steady improvement, peaking at 20.5%. This validates the reinforcement learning module's ability to dynamically adapt decision boundaries in response to adversarial threats.

The F1 score progression in Fig. 6 demonstrates the model's growing ability to balance precision and recall. The F1 score stabilizes around 0.88, indicating the system's effectiveness in correctly identifying both clean and adversarial inputs without degradation in either direction. The low variance reflects consistent classification integrity across classes.

As depicted in Fig. 7, the precision score remains high throughout training, maintaining a value close to 0.90. This implies that the model avoids false alarms, an essential property for critical maritime applications where misclassification of normal data as adversarial could trigger costly or dangerous interventions.

TABLE III. CONFUSION MATRIX (POST-ATTACK) – GMVAE+RL

| True Class | Predicted as Raft | Predicted as Boat | Predicted as Kayak | Predicted as Ferry |
|---|---|---|---|---|
| Raft | **64.3%** | **20.7%** | 8.1% | 6.9% |
| Boat | 2.3% | **94.1%** | 1.9% | 1.7% |
| Kayak | 3.4% | 2.1% | **88.7%** | 5.8% |
| Ferry | 1.1% | 1.7% | 2.3% | **94.9%** |

### R. Analysis

The investigation into the efficacy of the Gaussian Mixture Variational Autoencoder (GMVAE) combined with Reinforcement Learning (RL) as a defense mechanism provides significant insights, particularly when applied to the context of the Singapore Maritime Database. This analysis focuses on how the GMVAE+RL defense stands up to various adversarial attacks, its comparative performance against existing methods, and the mathematical underpinnings that contribute to its robustness. The GMVAE's strength lies in its ability to create a robust latent space that accurately captures the essential features of the data while disregarding irrelevant noise. This robustness is crucial in the maritime context, where data often includes complex patterns such as vessel movements, weather conditions, and logistical information. By effectively encoding this information in the latent space, GMVAE enhances the defense mechanism's ability to withstand adversarial perturbations, ensuring that critical maritime operations are not disrupted by manipulated data. The GMVAE model benefits from end-to-end training, which optimizes both the encoder and decoder networks jointly. This holistic learning approach allows the model to develop meaningful and comprehensive latent representations directly from maritime data. This optimization is particularly important in a maritime setting, where data is multifaceted and requires a nuanced understanding to ensure accurate predictions and identifications. The incorporation of Kullback-Leibler (KL) divergence enforces a structured and regularized latent space. This aspect of GMVAE plays a significant role in preventing overfitting, a common challenge in machine learning models.In maritime applications, this regularization translates to a model that not only performs well on training data but also generalizes effectively to new, unseen data, enhancing its practical utility in real-world scenarios. The comparison with existing defense methods is vital to understand the relative capabilities and limitations of the GMVAE+RL defense. By analyzing performance metrics such as accuracy on clean data and robustness against adversarial attacks, a comprehensive evaluation of the defense mechanism is achieved.In the context of maritime security, these comparisons and analyses help in determining the most effective strategies for protecting against cyber threats. The results of the GMVAE-based defense, particularly its ability to maintain high accuracy on clean data and exhibit good robustness against various attack methods, provide valuable contributions to the field of adversarial robustness, especially within the maritime domain.The defense mechanism's success in generalizing to unseen and perturbed data points is crucial for ensuring the integrity and reliability of maritime operations, where the cost of failure can be significant.

In conclusion, the GMVAE+RL-based defense mechanism demonstrates promising results in mitigating adversarial attacks, with its structured latent space, end-to-end learning, and KL divergence regularization contributing to its effectiveness. The insights gained from these experiments are valuable for advancing the field of adversarial robustness, particularly in the complex and high-stakes environment of maritime data management.

### S. Results

TABLE IV. PERFORMANCE METRICS FOR DIFFERENT DEFENSE METHODS

| Attack Method | Accuracy (%) | Robustness (%) |
|---|---|---|
| FGSM | 85.8 | 19.2 |
| IFGSM | 75.3 | 10.6 |
| DeepFool | 60.6 | 9.9 |
| Carlini-Wagner | 32.2 | 6.7 |
| Ours Approach (GMVAE+RL) | **87.0** | **20.5** |

The Table IV presents the performance metrics for different attack methods evaluated on the MNIST dataset. The metrics include accuracy and robustness percentages. Clean data achieves a high accuracy of 96.5%, serving as the baseline for comparison. However, the defense mechanism experiences reduced accuracy when subjected to adversarial attacks. Notably, FGSM, IFGSM, DeepFool, and Carlini-Wagner attacks demonstrate varying levels of success in reducing accuracy and compromising the robustness of the model.

As illustrated in Fig. 9, the GMVAE+RL model maintains strong classification fidelity for major maritime classes, particularly Boat and Ferry, even under adversarial conditions. However, a notable misclassification rate is observed in the Raft-to-Boat prediction, indicating a potential area for improvement.

## VII. CONCLUSION

The evaluation of the Gaussian Mixture Variational Autoencoder (GMVAE) combined with Reinforcement Learning (RL) as a defense mechanism against adversarial attacks in the context of the Singapore Maritime Database opens up promising avenues for future research and development.Fine-tuning the GMVAE+RL defense to address sophisticated and evolving adversarial attack strategies is crucial. As adversaries continually develop new methods to compromise maritime data and operations, the defense must adapt to these challenges. This could involve exploring reinforcement learning techniques that enable the defense to learn and evolve its strategies in response to emerging threats.The GMVAE+RL defense into real-world maritime systems and operations is a promising direction. By implementing this defense mechanism in maritime data processing pipelines, vessel monitoring systems, and other critical infrastructure, the maritime industry can enhance its cybersecurity posture and ensure the integrity of its data.

One key area for future exploration is the adaptation of this defense mechanism to more extensive and complex maritime datasets. The Singapore Maritime Database provides an excellent starting point, but expanding its application to larger and

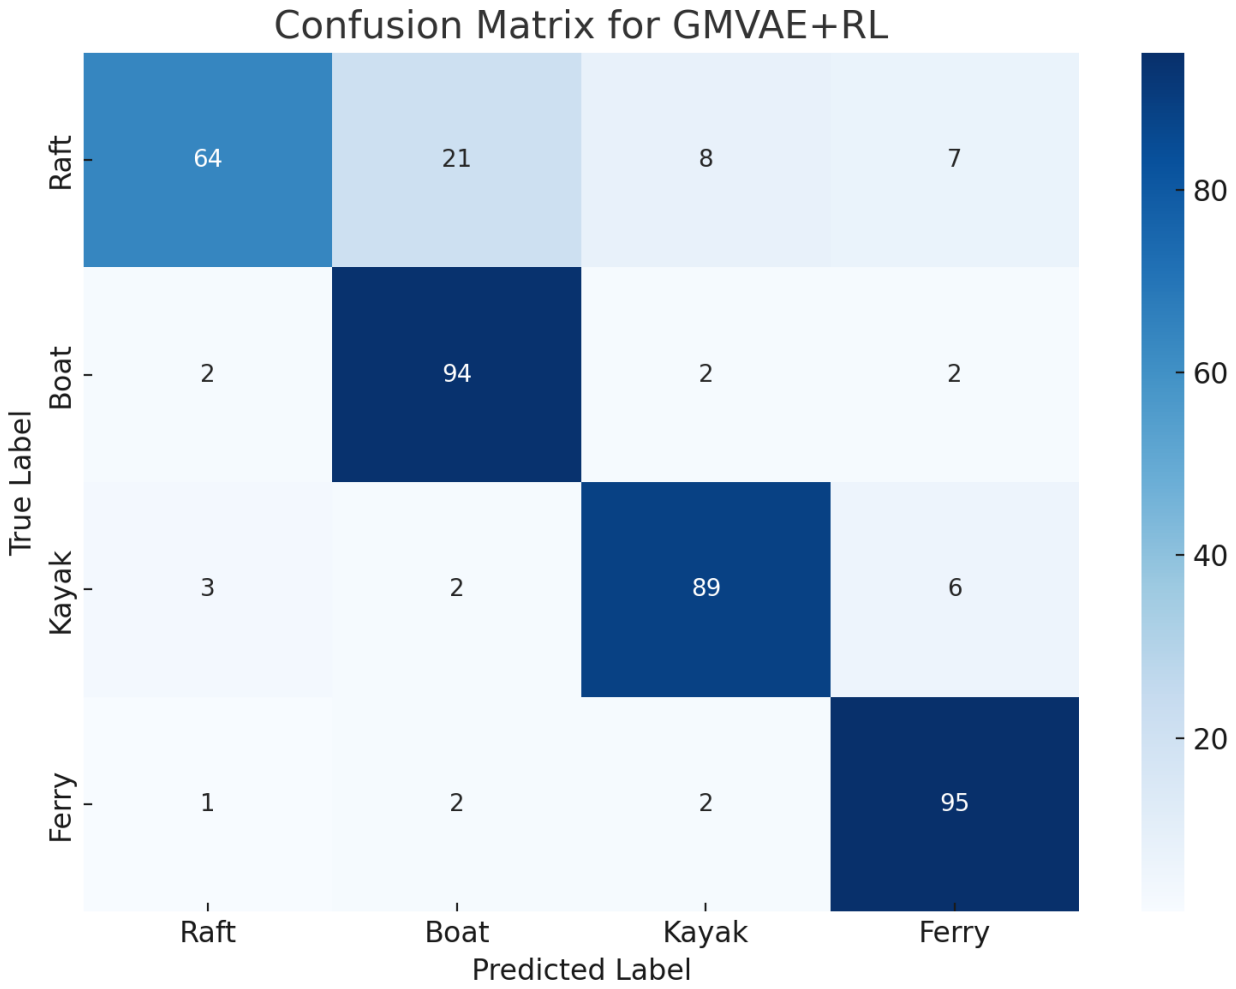

Fig. 9. Confusion Matrix for GMVAE+RL model showcasing classification accuracy across maritime classes under adversarial evaluation.

more diverse datasets from various maritime domains could further validate its effectiveness and robustness.

The future scope of the GMVAE+RL defense mechanism in the maritime industry involves further research, adaptation to diverse datasets, resilience against evolving attacks, integration into operational systems, and collaboration with industry experts. These efforts aim to fortify the maritime sector's cybersecurity defenses and ensure the secure and uninterrupted flow of maritime operations in an increasingly digitized world.

# Evaluating the Performance of Tree-Based Model in Predicting Haze Events in Malaysia

Mahiran Muhammad, Ahmad Zia Ul-Saufie*, Fadhilah Ahmad Radi
Faculty of Computer Science and Mathematics, Universiti Teknologi MARA, Shah Alam, Selangor, Malaysia

***Abstract*—Predicting haze is crucial in controlling air pollution to reduce its impact, especially on human health. Accurate prediction of extreme values is vital to raising public awareness of this issue and better understanding of air quality management. Extreme values in air pollution refer to unusually high measurements of pollutants that diverge significantly from the normal range of observed values. Extreme values are normally caused by haze from various factors. Neglecting extreme values can cause unreasonable predictions. Therefore, this study aims to evaluate the performance of a tree-based algorithm in predicting haze events. Predictive analytics were based on hourly air pollution data from 2013 to 2022 in Shah Alam, Malaysia. The ten parameters are chosen Relative Humidity (RH), Temperature (T), Wind Direction (WD), Wind Speed (WS), $PM_{10}$, NOx, $NO_2$, $SO_2$, $O_3$ and CO. Decision Tree (DT), Gradient Boosting Regression (GBR) and Extreme Gradient Boosting (XGBoost) are compared in determining the best approach for modeling $PM_{10}$ concentrations for the next 24 hours ($PM_{10,t+24h}$) for overall air quality data and three air quality blocks: Good air quality (Block 1), Moderate air quality (Block 2) and Extreme air quality (Block 3). The performance of RMSE, MAE and MAPE indicate that XGBoost outperforms GBR and DT with the RMSE(21.5921), MAE(14.2396) and MAPE(0.4816). When evaluating the performance across the three air quality blocks, XGBoost remains as the top-performing model. However, XGBoost faces challenges in accurately predicting extreme values.**

***Keywords*—Extreme Gradient Boosting (XGBoost); Gradient Boosting Regression (GBR); Decision Tree (DT), extreme values; Particulate Matter (PM)**

## I. Introduction

Malaysia has experienced air pollution, which creates an environmental health threat. Air pollution can lead to a variety of critical illnesses in humans, including bronchitis, heart disease, pneumonia and lung cancer [1]. Bad air quality gives rise to other current environmental issues like global warming, acid rain, reduced visibility, smog, aerosol formation, climate change and premature death [2]. Primary pollutants that impact on most countries constitute Particulate Matter (PM), Nitrogen Dioxide ($NO_2$), Carbon Monoxide (CO), Ozone ($O_3$), Sulphur Dioxide ($PM_{10}$) [3]. Particulate Matter (PM) are notable pollutant within the air and it has a greater effect on human beings compared to other pollutants. Two types of particulate matter are $PM_{10}$ and $PM_{2.5}$. The value of the $PM_{10}$ concentration usually represents the API in Malaysia. This is because $PM_{10}$ concentration in Malaysia is always higher than any other pollutants [4] [5]. Monitoring and predicting $PM_{10}$ concentration, especially in urban areas, has become a vital and challenging task with increasing motor and industrial developments.

*Corresponding author.

According to study [6], extreme values are defined as events that occur less frequently than common events. Extreme values in air pollution refer to unusually high pollutant measurements that deviate significantly from the normal range. An uncommonly high $PM_{10}$ concentration level can result in the existence of extreme values in air pollution data. These anomalies are typically caused by haze events, coming from wildfires, industrial accidents, temperature inversion and are sometimes caused by measurement errors. There is research that demonstrates the meteorological influence on air quality [7]. The $PM_{10}$ concentrations and CO were found to have a strong to moderate correlation when episodic haze was recorded. Meanwhile, the relationship of $PM_{10}$ level with $SO_2$ was found to be significant in 2013 and negatively correlated with relative humidity (RH) [8]. Weak correlation between $PM_{10}$ and NOx was measured in study areas, likely because of low contribution of domestic artificial sources towards haze events in Malaysia [8]. Neglecting extreme values can cause unreasonable predictions when using the original data set directly. Therefore, it is fundamental to precisely cope with the problem of extreme values to boost the effectiveness of prediction models.

Various predictive models, spanning from statistical approaches to machine learning methods, have been employed to forecast $PM_{10}$ concentrations [9]. Several researchers have applied and developed machine learning models to predict $PM_{10}$ concentrations in Malaysia [12] [11] [14] [13] [15]. Based on the outcomes of all the ML models, machine learning effectively addresses the challenges of nonlinear and complex models in predicting $PM_{10}$ concentrations. Predictive models based on machine learning (ML) are more accurate and consistent [10].

Globally, several tree-based machine learning models have demonstrated high accuracy in predicting $PM_{10}$ concentrations compared with other machine learning models. These tree-based ML models are often used for classification and regression tasks because they require less time to train and tune the model parameters [17] [18] [19] [16] [20]. Tree-based machine learning models, such as Decision Tree (DT), Random Forest (RF), Gradient Boosting Regression (GBR), and Extreme Gradient Boosting (XGBoost) have gained prominence in air quality research due to the interpretability, robustness and strong predictive performance [21]. These models are particularly well-suited for handling complex, non-linear relationships that often found in environmental datasets [16].

Several studies have demonstrated the effectiveness of tree-based models in predicting air pollution. A study comparing various machine learning models found that XGBoost achieved the highest $R^2$ value (0.9985) and the lowest error metrics,

outperforming Lasso regression in forecasting $PM_{10}$ concentrations [22]. The study in [19] compare a linear forecast technique (multiple linear regression) with proposed non-linear algorithms, Random Forest, Support Vector Machine (SVR) and Gradient Boosting Regression (GBR). Their results revealed that GBR outperformed others to predict $PM_{10}$ concentrations. The study in [17] showed that XGBoost performs better than Light GBM in terms of prediction estimation with RMSE of 12.846, but it takes longer to train and tune the model's parameters. DT is one of the simplest, yet powerful models used in environmental modelling. Studies have demonstrated that DT models can efficiently capture local pollution patterns [25]. The study [23] stated that XGBoost outperforms other deep learning models due to the consideration of small sample size in datasets. The study [24] found ANN requires extensive tuning parameters and longer computational time and were found to be less effective as XGB and RF to predict air pollution.

Numerous research studies have been conducted in comparing different machine learning methods in air pollution prediction. However, limited research has been conducted on comparing the performance of tree-based machine learning models in predicting extreme events of $PM_{10}$ concentrations across different air pollution levels. Therefore, this research is motivated by the intention to evaluate the performance of the DT, GBR and XGBoost models in determining the best approach in predicting extreme or haze events of $PM_{10,t+24h}$ concentrations. Three air quality blocks: $PM_{10,24h}$ concentration $\leq 50\,\mu g/m^3$ (Block 1, Good air quality status), $50\,\mu g/m^3 < PM_{10,24h}$ concentration $\leq 150\,\mu g/m^3$ (Block 2, moderate air quality status), and $PM_{10,24h}$ concentration $> 150\,\mu g/m^3$ (Block 3, extreme air quality status) will be compared to assess their impact on predicting haze events in air pollution data. In this study, the primary focus is on Block 3, which is characterized as extreme haze events when the $PM_{10}$ concentrations exceed $150\mu g/m^3$ In summary, the key contribution of this research work is a comparison and evaluation of the proposed machine learning model for predicting extreme or haze events in Malaysia. This paper is organized as follows: I. Introduction, II. Methodology, III. Results and Discussion. Followed by the conclusion in Section IV and the reference list.

## II. Methodology

### A. Research Flow

Fig. 1 presents a flowchart outlining this study to evaluate the performance of a tree-based algorithm in predicting haze events of $PM_{10}$ concentrations in Shah Alam, Malaysia. This study utilizes air quality data from 2013 to 2022 provided by the Department of Environment, Malaysia. The process begins with data extraction, followed by data preprocessing. Data extraction is the first step in the process, which is then followed by extensive data pre-processing. Next, the air quality data are then used to train the DT, GBR and XGBoost. The model performance is then evaluated based on the accuracy of RMSE, MAE and MAPE. Finally, the best model that provides the most accurate prediction for extreme values is identified.

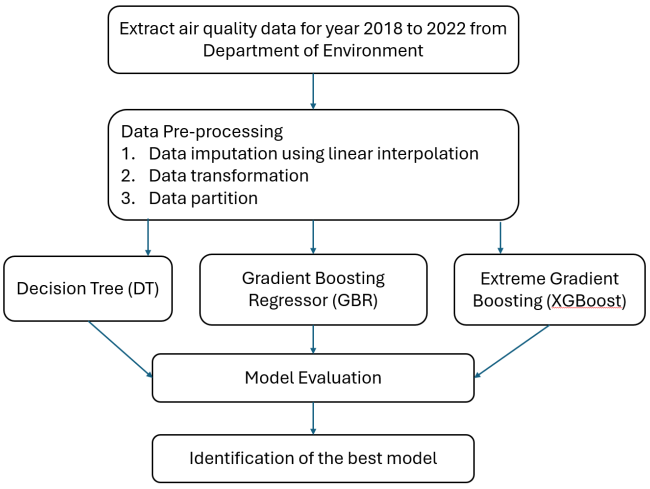

Fig. 1. Research flow.

### B. Data Description

This study obtained secondary data from the Malaysian Department of Environment (DOE) from 2013 to 2022. The stations are situated in Shah Alam, Selangor, and consist of 83,431 air quality data points for 10 variables, such as air pollutants and meteorological parameters. The air pollutants included: $PM_{10}$, $SO_2$, $NO_x$, $NO_2$, $O_3$ and CO, whereas meteorological parameters included: WS, WD, RH and T. Table I shows the variable in this study with their respective level of measurements and role. $PM_{10}$ concentration for the next 24 hours, $PM_{10,t+24h}$ serve as dependent variable. Meanwhile, the other variables serve as independent variables.

TABLE I. Description of Variables

| Variable | Description | Level of measurement | Role |
|---|---|---|---|
| **Particulate Matter for the next 24h ($PM_{10,t+24h}$)** | Hourly concentration of $PM_{10,t+24h}$ ($g/m^3$) | Interval | Dependent |
| **Particulate Matter 10 ($PM_{10}$)** | Hourly concentration of $PM_{10}$ ($g/m^3$) | Interval | Independent |
| **Sulphur Dioxide ($SO_2$)** | Hourly concentration of Sulphur dioxide (ppb) | Interval | Independent |
| **Nitric Oxide and Nitrogen Dioxide ($NO_x$)** | Hourly concentration of nitric oxide and nitrogen dioxide (ppb) | Interval | Independent |
| **Nitrogen Dioxide ($NO_2$)** | Hourly concentration of nitrogen dioxide (ppb) | Interval | Independent |
| **Ozone ($O_3$)** | Hourly concentration of ozone (ppb) | Interval | Independent |
| **Carbon Monoxide (CO)** | Hourly concentration of carbon monoxide (ppb) | Interval | Independent |
| **Wind Speed (WS)** | Hourly wind speed (m/s) | Interval | Independent |
| **Wind Direction (WD)** | Hourly wind direction (°) | Interval | Independent |
| **Relative Humidity (RH)** | Hourly relative humidity (%) | Interval | Independent |
| **Ambient Temperature (T)** | Hourly temperature (°c) | Interval | Independent |

In this study, the dataset was segmented based on the Air Pollution Index (API) by [49]. Table II shows the API level, which is categorised as good, moderate, unhealthy,

very unhealthy and hazardous, which can be of air quality management level or decision making for data interpretation processes. API is an effortless and encompassing technique for defining air quality conditions that is easily understood [5]. It is categorised based on the highest values of five main air pollutants. Meanwhile, Table III shows the calculation of the breakpoint concentration for $PM_{10}$ corresponding to each API category. For example, a $PM_{10}$ concentration between 50 μg/m$^3$ and 150 μg/m$^3$ falls into the API category of 51-100 (moderate air quality). Therefore, the air quality blocks are categorised into three blocks according to the breakpoint of $PM_{10}$ concentrations established in Malaysia. These blocks are defines as follows: For Good air quality status where $PM_{10,24h}$ concentration $\leq$ 50 μg/m$^3$ served as Block 1, for moderate air quality status which is 50 μg/m$^3$ $<$ $PM_{10,24h}$ concentration $\leq$ 150 μg/m$^3$ served as Block 2, and for extreme air quality status which is $PM_{10,24h}$ concentration $>$ 150 μg/m$^3$ served as Block 3. The performance of each block is then compared to evaluate their influence on the prediction of extreme events in air pollution data.

TABLE II. THE API INDEX [49]

| API Range | Air Quality Status |
|---|---|
| 0–50 | Good |
| 51–100 | Moderate |
| 101–200 | Unhealthy |
| 201–300 | Very Unhealthy |
| $>$ 300 | Hazardous |

### C. Data Preprocessing

Data preprocessing encompasses missing value imputation, data transformation and data partition. Missing values can originate from multiple sources, such as sensor malfunctions, environmental factors, or data transmission errors [26]. A high proportion of missing data may lead to biases or weaken the statistical power of the analysis [26]. According to study [27], Malaysian missing air pollution data belong to Missing at Random (MAR) and the linear interpolation method assumes that the pattern of missingness does not disrupt the underlying trends in the data. In most air pollution data, Linear interpolation is the most ordinary imputation method to treat short gaps of missing data in the air pollution dataset [13]. For data transformation, the units of air pollutants $SO_2$, $NO_2$, $NO_x$, $O_3$, and CO in ppm need to be converted to ppb since the ppm unit is too small, thus affecting the accuracy of the results. The WD variable, which is expressed in degrees, has been converted to wind direction index (dimensionless) [28]). According to study [10], the formula for conversion is

$$\text{Wind Direction Index (WDI)} = 1 + \sin(\theta - 45^\circ) \quad (1)$$

In this study, data partition is conducted by employing splitting methods. Two subsets of the dataset are selected, with 80% ($n$ = 65,945) of the data going to training and 20% ($n$ = 16,486) to testing (80% for model development and 20% to measure the performance of the model). According to [29] , empirical studies show that the optimal results are achieved if 80% of the data is allocated for training and 20% is used for testing. Random sampling is applied to partition the data into train and test sections [30].

### D. Machine Learning Model

This part gives a brief introduction to DT, GBR and XGBoost. In this study, the machine learning model was used to evaluate the performance in predicting haze events. The general model for each machine learning model are shown in Table IV. The table shows the general model for each tree-based algorithms model, DT, GBR and XGBoost. The general model shows the prediction for $PM_{10}$ concentration for the next 24 hours. t represents time.

*1) Decision Tree (DT):* Decision Tree (DT) is a well-known machine learning model that falls under the category of supervised learning [31]. DT can be used for both classification and regression problems [32]. Additionally, DT can effectively handle both numeric and nominal data formats [33]. It constructs a tree-like structure of decisions and their potential outcomes, starting with a root node representing the entire dataset and branching into multiple internal and leaf nodes [25]. Each internal node represents a decision or feature test, and the edges leaving that node represent the possible outcomes of the test [33]. The path from the root node to the leaf node indicates a collection of decisions that leads to a prediction for each given sample [34]. The tree is constructed by recursively splitting the dataset based on the Mean Square Error (for regression trees) that provides the lowest variance [34]. To determine the optimal split, this algorithm applies the usual variance formula.

$$\text{Mean Squared Error} = \frac{\sum(y_i - \hat{y_i})^2}{n} \quad (2)$$

where, $y_i$ is the actual PM concentration for the next 24 hours and $\hat{y}_i$ is the predicted PM concentration for the next 24 hours.

DT are fast and easy to understand. However, the model tends to overfit if the tree is allowed to grow too deep or if there are many noisy features in the data [35].

*2) Gradient Boosting Regressor (GBR):* The Gradient Boosting Regressor (GBR) is a machine learning for regression or classification that provides better prediction models in the form of ensemble weak prediction models [36]. GBR is another ensemble model that is an iterative collection of sequentially ordered tree models so that the following model learns from the error of the previous model [37]. This machine learning approach provides predictions by 'boosting' the ensemble of weak prediction models, usually decision trees, to form a more robust model [38]. The objective function of GBR is described by study [39] as:

$$\hat{F}(x) = \arg\min \sum_{i=1}^{N} L(y_i, \hat{y}_i) \quad (3)$$

$$L = \frac{1}{2} \sum_{i=1}^{n} (y_i - \hat{y}_i)^2 \quad (4)$$

where, $y_i$ is the actual PM concentration for the next 24 hours and $\hat{y}_i$ is the predicted PM concentration for the next 24 hours. Meanwhile, L denotes the loss function.

TABLE III. BREAKPOINT OF $PM_{10}$ CONCENTRATION LEVELS [5]

| Breakpoint of Concentration | Air Quality Status | Equation for API |
|---|---|---|
| Conc. $\leq 50$ | Good | API = conc. |
| $50 <$ conc. $\leq 150$ | Moderate | API $= 50 +$ (conc. $- 50) \times 0.5$ |
| $150 <$ conc. $\leq 350$ | Unhealthy | API $= 100 +$ (conc. $- 150) \times 0.5$ |
| $350 <$ conc. $\leq 420$ | Very unhealthy | API $= 200 +$ (conc. $- 350) \times 1.4286$ |
| $420 <$ conc. $\leq 500$ | Hazardous | API $= 300 +$ (conc. $- 420) \times 1.25$ |
| Conc. $> 500$ | Emergency | API $= 400 +$ (conc. $- 500$) |

TABLE IV. GENERAL MODEL FOR EACH ML MODEL

| Machine learning model | General model |
|---|---|
| Decision Tree (DT) | $PM_{10,t+24h}$ $\tilde{D}T$ ($PM_{10,t}$, $SO_{2,t}$, $NO_{2,t}$, $NO_{x,t}$, $O_{3,t}$, $CO_t$, $WS_t$, $WDI_t$, $RH_t$, $T_t$) |
| Gradient Boosting Regression (GBR) | $PM_{10,t+24h}$ $\tilde{G}BR$ ($PM_{10,t}$, $SO_{2,t}$, $NO_{2,t}$, $NO_{x,t}$, $O_{3,t}$, $CO_t$, $WS_t$, $WDI_t$, $RH_t$, $T_t$) |
| Extreme Gradient Boosting (XGBoost) | $PM_{10,t+24h}$ $\tilde{X}GB$ ($PM_{10,t}$, $SO_{2,t}$, $NO_{2,t}$, $NO_{x,t}$, $O_{3,t}$, $CO_t$, $WS_t$, $WDI_t$, $RH_t$, $T_t$) |

A GBR with M number of trees can be stated as;

$$f_M(x_j) = \sum_{m=1}^{M} \gamma_m h_m(x_j) \tag{5}$$

where, $h_m$ is a weak learner that performs poorly individually and $\gamma_m$ is a scaling factor adding the contribution of a tree to the model.

GBR employs the gradient descent loss function to minimize errors by updating the starting estimation with a new estimation [40]. Thus, a final model is created by combining all preliminary estimations with appropriate weights [40].

*3) Extreme Gradient Boosting (XGBoost):* XGBoost is a decision tree ensemble based on gradient boosting that is highly scalable [39]. XGBoost is a powerful approach for developing supervised regression models [41]. The validity of this statement can be determined by deliberating about the objective function and base learners of XGBoost [41].

The objective function consists of a loss function and a regularization term [42]. Like gradient boosting, XGBoost develops an additive expansion of the objective function by minimizing a loss function [42]. XGBoost is one of the ensemble learning approaches that involves training and combining individual models (known as base learners) to produce a single prediction [43]. Considering that XGBoost is focused only on decision trees as base classifiers, a variation of the loss function is used to control the complexity of the trees [39]. Unlike gradient boosting, the XGBoost objective function includes a regularization term to avoid overfitting [39].

Assume that a dataset, D is $\{(x_i, y_i) : i = 1, \ldots, n\}$. Let $\hat{y}_i$ be defined as a result given by an ensemble represented by the generalized model as follows (Pan, 2018)

$$\hat{y}_i = \phi(x_i) = \sum_{k=1}^{K} f_k(x_i) \tag{6}$$

where $f_k$ is a regression tree, $f_k(x_i)$represents t he score given by the $k$-th tree to the $i$-th observation in the data.

To functions fk, the following regularized objective function should be minimized:

$$\text{Obj} = L(\phi) = \sum_i L(\hat{y}_i) + \sum_k \Omega(f_k) \tag{7}$$

where, $L$ is the custom loss function. The loss function $L$ is a differentiable convex loss function that measures the difference between the prediction $\hat{y}_i$ and the observation $y_i$ [42]. This loss function can be integrated into the split criterion of decision trees, leading to a pre-pruning strategy.

To prevent too large a complexity of the model, the penalty term or regularization term $\Omega$ is included as follows:

$$\Omega(f_k) = \gamma T + \frac{1}{2}\lambda w^2 \tag{8}$$

where, $\lambda$ and $\gamma$ are the parameters controlling penalty for the number of leaves T and magnitude of leaf weights w respectively. The purpose of $\Omega(f_k)$ is to prevent over-fitting and to simplify models produced by this algorithm [44]. The additional regularization term helps to smooth the final learnt weights to avoid overfitting [44].

*4) Parameter setting for baseline model evaluation:* All models were built using general parameter settings as provided by the respective libraries (scikit-learn) to evaluate and compare performance foundations for DT, GBR and XGBoost in predicting $PM_{10}$ concentrations during haze events in Malaysia. This technique gives an unbiased and consistent comparison among the models, emphasizing their inherent learning capabilities despite the effect of tuning. Furthermore, utilizing general parameters provides a clear baseline for future tuning operations and represents common practices in preliminary model evaluation. Using general parameter setting provides comparable performance to adjusted models, suggesting that general parameter settings can be an appropriate starting point for model evaluation [45].

Eventhough DT, GBR and XGBoost are all tree-based models, they do not share the same general parameters. Each algorithm is based on different concepts, and their application represents these differences. The DT from scikit-learn constructs a single decision tree using all available attributes, with no limitations on depth `max_depth=None` by general. This enables the tree to develop as deep as needed to fit the training data, potentially cause to overfitting if the data is noisy. Other important setting includes `min_samples_split=2` and

`min_samples_leaf=1` which manage the tree's branching criteria. In contrast, the GBR builds an ensemble of short decision trees in stages. By general parameter setting, it uses `max_depth=3` to limit the complexity of each tree, along with a `learning_rate=0.1` to figure out how much each tree serves to the final model. This restrictive configuration is created to avoid overfitting while maintaining flexibility.

XGBoost Regressor is also an ensemble method based on boosting but utilizes more aggressive parameter setting compared to scikit-learn's gradient boosting. It sets `max_depth=6`, `learning_rate=0.3`, and includes additional parameters such as `min_child_weight=1`, `subsample=1`, and `colsample_bytree=1`. These settings attempt to achieve a balance between speed and accuracy, with built-in regularization capabilities. While all three models fall under the category of tree-based methods, their general parameters differ significantly due to their mechanical nature. Recognizing these variations is essential when performing baseline effectiveness in prediction tasks.

### *E. Model Performance*

In predicting $PM_{10}$ concentrations, proper model evaluation is essential. According to a previous study by [46], a comparison of the best statistical $PM_{10}$ forecasting methods with the lowest values of RMSE was conducted to select the best fit prediction model. Three statistical evaluations will be used to evaluate the model performance: Root Mean Square Error (RMSE), Mean Square Error (MSE) and Mean Absolute Percentage Error (MAPE). The difference between the estimated and observed values is obtained to investigate the performance of each estimation method. The most appropriate methods are selected based on the least value of each statistical evaluation. The criteria formulas are shown below:

$$\text{RMSE} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(\hat{Y}_i - Y_i)^2} \tag{9}$$

$$\text{MAE} = \frac{1}{n}\sum_{i=1}^{n}|\hat{Y}_i - Y_i| \tag{10}$$

$$\text{MAPE} = \frac{1}{n}\sum_{i=1}^{n}\frac{|Y_i - \hat{Y}_i|}{Y_i} \tag{11}$$

where, $n$ is the total number of hourly measurements of a particular station, $\hat{Y}_i$ is the estimated value of $PM_{10,t+24h}$, $Y_i$ is the observed value of $PM_{10,t+24h}$ and $\bar{Y}_i$ is the mean of the observed value of $PM_{10,t+24h}$

## III. Results and Discussion

The descriptive statistics and boxplot for maximum hourly $PM_{10}$ concentrations in Shah Alam from 2013 to 2022 are shown in Table V and Fig. 2. The box plot in Fig. 2 visualizes the distribution of $PM_{10,t+24h}$ concentrations across different years (2013-2022). The boxed interquartile range (IQR) in 2013-2016 are larger, meaning higher variability in $PM_{10}$ concentrations. From 2017 onward, the boxes are smaller, indicating that $PM_{10}$ concentrations have become more stable. The boxplot indicates that Shah Alam experienced the highest $PM_{10}$ concentration in 2014, followed by 2013 with the second highest concentrations. Additionally, the year 2015 observed an increment in the number of extreme $PM_{10}$ concentration values. This is because Shah Alam serves as an industrial hub. Shah Alam hosts numerous manufacturing plants, factories and processing industries, leading to significant emissions of pollutants. Ongoing construction projects release dust and particulate matter into the air, adding to the pollution burden. In 2015, the extreme values were attributed to transboundary haze pollution [47]. A noticeable reduction in extreme $PM_{10}$ values occurred between 2016 to 2018. From 2016 to 2017, the overall air quality was generally good to moderate. Malaysia suffered moderate haze outbreaks in 2016 caused by localized and transboundary pollution, however, overall air quality improved throughout this year [48] [49] [50].

From the Table V, the mean concentration in Shah Alam for 10 years from 2013 to 2022 for 5 pollutants are $PM_{10}$ (41.7043 $\mu gm^{-3}$), CO (740.0108 ppb), $NO_2$ (18.3214 ppb), $SO_2$ (1.9875 ppb) and $O_3$ (19.4478 ppb). The concentrations of $PM_{10}$ were very high in Shah Alam, Selangor, with a maximum concentration of 575 $\mu g/m^3$. The skewness of $PM_{10}$ is 4.5730, indicating a highly positively skewed distribution, which shows the presence of extreme values in the data. The mean values for meteorological parameters are represented by Relative Humidity (RH) (78.1675%), Temperature (T) (27.8690°c), wind direction (WD) (191.3082°) and wind speed (WS) (2.7661 m/s). The mean values of $PM_{10}$ (41.7043) higher than the median (35.0000) indicates that the pollutant distributions are having right-skewed distribution. All the variables are positively skewed when the skewness presents positive values for each variable (CO=1.1710, $NO_2$=1.1650, $O_3$=1.3600, $PM_{10}$=4.5730, $SO_2$=6.8020, $NO_x$=1.6030, WS= 1.7360, T=0.7070) except for RH(-0.395) and WD(-0.0200), which shows negatively skewed when the skewness presents negative values. In summary, the box plot shows that extreme $PM_{10}$ concentration values occurred annually from 2013 to 2022. To accurately predict these extreme values, tree-based algorithms will be further analysed to evaluate the most effective model for forecasting haze events in Shah Alam. Fig. 3 shows the correlation heatmap in Shah Alam which represents the correlation coefficients between different air pollution parameters. The colour gradient ranges from green (strong negative correlation, -1) to blue (strong positive correlation, +1), with yellowish shades indicating weaker correlations. This heatmap provides valuable insights into the relationships between meteorological conditions and air pollutants. From the heatmap, there was a negative relationship between $PM_{10}$ and Relative Humidity (RH) (r=0.051) and a moderate correlation was found between $PM_{10}$ and CO in Shah Alam (r=0.46). This is supported by [8] when their study shows negative correlation between $PM_{10}$ and RH and strong to moderate correlation between $PM_{10}$ and CO. This suggest that as humidity increases $PM_{10}$ concentrations tend to decrease slightly. Understanding these correlations helps in air quality modelling, especially when predicting extreme pollution events.

Table VI shows a comparative analysis to evaluate the performance of the DT, GBR, and XGBoost models for hourly $PM_{10,t+24h}$ concentration predictions at Shah Alam station from the period 2013 to 2022. This table summarizes quantitatively the performance in terms of RMSE, MAE and MAPE. The

TABLE V. DESCRIPTIVE STATISTICS OF AIR POLLUTION FROM 2013 TO 2022 IN SHAH ALAM, SELANGOR

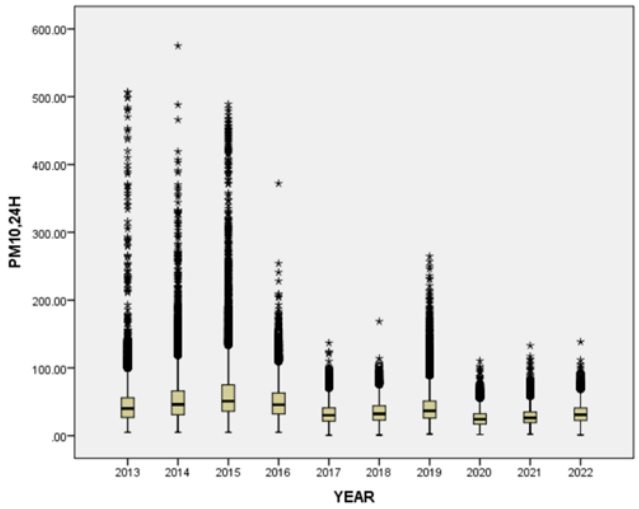

Fig. 2. Boxplot of PM10 concentrations in Shah Alam, Selangor.

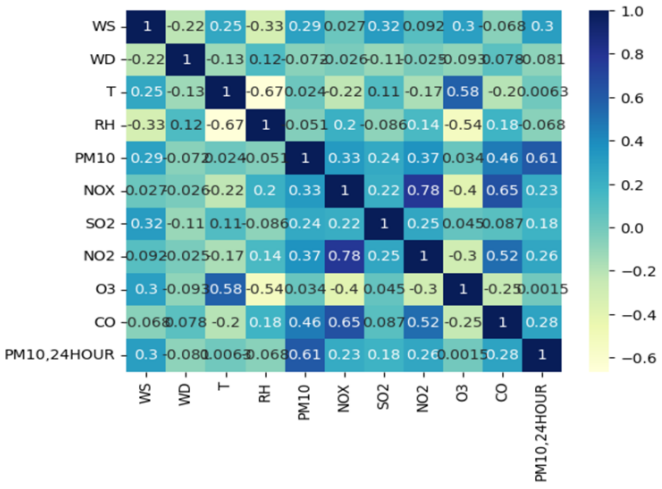

Fig. 3. The Correlation heatmap of air quality parameters in Shah Alam.

result shown are for overall air pollution data. According to the Table VI, it is observed that XGBoost outperforms all other models in the prediction of $PM_{10,t+24h}$ concentrations with the lowest value of RMSE, MAE and MAPE value. Meanwhile, DT generate the highest value of RMSE, MAE and MAPE value, indicating the DT is at lowest level of performance. This result aligns with the findings of [32] [44], which demonstrate that the XGBoost method is more effective than DT for predicting air pollution concentration. Fig. 4 presents the actual vs predicted graph for overall $PM_{10,t+24h}$ concentration using DT, GBR and XGBoost model. A) represents XGBoost model for the actual vs predicted $PM_{10,t+24h}$ concentration. B) represents GBR model for the actual vs predicted $PM_{10,t+24h}$ concentration and C) represents DT model for the actual vs. predicted $PM_{10,t+24h}$ concentration. From the graph, it can be concluded that XGBoost predictions are significantly more accurate than GBR and DT when the prediction line of XGBoost is closer to the actual line. In contrast, the GBR and DT models show a greater discrepancy, with their predicted lines deviating further from actual data. Therefore, for overall air pollution data, it can be concluded that XGBoost is the best model for $PM_{10,t+24h}$ air pollution predictions.

TABLE VI. PERFORMANCE RESULTS FOR OVERALL AIR QUALITY

| Performance Evaluation | Model | | |
|---|---|---|---|
| | **XGBoost** | **GBR** | **DT** |
| RMSE | 21.5921 | 24.5051 | 24.7156 |
| MAE | 14.2396 | 15.7770 | 15.5915 |
| MAPE | 0.4816 | 0.5528 | 0.5164 |

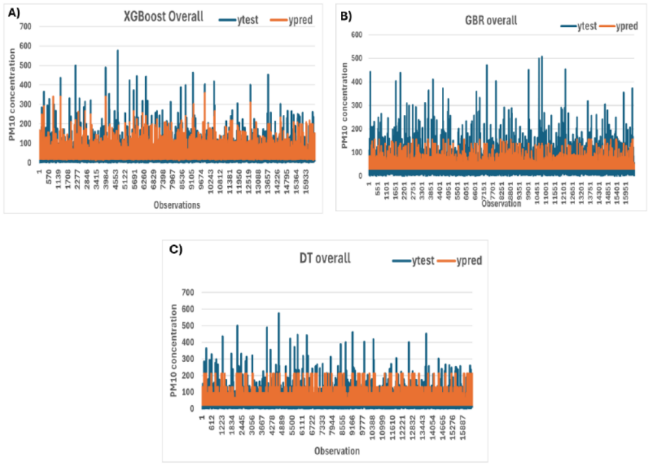

Fig. 4. Actual vs. Predicted for overall PM10 prediction A) XGBoost B) GBR C) DT.

The analysis is furthered through each block to evaluate the effectiveness of the tree-based model. From the result of the actual and predicted value of each model, the result is

arranged and blocked through the actual values of the model. The three blocks of air quality data are $PM_{10,24h}$ concentration $\leq 50\,\mu g/m^3$ (Block 1), $50\,\mu g/m^3 < PM_{10,24h}$ concentration $\leq 150\,\mu g/m^3$ (Block 2), and $PM_{10,24h}$ concentration $> 150\,\mu g/m^3$ (Block 3). This analysis is extended to evaluate each model's ability to predict extreme events and determine whether they can accurately capture extreme values.

Table VII shows the results of the performance indicator by using the XGBoost, GBR and DT for the three blocks of air quality data. Based on the XGBoost results, the three blocks of air pollution data show that the $PM_{10,t+24h}$ concentration below 50µg/m$^3$ (Block 1) had the lowest RMSE value of 14.1875, compared to 27.2372 for $PM_{10,t+24h}$ concentrations between 50µg/m$^3$ and 150µg/m$^3$ (Block 2) and 106.0264 for $PM_{10,t+24h}$ concentrations above 150 µg/m$^3$ (Block 3) respectively. Similarly, the MAE is the lowest for the $PM_{10,t+24h}$ concentrations below 50µg/m$^3$ (Block 1) at 10.6636. While $PM_{10,t+24h}$ concentrations between 50µg/m$^3$ and 150µg/m$^3$ (Block 2) and those above 150 µg/m$^3$ (Block 3) recorded higher MAE values of 22.0516 and 83.4721, respectively.

GBR and DT also exhibited an increment in error measures, particularly for Block 3. For GBR, $PM_{10,t+24h}$ concentration below 50µg/m$^3$ (Block 1) had the lowest RMSE value of 14.1673, compared to 28.9145 for $PM_{10,t+24h}$ concentrations between 50µg/m$^3$ and 150µg/m$^3$ (Block 2) and 140.4993 for $PM_{10,t+24h}$ concentrations above 150 µg/m$^3$ (Block 3) respectively. Similarly, the MAE was the lowest for the $PM_{10,t+24h}$ concentrations below 50µg/m$^3$ (Block 1) at 11.3487. While $PM_{10,t+24h}$ concentrations between 50µg/m$^3$ and 150µg/m$^3$ (Block 2) and those above 150 µg/m$^3$ (Block 3) recorded higher MAE values of 23.9327 and 124.5067, respectively. Meanwhile For DT, $PM_{10,t+24h}$ concentration below 50µg/m$^3$ (Block 1) had the lowest RMSE value of 15.2412, compared to 30.6125 for $PM_{10}$ concentrations between 50µg/m$^3$ and 150µg/m$^3$ (Block 2) and 131.3885 for $PM_{10,t+24h}$ concentrations above 150 µg/m$^3$ (Block 3) respectively. Similarly, the MAE was the lowest for the $PM_{10,t+24h}$ concentrations below 50µg/m$^3$ (Block 1) at 11.3487. While $PM_{10,t+24h}$ concentrations between 50µg/m$^3$ and 150µg/m$^3$ (Block 2) and those above 150 µg/m$^3$ (Block 3) recorded higher MAE value of 24.5156 and 108.5374, respectively. From this table, XGBoost demonstrates the best performance compared to DT and GBR, as it achieves the lowest RMSE, MAE, and MAPE values. However, from this table, the key observation is Block 3, where the $PM_{10,t+24h}$ concentration exceeds 150µg/m$^3$. This indicates that Block 3 experiences significantly higher pollution levels. Additionally, the data suggests that this block exhibits the lowest performance in terms of air quality compared to Block 1 and Block 2.

Overall, the graph in Fig. 4 presents that tree-based model performs well in predicting normal events. Nevertheless, in Table VII, when the data exceeds 150µg/m$^3$, none of the model achieve accurate predictions. This is due to the presence of extreme values, which pose challenges for the models in predicting these extreme events effectively. This analysis is further illustrated in Fig. 5, which shows the Block 3 of $PM_{10}$ for the next 24 hours prediction graphs for all tree-based models. The figure reveals a significant discrepancy between the actual and predicted $PM_{10,t+24h}$ values for all the models.

Table VIII shows the performance results of XGB, GBR and DT model for all air quality data. Based on the analysis of the overall data (without blocking) in Table VI, XGBoost outperforms the other two models, demonstrating greater efficiency in predicting $PM_{10,t+24h}$ concentrations (RMSE = 21.5921, MAE = 14.2396, MAPE = 0.4816). When comparing performance across blocks, XGBoost also surpasses DT and GBR. However, the performance gap is notably larger for the extreme air quality block compared to the good and moderate air quality blocks. This suggests that haze events have a significant impact on the models' accuracy. This disparity is due of the presence of extreme values in the extreme air quality block, leading to a highly skewed distribution and increased prediction error [51]. Previous studies have also highlighted this issue, where models effectively reduce overall error but struggle with accurately predicting extreme values [52] [53] [51] [54]. [55] further emphasized that another major challenge is the ability of standard learners to focus on the most important and extreme values. Therefore, neglecting these extreme values can result inaccurate model predictions.

TABLE VII. PERFORMANCE RESULTS FOR THREE BLOCKS AIR QUALITY

| Model | Performance Indicator | XGBoost | GBR | DT |
|---|---|---|---|---|
| $PM_{10,t+24h}$ concentration $\leq 50\ \mu g/m^3$ (Block 1) | | | | |

## IV. CONCLUSION

The primary contribution of this study is to focus on extreme values using machine learning methods. Additionally, the evaluation of ML models is further explored through data blocking to assess whether the skewed data can be effectively modelled using the same ML approach. Based on

TABLE VIII. PERFORMANCE RESULTS OF XGB, GBR AND DT MODEL FOR ALL AIR QUALITY DATA

| Model | Performance Indicator | Overall | $PM_{10,24h}$ concentration $\leq$ 50 µg/m$^3$ (Block 1) | 50 µg/m$^3$ < $PM_{10,24h}$ concentration $\leq$ 150 µg/m$^3$ (Block 2) | $PM_{10,24h}$ concentration > 150 µg/m$^3$ (Block 3) |
|---|---|---|---|---|---|

the discussion of all comparisons between the overall data and the blocks (as discussed above), XGBoost outperforms the other two models with RMSE(21.5921), MAE(14.2396) and MAPE(0.4816), indicating XGB model is more efficient for predicting $PM_{10}$ concentration. The comparison Block 1, Block 2, and Block 3 air quality data blocks show a decline in performance, as indicated by RMSE, MAE, and MAPE. The performance gap is significantly larger for the Block 3 air quality block compared to the overall, Block 1, Block 2 air quality blocks. This disparity arises from the presence of extreme values in the Block 3 air quality block, making it as challenging for the model to generate accurate predictions. As a result, the error indicators become significantly high, leading to a high discrepancy between actual and predicted $PM_{10}$ concentrations. For further analysis, since XGBoost outperforms the other models, it will be further utilized and enhanced to better handle extreme data, as this is essential for improving $PM_{10}$ concentration predictions, particularly during haze events with elevated $PM_{10}$ levels.

## ACKNOWLEDGMENT

We would like to express our sincere gratitude to Faculty of Computer Sciences and Mathematics and Universiti Teknologi Mara (UiTM) for their continuous support throughout this study. Additionally, we extend our deepest appreciation to the DOE Malaysia for providing air quality data used in this study.

***Abstract*—This paper examines the concept of implementing a hybrid optimization approach through combining analytical and meta-heuristic approaches to improve the performance of practical engineering systems. Designed in support of artificial intelligence strategy, the proposed approach ensures high stability and efficiency under actuators saturation constraint. This is a well-known and sensitive problem in robotics and control. Specifically, this paper deals with the problem of computing the stability region for controlled systems. While addressing this issue, research approaches take into consideration the fact that actuator saturation may occur. It is imperative to maintain this propriety and ensure the reliability of design control systems, particularly those developed to control robot actuators. Models of the studied systems are based on differential algebraic representations and polytypic regions in state space. The developed technique combines LMI with an improved meta-heuristic based optimization approach that fast searches and enlarge domains of attraction for robot actuators. The direct Lyapunov theory is used to analyze and validate stability key performance. A numerical example study has been conducted to validate the proposed approach's efficacy and efficiency. A comparative benchmarking study has been carried out to highlight the main concepts and results of this study.**

***Keywords*—Domain of Attraction (DA); Differential Algebraic Representation (DAR); meta-heuristic approach; actuators saturation***

## I. Introduction

### A. Motivation

In robotic systems, actuators saturation is a problem that requires careful consideration. Under faulty conditions, and/or model uncertainties, robots may be more likely to experience this problem, and its solution becomes more difficult. Among reliable robots examined are general architectures, spatial robots, and robots with parallel or serial architectures. As part of the control techniques, a model reference process is implemented as well as an estimated torque approach in the feed-forward approach [1].

Furthermore, the feedback process involves conventional controllers. In the context of stability assurance, these methods rescue the robot from unstable dynamics by considering actuator saturation during the design phase [2]. Previous studies indicate that the time regulation method coupled with basin of attraction enlargement techniques are suitable for robots control methods. Besides addressing totally failed actuator joints, these methods also provide solutions for partial defects of various actuator joints [3].

For a class of nonholonomic mobile robots, a saturated trajectory tracking control design is presented in study [1]. A bounded dynamic continuous feedback controller is developed to ensure finite-time kinematic convergence. Saturation constraints related to attraction domains as well as errors associated with tracking initial values are considered. In control systems theory, attraction domains provide a useful means of analyzing the consequences of system actuator input saturation [3]. Sets such as these identify the system initial conditions under which the control technique results in attraction to stable equilibrium points [3]. Describes these sets in the context of an exponentially unstable open-loop plant. A single actuator controls such a model that is characterized by actuator saturation and modeling time delay characteristics. Consequently, approaches to estimating attraction domains are relevant for robot control design theory since these approaches provide sufficient, and necessary conditions for attractivity.

Equally significant, these approaches allow the identification of operational stability sets in which system actuators can perform in a non-saturated state.

### B. Fundamental Context

In general, in the real world, all physical control systems are inherently nonlinear: so, it is difficult to develop an analytical technique that can be applied to any nonlinear system [4]. In almost all physical control, the presence of an input saturation has been identified practically and this occurrence of saturation could result in nonlinear phenomena [4], [5], [10]. This has garnered a lot of interest to conduct numerous studies focusing on the modeling as well as assessment of its impact on the global stability and dynamical performance pertaining to closed-loop controlled systems. The results of most of these studies have accounted for the restricted class of linear open-loop systems. In such a particular case, even when the closed-loop controlled system is deemed to be linear locally , the nonlinearity could result in degradation of their performance or lead to instability. Thus, numerous analysis techniques were regarded to assess the DA pertaining to linear models

subject to a control input saturation constraint. Many works can describe the saturation of inputs in different representations for the sake of facilitating stability analysis. However, a good approach would be employing the generalized sector condition pertaining to dead zone nonlinearities. Furthermore, a key part of stability analysis is the representation of the system. Dynamic nonlinear systems can be represented in a variety of ways in the literature. As a consequence, commonly used the Differential Algebraic Representations (DAR) modeling indicates that the system offers results which are conservative than the Linear Fractional Representation(LFR), as well as the Linear Parameter Varying (LPV) forms thereof. A few notable representation systems are the LPV [6], the LFR [7], [8] and the DAR. The introduction of free multipliers to the studied system may be an effective approach to decreasing this late latent conservativeness. In this way, there would be less reliance on selecting control system matrices, as suggested by [6], taking advantage of different approaches. With regards to the framework pertaining to this problem, Coutinho, Trofino and co-workers [2], [9], [10], [11], [12], [56] put forward the Differential Algebraic Representations (DAR) to enable stability analysis, deal with control synthesis problems and employ to achieve tractable stability condition as linear matrix inequalities (LMI)[10]. The authors in [2] showed that DAR results in less conservative estimates pertaining to the region of attraction. DA signifies those initial conditions in which the system state converges with that of the equilibrium in an asymptotic manner. Numerous analysis techniques have been put forward for the estimation of the DA pertaining to linear models subject to input actuators saturation constraints. Different methods have been put forward to enable calculation of inner estimates for instance, approaches such as the La Salle method [13], Zubov method [14] and the trajectory reversing. In most situations, the DA estimation problem has been segregated to non-convex or convex optimisation problems for simplification [15], [16]. This has been dealt with by employing optimisation techniques such as SOS [17], [18], intelligent optimisation techniques [18],[19],[20] LMI [21], integration of the genetic as well as LMI. There are some other techniques to generate Lyapunov: for example, in [22] we proposed numerical techniques that define rational and quadratic Lyapunov functions based on Carleman linearization that permits the computation of the developed DA.

Generally in the literature estimating the domain of attraction is a complex problem. Some famous technique analysis stabilities are Lyapunov and Non-Lyapunov methodologies. The first family, described based on the Lyapunov function, set level associated in the region when a negative sign is included in its time derivative, which can be explained by a mathematical translation pertaining to an elementary observation: when a system's total energy lowers with time, then this system (linear or nonlinear, stationary, or not) tries to revert to an equilibrium state.

Generally, the literature indicates that the Lyapunov theory-based techniques are widely used to estimate the DA [23],[24],[25],[26],[27]. Linear Matrix Inequalities (LMI) optimization was employed by Coutinho et al. To estimate the domain of attraction for dynamic systems by considering the sets of levels of Lyapunov functions [28],[29]. The Largest Approximation of the DoA (LADoA) can be defined based on a Lyapunov Function (LF) for which the local asymptotic stability pertaining to the equilibrium point can be satisfied, characterized by a certain shape, by the LF itself. In such a case, the selection of the LF could significantly impact the conservativeness pertaining to the estimated domain.

### C. Literature Review

This study aimed to develop a method for determining the largest approximation DA pertaining to stable equilibrium's by investigating the maximal LFs. The main idea is to identify the best peaks providing an optimal region. The determination of the largest estimation of the DOA via the lyapunov function can be approached by serval method.[55] genetic algorithm will be implemented to adjust the coefficients of lyapunov function and control parameters, in [54] the article aims to develop an original numerical algorithm to construct a polynomial lyapunov function and maximizing domain of attraction using PSO algorithm. With this in mind, a great deal of research has focused on the integration of metaheuristic algorithms as an optimization tool to broaden the domain of attraction. It therefore seems appropriate to provide an overview of the main families of metaheuristic algorithms that can be used in this context. Many problems of optimization can be classified in these categories; Analytic or deterministic; heuristic or random: multi-objective or single objective[16], [30]. As well as we can classify these algorithms, two main classes can be identified: Meta heuristic and gradient. The first class are nature-inspired, and as they have been developed, based on some abstraction of nature. The second class is based on the gradient calculation theory; this class is very complex and risks peeling. In this work, we are interested in the meta heuristic algorithms as they are easy to manipulate and very efficient global search algorithms. Since then, many meta-heuristic nature-inspirited techniques have been developed: the particle swarm optimization (PSO)[49] is an algorithm designed to minic the foraging behavior of brids. Evolutionary strategy (ES)[31], firefly algorithm (FA) [32], ant colony optimization (ACO)[33], differential evolution (DE) [34], probability-based incremental learning (PBIL) [35], big bang–big crunch algorithm [36], bio-geography-based optimization (BBO) [36], harmony search (HS) [37], animal migration optimization (AMO) [38], krill herd method (KH) [39], [40], bat algorithm (BA) [41], teaching learning-based optimization (TLBO) [42], dragonfly algorithm (DA) [43], the Secretary Brid Optimization Algorithm(SBOA) [53]. (SBOA) is an innovative population based meta-heuristic approach such that is inspired from the survival behaviours of secretary brids in their natural habitat. the implementation of SBOA is structured into phases: an exploration step simulating a hunting strategy and an exploitation step simulating a escape strategy. In this work, we are interested by the secretary bird optimization algorithm. The SBOA algorithm offers advantages due to its simplicity showcasing its robustness and wide applicability.

This study employs the secretary birds optimization algorithm (SBOA) to assess the optimal value pertaining to the vertices for optimal domain of attraction (DA) estimation. SBOA is expected to offer higher performance versus the techniques suggested in [2],[12]. This paper aims to ameliorate the technique analyzed in [2] by combining the LMI with SBOA.

The paper is structured as follows: statement problem

preliminaries are introduced in Section II, and estimation DA using DAR representation in Section III. In this we further detail the DAR representation and signify the candidate Lyapunov and LMI formulation. In Section IV, we present the Secretary Brids Optimization algorithm implementation. Section V, is reserved for a numerical analysis study. Section VI introduce the discussion of the results, while Section VII ends the paper.

## II. Problem Statement and Preliminaries

Given a nonlinear affine systems described by:

$$\begin{cases} \dot{x} = f(x) + g(x)\, sat(u) \\ u = Kx \end{cases} \tag{1}$$

where, $x \in \Re^n$ represents the state variables vector, $u \in \Re$ signifies the control variable, with, $K \in \Re^{1\times n}$can be defined as the assumed constant vector denoting an input gain vector that relies linearly on the system state variables. $f(x), g(x) : \Re^n \to \Re^n$ defines a vectors of a nonlinear value function that satisfies the constraints pertaining to the uniqueness and existence of solution for all $x \in D_x$ and the equilibrium point of interest is the origin. A classical unitary saturation function is defined as follows [2]:

$$sat(u) := sign(u) \min\{|u|, 1\} \tag{2}$$

Analysis of the stability of the system (1) can employ Lyapunov theory [47]. **Lemma** [2]

Assume $V(x)$ to be a Lyapunov function pertaining to the system as Eq. (1) in the following region:

$$J = \{x : V(x) \leq 1\} \tag{3}$$

Should $\dot{V}(x)$ be negative, then may be defined as:

$$\dot{V}(x) = \frac{dV(x)}{dt} f(x) \tag{4}$$

The system seemed to be asymptotically stable and for all $x(0) \in J$ the trajectory $x(t)$ corresponds to $J$ while approaching the origin as $t \to \infty$. $\xi(x)$

### A. Determining a LF Candidate

This section is dedicated to introduce fundamental outcomes of the Lyapunov theory. Consider the following function:

$$V(x) = \xi(x)^T P \xi(x) \tag{5}$$

where, $\xi(x) \in \Re^{n_\xi}$ represents a rational vector function pertaining to $x$ and $P = P^T \in \Re^{n_\xi \times n_\xi}$ signifies the constant matrix that must be computed. The time derivate pertaining to $V(x)$ has been represented as follows: $\frac{dV(x)}{dt} = \dot{\xi}^T(x) P \xi(x) + \xi^T(x) P \dot{\xi}(x)$. It needs to be noted that $\xi(x)$ and $\dot{\xi}(x)$ denote the rational vector function pertaining to $x$ and $\dot{x}$.

*Remark:* The Lyapunov function has been presented in [13], which covers a broad class of physical process, including:

- Quadratic LF [8] where; $\xi(x) = x$.
- Bi-quadratic LF [28] and polynomial [29], where $\xi(x)$ being a polynomial vector function in $x$.
- Rational LF where $\xi(x)$ being a non-singular rational function of $x$ .

As a generally accepted rule, the more complex this vector is, the more conservative the results obtained. Hereafter we assume there exist DAR of $\xi(x)$ and $\dot{\xi}(x)$ defined as follows [2]:

$$\begin{cases} \xi(x) = E_1 x + E_2 \varsigma(x) \\ 0 = \Gamma_1(x) x + \Gamma_2(x) \varsigma(x) \end{cases} \tag{6}$$

$$\begin{cases} \dot{\xi}(x) = F_1 x + F_2 \chi(x, \dot{x}) \\ 0 = \phi_1(x)\dot{x} + \phi_2(x)\chi(x, \dot{x}) \end{cases} \tag{7}$$

where, $\varsigma(x) \in \Re^{n_\varsigma}, \chi(x, \dot{x}) \in \Re^{n_\chi}$ are nonlinear vector functions, $E_1 \in \Re^{n_\xi \times n}, E_2 \in \Re^{n_\xi \times n_\varsigma}, F_1 \in \Re^{n_\xi \times n}, F_2 \in \Re^{n_\xi \times n_\chi}$ are constant matrices, $\Gamma_1(x) \in \Re^{n_\phi \times n}, \Gamma_2(x) \in \Re^{n_\phi \times n_\varsigma}, \phi_1(x) \in \Re^{n_\phi \times n}, \phi_2(x) \in \Re^{n_\phi \times n_\chi}$ are affine matrix functions of $x$. The representation is called well defined if the following hypotheses satisfied: $\Gamma_2(x), \phi_2(x)$ have full column-rank for all $x \in D_x$.
Using Eq. (6) and Eq. (7) it comes,

$$V(x) = \begin{bmatrix} x \\ \varsigma(x) \end{bmatrix}^T \Delta P \begin{bmatrix} x \\ \varsigma(x) \end{bmatrix} \tag{8}$$

$$\begin{aligned} \dot{V}(x) &= \begin{bmatrix} \dot{x} \\ \dot{\varsigma}(x) \end{bmatrix}^T \Delta P \begin{bmatrix} x \\ \varsigma(x) \end{bmatrix} + \begin{bmatrix} x \\ \varsigma(x) \end{bmatrix}^T \Delta P \begin{bmatrix} \dot{x} \\ \dot{\varsigma}(x) \end{bmatrix} \\ &= 2 \begin{bmatrix} x \\ \varsigma(x) \end{bmatrix}^T \Psi P \begin{bmatrix} \dot{x} \\ \chi(x, \dot{x}) \end{bmatrix} \end{aligned} \tag{9}$$

with, $\Delta P = \begin{bmatrix} E_1^T P E_1 & E_1^T P E_2 \\ E_2^T P E_1 & E_2^T P E_2 \end{bmatrix}$,

$\Psi P = \begin{bmatrix} E_1^T P F_1 & E_1^T P F_2 \\ E_2^T P F_1 & E_2^T P F_2 \end{bmatrix}$

### B. Domain of Attraction

Domain of attraction (DA) can be described as those initial conditions in which the states converge towards equilibrium asymptotically [44], [46], [45]. According to the Lyapunov function introduced in the Section II-A we can estimate the domain of attraction. A region of attraction is given as follows;

$$J = \left\{ x \in D_x : \xi(x)^T P \xi(x) \leq 1 \right\} \tag{10}$$

where, $P \in \Re^{n\times n}$ is a positive definite matrix and $J$ is the normalised ellipsoid. When the condition $\dot{V}(x)$ hold for all $x(0) \in J$, the region $J$ can be represent an estimated domain of attraction for system (1), this means that any trajectory starting within $J$ will converge to the origin, without exiting $J$.

### C. Statement of the Generalized Sector-Based Constraint

Consider $H \in \Re^{1\times n}$ the row vector function and define the set below:

$$S = \{x \in \Re^n; |(K-H)x| \leq 1\} \tag{11}$$

when $x$ belongs to $S$, the relation can be stated as [5], then the deadzone nonlinearity $\psi(Kx)$ meets the following inequality which is valid for any positive scalar $\mu$.

$$\psi(Kx)^T \mu \left[\psi(Kx) - Hx\right] \leq 0 \tag{12}$$

Let the set $J$ and $S$ defined respectively in (10) and (11) and consider a matrix $C(x) \in \Re^{n_c\times(n+n_\xi)}$ affine in x, where $C(x)\left[\begin{array}{cc} x & \varsigma(x)\end{array}\right] = 0$. Let $S$ included in $J$. If a matrix $\Xi$ exists the following condition is satisfied:

$$\left[\begin{array}{cc} 1 & \left[\begin{array}{cc}(K-H) & 0\end{array}\right] \\ \left[\begin{array}{c} K^T - H^T \\ 0\end{array}\right] & \left(\sum(P) + NC(x) + C(x)^T N^T\right)\end{array}\right] \geq 0 \tag{13}$$

### D. Polytope in State Space

Let $D_x$ is given polytope (with $n_e$ vertices), which defines the intiales conditions and contains the origin. Therefore, the polytope can be defined as follows:

$$D_x = \left\{x \in \Re^n : a_i^T x \leq 1, i = 1, ....., n_e\right\} \tag{14}$$

with, the constant vectors $a_i \in \Re^n$ are defined such that $a_i^T x = 1$ for all groups of adjacent vertices.
Similarly, to the result of section II-C the set $J$ include in $D_x$ and a matrix $C(x)\left[\begin{array}{cc} x & \varsigma(x)\end{array}\right] = 0$, if the following condition is satisfied:

$$\begin{array}{l}\left[\begin{array}{cc} 1 & \left[\begin{array}{cc}-a_i^T & 0\end{array}\right] \\ \left[\begin{array}{c} -a_i \\ 0\end{array}\right] & \left(\Sigma(P) + RC(x) + C(x)^T R^T\right)\end{array}\right] \geq 0, \\ \forall k \in \{1, \ldots, n_e\}\end{array} \tag{15}$$

## III. Estimation of the Domain of Attraction using DAR Representation

### A. Differential Algebraic Representation DAR

Set the nonlinearity of the following dead zone [48]

$$\psi(u) = u - sat(u) \tag{16}$$

A nonlinear dead-zone $\psi(u)$ is defined in this work to justify the occurrence of the saturation nonlinearity. Taken into accounts, Eq. (16) the system Eq. (1) is presented as follows:

$$\left\{\begin{array}{l}\dot{x} = f(x) + g(x)u - g(x)\psi(u) \\ u = Kx\end{array}\right. \tag{17}$$

A nonlinear system can be described in many different representation. In this case, the system is represented by the differential algebraic representation (DAR). That is defined as follows:

$$\left\{\begin{array}{l}\dot{x} = A_1 x + A_2 z(x) + A_3 sat(Kx) \\ 0 = \pi_1 x + \pi_2 z(x) + \pi_3 sat(Kx)\end{array}\right. \tag{18}$$

where $z \in \Re^{n_z}$ signifies a nonlinear auxiliary vector pertaining to $x$, which includes the nonlinear elements in $f(x)$. $A_1 \in \Re^{n\times n}$, $A_2 \in \Re^{n\times n_z}$ and $A_3 \in \Re^{n\times 1}$ can be defined as constant matrices, and $\pi_1 \in \Re^{n_z\times n}$,$\pi_2 \in \Re^{n_z\times n_z}$,$\pi_3 \in \Re^{n_z\times n}$ represent the affine matrix functions pertaining to $x$. To ensure the differential algebraic representation is well determined and the solution $x$ is unique, the previous assumptions have been implemented. If $z$ is invisible, considering Eq. (18) we have that:

$$z(x) = -\pi_2^{-1}\left(\pi_1 x + \pi_3 sat(u)\right) \tag{19}$$

System (1) can be expressed as follows:

$$\dot{x} = (A_1 - A_2\pi_2^{-1}\pi_1)x + (A_3 - A_2\pi_2^{-1}\pi_3)sat(u) \tag{20}$$

As a result, the term $sat(u)$ can be substituted with Eq. (16), so the system Eq. (1) can be expressed in the following form:

$$\left\{\begin{array}{l}\dot{x} = (A_1 + BK)x + A_2 z(x) - B\psi(Kx) \\ 0 = (\pi_1 + \pi_3 K)x + \pi_2 z(x) - \pi_3\psi(Kx)\end{array}\right. \tag{21}$$

with, $B = A_3 \in \Re^{n\times 1}$.

### B. LMI Formulation

In this part of the study, we made a proposition for LMI condition development to ensure the Lypaunov function presented in Eq. (8). This LMI is attained by integrating the linear annihilator condition [10] and Finsler's lemma [47]. Thus, it is possible to define the solution of estimating the area of attraction with respect to LMIs that are state dependent as shown in the theorem given below.

For the system represented in Eq. (21), the Lypaunov function in Eq. (8) and its time derivative in Eq. (9) are considered first with, $\nu = \left[\begin{array}{cccc}\xi & \varphi & z & \psi(Kx)\end{array}\right]$

Than it comes:

$$\begin{array}{l}\frac{dV(x)}{dt} = \\ \left[\begin{array}{c}\xi \\ \varphi \\ z \\ \psi(Kx)\end{array}\right]\left[\begin{array}{cccc} 0 & \Psi P & 0 & 0 \\ \Psi P^T & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0\end{array}\right]\left[\begin{array}{c}\xi \\ \varphi \\ z \\ \psi(Kx)\end{array}\right]^T < 0\end{array} \tag{22}$$

According to the Section II-C if the relation in Eq. (12) is verified for any positive scalar such that

$$\frac{dV(x)}{dt} - 2\psi(Kx)^T \mu(\psi(Kx) - Qx) < 0 \tag{23}$$

Therefore (23) can be written as follows

$$\nu^T \Lambda \nu < 0 \tag{24}$$

$$\text{with, } \Lambda = \begin{bmatrix} 0 & \Psi P & 0 & \begin{bmatrix} \mu H^T \\ 0 \end{bmatrix} \\ \Psi P^T & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \begin{bmatrix} \mu H & 0 \end{bmatrix} & 0 & 0 & -\mu \end{bmatrix}$$

by exploiting the DAR's property of equality in Eq. (21), Eq. (6), Eq. (7) and the linear annihilator obtained by the formula [10] can be utilized to obtain that

$$\begin{bmatrix} L(x) & 0 & 0 & 0 \\ \Gamma_1(x) & \Gamma_2(x) & 0 & 0 \\ 0 & 0 & \phi_1(x) & \phi_2(x) \\ A_{cl} & 0 & -\mathrm{I}_n & 0 \\ \pi_1(x) + K\pi_3(x) & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ A_2 & -B \\ \pi_2(x) & \pi_3(x) \end{bmatrix} \begin{bmatrix} x \\ \varsigma(x) \\ \dot{x} \\ \chi(x, \dot{x}) \\ z \\ \psi(x) \end{bmatrix} = 0 \tag{25}$$

with, $A_{cl} = A_1 + BK$.

Using the Finsler's lemma[47] for Eq. (24), Eq. (25) such that:

$$\begin{bmatrix} 0 & \Psi P & 0 & \begin{bmatrix} \mu H^T \\ 0 \end{bmatrix} \\ \Psi P^T & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \begin{bmatrix} \mu H & 0 \end{bmatrix} & 0 & 0 & -\mu \end{bmatrix} + \tag{26}$$

$$MX(x) + X^T(x) M^T < 0,$$

$$\text{with, } L(x) = \begin{bmatrix} x_2 & -x_1 & 0 & \cdots & 0 \\ 0 & x_3 & -x_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & x_n & -x_{(n-1)} \end{bmatrix},$$

$$C(x) = \begin{bmatrix} L(x) & 0 \\ \Gamma_1(x) & \Gamma_2(x) \end{bmatrix}$$

**Theorem 1**

Consider the nonlinear system with saturating actuators given in Eq. (1) with $u(t) = Kx(t)$ and let $\xi(x)$ be a rational vector function in terms of $x$ with DAR of $\xi(x)$ and $\dot{\xi}(x)$ as given in Eq. (6) and Eq. (7) and lets define a polytope $D_x$. If there exists matrices $P = P^T, H, R, N, M$ and $\Upsilon$, of appropriate dimensions that satisfy the following LMIs for all $x \in \Theta(D_x)$. For instance, the following LMIs can be represented:

$$\Delta P + \Upsilon C(x) + C(x)^T \Upsilon^T > 0 \tag{27}$$

$$\begin{bmatrix} 1 & \begin{bmatrix} -a_i^T & 0 \end{bmatrix} \\ \begin{bmatrix} -a_i \\ 0 \end{bmatrix} & \Delta P + RC(x) + C^T(x) R^T \end{bmatrix} \geq 0 \tag{28}$$

$$\begin{bmatrix} 1 & \begin{bmatrix} K - H & 0 \end{bmatrix} \\ \begin{bmatrix} K^T - H^T \\ 0 \end{bmatrix} & \Delta P + NC(x) + C^T(x) N^T \end{bmatrix} \geq 0 \tag{29}$$

$$\begin{bmatrix} 0 & \psi P & 0 & \begin{bmatrix} H^T \mu \\ 0 \end{bmatrix} \\ \psi P & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \begin{bmatrix} H\mu & 0 \end{bmatrix} & 0 & 0 & -\mu \end{bmatrix} + MX(x) + \tag{30}$$

$$\mathrm{X}^T(x) M^T < 0$$

So, for all $x(0) \in J$, trajectory $x(t)$ belongs to $J$ and $V(x) = \xi(x)^T P \xi(x)$ in Eq. (5) is a Lyapunov function in $D_x$. Theorem 1 establishes a sufficient condition to guarantee that an $J$ formed by a Lyapunov function, is an domain of asymptotic stability for the closed loop system. Also, let try to find a domain estimate as large as possible. Therefore, the idea is to select among all possible feasible solutions for LMI in Eq. (27)-(30) the one that offers the largest possible set $J$, taking into account a volume size criterion. In the more general case described here, where the domain of attraction is an ellipsoid, a solution to the volume maximization problem can be directly addressed through the following optimization problem:

$$\begin{cases} Max\,(Vol) = \frac{1}{trace(P)} \\ subject\ to: (27) - (30) \end{cases} \tag{31}$$

The domain of attraction volume maximization cannot exist when parameters introduced in LMI are not well chosen. For example if we leave $\mu$ free, or badly chosen we lose the convexity of the conditions of Theorem 1 and consequently LMI does not give solutions from where it will not be feasible. On the other hand, the polytope search of admissible states gives the largest domain of the state space $D_x(a_1, a_2)$ so that the system is stable by solving Eq. (27-30), for an optimal pair $(a_1, a_2)$. In the end the attraction domain search will be bounded in the admission polytope by selecting the optimal Lyapunov function.

## IV. Main Results

In this section we develop an algorithm to expand the domain of attraction using the SBOA-based meta-heuristic method. This section introduces a strategy for selecting the right parameter $\mu$ to guarantee the convexity of theorem 1, the best pair $(a_1, a_2)$ to maximize the admissible polytope of the states and the right choice of the optimal Lyapunov function matrix $P$. Evalutionary tehniques are emloyed to determine the parameters $\mu$, and the coefficients of the Lyapunov function. The form of the candidate Lyapunov function defined by the user, and its corresponding domain are validated for and the LMIs of theorem 1, are feasible. In case these conditions are not met and the LMIs are not feasible, we repeatedly estimate the parameters in question and the coefficients of the Lyapunov function until the LMI optimization has a solution. The basis of this criterion is to obtain optimal parameters through the use of evolutionary algorithms.

### A. Proposed Method to Enlarging DA

*1) Secretary Birds Optimization Algorithm:* Secretary birds [53] are large, terrestrial birds of prey that generally found in tropical savannas or semi-desert regions. Secretary birds are perdators of snakes on the Arican continent including species like the black mamba and Cobra. The SBOA algorithm derives inpiration from the survival techniques of searching or prey and escaping tough ecologies. A secretary birds optimisation algorithm is created to handle complex optimisation challenges. The secretary brid's itelligence is showcased in its strategies for evading predators. The SBOA is composed of the following parts:

**Initiation Phase:** The first step in solving a typical minimization problem $f(x)$ is to determine the initial solutions that will be used to initiate the search. In the population, each individual represents a solution to the optimization problem and this solution is initialized according to the following equation:

$$X_j = lb + r \times (ub - lb), j = 1, 2, \ldots, N \tag{32}$$

where, $X_j$ is the postion of the $j^{th}$ $lb$ and $ub$ are the lower and upper bounds. $rand$ designates a random number in $[0, 1]$. $N$ is the dimension of the problem. In addition, the fitness value of the solution $X_i$ denoted as $F_i = f(X_i)$ is a measure of its quality.

**Hunting Strategy of Secretary Birds (Exploration step):** Contraty to the other fierce predators secretay birds employ a more intelligent strategy for hunting snakes. Therefore, the whole hunting process can be broken down into three steps, they include searching prey, consuming prey, and attacking prey.

- Searching prey: In this stage, secretary birds need seek prey while keeping a safe range. By referencing the positions of the others two secretary birds, the secretary brid can scout new potential areas. For this reason, the differential mutation operations are incoperated to maintain algorithm diversity. The position of each individual $X_i$ is updated using equations (33) and (34) when the current iteration time $t$ is smaller than one-third of the maximum iterations $T$.

$$X_t^{newP}(t) = X_t(t) + (X_{random_1}(t) - X_{random_2}(t)) \times R_1 \tag{33}$$

$$\begin{cases} X_t(t+1) = X_t^{newP}(t), & if \quad F_t^{newP} < F_i \\ X_t(t+1) = X_t(t), else \end{cases} \tag{34}$$

  Where, $R_1$ is a random vector consisting of $1 \times M$ elements chosen randoml from $[0, 1]$. $X_{random_1}, X_{random_2}$ represent two individuals randomly chosen from the present population.

- Consuming prey: When secretary brids identify potential prey their first action is to hover around the snake exhibiting aile footwork and maneuvers. Through observing and baiting opponents while circling, the prey's patience will be exhausted, causing it to lower its guard. Considering the current best individual as the prey, other secretary birds adjust their positions to move closer to it. In this stage, we use Brownian motion (RB) to simulate a random movement of the secretary birds such that is given by:

$$RB = randn(1, D) \tag{35}$$

  Hence, updating the secretary birds position during the consuming pery stage can be represented as follows:

$$X_t^{newP}(t) = X_{best}(t) + e^{\left(\frac{t}{T}\right)^4} \times (RB - 0.5) \times (X_{best}(t) - X_t(t)) \tag{36}$$

$$\begin{cases} X_t(t+1) = X_t^{newP}(t), & if \quad F_t^{newP} < F_t \\ X_t(t+1) = X_t(t), else \end{cases} \tag{37}$$

  where, $X_{best}$ represent the best solution for the current population.

- Attacking prey: When, the prey well exhausted, so it the time to start the attack. Here the secretary brid used the Levy flight approach. Therefore, the characteristics of this stage are describe by the following Eq. (38), (39)

$$X_t^{newP}(t) = X_{best}(t) + \left(\left(1 - \frac{t}{T}\right)^{\frac{2 \times t}{T}}\right) \times X_t(t) \times RL \tag{38}$$

$$\begin{cases} X_t(t+1) = X_t^{newP}(t), if \quad F_t^{newP} < F_t \\ X_t(t+1) = X_t(t), else \end{cases} \tag{39}$$

  where $RL$ represents a random movement(the levy fight representation) which is defined as follows:

$$RL = 0.5 \times Levy(M) \tag{40}$$

**Escape Strategy for Secretary Birds (Exploitation step):** In nature the main enemies of secretary bird are large predators. Such as eagles, hawks, foxes, and jackals, which may attack them or steal their food. In this cas we proposed two categories:

- Camouflage based on environment: When secretary birds are confronted by enemies, their first strategy is to camouflage themselves in order to avoid danger. The secretary birds modify their positions around the prey (which represents the best individual) reflecting the behavior of attempting to evade local optimal algorithms. The following Eq. (41),(42) present the mathematical model of this approach.

$$\mathrm{X}_t^{newP}(t) = \mathrm{X}_{best}(t) + (2 \times RB - 1) \times \left(1 - \tfrac{t}{T}\right)^2 \times \mathrm{X}_t(t) \tag{41}$$

$$\begin{cases} X_t(t+1) = X_t^{newP}(t), if \quad F_t^{newP} < F_t \\ X_t(t+1) = X_t(t), else \end{cases} \tag{42}$$

  Where,$\left(1 - \frac{t}{T}\right)^2$ is a disturbance factor that helps to strike a balance between exploration (seeking new solutions) and exploitation (using known solutions).

- Running mode: Then in this step, if they can't avoid they enem we use the approach of flight or rapid running to maintain their saftey. Secretary brid updated their new position by using the following equation

$$X_t^{newP}(t) = X_{best}(t) + R_2 \times (X_{rand}(t) - K \times X_t(t)) \tag{43}$$

$$\begin{cases} X_t(t+1) = X_t^{newP}(t), if \quad F_t^{newP} < F_t \\ X_t(t+1) = X_t(t), else \end{cases} \tag{44}$$

In a SBOA, the main operation involves computing the fitness function. Therefore the quality of the particle is evaluated using its objective function, the goal being to maximize it.

$$v = \frac{1}{trace(P)} \tag{45}$$

To achieve this objective, a meta-heuristic technique is used. We developed a technique to expand the DA by integrating the SBO algorithm and an LMI technique to ensure the computing of the maximal LF defined in Eq. (4). In this work we estimate again by SBOA $\mu$ and the values of the vertices $a_1$ and $a_2$ to expand the domain of attraction defined by Eq. (10).

$$\begin{cases} Max(Vol(J)) = \frac{1}{trace(P)} \\ s.t: \begin{cases} \min \ \theta \\ s.t: LMI \ (27)-(30), \ a \quad feasible \quad solution \\ \theta - trace\left(\Delta P + \Upsilon C(x) + C(x)^T \Upsilon^T\right) > 0 \end{cases} \end{cases} \tag{46}$$

The designed approach is synthesized in the following flowchart depicted in the Fig. 1.

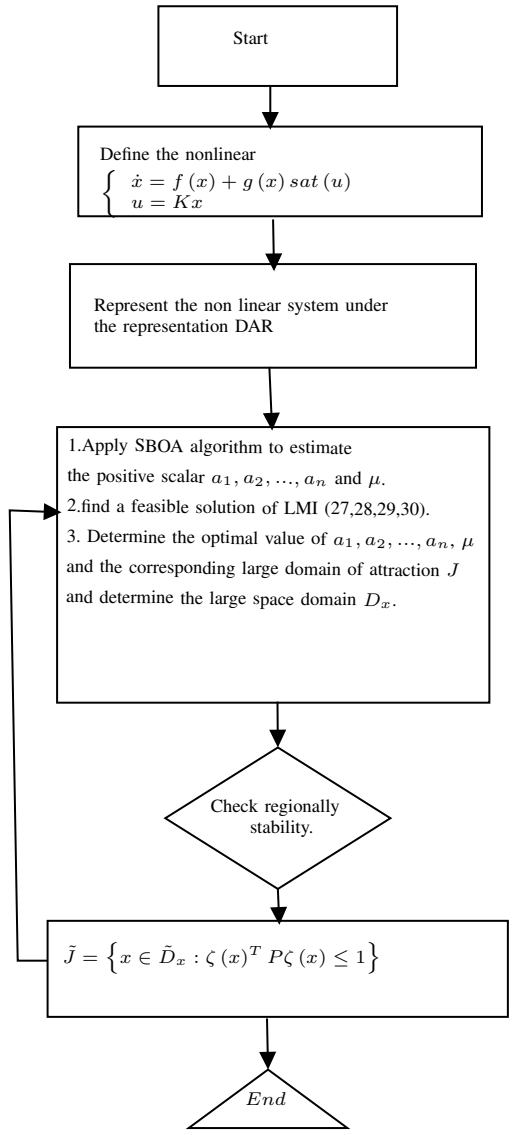

Fig. 1. Flowchart of the meta-heuristic technique for estimating the DA of a nonlinear system with input saturation.

## V. Numerical Examples

In this section, numerical examples are presented to verify the effectiveness of the proposed approach. The conditions introduced in this paper were implemented in MATLAB (R2015) using the parser Yalmip and the solver SDPT3.

*Example 1*

Consider a nonlinear system with saturated input given by [2]:

$$\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = (1+x_1^2)x_1 + (2+8x_2^2)x_2 + sat(u) \\ u = Kx \end{cases} \tag{47}$$

The state is $x = \begin{bmatrix} x_1 & x_2 \end{bmatrix}^T$ and the control input is $u(t) = -2x_1(t) - 4x_2(t)$. In this paper, we search for the Lyapunov function that stabilizes the system asymptotically, minimizes the cost function represented by the trace of Matrix P definite positive, and has the largest estimation of the DA of system (47) in a closed loop. We use the proposed method for example 1. Note that, $D_x(a_1, a_2) := \left\{x \in \Re^2 : |x_1| \leq a_1, |x_2| \leq a_2\right\}$ is a state admissible, with $a_1, a_2$ tow positive predefined scalars. First, we reformulate the system (47) in the DAR form. Then, by applying the equation (16)-(18), a DAR of this system is given by:

$$\begin{cases} \dot{x} = (A_1 + BK)x + A_2 z(x) - B\psi(Kx) \\ 0 = (\pi_1 + \pi_3 K)x + \pi_2 z(x) - \pi_3 \psi(Kx) \end{cases} \tag{48}$$

where, $z = \begin{bmatrix} x_1^2 & x_2^2 & x_1^3 & x_2^3 \end{bmatrix}^T$, $A_{cl} = A_1 + BK$, $A_3 = B$,

$$A_{cl} = \begin{bmatrix} 0 & 1 \\ -1 & -2 \end{bmatrix}, A_2 = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 8 \end{bmatrix}, B = \begin{bmatrix} 0 \\ 1 \end{bmatrix},$$

$$\pi_1 = \begin{bmatrix} x_1 & 0 \\ 0 & x_2 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}, \pi_2 = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ x_1 & 0 & -1 & 0 \\ 0 & x_2 & 0 & -1 \end{bmatrix}, \pi_3 = 0$$

As a means of evaluating the stability of the system, two distinctive Lyapunov functions are taken. First, the quadratic Lyapunov

function is analyzed:

$$V_1(x) = \xi_1^T(x) P_1 \xi_1(x) \tag{49}$$

Second a polynomial Lyapunov function is considered:

$$V_2(x) = \xi_2^T(x) P_2 \xi_2(x) \tag{50}$$

where $\xi_1(x) = x$, $\xi_2(x) = \begin{bmatrix} x_1^2 & x_1x_2 & x_2^2 & x_1 & x_2 \end{bmatrix}^T$. $P_1 \in \Re^{2\times 2}$ and $P_2 \in \Re^{5\times 5}$ are two symmetric matrices to be computed. The polynomial LF calculation requests the decomposition of $\xi_2(x)$ and $\dot{\xi}_2(x)$ as stated below.

$$\begin{cases} \xi_2(x) = E_1 x + E_2 \varsigma(x) \\ 0 = \Gamma_1(x)x + \Gamma_2 \varsigma(x) \\ \dot{\xi}_2(x) = F_1 \dot{x} + F_2 \chi(x,\dot{x}) \\ 0 = \phi_1(x)\dot{x} + \phi_2 \chi(x,\dot{x}) \end{cases}, \tag{51}$$

where, $\varsigma(x) = \begin{bmatrix} x_1^2 & x_1x_2 & x_2^2 \end{bmatrix}^T$, $E_1 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{bmatrix}$,

$$E_2 = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \Gamma_1(x) = \begin{bmatrix} x_1 & 0 \\ 0 & x_1 \\ 0 & x_2 \end{bmatrix},$$

$$\Gamma_2 = \begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}, \chi(x,\dot{x}) = \begin{bmatrix} x_1\dot{x}_2 \\ x_1\dot{x}_2 \\ x_2\dot{x}_1 \\ x_2\dot{x}_2 \end{bmatrix},$$

$$F_1 = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{bmatrix}, F_2 = \begin{bmatrix} 2 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 2 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix},$$

$$\phi_1(x) = \begin{bmatrix} x_1 & 0 \\ 0 & x_1 \\ x_2 & 0 \\ 0 & x_2 \end{bmatrix}, \phi_2 = \begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}$$

the optimization problem (46) was solved to obtain the largest admissible polytope in state space and that maximizes the domain of attraction. The Fig. 2 shows the dynamic of the cost function. The optimal domain is obtained as:

$$\begin{cases} (a_1, a_2) = \begin{bmatrix} 0.51233 & 0.32322 \end{bmatrix} \\ P_{opt} = \begin{bmatrix} 4.6221 & 3.0714 \\ 3.0714 & 11.6130 \end{bmatrix}, \\ \theta = 16.2351 \end{cases} \tag{52}$$

Fig. 3 shows the evolution of the DA for the system Eq. (47) using SBOA approach. Fig. 4 represents the dynamic of the state space initialized from the tangency point state locus and the evolution of the input control of the system.

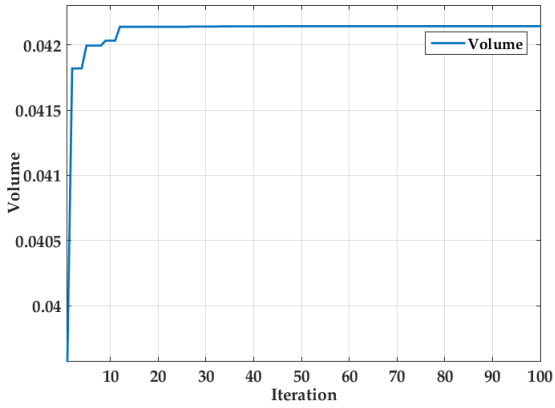

Fig. 2. Dynamic of the cost function using the SBOA approach for system (47) for obtain the optimal value of $\mu$.

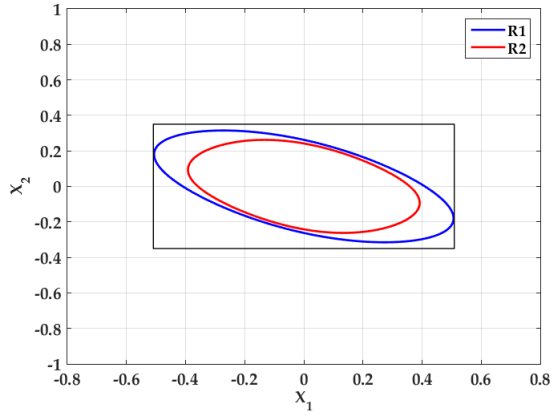

Fig. 3. Approximation of the DA for the system Eq. (47) using quadratic LF (Blue ellipsoid using SBOA technique - red ellipsoid analytical technique).

*Example 2*

Considering a single-link robot arm in [50]

$$\ddot{\theta}(t) = -\frac{Mgl}{J}\sin(\theta) - \frac{D}{J}\dot{\theta} + \frac{1}{J}u \tag{53}$$

where,

- $\theta$ is the angle position of the arm
- $u$ is the input control.
- $M$ is the mass of the poyload.
- $J$ is the moment of inertia.
- $g$ is the acceleration of gravity and $l$ is the length of the arm.

Assume, $x_1 = \theta, x_2 = \dot{\theta}$ then we obtain the following state space model of the robotic arm manipulator

$$\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = -\frac{Mgl}{J}\sin(x_1) - \frac{D}{J}x_2 + \frac{1}{J}u \\ y = x \end{cases} \tag{54}$$

Then the values parameters for robotic arm are given by: $g = 9.81$, $l = 0.5$, for this work we consider the nominal value of $D =$

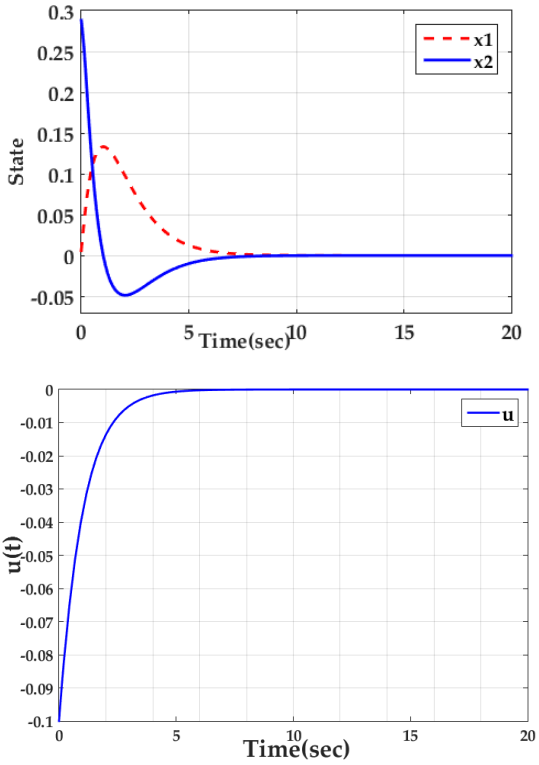

Fig. 4. Results of simulations for example 1: states dynamics and control input.

$D_0 = 2$ and for $J$ and $M$ we consider the mode 1 so $M = J = 1$, With this parameters chosen we obtain the following representation.

$$\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = -4.905 \times \sin(x_1) - 2 \times x_2 + u \\ y = x \end{cases} \tag{55}$$

Using the Taylor series $\text{atsin}(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \cdots$ then in this work we stop at $n = 3$ therefore $\sin(x) = x - \frac{x^3}{3!}$. Then, we obtain the following state-space:

$$\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = -4.905 \times x_1 + \frac{4.905}{6} \times x_1^3 - 2 \times x_2 + u \\ y = x \end{cases} \tag{56}$$

This example cannot be applied with this approach because the absence of any indication for the command $u$. Where, $u = k_1 x_1 + k_2 x_2$ to find the parameters of the command $u$ we want to apply Chesi 2004 [51]. Therefore, we linearize in the vicinity of the equilibrium to establish a Lyapunov function LF:

$$A = \frac{\partial f}{\partial x}\bigg\|_{(0,0)} = \begin{bmatrix} 0 & 1 \\ -4.905 & -2 \end{bmatrix} \tag{57}$$

Then, for determine the matrix $P$ we used this equation: $A^T P + PA = -Q$ with $Q = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$. Such that, we obtain the following matrix $P$

$$P = \begin{bmatrix} 1.68 & 0.102 \\ 0.102 & 0.301 \end{bmatrix} \tag{58}$$

with $V(x) = 1.68x_1^2 + 0.204x_1x_2 + 0.301x_2^2$ and the controller class defined by $\phi(y) = y$,
$\Im = \left\{U = \begin{bmatrix} u_1 & u_2 \end{bmatrix} : u \in \begin{bmatrix} -1 & 1 \end{bmatrix}\right\}$. Let us examine the structure of the GEVP introduced in [51]. The degree of $\dot{V}$ denoted as $\delta_d$ is 4. As a result, $\delta_s$ can be chosen as follows: $\delta_s = 1$, so $m = 2$ and $x^{\{\delta_v\}} = x^{\{\delta_s\}} = \begin{bmatrix} x_1 & x_2 \end{bmatrix}^T, x^{\{m\}} = \begin{bmatrix} x_1x_2 x_1^2 x_1x_2 x_2^2 \end{bmatrix}^T$, it is found that

$$D_f(\alpha) = \begin{bmatrix} -1.0006 & -4 \times 10^{-4} & 0 & \alpha_1 & \alpha_2 \\ -4 \times 10^{-4} & -1 & -\alpha_1 & -\alpha_2 & 0 \\ 0 & -\alpha_1 & 0.2501 & 0.2460 & \alpha_3 \\ \alpha_1 & -\alpha_2 & 0.2460 & -2\alpha_3 & 0 \\ \alpha_2 & 0 & \alpha_3 & 0 & 0 \end{bmatrix},$$

$$D_g(U) = \begin{bmatrix} 0.204u_1 & 0.301u_1 + 0.102u_2 \\ 0.301u_1 + 0.102u_2 & 0.602u_2 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

In order to compute $W(S)$, let's note that $V = I_2$. Therefore, we have that $s = \begin{bmatrix} s_1 & s_2 \\ s_2 & s_3 \end{bmatrix}$,

$$K = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix},$$

$$W(S) = \begin{bmatrix} s_1 & s_2 & 0 & 0 & 0 \\ s_2 & s_3 & 0 & 0 & 0 \\ 0 & 0 & \tau s_1 & \tau s_2 & 0 \\ 0 & 0 & \tau s_2 & \tau(s_1 + s_3) & \tau s_2 \\ 0 & 0 & 0 & \tau s_2 & \tau s_3 \end{bmatrix}$$

$$W_2(S) = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1.68s_1 \\ 0 & 0 & 0.84s_2 + 0.102s_1 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0.84s_2 + 0.102s_1 & 0 \\ 1.68s_3 + 0.408s_2 + 0.301s_1 & 0.102s_3 + 0.302s_2 \\ 0.102s_3 + 0.302s_2 & 0.301s_3 \end{bmatrix}$$

The obtained input control $u$ is given by: $u = -0.5043x_1 - 0.2863x_2$. In this step, we want to apply our proposal and given the DAR representation Eq. (21) with the auxiliary vector $z = x_1^2$, we consider

$A_1 = \begin{bmatrix} 0 & 1 \\ -5.4093 & -2.2863 \end{bmatrix}, A_2 = \begin{bmatrix} 0 \\ x_1 \end{bmatrix}, A_3 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \pi_1 = \begin{bmatrix} x_1 & 0 \end{bmatrix}, \pi_2 = -1$ and $\pi_3 = 0$.

To analyze the stability, we consider a quadratic Lyapunov function. SBOA is implemented with (maximum number of iterations 100 and the swarm size is 30). To obtain the optimal value of $\mu$, $(a_1, a_2)$. Fig. 5 present the evolution of the SBOA process for 100 iterations.

$$\begin{cases} (a_1, a_2) = \begin{bmatrix} 1.4221 & 2 \end{bmatrix} \\ P_{opt} = \begin{bmatrix} 0.6106 & 0.1142 \\ 0.1142 & 0.2714 \end{bmatrix} \\ \theta = 0.8819 \end{cases} \tag{59}$$

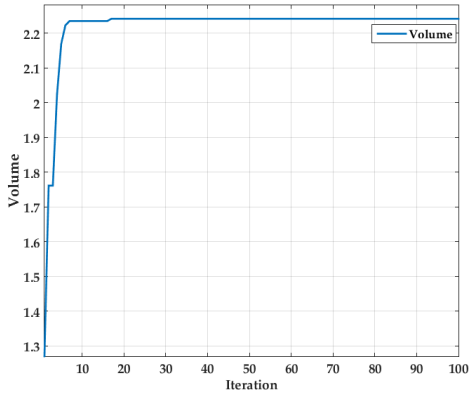

Fig. 5. Dynamic of cost function volume using the SBOA approach for nonlinear system to obtain the optimal value of $\mu$.

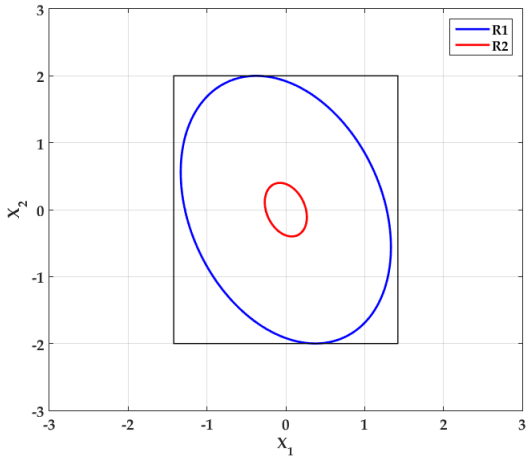

Fig. 6. Estimation of the DA for system Eq. (54) using quadratic LF (Blue ellipsoid using SBOA technique-Red ellipsoid using analytical technique).

The largest DA is represented by the blue ellipsoid in Fig. 6. Fig. 7 presents the evolution of the state space and the input control.

## VI. Discussion

This section seeks to compare the advantages of the current work's strategy with those of works presented in study [12] and study [2] as part of a bench-marking study. Table I summarizes the different results achieved for four dynamic nonlinear systems taking into account input saturation. The implementation of the SBOA method incorporates both quadratic Lyapunov functions. In this study, obtaining the maximum volume of the region of attraction serves as the primary criterion for evaluation. As far as the domain of attraction values are concerned, the results obtained are clearly superior. DA features are shown in table I for four nonlinear dynamic systems with quadratic Lyapunov functions. Systems of E1, E2 and E3 are second-order systems. However, E4 is a nonlinear third order system.

TABLE I. Summary of the Bench-Marking Comparative Study

| Example | System dynamic | Lyapunov Function | Estimation of DA | | Estimation of DA with SBOA | |
|---|---|---|---|---|---|---|
| | | | Polytope | Volume | Volume | Polytope |
| E1[12] | $\begin{cases} \dot{x}_1 = -2x_1 + x_1x_2 \\ \dot{x}_2 = x_1 + x_2 + x_1x_2 + sat(u) \end{cases}$ | Quadratic | $\begin{vmatrix} x_1 \\ x_2 \end{vmatrix} \vee \begin{vmatrix} 0.7, \\ 0.7 \end{vmatrix}$ | $v = 0.2421$ | $\begin{vmatrix} x_1 \\ x_2 \end{vmatrix} \vee \begin{vmatrix} 1.1889, \\ 0.80046 \end{vmatrix}$ | $v = 0.3251$ |
| E2[12] | $\begin{cases} \dot{x}_1 = \frac{1+x_1^2}{2}x_2 \\ \dot{x}_2 = \frac{2}{1+x_1^2}x_1 - x_2 - \frac{1-x_1^2}{1+x_1^2}sat(u) \end{cases}$ | Quadratic | $\begin{vmatrix} x_1 \\ x_2 \end{vmatrix} \vee \begin{vmatrix} 0.4, \\ 0.6 \end{vmatrix}$ | $v = 0.1024$ | $\begin{vmatrix} x_1 \\ x_2 \end{vmatrix} \vee \begin{vmatrix} 0.44745, \\ 0.94678 \end{vmatrix}$ | $v = 0.1116$ |
| E3 [52] | $\begin{cases} \dot{x} = \begin{bmatrix} 01 \\ -\frac{c_3}{M} - \frac{c_1+c_2x_1^2}{M} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} 0 \\ \frac{1+c_4x_2^2}{M} \end{bmatrix} u, \\ y = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} \end{cases}$ | Quadratic | $\begin{vmatrix} x_1 \\ x_2 \end{vmatrix} \vee \begin{vmatrix} 0.45, \\ 0.32 \end{vmatrix}$ | $v = 0.0679$ | $\begin{vmatrix} x_1 \\ x_2 \end{vmatrix} \vee \begin{vmatrix} 01.5, \\ 1.4018 \end{vmatrix}$ | $v = 1.0489$ |
| E4[28] | $\begin{cases} \dot{x}_1 = x_2 \\ \dot{x}_2 = \varepsilon_1 x_2 + \varepsilon_2 \tau_1 + \eta_1 \\ \dot{x}_3 = \cos x_1 x_2 \\ 0 = \tau_1 - \varepsilon_4 x_3 - \varepsilon_5 \cos x_1 \\ 0 = x_3^2 + \cos x_1^2 - 1 \end{cases}, x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix}$ | Quadratic | $\begin{vmatrix} x_1 \\ x_2 \\ x_3 \end{vmatrix} \vee \begin{vmatrix} 1.1 \\ 1.1 \\ 8 \end{vmatrix}$ | $v = 0.0769$ | $\begin{vmatrix} x_1 \\ x_2 \\ x_3 \end{vmatrix} \vee \begin{vmatrix} 1.4984 \\ 1.5 \\ 2 \end{vmatrix}$ | $v = 0.2033$ |

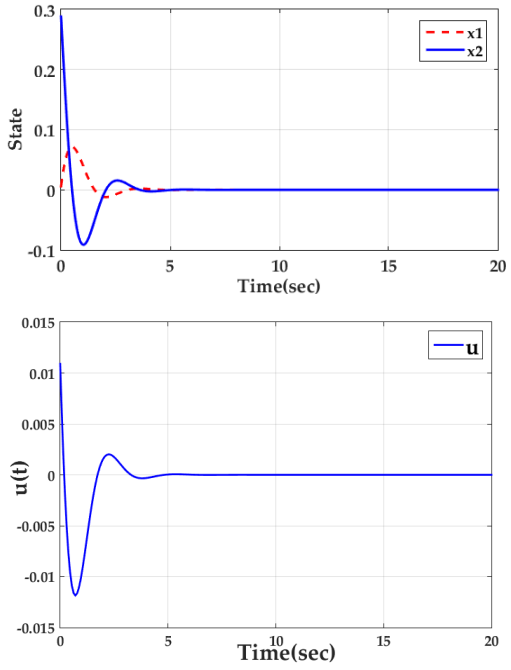

Fig. 7. Simulation results of example 2: states and input control.

The example 5.1 illustrates the advantage of a polynomial Lyapunov function over a quadratic Lyapunov function. Please be aware that the domain of volume serves as the primary evaluation factor. For each example, going through three stages using the SBOA approach, and comparing the results obtained by the technique presented in study [2].

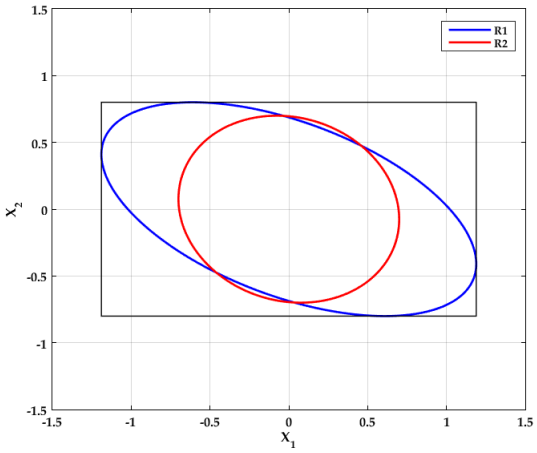

Fig. 8. DA that is approximation based on the SBOA approach for the origin in case E1 that is listed in Table I.

Fig. 8, 9, 10 and 11 illustrates the approximate domain of attraction for example E1-E4 described in Table I. The blue ellipsoid illustrates the estimated DA as determined by the SBOA method, while the red ellipsoid illustrates the estimated DA as determined by the approach described in study [2]. As a result, Fig. 12, 13, 14 and 15 depict the dynamic of state variables and their control inputs for each of the examples in Table I. A stable equilibrium point can be established asymptotically by the state variables. In this regard,

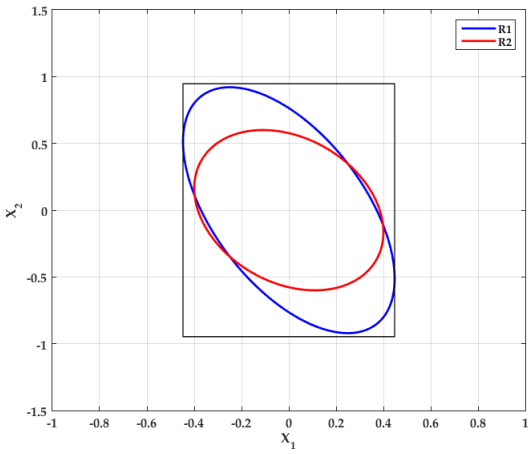

Fig. 9. DA that is approximation based on the SBOA approach for the origin in case E2 that is listed in Table I.

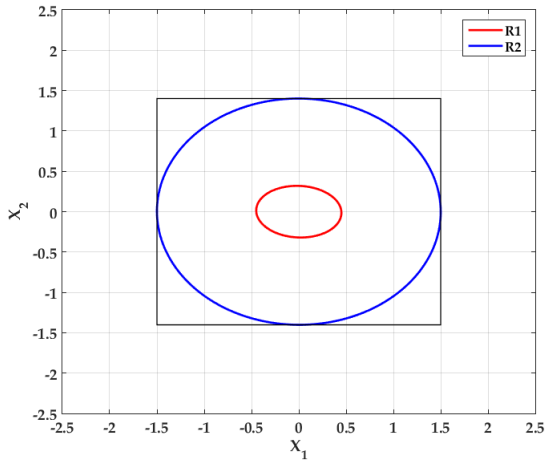

Fig. 10. DA that is approximation based on the SBOA approach for the origin in case E3 that is listed in Table I.

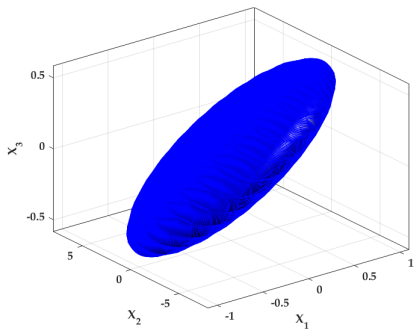

Fig. 11. DA that is approximation based on the SBOA approach for the origin in case E4 that is listed in Table I.

the strategy developed offers a complete solution that begins by guaranteeing the local stability of the system, then estimates the states admissible, and finally provides the maximal domain volume possible.

Furthermore, Table I clearly illustrates that, for the four examples studied, the SBOA technique yields significantly better estimates of the basin of attraction than the approach presented in study [2].

## VII. Conclusion

This paper discusses the concept of combining analytical and meta-heuristic approaches. This approach improve the performance of practical engineering systems using hybrid optimization techniques. Under the constraint of actuator saturation, the proposed method ensures high stability and efficiency. Among the fields of robotics and control, this is a well-known and sensitive issue. As a result, it is established that the developed technique maintains this feature and

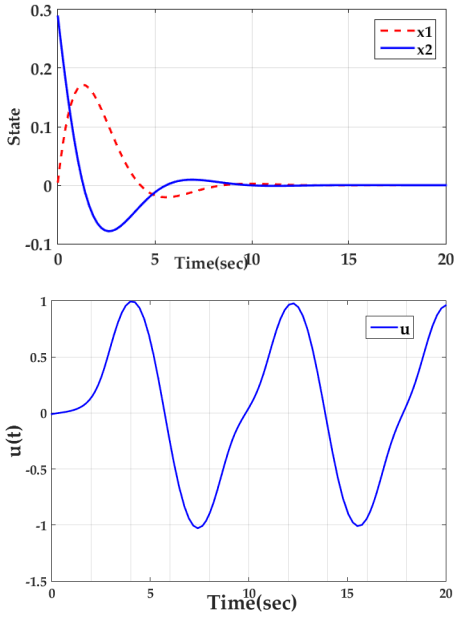

Fig. 14. Simulation results of E3; states and input control.

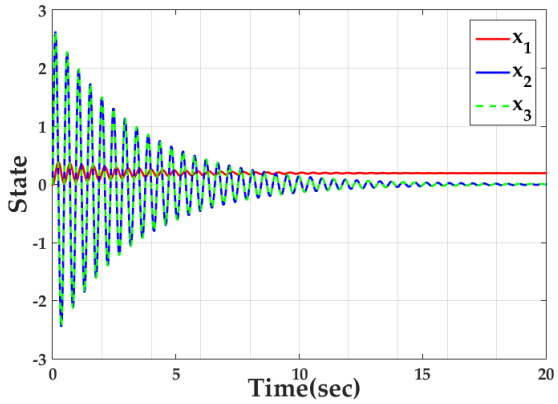

Fig. 15. Simulation results of E4; states.

ensures the reliability of controlled systems. Particularly, the method has been proven effective in controlling robot actuators. The study focuses on the maximization of the attraction region. Furthermore, the attraction region that is studied is deducible by the defined state space polytopic regions. The main idea is to combine the generalized sector condition, with the Finsler lemma and linear annihilator in order to reduce the conservativeness. The designed outline presented in this research relied on the central idea of computing best vertices of the polytypic and determining the associated optimal Lyapunov function to find the largest attraction region. To obtain the largest domain of attraction we implemented a meta-heuristic approach, with encoding the variable of the vertices of the polytope of admissible state to be determined as particle position was presented. The meta-heuristic technique introduced in this study is powerful in problem solving, and a very efficient global search algorithm. As well as the result, the numerical example shows that using meta-heuristic leads to the biggest DA. A novel perspective on the enlarging of the DA could be performed by implementing meta optimization method for tuning the controller gains of nonlinear system with input saturation and model parameter uncertainties.

# Optimizing Data Transmission and Energy Efficiency in Wireless Networks: A Comparative Study of GA, PSO, and Hybrid Approaches

Suhare Solaiman
Department of Computer Science-College of Computers and Information Technology, Taif University
P.O. Box 11099, Taif 21944, Saudi Arabia

***Abstract*—As wireless communication technology evolves, efficient resource allocation in Orthogonal Frequency Division Multiple Access (OFDMA) networks is becoming more important. This study looks at three resource allocation algorithms: Genetic Algorithms (GA), Particle Swarm Optimization (PSO), and a hybrid approach that combines both. The hybrid algorithm takes advantage of the strengths of both methods to improve data transmission and energy efficiency. Using simulations in MATLAB, the study assesses algorithms based on key metrics such as data rate, energy consumption, and computational complexity. The findings show that the hybrid approach generally performs better than both GA and PSO, especially in maximizing data rates. This research offers useful information for network operators looking to implement effective resource management strategies in practical wireless communication settings.**

***Keywords*—Resource allocation; optimization; genetic algorithms; particle swarm optimization; hybrid algorithm**

## I. Introduction

As wireless communication technology rapidly evolves, the importance of efficient resource allocation has increased. Orthogonal Frequency Division Multiple Access (OFDMA) networks are the foundation of modern communication, enabling everything from our smartphones to high-speed Internet connections. OFDMA divides the available bandwidth into multiple distinct subcarriers, allocating a unique set to each user. This separation allows users to communicate simultaneously without interference, ensuring a seamless and efficient experience [1] [2].

OFDMA is commonly used in various wireless communication standards, including WiMAX, LTE, and 5G networks. It effectively manages bandwidth, allowing multiple users to connect at the same time while keeping latency low and throughput high. By dynamically allocating subcarriers based on user demand and channel conditions, OFDMA improves overall network performance. This makes it a practical choice for modern networks, where reliable connections for activities, such as video streaming and online gaming are increasingly important [3].

In a world where staying connected is essential, the task of effectively distributing limited resources, such as bandwidth and power, has become more complicated than ever. Energy efficiency plays an important role, helping to lower operational costs for network providers, extend battery life for mobile devices, and reduce the environmental impact of increased technology use. Optimizing resource allocation is increasingly seen as both a practical necessity and a responsible choice. Implementing energy-efficient practices can help reduce carbon footprints and support efforts to address climate change.

To address these challenges, a variety of algorithms are adopted, each offering unique strengths and tailored solutions for resource allocation. For instance, the Water-Filling Algorithm is recognized as a fundamental method for distributing power according to the varying channel conditions of different users. This algorithm efficiently allocates power to users with better channel quality, thereby maximizing overall system performance [4] [5]. In addition, the Bisection Algorithm plays a crucial role by systematically narrowing the search for optimal solutions, ensuring effective and efficient resource utilization. Maintaining high quality of service is especially important in crowded networks as the number of connected devices and bandwidth demands increase [6] [7].

Adaptive resource allocation challenges can also be addressed using heuristics such as Genetic Algorithm (GA) [8] and Particle Swarm Optimization (PSO) [9]. GA draws inspiration from natural processes, beginning with a set of potential solutions that are refined over time through selection, crossover, and mutation. As these solutions evolve across multiple generations, they continuously improve, making GA particularly effective for complex problems that traditional methods may struggle to solve [10] [11]. On the other hand, PSO mimics the collective behavior of birds and fish. In this approach, each *particle* represents a potential solution that navigates the solution space based on its own experiences and those of its neighbors. The position of a particle is adjusted according to two factors: the best solution it has discovered and the locations of its neighbors. This collaborative effort enables PSO to explore the solution space effectively, often leading to optimal solutions in complex scenarios [12] [13]. The hybrid approach combines the evolutionary characteristics of GA with the collaborative search capabilities of PSO, resulting in a more robust and efficient method for optimizing data transmission and energy efficiency in OFDMA networks [14] [15].

In this study, a comprehensive comparison of three resource allocation algorithms is presented: GA, PSO, and a hybrid method that effectively combines the strengths of both GA and PSO. The evaluation will focus on key performance metrics such as data rate, energy consumption, and time complexity. By analyzing these algorithms across a range of scenarios, the study aims to identify the best algorithm in terms of data rates and energy consumption. The findings seek to bridge the gap

between theoretical models and practical applications, offering information that can enhance the operational efficiency of wireless networks. As the industry encounters increasingly complex and demanding environments, understanding how to optimize resource allocation will be essential for ensuring sustainable, high-quality service delivery. This research will contribute to informed decision making and strategic planning in resource management, ultimately supporting the evolving needs of modern communication systems.

### A. Contributions

This work offers several key contributions to the field of wireless communication:

- A comparative evaluation of three existing algorithms, GA, PSO, and a hybrid algorithm that combines GA and PSO, is presented to optimize data transmission and energy efficiency in wireless networks, highlighting their respective advantages and limitations.
- The preliminary results indicate that the proposed hybrid protocol outperforms the individual algorithms in key metrics, such as data rate and energy consumption, suggesting a more efficient use of resources.
- The findings provide practical guidelines for network operators seeking to implement more effective resource management strategies in real-world wireless communication scenarios.

## II. System Model and Problem Formulation

### A. System Model

In a single cell, there exists a collection of User Equipment (UE) devices that are tasked with transmitting data. Each device operates under specific power constraints, limiting the amount of transmit power it can utilize. In addition, these devices are allocated a portion of the available bandwidth, which restricts their data transmission capacity.

At the core of this network is a base station responsible for receiving data from all UE devices. This base station not only facilitates communication between the devices but also operates under its own set of power and bandwidth constraints, ensuring efficient data handling and network performance. To enhance this performance, OFDMA is utilized in this network. OFDMA allows multiple users to share the same frequency band by dividing it into numerous orthogonal subcarriers, enabling simultaneous transmission without interference. This approach optimizes bandwidth usage and improves overall system capacity, making it particularly effective in environments with varying channel conditions.

Each UE device has a transmit power used for communication, which is determined by regulatory limits and device capabilities. A finite total bandwidth $B_{\text{total}}$ is shared among all devices, necessitating effective scheduling and allocation methods to maximize throughput. OFDMA plays a crucial role in this allocation process, dynamically assigning subcarriers based on user demand and channel quality. Each device can transmit data for a certain time period, contributing to the overall energy consumption. This energy consumption is a critical factor, as it impacts the battery life of the devices and the overall sustainability of the network. Understanding the interplay of these constraints is essential for optimizing performance and ensuring reliable service delivery in wireless communication systems.

*1) Data transmission model:* The data rate for each device can be modeled using the Shannon capacity formula:

$$R_k = B_k \cdot \log_2 \left(1 + \frac{P_k}{N_0 \cdot B_k}\right), \tag{1}$$

where $R_k$ is the data rate of device $D_k$, $B_k$ is the bandwidth allocated to device $D_k$, $P_k$ is the power allocated to device $D_k$, and $N_0$ represents the spectral density of the noise power.

*2) Energy consumption:* The energy consumed by each device during transmission can be calculated as:

$$E_k = P_k \cdot T_k, \tag{2}$$

where $E_k$ is the energy consumed by device $D_k$ and $T_k$ is the transmission time for device $D_k$.

### B. Problem Formulation

The primary objective of the proposed resource allocation model is to maximize the total data rate across all devices while minimizing the overall energy consumption. This can be formulated as a multi-objective optimization problem:

$$\text{Maximize } \sum_{k=1}^{N} R_k - \lambda \sum_{k=1}^{N} E_k, \tag{3}$$

Subject to:

$$\text{C1: } \sum_{k=1}^{N} P_k \leq P_{\text{total}},$$
$$\text{C2: } \sum_{k=1}^{N} B_k \leq B_{\text{total}},$$
$$\text{C3: } \sum_{k=1}^{N} T_k \leq T_{\text{total}},$$

where where $N$ represents the total number of devices in the network. $R_k$ represents the data rate for device $D_k$; $P_k$ denotes the transmission power for device $D_k$; $T_k$ is the transmission time allocated for device $D_k$; $B_k$ is the bandwidth allocated to device $D_k$; and $h_k$ indicates the gain in the channel for device $D_k$. In constraint C1, the total power allocated to all devices should not exceed the maximum available power. In constraint C2, the total bandwidth allocated to all devices should not exceed the available bandwidth. In constraint C3, the total transmission time allocated to all devices must not exceed the maximum allowed transmission time.

The optimization problem here is mixed integer nonlinear programming (MINLP). Having integer and continuous decision variables leads to this classification. Mixing integers

means that some variables, such as the number of UE devices $N$, can have integer values, while others, such as power $P_k$, bandwidth $B_k$, and transmission time $T_k$, can have continuous values. Additionally, the objective function may include nonlinear relationships, such as maximizing total revenue minus a penalty for energy consumption. As a result, if any part of the objective function or constraints shows nonlinearity, the problem is classified as nonlinear. Due to this complexity, specialized algorithms are necessary for finding effective solutions.

## III. Optimization Techniques

To effectively solve the optimization problem defined in Eq. (3), population-based algorithms can be employed, including GA, PSO, and hybrid algorithm that combine the strengths of both GA and PSO.

### A. Resource Allocation Using GA

GAs utilize principles of evolution to optimize complex problems. They represent candidate solutions as chromosomes, employing a population-based approach where multiple solutions are evaluated concurrently. Each candidate solution is assessed based on an objective function, as defined in Eq. (3).

The selection process in GA strategically prioritizes fitter individuals, allowing them to pass advantageous traits to the next generation through mechanisms such as crossover (where parts of two parent solutions are combined) and mutation (where random alterations are made to a solution). This evolutionary strategy not only improves the quality of solutions, but also fosters genetic diversity within the population, which is essential to avoid local optima. To effectively manage constraints (C1, C2, and C3), GA often implements penalty functions. These penalties reduce the fitness scores of solutions that violate established constraints, thereby discouraging infeasible solutions. This mechanism promotes the exploration of viable solutions while ensuring a diverse search space. Such diversity is crucial for navigating complex non-linear optimization problems, enabling GA to discover high-quality solutions that satisfy all constraints.

A comprehensive overview of the processes involved in GA, including specific steps and methodologies, is shown in Table I.

TABLE I. Optimized Resource Allocation Using GA

**Input:**

- Population size $P$: Number of individuals in each generation.
- Number of generations $G$: Maximum iterations for the GA.
- Crossover rate $C_{\text{rate}}$: Probability of crossover between parents.
- Mutation rate $M_{\text{rate}}$: Probability of mutation for individuals.

**Output:**

- The best solution representing the optimal resource allocation with its fitness value.

1. **Initialize population:**
Each individual is represented by a random vector:

$$\text{individual}_i = \begin{pmatrix} P_1 & P_2 & \cdots & P_N \\ B_1 & B_2 & \cdots & B_N \\ T_1 & T_2 & \cdots & T_N \end{pmatrix} \tag{4}$$

2. **Evaluate Fitness:**
The fitness of each individual is evaluated based on the objective function:

$$\text{fitness}(\text{individual}_i) = \sum_{k=1}^{N} R_k - \lambda \sum_{k=1}^{N} E_k \tag{5}$$

Ensure that the individual satisfies the constraints $C_1, C_2$, and $C_3$. If constraints are violated, apply a penalty to the fitness score:

$$\text{fitness}(\text{individual}_j) = \begin{cases} \text{fitness}(\text{individual}_j) - P & \text{if constraints violated} \\ \text{fitness}(\text{individual}_j) & \text{otherwise} \end{cases} \tag{6}$$

3. **Selection:**

- Select parents based on fitness.
- Choose a predetermined number of parents to form a mating pool.

4. **Crossover:**

- For each pair of parents in the mating pool, generate $r$, which represents a random value generated uniformly within a specific range between $[0, 1]$.
- If $r < C_{\text{rate}}$, perform crossover to create offspring:

$$O = \begin{pmatrix} P_1[1:q] \\ P_2[q+1:N] \end{pmatrix} \tag{7}$$

where $q$ is a randomly chosen crossover point.

5. **Mutation:**

- Apply mutation to offspring based on the mutation rate:

$$O[j] = \begin{cases} O[j] + \Delta & \text{if } r < M_{\text{rate}} \\ O[j] & \text{otherwise} \end{cases} \tag{8}$$

where $\Delta$ is a random value drawn from a specified distribution. $j$-th offspring in the population array $O$.

6. **Evaluate offspring fitness:**

- For each offspring, calculate its fitness based on the resource allocation efficiency using equation (5).

7. **Replacement:**

- Form a new population by selecting the best individuals from both the current population and the new offspring.

8. **Termination:**

- If the maximum number of generations $G$ is reached or if a satisfactory solution (fitness) is found, stop the algorithm. Otherwise, return to step 3.

### B. Resource Allocation Using PSO

Social behaviors are replicated in PSOs by mimicking natural phenomena, such as flocks of birds or schools of fish. In this algorithm, particles represent potential solutions that dynamically adjust their positions in the search space based on both their individual experiences and the collective knowledge of the swarm. Each particle evaluates the objective function to determine its fitness, which guides its movement towards areas of higher quality solutions. The motion of a particle is influenced by two main factors: its previous best position and the best position found by any particle in the swarm. This dual influence allows PSOs to effectively balance exploration (searching new areas of the solution space) and exploitation (known good solutions). Additionally, when particle positions violate established constraints, PSOs typically employ strategies to either adjust the particles back into feasible regions or apply penalties that reduce their fitness scores. This penalty mechanism discourages the swarm from exploring infeasible solutions, thereby maintaining a focus on viable options. PSOs are particularly effective for continuous optimization problems, where the solution space is defined by real valued variables. The algorithm's inherent ability to adaptively explore while converging towards an optimal solution makes it suitable for a wide range of applications, including engineering design, machine learning parameter tuning, and resource allocation. Moreover, the simplicity of PSO, combined with its flexibility, allows it to be easily hybridized with other optimization techniques, further enhancing its performance in complex problem

TABLE II. OPTIMIZED RESOURCE ALLOCATION USING PSO

**Input:**

- Population size $P$: Number of particles in the swarm, determining the diversity of solutions.
- Maximum iterations $G$: The upper limit on the number of iterations for the PSO algorithm, defining its computational duration.
- Cognitive coefficient $c_1$: Weighting factor that influences how much each particle is attracted to its own best-known position.
- Social coefficient $c_2$: Weighting factor that influences how much each particle is attracted to the swarm's best-known position.

**Output:**

- The best solution found by the swarm along with its corresponding fitness value, indicating the effectiveness of the resource allocation.

1. **Initialize Swarm:**
Each particle $i$ is represented with a random position and velocity:

- The position vector for particle $i$ is defined as:

$$\mathbf{X}_i = \begin{pmatrix} P_1 & P_2 & \cdots & P_N \\ B_1 & B_2 & \cdots & B_N \\ T_1 & T_2 & \cdots & T_N \end{pmatrix} \tag{9}$$

  where $N$ is the number of devices or resources.
- The velocity vector for particle $i$ is defined as:

$$\mathbf{V}_i = \begin{pmatrix} v_{P1} & v_{P2} & \cdots & v_{PN} \\ v_{B1} & v_{B2} & \cdots & v_{BN} \\ v_{T1} & v_{T2} & \cdots & v_{TN} \end{pmatrix} \tag{10}$$

- Initialize each particle's best position $pbest_i$ to its initial position.

2. **Evaluate Fitness:**

- Calculate the fitness for each particle using the fitness function:

$$\text{fitness}(x_i) = \sum_{k=1}^{N} R_k - \lambda \sum_{k=1}^{N} E_k \tag{11}$$

  where $R_k$ represents the reward from resource $k$ and $E_k$ denotes the energy consumption.
- Update the particle's best position $pbest_i$ if the current position yields a better fitness value.
- Ensure that the constraints $C_1$, $C_2$, and $C_3$ are satisfied for each particle's position.

3. **Update global best:**

- Update the swarm's best position $gbest$ based on the best positions found by all particles.

4. **Update velocities and positions:**

- Update the velocity for each particle $i$:

$$v_i = w \cdot v_i + c_1 \cdot r_1 \cdot (pbest_i - x_i) + c_2 \cdot r_2 \cdot (gbest - x_i) \tag{12}$$

- Update the position for each particle $i$:

$$x_i = x_i + v_i \tag{13}$$

- Re-evaluate $C_1$, $C_2$, and $C_3$ after updating positions to ensure validity.

5. **Termination:**

- The algorithm stops if the maximum number of iterations $G$ is reached or if a satisfactory solution based on fitness is found.
- If neither condition is met, return to step 2 for further iterations.

domains.

A complete overview of the processes involved in PSO, including specific steps and methodologies, is illustrated in Table II.

### C. Resource Allocation using Hybrid Algorithm

In hybrid algorithm, GA and PSO are integrated to improve overall optimization performance. This combination leverages the strengths of both techniques: initial solutions are generated using genetic principles, which emphasize diversity and broad exploration, while subsequent refinements are achieved through swarm intelligence, which focuses on effective local search. By merging these two algorithms, hybrid algorithm can take advantage of the advantages of genetic operations, such as cross-linking and mutation, to explore a wide solution space. This broad exploration is critical for identifying promising regions in complex landscapes. Once potential solutions are identified, the dynamics of the swarm come into play, allowing for precise fine-tuning of these solutions based on the collective knowledge of the swarm. This dual approach improves the convergence speed and the quality of the solution. Moreover, the hybrid algorithm employs penalty mechanisms to handle constraint violations, similar to traditional GA and PSO. By discouraging infeasible solutions, this algorithm maintains a focus on viable options, ensuring that the search remains within the bounds of acceptable solutions. This capability is especially advantageous in complex optimization scenarios where constraints are stringent and multifaceted.

The hybrid approaches are particularly effective for tackling challenging optimization problems, as they can successfully navigate both local and global search spaces. The combination of exploratory genetic principles with the exploitative strengths of swarm intelligence enables this algorithm to escape local optima while still converging toward high-quality global solutions. This versatility makes the hybrid algorithm suitable for a wide range of applications, including engineering design, logistics, financial modeling, and machine learning, where the complexity of the problem demands a robust and adaptive optimization strategy.

A comprehensive overview of the processes involved in the hybrid approach, including specific steps and methodologies, is shown in Table III.

## IV. SIMULATION AND RESULTS

The network for the study was simulated using MATLAB, a widely used tool for numerical analysis and data visualization. GA, PSO, and the hybrid algorithm are implemented to assess their effectiveness in resource allocation. The simulation allowed for easy adjustment of parameters and visualization of results in real time, providing insights into network performance under different conditions.

The time complexities associated with solving the resource allocation problem in OFDMA networks vary significantly among the algorithms employed. The GA exhibits a time complexity of $O(P \cdot G \cdot N)$, where $P$ denotes the size of the population, $G$ represents the number of generations, and $N$ corresponds to the number of User Equipment (UE) devices. This complexity arises from the need to evaluate and evolve a population of candidate solutions over multiple generations, each requiring assessment of the fitness of $N$ devices. In parallel, the PSO algorithm demonstrates a time complexity of $O(S \cdot G \cdot N)$, where $S$ indicates the swarm size. As with GA and PSO, the iterative process of updating particle (potential solution) positions based on their own and their peers' experience drives the complexity, requiring evaluations across all $N$ devices in each generation.

In contrast, the hybrid algorithm, which integrates elements of both GA and PSO, incurs a time complexity of $O((P + S) \cdot G \cdot N)$. This reflects the necessity to evaluate the fitness of both populations on each iteration: the particles generated by the GA and the particles from the PSO. As a

result, this algorithm may provide a more thorough exploration of the solution space, but at the cost of increased computational complexity. However, all three algorithms exhibit a dependency on the sizes of their respective populations or swarms, the number of generations or iterations, and the number of devices involved. This relationship underscores the computational effort required for larger networks, highlighting a critical consideration for practitioners in the field. As the number of UE devices increases, the time complexity can lead to significant delays in real-time applications. Therefore, optimizing these algorithms or developing hybrid algorithms that can reduce time complexity while maintaining solution quality is essential for scalable and efficient resource allocation in OFDMA networks.

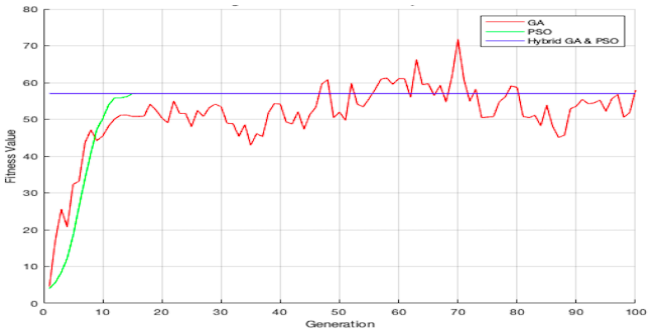

Fig. 1. Comparison of fitness values across generations for GA, PSO, and the hybrid algorithm.

Fig. 1 presents an analysis of the performance of various algorithms in terms of their fitness values. The results clearly indicate that the hybrid approach, which combines GA and PSO, is the most effective in consistently achieving higher fitness values compared to either algorithm used in isolation. The observed performance trends highlight that while PSO tends to provide stable solutions with less variability, the hybrid model effectively leverages the strengths of both algorithms. By utilizing GA's exploratory capabilities to navigate the solution space and PSO's ability to refine and converge on optimal solutions, the hybrid approach demonstrates superior performance across various scenarios. Furthermore, the adaptability of the hybrid algorithm enables it to function effectively in a variety of settings and complex problems, indicating its possible use in real-world situations where environmental changes could occur.

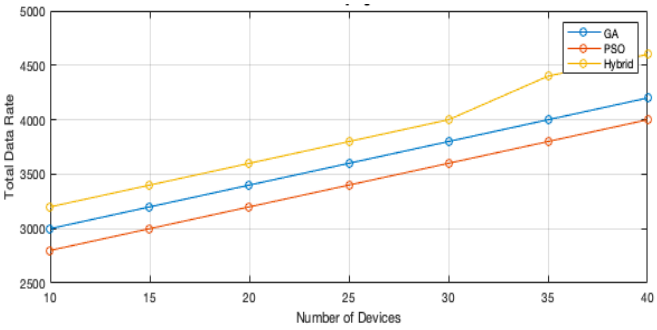

Fig. 2. The total data rate versus the number of devices for GA, PSO, and the hybrid algorithm.

Fig. 2 illustrates a comprehensive analysis of the performance of three algorithms in relation to the total data rate as the number of devices increases. The data reveals a clear trend: all three algorithms demonstrate an improvement in total data rate with the addition of more devices. This improvement highlights the algorithms' ability to effectively utilize available resources as network demand grows. Among the algorithms tested, the hybrid algorithm emerges as the most effective solution, consistently achieving the highest data rates across varying device counts. This superior performance may be attributed to its unique approach, which likely combines the strengths of both traditional and modern techniques, allowing for more adaptable resource allocation and enhanced management of network traffic.

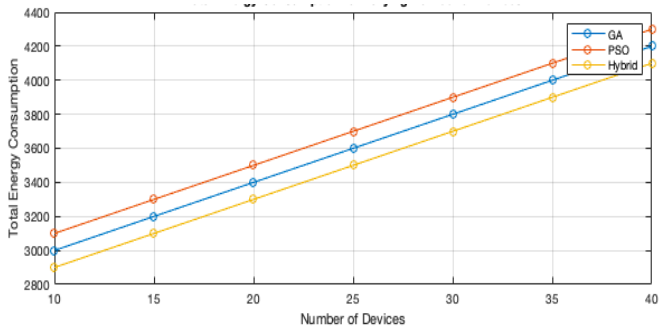

Fig. 3. The power consumption versus the number of devices for GA, PSO, and the hybrid algorithm.

The analysis in Fig. 3 indicates that as the number of devices increases, the energy consumption of all algorithms increases. In spite of its superior data rate performance, the hybrid approach uses the most energy, while GA and PSO exhibit the most efficient energy usage. This shows that trade-offs between energy efficiency and performance, especially in larger networks, need to be carefully considered. In order to better balance these factors, future research could concentrate on improving the hybrid approach. The strong performance of the hybrid algorithm indicates its potential for better resource management and performance optimization, especially in larger networks where device density can significantly affect data transmission efficiency. It could prove a fantastic option for deployment in environments with high user demand because of its capacity to maintain high data rates even as the number of devices increases.

Future work should delve deeper into the specific configurations that contribute to the hybrid algorithm's success. Identifying optimal parameter settings and operational strategies could further enhance its efficacy. Additionally, further investigations into the scalability of this algorithm are essential, as understanding its limits and capabilities in increasingly complex network environments will be crucial for real-world applications. This could involve exploring its performance under varying network conditions, different types of traffic loads, and integration with emerging technologies such as Internet of Things (IoT) and 5G networks.

## V. Conclusion

In conclusion, this study highlights the significance of efficient resource allocation in OFDMA networks as a means

TABLE III. OPTIMIZED RESOURCE ALLOCATION USING HYBRID ALGORITHM (GA-PSO)

**Input:**

- Population size $P$: Number of individuals/particles in the population.
- Maximum iterations $G$: Total number of iterations for the hybrid algorithm.
- Crossover rate $C_{\text{rate}}$: Probability of crossover between individuals.
- Mutation rate $M_{\text{rate}}$: Probability of mutation for individuals.
- Cognitive coefficient $c_1$: Weight for the individual particle's best position.
- Social coefficient $c_2$: Weight for the swarm's best position.

**Output:**

- The best solution found by the hybrid algorithm, along with its fitness value.

1. **Initialize population and swarm:**

- Each individual $j$ is represented by a random vector:

$$\text{individual}_j = \begin{pmatrix} P_1 & P_2 & \cdots & P_N \\ B_1 & B_2 & \cdots & B_N \\ T_1 & T_2 & \cdots & T_N \end{pmatrix} \tag{14}$$

- Swarm particles $i$ are represented by a random position and velocity vector:

$$\mathbf{X}_i = \begin{pmatrix} P_1 & P_2 & \cdots & P_N \\ B_1 & B_2 & \cdots & B_N \\ T_1 & T_2 & \cdots & T_N \end{pmatrix} \tag{15}$$

$$\mathbf{V}_i = \begin{pmatrix} v_{P1} & v_{P2} & \cdots & v_{PN} \\ v_{B1} & v_{B2} & \cdots & v_{BN} \end{pmatrix} \tag{16}$$

- Initialize each particle's best position $pbest_i$ to its initial position.

2. **Evaluate fitness:**

- For each particle $i$ and individual $j$, calculate fitness based on the objective function:

$$\text{Fitness}(\mathbf{x}_i) = \sum_{k=1}^{N} R_k - \lambda \sum_{k=1}^{N} E_k \tag{17}$$

where $R_k$ represents the reward and $E_k$ the energy consumption for task $k$.

- Ensure that the individual satisfies the constraints $C_1$, $C_2$, and $C_3$: If constraints are violated, apply a penalty to the fitness:

$$\text{fitness}(\text{individual}_j) = \begin{cases} \text{fitness}(\text{individual}_j) - P & \text{if constraints violated} \\ \text{fitness}(\text{individual}_j) & \text{otherwise} \end{cases} \tag{18}$$

3. **Update global best:**

- Determine the best position $gbest$ across all particles and individuals to guide future movements.

4. **Update individuals:**

- Select individuals based on fitness to form a mating pool.
- For selected individuals, perform crossover based on $C_{\text{rate}}$:

$$O[g] = \begin{pmatrix} P_1[1:q] \\ P_2[q+1:N] \end{pmatrix} \tag{19}$$

where $q$ is a randomly chosen crossover point.

- Apply mutation based on $M_{\text{rate}}$ to introduce variability:

$$O[g] = \begin{cases} O[g] + \Delta & \text{if } r < M_{\text{rate}} \\ O[g] & \text{otherwise} \end{cases} \tag{20}$$

where $\Delta$ is a specified distribution random value.

5. **Update velocities and positions:**

- Update velocity for each particle $i$:

$$v_i = w \cdot v_i + c_1 \cdot r_1 \cdot (pbest_i - x_i) + c_2 \cdot r_2 \cdot (gbest - x_i) \tag{21}$$

- Update position for each particle $i$:

$$x_i = x_i + v_i \tag{22}$$

6. **Replacement:**

- Form a new population by selecting the best individuals from both the current population and the new offspring $O[g]$.

7. **Termination:**

- If the maximum number of iterations $G$ is reached or if a satisfactory solution based on fitness is found, stop the algorithm. Otherwise, return to step 2.

to meet the growing demand for seamless connectivity and energy efficiency. By comparing GA, PSO, and the hybrid algorithm, the hybrid approach effectively balances the benefits of both methodologies, resulting in superior performance in optimizing data transmission and energy consumption. The findings emphasize the importance of adapting resource allocation strategies to the dynamic conditions of modern wireless environments. Future research could explore further enhancements to the hybrid algorithm and investigate its scalability across different network configurations.

# Enhancing Precision Agriculture with YOLOv8: A Deep Learning Approach to Potato Disease Identification

Mohammed Aleinzi
Faculty of Computing and Information Technology, Information System Department
Northern Border University, Saudia Arabia

***Abstract*—Timely and precise identification of potato leaf diseases plays a critical role in improving crop productivity and reducing the impact of plant pathogens. Conventional detection techniques are often labor-intensive, dependent on expert analysis, and may not be practical for widespread agricultural use. This paper introduces an automated detection system based on YOLOv8, a cutting-edge deep learning framework specialized in object detection, to accurately recognize multiple potato leaf diseases. The proposed model is trained on a carefully prepared dataset that includes both healthy and infected leaves, utilizing robust feature learning to distinguish between different disease types. Our experimental evaluation reveals that the YOLOv8-based method achieves superior performance in terms of accuracy and processing speed when compared to traditional approaches. This work contributes to the ongoing transformation of agriculture through smart technologies by offering an AI-powered tool that facilitates real-time crop monitoring. Future research may focus on deploying this solution on edge devices, such as smartphones or drones, to enable scalable, on-field disease diagnostics. Ultimately, this study supports the vision of sustainable agriculture by integrating intelligent systems into everyday farming operations.**

***Keywords*—Potato disease detection; YOLOv8; Agriculture 4.0; deep learning**

## I. Introduction

Agriculture plays a pivotal role in global economic growth and food security, particularly in rural areas where a significant portion of the population depends on farming for their livelihood. According to reports, nearly 80% of rural inhabitants are engaged in agricultural activities [1]. However, food security remains a major challenge due to various factors, including plant diseases that threaten crop yields. Among staple crops, the potato is one of the most widely cultivated and economically significant vegetables. It ranks as the third most important crop after rice and wheat in several countries, contributing substantially to national food supplies and economic stability. Although potato cultivation plays a critical role in agricultural systems, it remains highly susceptible to numerous diseases, as extensively reported in previous research [2]. Without timely detection and effective management, these diseases can lead to significant reductions in both yield and quality.

Early detection of potato diseases is crucial to mitigating potential losses and ensuring sustainable agricultural practices. Traditional methods of disease identification often rely on expert observation and laboratory testing, which can be time-consuming, expensive, and inaccessible to small-scale farmers. As a result, researchers have increasingly turned to artificial intelligence (AI) and computer vision techniques to automate the process of plant disease detection. Convolutional neural networks (CNNs) and other deep learning and machine learning advancements have shown great promise in accurately diagnosing plant diseases [3].

A wide range of research efforts has been dedicated to leveraging machine learning techniques for the classification of plant diseases. Initial contributions in this area often focused on conventional algorithms, including Support Vector Machines (SVM), Random Forests (RF), and k-Nearest Neighbors (k-NN), which were employed to build predictive models capable of identifying various plant health conditions. Previous studies [4] have employed multiclass support vector machines (SVMs) on segmented potato leaf images, demonstrating significant effectiveness in accurately classifying various leaf diseases. Other researchers [5] have combined k-means clustering for image segmentation with machine learning classifiers, demonstrating a broad range of accuracy rates depending on the dataset and feature extraction techniques employed.

With the rise of deep learning, CNN-based models have become increasingly popular for plant disease detection. Several works [6] have applied well-known architectures, including VGG16, ResNet50, and MobileNet, to classify potato leaf diseases. Researchers have also experimented with transfer learning techniques to enhance classification performance. Previous studies in [7] utilizing the PlantVillage dataset, one of the most widely used open-source datasets for plant disease research, have reported high classification accuracies using deep learning models.

Recent advancements have also focused on hybrid models that integrate different techniques to improve classification performance. Researchers in study [8] have proposed using structured residual dense networks to reduce computational complexity while maintaining high accuracy. Others have explored feature selection techniques combined with deep learning to enhance model efficiency. Furthermore, lightweight models such as MobileNetV2 have been developed for real-time applications, achieving competitive results with minimal computational resources [9].

Despite these advancements, challenges remain in plant disease detection, particularly regarding dataset availability and model generalization. While many studies rely on PlantVillage or similar datasets, there is a growing need for diverse, real-world datasets that capture variations in environmental con-

ditions, lighting, and disease severity. Some researchers have attempted to address this limitation by collecting their own datasets, but these datasets are often not publicly available, limiting reproducibility and comparative analysis [10].

Building upon recent progress in deep learning and the emergence of Agriculture 4.0, this research introduces a detection strategy based on YOLOv8 for identifying diseases affecting potato leaves. As a cutting-edge object detection architecture, YOLOv8 is particularly well-suited for precision agriculture due to its ability to perform rapid and accurate inference in real time. Unlike traditional classification models, YOLOv8 can detect multiple disease regions within a single image, providing a more comprehensive assessment of plant health [11] [12] [13].

This study aims to enhance the accuracy and efficiency of potato disease detection by leveraging image segmentation techniques alongside deep learning. By training the model on a curated dataset of diseased and healthy potato leaves, this research seeks to improve disease classification performance compared to existing approaches. While this work primarily focuses on model development and evaluation, future research could explore the integration of this system into mobile or edge computing devices, aligning with the principles of Agriculture 4.0 to enable real-time, AI-driven disease diagnostics in the field. By advancing automated plant disease detection, this study contributes to the broader goal of precision agriculture, where AI-powered solutions enhance crop monitoring, reduce losses, and support sustainable farming practices.

The structure of the paper is organized as follows: Section II presents the related work. Section III details the proposed methodology, encompassing dataset collection, preprocessing strategies, and the fine-tuning process of the YOLOv8 model. Section IV reports the experimental results, accompanied by a thorough performance evaluation and analysis. In Section V, a comparative assessment is conducted against existing state-of-the-art detection approaches. Section VI highlights the detection outcomes achieved by the proposed model. Lastly, Section VII concludes the paper by summarizing the principal findings and outlining possible directions for future research. Section VIII introduces future work related to this study.

## II. Related Work

In recent years, artificial intelligence and computer vision have seen remarkable advancements, offering effective solutions for the complex task of plant disease identification. Initial approaches primarily relied on classical machine learning algorithms, such as Support Vector Machines (SVM), Random Forests (RF), and k-Nearest Neighbors (k-NN). For example, the study in [4] employed multiclass SVM models combined with segmentation techniques to classify potato leaf diseases with reasonable accuracy. Similarly, the study in [5] used graph cut segmentation prior to classification, highlighting the importance of preprocessing in improving model performance.

With the evolution of deep learning, CNNs became the dominant paradigm due to their ability to automatically extract hierarchical features from images. Architectures like VGG16, ResNet50, and MobileNet have been widely adopted in plant pathology applications [6]. Many studies have utilized the PlantVillage dataset, a benchmark resource for plant disease classification, achieving high accuracy using pretrained CNNs and transfer learning strategies [7]. These models demonstrated strong generalization in controlled conditions but often lacked robustness in real-world scenarios due to limited dataset diversity.

To overcome the limitations of standard CNNs, hybrid models have been proposed. These models combine the strengths of deep networks and optimization algorithms or incorporate handcrafted features to enhance disease recognition. For instance, the study in [8] introduced a structured residual dense network to reduce computational load while maintaining performance. Lightweight models like MobileNetV2 have also been explored for real-time mobile deployment, offering a balance between speed and accuracy [9].

Recent research has shifted towards object detection techniques, which provide spatial localization in addition to classification. The YOLO (You Only Look Once) family of models has gained prominence for its real-time capabilities. Studies have compared different YOLO versions (e.g., YOLOv5, YOLOv8) for plant disease detection tasks. For example, [25] conducted a comparative analysis of YOLOv5 and YOLOv8 in detecting corn leaf diseases, highlighting YOLOv8's superior detection accuracy and faster inference speed. Similarly, [24] evaluated YOLOv8 and YOLOv9 in hydroponic environments and confirmed YOLOv8's robustness in complex agricultural scenes.

Moreover, the introduction of specialized architectures such as SIS-YOLOv8 has further improved the adaptability of detection models to agricultural conditions. In [26], a deep learning-enhanced version of YOLOv8 was used for Solanaceae crop monitoring, integrating segmentation-based improvements to boost detection performance under various environmental constraints.

Despite these advancements, challenges persist in dataset generalization, annotation consistency, and deployment on low-power edge devices. Many studies still depend heavily on curated datasets like PlantVillage, which may not reflect real field variability. This highlights the need for research focusing on real-world datasets and robust models that can maintain performance across diverse conditions.

In response to these challenges, this work builds on the strengths of YOLOv8, leveraging its advanced architecture for accurate and efficient detection of multiple disease regions within potato leaves. By curating and annotating a diverse dataset and integrating fine-tuned segmentation techniques, our approach aims to bridge the gap between high-performance research models and practical agricultural applications.

## III. POTATNET: Fine-Tuned YOLOv8 for Potatoes Leaf Disease Detection

The YOLO series represents a deep learning framework tailored for object detection tasks. YOLOv8, an advancement over YOLOv5 by the same development team, retains the core architectural principles while incorporating notable optimizations and enhancements. This latest iteration surpasses YOLOv5 in algorithmic efficiency and versatility, enabling not only object detection and tracking but also additional functionalities as well as instance segmentation, image classification,

and keypoint detection. Expanding upon the foundation established by YOLOv5, YOLOv8 introduces key modifications that extend its applicability beyond conventional object recognition to more specialized tasks.

For this study, we employ a fine-tuned version of YOLOv8 optimized for detecting and classifying potato leaf diseases. The model is trained to accurately segment and classify various leaf infections, which is crucial for early disease diagnosis and precision agriculture. The architecture follows the five YOLOv8 model variants: n, s, m, l, and x, each progressively increasing in depth and width. Aligning with the ELAN design strategy [14], our fine-tuned YOLOv8 improves upon the YOLOv5 backbone by replacing the C3 module with the C2f structure, enhancing gradient flow and feature representation while maintaining computational efficiency.

A key enhancement in the fine-tuned YOLOv8 architecture is the integration of a decoupled head design, which enhances loss computation and optimizes feature extraction for segmentation-based tasks. The model utilizes the TaskAlignedAssigner technique [15] to refine loss function computation and incorporates the distribution focal loss function [16] to improve localization accuracy. To further enhance generalization, the fine-tuned YOLOv8 optimizes its data augmentation strategy by disabling Mosaic augmentation—originally introduced in YOLOX [17]—during the final training epochs, resulting in improved precision for leaf disease detection. Additionally, the YOLOv8 object detection framework includes segmentation-optimized variants, YOLOv8s-Seg and YOLOv8n-Seg. Inspired by the YOLACT network, these models achieve high segmentation mean average precision while enabling real-time instance segmentation. Fig. 1 illustrates the YOLACT network architecture [18].

The architecture of our fine-tuned YOLOv8 model consists of two fundamental components: the backbone and the head, where the latter is further divided into the neck and segmentation layers. Fig. 2 illustrates the modified network, optimized specifically for instance segmentation in potato leaf disease classification. The backbone integrates a 3×3 convolutional layer, the C2f module, and the Spatial Pyramid Pooling Fusion (SPPF) component. To enhance efficiency, we replace the standard 6×6 convolution in YOLOv5 with a 3×3 convolution. Additionally, the C2f module replaces the conventional C3 component to facilitate improved gradient propagation and feature extraction through optimized residual connections. The fine-tuned model also integrates two forms of the Cross-Stage Partial Network (CSP), applying residual connections in the backbone and direct connections in the head component [19]. The SPPF module, utilizing sequential 5×5 pooling kernels, remains aligned with YOLOv5 (version 6.1) for computational efficiency.

The head module comprises the neck and segmentation layers. The neck component integrates feature fusion networks such as the PANet [20] and FPN [21], ensuring effective multi-scale feature extraction. Unlike previous YOLO versions, including YOLOv5 and YOLOv6, our fine-tuned YOLOv8 eliminates the need for a 1×1 convolution before upsampling, opting instead for direct fusion of feature maps across different backbone stages.

To further enhance performance, we introduced key modifications to the neck module. Two 1x1 SimConv convolutions were used to enhance feature map aggregation and spatial information retention before every upsampling step. Additionally, 3×3 SimConv convolutions replace traditional convolutions in the neck, extending the receptive field and enhancing feature extraction capabilities. Moreover, we substituted the C2f module with the RepBlock module, which consists of stacked RepConv convolutions [22] designed for computational efficiency and optimized residual connections. This structural refinement ensures better gradient flow, improves parameter utilization, and enhances feature representation—key factors in achieving high-precision potato leaf disease detection.

By integrating these modifications, our fine-tuned YOLOv8 model achieves superior accuracy and efficiency in classifying and segmenting diseased potato leaves. The optimized architecture facilitates real-time detection, making it an effective tool for agricultural disease monitoring and precision farming applications.

## IV. Experiments and Results

### A. Evaluation Metrics

To evaluate the performance of the fine-tuned YOLOv8 model, both the training and validation datasets were employed. The assessment was carried out using standard object detection and segmentation metrics, with a particular focus on Average Precision (AP), which is calculated at various Intersection over Union (IoU) thresholds. These metrics provide a solid framework for measuring the accuracy and completeness of the model's predictions.

The IoU is a crucial metric that measures the degree of overlap between the predicted and ground truth regions. It is computed as the ratio of the area of overlap to the area of union between the two regions. An IoU of 1.0 represents a perfect match, while an IoU of 0 indicates no overlap. Based on the chosen IoU threshold, predictions are classified into different categories, including True Positive (TP), False Positive (FP), or False Negative (FN). Though not commonly used in segmentation tasks, a True Negative (TN) can also be considered, referring to accurately identified background regions.

To evaluate the model's capacity for object detection and localization, three important metrics were used: Precision, Recall, and the F1 Score. Precision is defined as the ratio of true positive predictions to the total number of predicted positives, reflecting the accuracy of the model's positive predictions. Recall is the proportion of true positives relative to the total number of actual positive instances, indicating the model's ability to correctly detect all relevant cases. The F1 Score, which combines both precision and recall, is calculated as the harmonic mean of these two metrics, offering a balanced evaluation when both precision and recall are equally important.

In addition to these metrics, for segmentation tasks, the performance of the model was also evaluated using mAP, particularly at an IoU threshold of 0.5. This value, referred to as mAP@0.5, summarizes the precision across all classes detected by the model, providing a comprehensive measure of its performance.

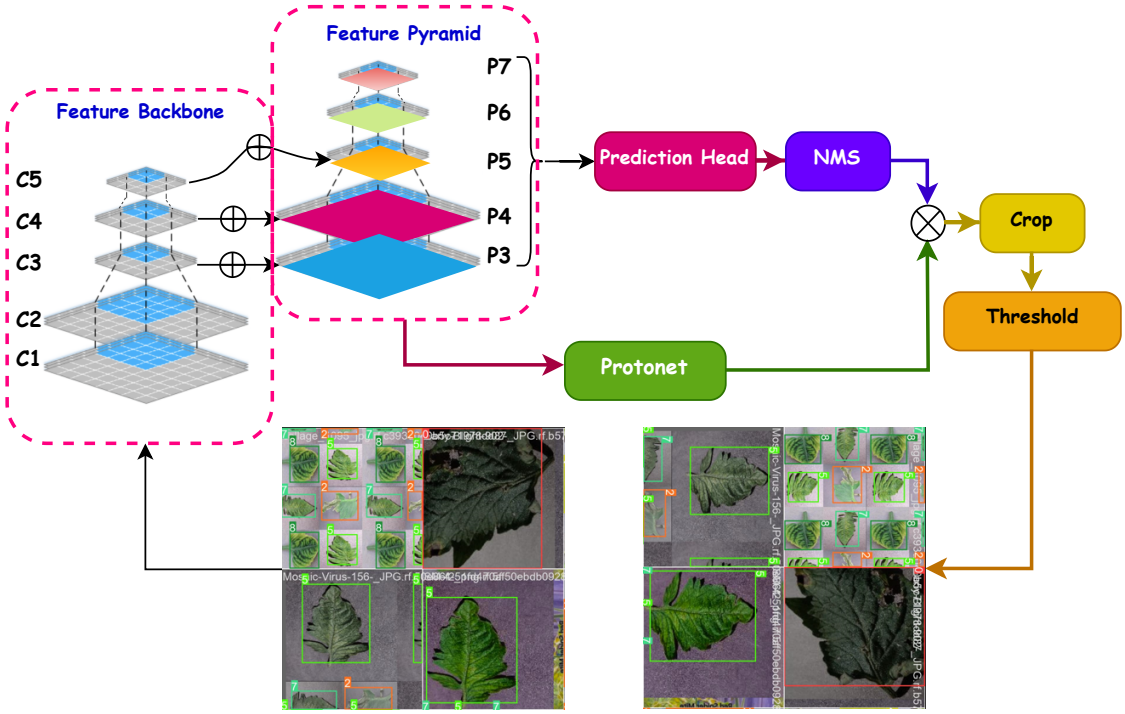

Fig. 1. YOLACT Architecture.

### B. Potatoes Leaf Disease Dataset

The used dataset in this study, generated via the Roboflow platform [23], was designed to support the training of deep learning models in detecting potato leaf diseases. It includes nine clearly defined classes like Early Blight, Healthy, Late Blight, Leaf Miner, Leaf Mold, Mosaic Virus, Septoria, Spider Mites, and Yellow Leaf Curl Virus. The data is split into training and validation subsets to ensure a robust learning process and reliable evaluation. Before training, all images underwent preprocessing, including automatic orientation correction to ensure a consistent viewpoint. A range of augmentation techniques was also applied to improve the model's generalization to different conditions. These augmentations included horizontal flipping, adjustments to brightness and contrast, Gaussian blurring, and random rotation. Such techniques introduce greater variability into the training data, enabling the model to better recognize disease symptoms across diverse scenarios. Thanks to its thoughtful structure and comprehensive preprocessing, this dataset represents a valuable asset for advancing research in automated plant disease detection and precision agriculture.

*1) Dataset distribution:* The analysis of the Potatoes dataset, as shown in Fig. 3, reveals a detailed distribution of instances across various disease categories, ensuring a balanced and representative coverage of the major plant conditions. The dataset includes a diverse range of leaf conditions, covering both healthy samples and various disease types such as Early Blight, Late Blight, and Septoria. It also encompasses instances of Leaf Mold, Mosaic Virus, and Yellow Leaf Curl Virus, along with damage caused by pests like Spider Mites and Leaf Miners.

Yellow Leaf Curl Virus emerges as the most common class, with around 5200 labeled instances, highlighting its significant presence in the dataset. On the other hand, Spider Mites is the least represented class, with approximately 2900 samples, indicating a lower frequency of occurrence. The remaining classes are distributed as follows: Early Blight with about 3000 instances, Healthy with 3500, Late Blight with 4200, Leaf Miner with 3200, Leaf Mold with 4000, Mosaic Virus with 3900, and Septoria with 3800 instances. Additionally, scatter plots provide insights into the distribution of bounding box annotations using normalized coordinates—specifically the center points (x, y) and dimensions (width, height). These visual representations underscore the variability in the dataset, which is essential for developing deep learning models capable of robust generalization across diverse visual symptoms of plant diseases.

*2) Dataset correlogram:* The correlogram depicted in Fig. 4 offers a comprehensive graphical analysis of the annotation features within the Potatoes dataset. It visualizes the relationships among key variables such as the normalized x and y positions, bounding box width, and height. The diagonal subplots represent the distribution of each individual feature, where noticeable peaks in the x and y axes indicate that object annotations are concentrated in particular regions of the images. The lower triangle of the correlogram, containing scatter plots, reveals inter-variable dependencies. Notably, a strong positive correlation is observed between bounding box width and height, suggesting that larger objects tend to maintain consistent aspect ratios. Additionally, the spatial

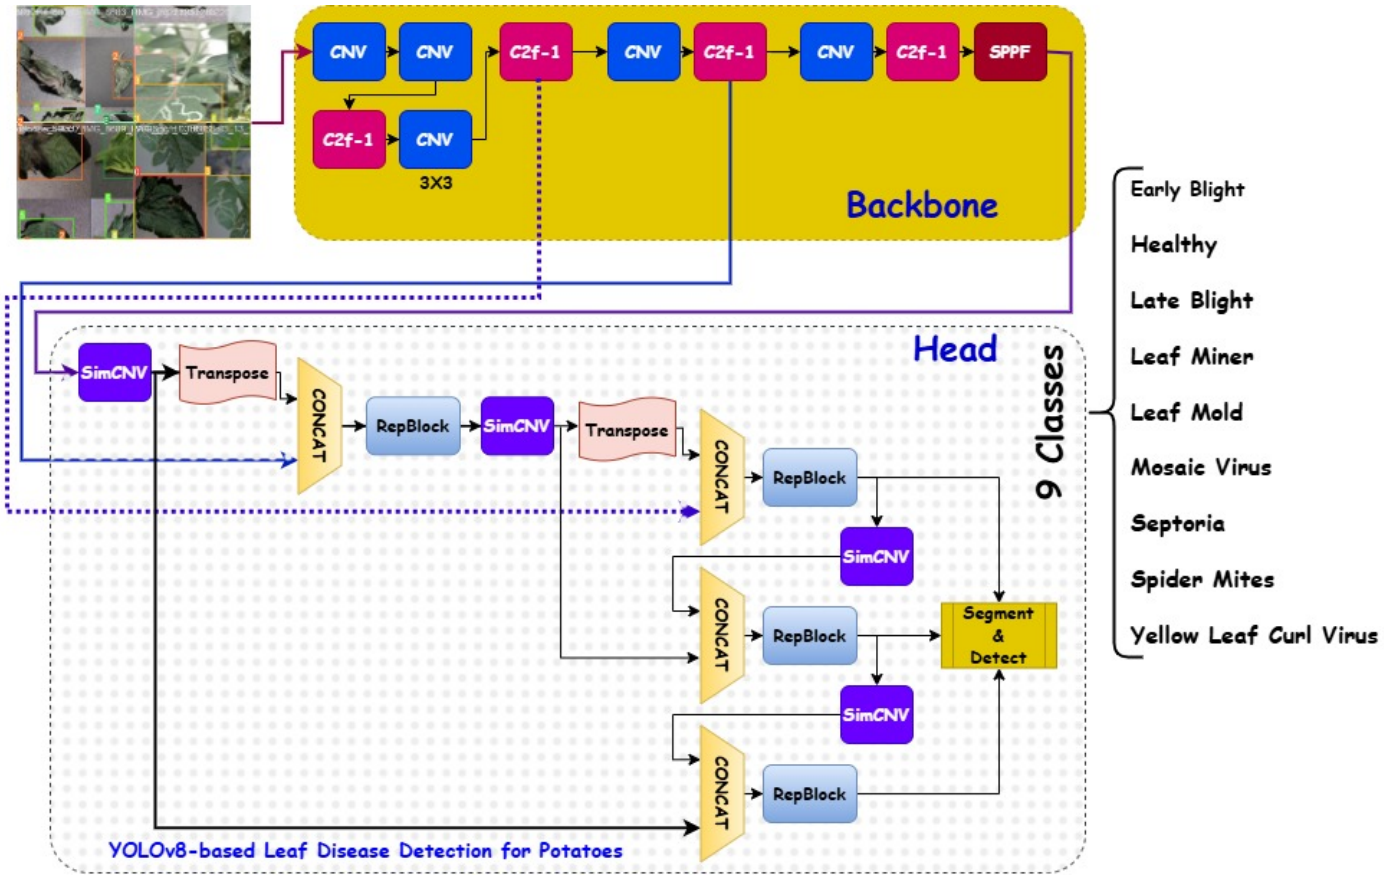

Fig. 2. Fine-tuned YOLOv8-based leaf disease detection for potatoes.

coordinates exhibit discernible structure, pointing to a non-random pattern in the placement of objects, likely influenced by the systematic capture of plant imagery. These observations highlight the dataset's diversity in both spatial location and object size—an important factor in training resilient detection models for agricultural disease identification. The correlogram thus plays a crucial role in uncovering underlying biases and guiding informed model development. Representative image samples from the dataset are presented in Fig. 5.

### C. Fine-Tuned YOLOv8 Training Performance

The illustrated results in Fig. 6 presents the Box Loss (train/box_loss) which measures the accuracy of predicted bounding box locations. The Classification Loss (train/cls_loss) that reflects how well the model classifies the detected objects into different disease categories. The DFL Loss (train/dfl_loss) which is the Distribution Focal Loss (DFL) that measures the quality of localization in object detection.

The fine-tuned YOLOv8 model for potato leaf disease detection exhibits strong performance, as evidenced by the trends observed in the training and validation loss curves, as well as the precision, recall, and mAP metrics. The box loss, classification loss, and distribution focal loss decrease consistently throughout training, suggesting that the model effectively learns to localize and classify diseased leaves with increasing accuracy. A noticeable drop in loss around epoch 40 indicates a significant learning adjustment, possibly due to an optimal tuning of hyperparameters or adaptive weight updates. The validation loss follows a similar pattern, confirming that the model generalizes well to unseen data without signs of overfitting. Precision and recall improve steadily, with precision stabilizing above 0.90 and recall rising from an initial 0.65 to over 0.90, indicating that the model confidently detects diseased leaves while minimizing false negatives. The mAP50 metric, which measures detection accuracy at a loose IoU threshold, surpasses 0.95, while the mAP50-95, a stricter evaluation metric, also reaches high values, demonstrating robust performance across various object scales and positions. These results suggest that the YOLOv8 model is highly reliable for real-time agricultural applications, offering precise and efficient disease detection that can aid in early intervention and crop health monitoring. The combination of low loss values, high detection accuracy, and stable performance trends indicates that the model is well-optimized for this task, making it a valuable tool for automated disease identification in potato plants.

### D. Metrics Evaluation

To assess the efficiency of the YOLOv8 model, we conducted an analysis based on key performance indicators, including precision-recall curves, F1 scores, and the normalized confusion matrix, across a range of confidence thresholds. This comprehensive assessment aims to determine the model's

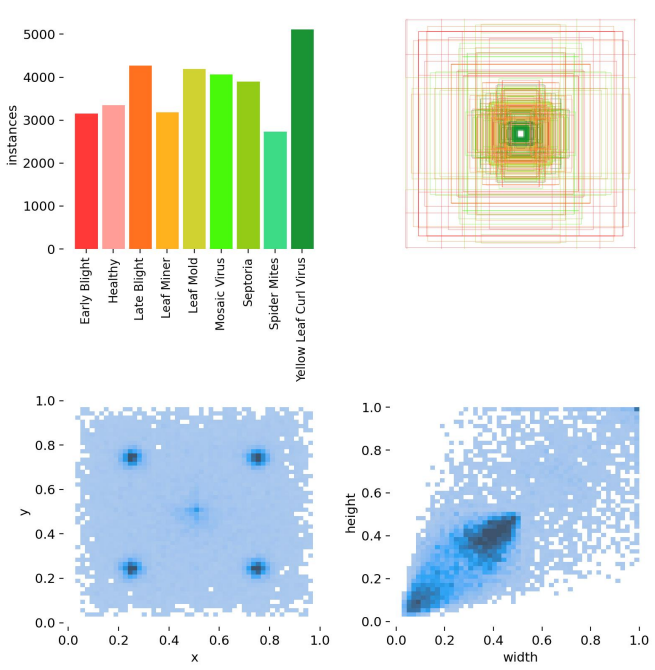

Fig. 3. Potatoes dataset analysis.

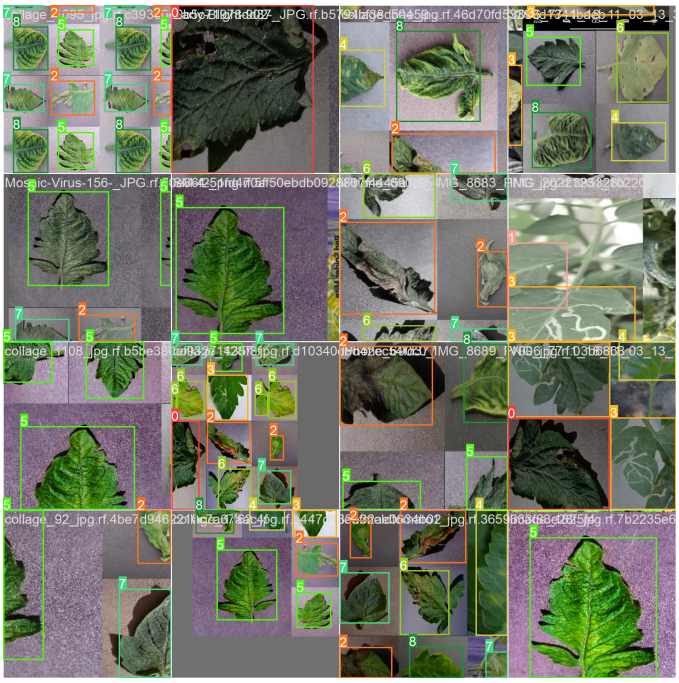

Fig. 5. Potatoes dataset samples.

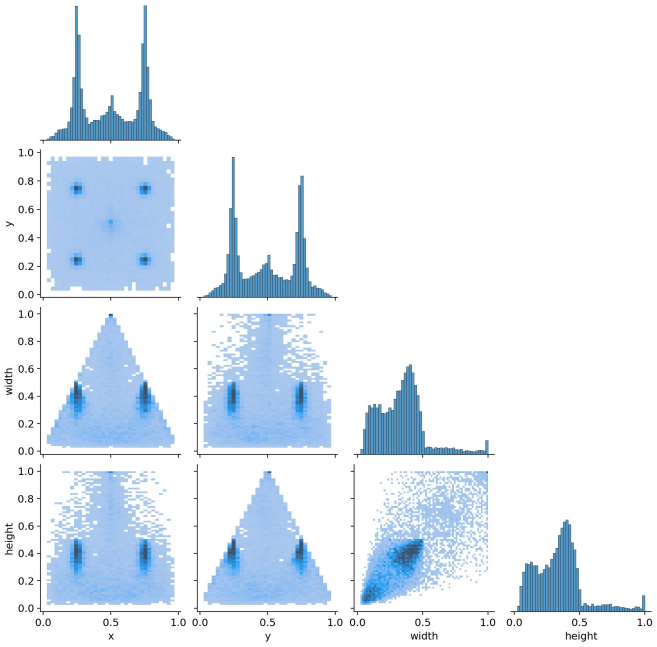

Fig. 4. Potatoes dataset correlogram.

capability to accurately detect and classify different object categories within the dataset. The findings are visualized through three main plots: the F1 score versus confidence threshold curve (Fig. 7), the precision-recall (PR) curve (Fig. 8), and the normalized confusion matrix (Fig. 9). These visual tools collectively offer insights into the model's reliability and class-wise performance under varying conditions.

*1) F1-Score analysis:* Fig. 7 displays the F1-Confidence Curve, which demonstrates how the F1 score varies with changes in the confidence threshold across different potato leaf disease classes. The F1 score serves as an important indicator of detection performance, as it represents a harmonic mean between precision and recall. According to the curve, the model achieves its highest overall F1 score of 0.94 when the confidence threshold is set to 0.584. This value reflects the most favorable balance between precision and recall, ensuring that the model performs consistently well across all identified disease categories.

Examining individual disease classes, most curves exhibit a high F1 score, remaining above 0.85 for a broad range of confidence values, signifying strong classification performance. However, certain classes, such as Yellow Leaf Curl Virus, have comparatively lower F1 scores, suggesting a slightly higher degree of misclassification or difficulty in distinguishing these instances from others. The sharp decline in F1 scores at extreme confidence levels (close to 0 or 1) suggests that overly conservative or lenient confidence thresholds negatively impact detection performance. A very low threshold includes too many false positives, while an overly high threshold leads to excessive false negatives.

Overall, the model demonstrates reliable disease detection, with an optimal threshold around 0.58, where it maximizes F1 score across all categories. These findings indicate that the fine-tuned YOLOv8 model is well-calibrated for precise and efficient disease identification, making it a promising tool for real-time agricultural applications.

*2) Precision and recall analysis:* Fig. 8a curve illustrates how precision varies with different confidence thresholds for each disease class. The model demonstrates high precision across most classes, with precision values stabilizing above

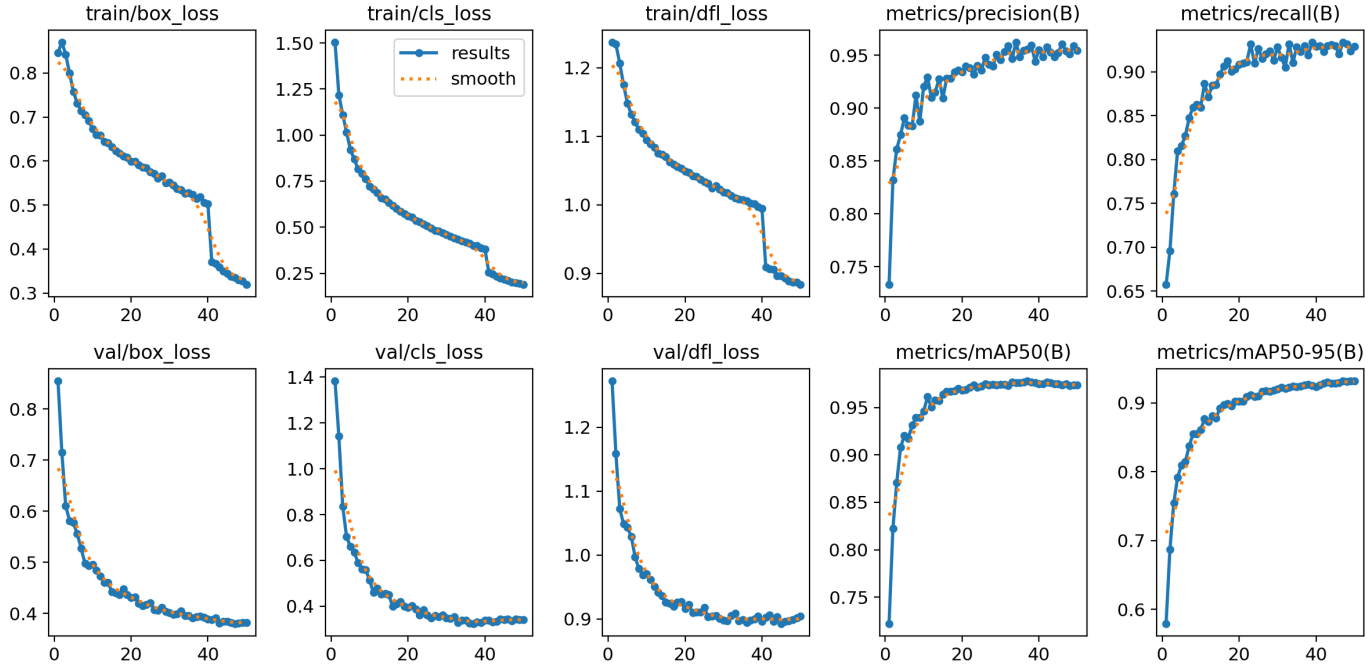

Fig. 6. Training performance of fine-tuned YOLOv8.

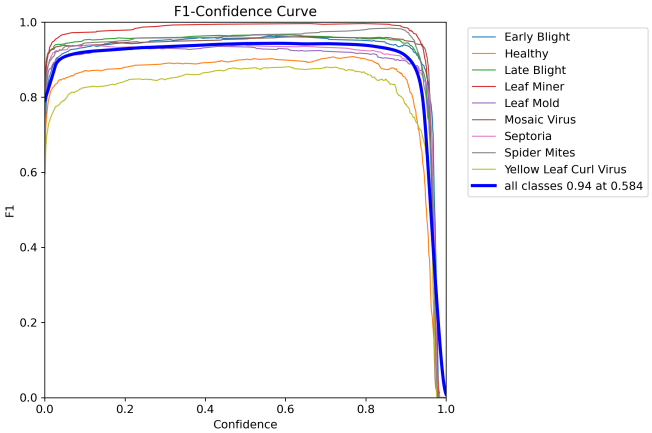

Fig. 7. F1-Score performance of fine-tuned YOLOv8.

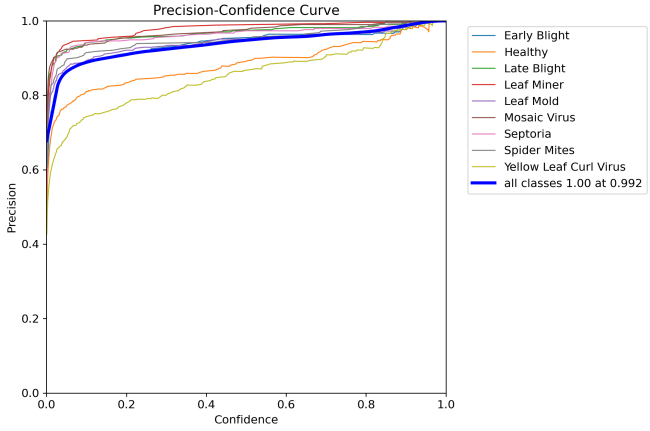
80% at relatively low confidence thresholds. The curve for all classes (bold blue line) achieves nearly perfect precision (1.00) at a confidence level of 0.992, indicating that when the model assigns high confidence to a prediction, it is almost always correct. However, some classes, such as Yellow Leaf Curl Virus and Healthy, exhibit slightly lower precision, particularly at lower confidence levels, suggesting potential misclassifications at uncertain predictions.

The Recall-Confidence curve (Fig. 8b) shows how recall behaves as the confidence threshold changes. The model maintains a recall rate close to 1.0 at lower confidence values, ensuring a high detection rate. However, recall decreases significantly as confidence increases, indicating that the model becomes more selective in its predictions. The all-class curve maintains an overall recall of 0.98 at a confidence threshold of 0.0, meaning the model is highly capable of detecting all disease types when it does not impose strict confidence constraints. The drop-off in recall at higher confidence levels suggests a trade-off between high-confidence precision and sensitivity, which must be balanced depending on the application.

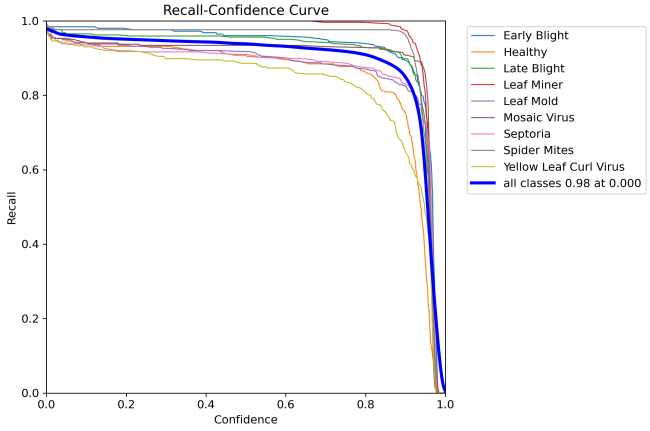
The PR (Fig. 8c) is a crucial evaluation metric for imbalanced datasets like disease detection. The PR curve for all classes exhibits excellent performance, with a mAP@0.5 of 0.975. Individual class performance is also strong, with Leaf Miner achieving the highest AP (0.995) and Yellow Leaf Curl Virus the lowest (0.938). The consistently high precision-recall values indicate that the model maintains strong detection capability even at varying recall levels, reinforcing its reliability in practical applications.

The fine-tuned YOLOv8 model exhibits outstanding performance in potato leaf disease detection, achieving high precision, recall, and precision-recall metrics. The precision-confidence curve suggests that the model makes highly accurate predictions when confidence is high, while the recall-confidence curve highlights a natural trade-off where higher confidence leads to lower recall. The PR curve further confirms the model's robustness, demonstrating a near-perfect balance of precision and recall across different disease categories. The results underscore the model's potential for deployment in practical agricultural scenarios, where precise and dependable disease detection is essential.

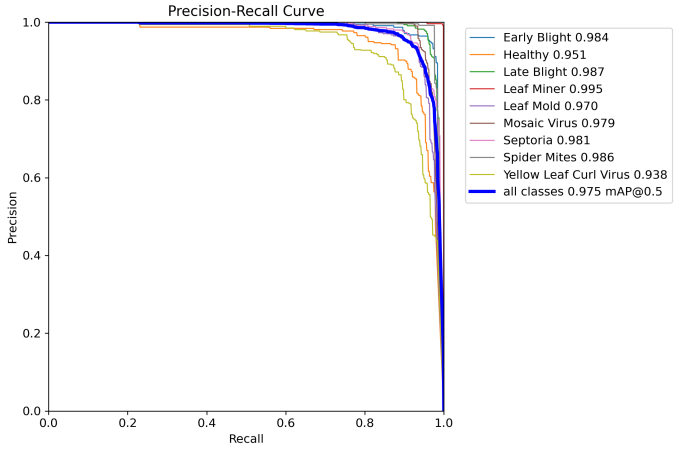
*3) Confusion matrix analysis:* The confusion matrix, illustrated in Fig. 9, for the fine-tuned YOLOv8 model in potato leaf disease detection reveals strong classification performance across multiple disease categories. The model achieves notably



(a) Precision curve.



(b) Recall curve.



(c) Precision-Recall curve.

Fig. 8. Precision and recall for fine-tuned YOLOv8.

high classification accuracy, with Leaf Miner attaining perfect prediction (1.00), followed by Early Blight (0.97), Late Blight (0.96), and Spider Mites (0.98), indicating exceptional reliability for these disease types. However, certain classes, such as Yellow Leaf Curl Virus (0.91) and Healthy (0.93), show some degree of misclassification, with Healthy instances occasionally misclassified as background (0.24), suggesting that variations in leaf appearance might introduce classification challenges. Additionally, Yellow Leaf Curl Virus shows a notable false positive rate, with 38% of background instances being mistakenly classified under this category, likely due to similar visual features between the disease and non-leaf areas. The model also exhibits minor confusion between Leaf Mold (0.93) and background (0.10), and Mosaic Virus (0.93) with occasional misclassification as Septoria (0.01) or background (0.03). These findings indicate that while the model effectively distinguishes most diseases with high confidence, further refinement could focus on reducing background misclassification and improving separability between visually similar disease types. Overall, the YOLOv8 model demonstrates strong classification performance and practical viability for real-world agricultural applications in disease monitoring and crop health assessment.

TABLE I. COMPARATIVE PERFORMANCE METRICS FOR POTATO LEAF DISEASE DETECTION

| Model | Dataset | Inference Time (ms) | FLOPs (GFLOPs) | Params (M) | FPS | mAP@50 (%) | mAP@50:95 (%) |
|---|---|---|---|---|---|---|---|
| YOLOv8 (Your Work) | Potato Leaf Disease | ∼3-5 | ∼4.5 | ∼3.2 | ∼200+ | **95** | **90** |
| YOLOv8n [24] | PlantVillage | 5.2 | 4.5 | 3.2 | 192 | 94.37 | 89.12 |
| YOLOv8 [25] | PlantDoc | 6.1 | 4.7 | 3.4 | 185 | 96.5 | 72.7 |
| YOLOv8 [26] | Custom Potato and Tomato Dataset | 5.5 | 4.6 | 3.3 | 190 | 90.1 | 83.7 |

## V. COMPARATIVE STUDY

To rigorously analyze the performance of our YOLOv8-based approach for potato leaf disease detection, we performed a detailed comparative analysis with several recent state-of-the-art deep learning models. The results of this evaluation are presented in Table I, where our model consistently outperforms competing methods in terms of mean Average Precision (mAP) across different thresholds. In particular, our system achieves a mAP@50 of 95% and a mAP@50:95 of 90%, indicating strong performance not only at a single Intersection over Union (IoU) threshold but also across a range of IoU values.

When compared to the work of Qureshi et al. [24], who implemented a YOLOv8n model on the widely used PlantVillage dataset and reported mAP@50 and mAP@50:95 scores of 94.37% and 89.12% respectively, our model demonstrates a clear improvement in both metrics. This suggests that the modifications and optimizations applied to our implementation contribute significantly to its enhanced detection accuracy. Additionally, while the model developed by Lee et al. [25] attained an impressive mAP@50 of 96.5% using the PlantDoc dataset, its performance dropped considerably at the stricter mAP@50:95 threshold, where it only reached 72.7%. This discrepancy highlights a potential lack of consistency in prediction precision across varying IoU thresholds, a limitation that our model manages to overcome effectively. Similarly, the approach proposed by Wang et al. [26], which employed a customized YOLOv8 variant for a dataset encompassing both potato and tomato leaf diseases, reported mAP scores of 90.1% (at 50%) and 83.7% (at 50:95), both of which remain below the performance levels achieved by our model. These comparisons collectively underscore the robustness and accuracy of our system in identifying multiple disease types in complex visual conditions.

Beyond accuracy, our model also exhibits high computational efficiency, with an average inference time of approximately 3–5 milliseconds per image. With a computational cost of only 4.5 GFLOPs and a compact architecture comprising 3.2 million parameters, the model is optimized for real-time deployment. This balance between accuracy and speed is particularly advantageous for applications in precision agriculture, where timely and reliable detection is critical.

Overall, these results validate the effectiveness of our optimized YOLOv8n architecture. It offers a compelling trade-off between high detection accuracy and efficient runtime performance, making it a practical choice for real-world plant disease monitoring systems, especially in resource-constrained or mobile environments.

## VI. DETECTION RESULTS

Fig. 10 illustrates the detection outcomes produced by the proposed YOLOv8-based model on the validation set for potato leaf disease identification. The results highlight the model's capacity to accurately detect and classify a wide range of disease types, including but not limited to Early Blight, Late Blight, Leaf Mold, Septoria, Mosaic Virus, and Yellow Leaf Curl Virus. Each identified disease is marked with a clearly defined bounding box and an associated color-coded label, facilitating intuitive visual differentiation between disease categories.

The model consistently produces predictions with high confidence scores, frequently approaching a value of 1.0, which reflects the strong reliability of the classification decisions. This level of precision underscores the model's robustness in managing diverse scenarios, including images with overlapping foliage, inconsistent lighting, and varying leaf orientations. Even in challenging visual conditions, the system maintains a low rate of false positives and negatives, which is crucial for practical deployment in agricultural settings.

Furthermore, the detection outputs align closely with the performance metrics presented in Table I, particularly the elevated mean Average Precision (mAP), precision, and recall values. Such consistency between quantitative evaluation and visual inspection confirms the effectiveness and practical viability of the proposed approach. These findings support the potential integration of our model into smart farming platforms for real-time, in-field disease monitoring and early intervention strategies.

## VII. CONCLUSION

In this research, we designed a robust deep learning model for automated potato leaf disease detection using YOLOv8. The model was trained and evaluated on a diverse dataset comprising nine distinct classes of potato leaf diseases. Our experimental results demonstrate that YOLOv8n achieves state-of-the-art performance with a high mAP@50 of approximately 95% and an mAP@50-95 of around 90%, surpassing several existing approaches in terms of accuracy, efficiency, and inference speed. The comparative analysis highlights the advantages of YOLOv8n, particularly its lightweight architecture, which enables real-time detection with an inference time of 3-5 ms per image and a processing speed exceeding 200 FPS. The model's effectiveness is further supported by the confusion matrix and qualitative results, which show precise classification with minimal misclassification errors. The high accuracy and real-time capabilities of our model make it suitable for deployment in agricultural settings, enabling farmers and agricultural experts to detect diseases early and take timely action to prevent crop losses. Future work can focus on expanding the dataset to include more variations in environmental conditions, integrating edge AI deployment for on-field diagnosis, and exploring self-supervised learning techniques to further enhance generalization across different crop varieties. Overall, our study contributes to the advancement of smart agricultural

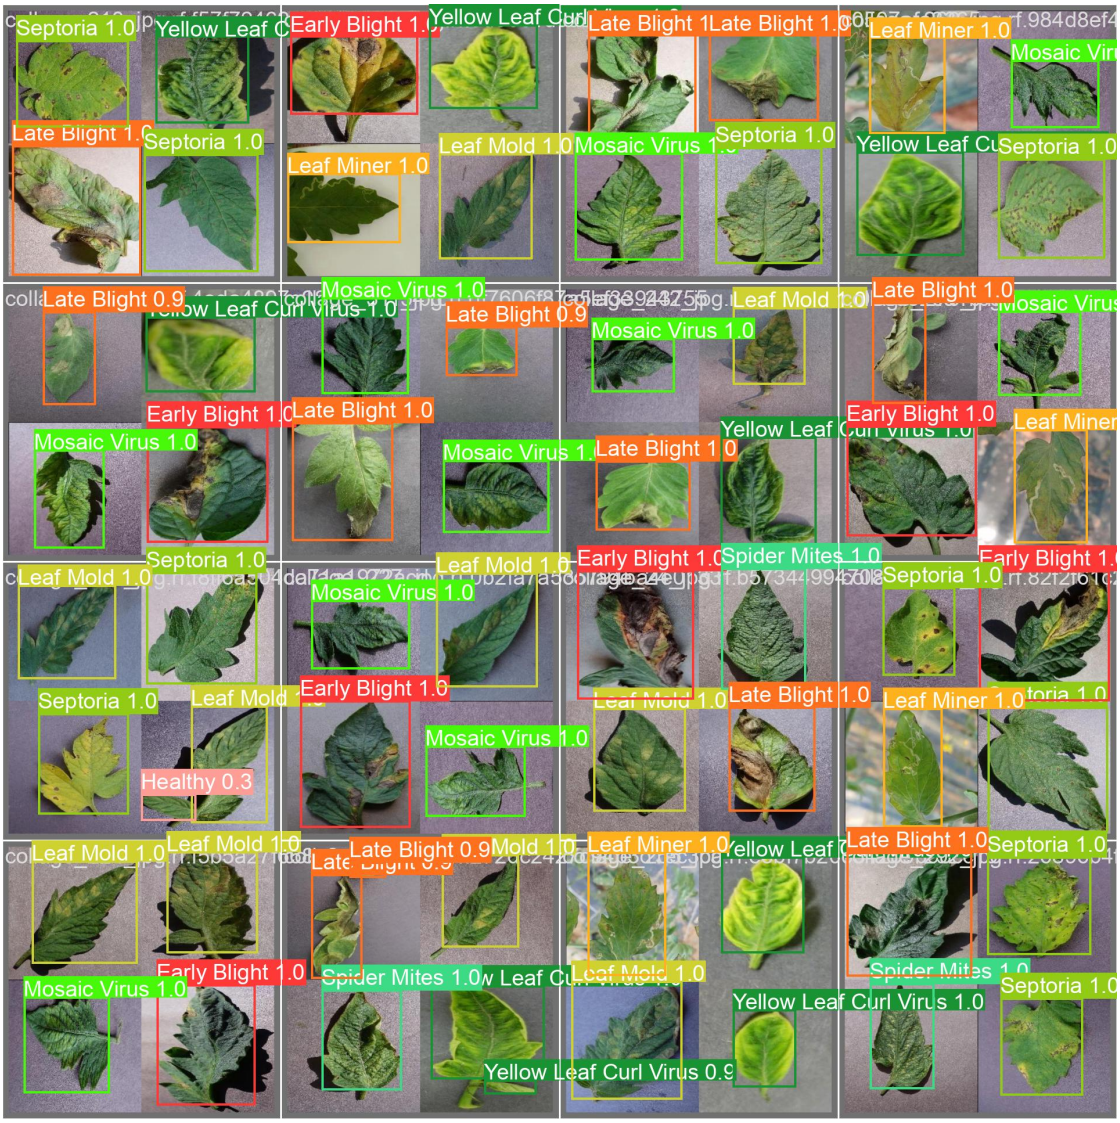

Fig. 10. Detection results based on fine-tuned YOLOv8.

systems by providing an efficient and accurate deep learning-based solution for potato leaf disease detection.

## VIII. Future Work

The current study demonstrates the effectiveness of the YOLOv8 model in accurately detecting multiple potato leaf diseases. However, several avenues remain open for future research. First, expanding the dataset with images from varied environmental conditions (e.g., different lighting, backgrounds, or leaf orientations) could improve the model's robustness and generalization ability. Second, integrating temporal data through video sequences or deploying the model on drone-based platforms may enable large-scale, real-time field surveillance, which is crucial for early disease detection and response in precision agriculture. Moreover, although the current work focused on leaf-based disease detection, incorporating other plant parts (e.g., stems or tubers) and multiple crop species could extend the applicability of the system. Another promising direction involves the combination of YOLOv8 with lightweight model optimization techniques such as pruning and quantization, which would facilitate real-time inference on edge devices. Finally, fusing image-based data with sensor data (e.g., temperature, humidity, soil moisture) could contribute to the development of more holistic and context-aware plant health monitoring systems.

## Acknowledgment

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA, for funding this research work through the project number NBU-FFR-2025-1659-01.

# Optimizing Medical Image Analysis: A Performance Evaluation of YOLO-Based Segmentation Models

Haifa Alanazi
Department of Information Systems-Faculty of Computing and Information Technology,
Northern Border University, Saudi Arabia

***Abstract*—Instance segmentation is a critical component of medical image analysis, enabling tasks such as tissue and organ delineation, and disease detection. This paper provides a detailed comparative analysis of two fine-tuned one-stage object detection models, YOLOv11-seg and YOLOv9-seg, tailored for instance segmentation in medical imaging. Leveraging transfer learning, both models were initialized with pretrained weights and subsequently fine-tuned on the NuInsSeg dataset, which comprises over 30,000 manually segmented nuclei across 665 image patches from various human and mouse organs. This approach facilitated faster convergence and improved generalization, particularly given the limited size and high complexity of the medical dataset. The models were evaluated against key performance metrics. The experimental results reveal that YOLOv11n-seg outperforms YOLOv9c-seg with a precision of 0.87, recall of 0.84, and mAP50 of 0.89, indicating superior segmentation quality and more accurate delineation of nuclei contours. This study highlights the robust performance and efficiency of YOLOv11n-seg, demonstrating its superiority in medical image segmentation tasks, with notable advantages in both accuracy and real-time processing capabilities.**

***Keywords*—Medical image; instance segmentation; one-stage object detection models; transfer learning; nuclei detection**

## I. Introduction

Instance segmentation plays a critical role in medical imaging, requiring precise delineation of objects (such as organs, tissues, or cellular structures) is essential for accurate diagnosis and treatment planning. By combining object detection and semantic segmentation, instance segmentation can identify and segment individual objects in an image, making it highly valuable for applications like tumor detection, organ delineation, and cell segmentation in microscopic images. In particular, instance segmentation is pivotal in analyzing high-resolution medical images, such as histopathology slides, MRI scans, and CT images, where the spatial precision required can significantly impact clinical outcomes [1], [2]. Accurate instance segmentation can significantly improve the quality and efficiency of medical diagnoses by automating the process of identifying and delineating structures in medical images. In the context of histopathology, for instance, instance segmentation can help pathologists more effectively count and identify individual cells or nuclei within tissue samples, improving the accuracy of disease detection, particularly for cancers and other abnormalities [3]. Furthermore, automated segmentation enables the analysis of large datasets with high reproducibility and minimal human error, making it an essential tool for clinical research and practice. In organ segmentation, precise delineation of structures from MRI or CT scans can aid in better surgical planning, radiotherapy, and monitoring disease progression. As medical imaging becomes more integral to healthcare, the demand for high-performance instance segmentation models continues to grow, making it imperative to explore and refine algorithms that can meet these clinical challenges [4].

Medical image analysis poses several unique challenges that differentiate it from general image processing tasks. One of the primary difficulties lies in the variability of tissue structures across different medical images. Tissues from different organs have distinct characteristics, and within the same organ, structures can vary based on disease progression or patient conditions. For example, in histopathological images, tissue samples can show irregularities in the size, shape, and color of cells, which complicates the segmentation task. Moreover, images may have varying resolutions, noise levels, and artifacts, which can obscure important features and make it difficult for models to generalize effectively [5]. Another challenge is the need for high-resolution image processing. Medical images often contain fine-grained details, such as small tumors, lesions, or nuclei, requiring segmentation models to maintain accuracy at pixel-level precision. These models must also be robust to variations in imaging modalities, such as differences between CT, MRI, or histology slides [6]. Furthermore, real-time processing is increasingly required, particularly in clinical settings where time-sensitive decisions must be made. This makes model efficiency and inference speed important factors in developing practical solutions for medical imaging [7].

One-stage object detection models, known for their ability to perform real-time detection with high accuracy, have been a significant advancement in the field of object detection [1]. Over time, the architecture of these models has evolved, improving detection accuracy and handling more complex tasks, including instance segmentation [8]. YOLOv9, one of the earlier iterations in the series, introduced several optimizations, particularly in terms of speed and accuracy, making it effective for various real-time applications, including medical image segmentation. Despite its success, YOLOv9 still faces challenges with fine-grained segmentation tasks, especially in detecting small objects or distinguishing between closely packed structures, which is crucial for medical imaging applications [9].

YOLOv11, the latest model in this one-stage object detection series, builds upon the strengths of its predecessors, incorporating enhancements like improved feature pyramids, attention mechanisms, and advanced loss functions to address the limitations of previous versions. These innovations allow YOLOv11 to better handle variations in object size and shape, making it more suitable for instance segmentation in complex

medical images. YOLOv11's ability to efficiently perform both segmentation and detection tasks in real-time, while maintaining high accuracy, positions it as a promising solution for medical image analysis [4].

The objective of this study is to evaluate and compare the performance of YOLOv9 and YOLOv11 for medical image instance segmentation, particularly focusing on the segmentation of nuclei in histopathological images using the NuInsSeg dataset. Both models will be fine-tuned on the dataset, which consists of over 30,000 manually annotated nuclei across 665 image patches from various human and mouse organs. The study will assess the models based on key evaluation metrics, such as precision, recall, mean Average Precision (mAP), and Intersection over Union (IoU). The aim is to determine whether YOLOv11's architectural improvements lead to better performance in terms of segmentation accuracy, and how both models compare in terms of computational efficiency and applicability to medical imaging tasks.

The paper is structured as follows: Section II provides an overview of related works in the field. Section III outlines the proposed methodology for instance segmentation in medical imaging. Section IV presents a discussion of the findings. Section V details the experimental results, including performance comparisons and a detailed analysis. Finally, Section VI concludes the paper and suggests potential directions for future research.

## II. Related Work

Instance segmentation in medical imaging has garnered significant attention due to its critical role in accurate diagnosis and treatment planning. Several studies have explored the application of deep learning models for this task, leveraging advancements in convolutional neural networks (CNNs) and attention mechanisms to enhance segmentation accuracy and performance.

One of the pioneering works in medical image segmentation is the U-Net architecture, proposed by Ronneberger et al. [1]. U-Net introduced a fully convolutional network with a symmetric encoder-decoder structure, which has become a standard for biomedical image segmentation due to its ability to handle high-resolution images and produce precise segmentation masks. This architecture has been widely adopted and adapted for various medical imaging tasks, including nuclei segmentation in histopathological images.

Recent advancements in one-stage object detection models, such as the YOLO (You Only Look Once) series, have shown promise in real-time medical image analysis. YOLOv9, an earlier iteration, introduced optimizations for speed and accuracy, making it suitable for real-time applications [9]. However, challenges remain in handling fine-grained segmentation tasks, particularly in detecting small or densely packed objects, which are common in medical images. The latest iteration, YOLOv11, builds upon the strengths of its predecessors by incorporating enhanced feature pyramids and attention mechanisms, which improve its ability to handle complex and overlapping objects [4]. These advancements make YOLOv11 particularly suitable for medical image segmentation tasks, where precise delineation of structures is crucial. Transfer learning has also been widely used to adapt pre-trained models to specific medical imaging tasks. By leveraging large, general datasets like COCO, models can be fine-tuned to achieve better performance on specialized medical datasets [5]. This approach has been shown to improve segmentation accuracy and reduce the need for extensive annotated medical datasets, which are often limited in availability.

Several studies have focused on nuclei segmentation in histopathological images, highlighting the importance of accurate segmentation for disease diagnosis and research. For instance, Lee and Kumar [10] provided a comprehensive review of nuclei segmentation techniques, emphasizing the challenges posed by variations in staining, image quality, and tissue complexity. Similarly, Jiang and Zhang [11] discussed the application of deep learning models for tissue segmentation, highlighting the need for robust models capable of handling diverse imaging conditions.

In summary, the evolution of deep learning models, particularly the YOLO series, has significantly advanced the field of medical image segmentation. The integration of attention mechanisms, feature pyramids, and transfer learning techniques has enabled the development of models that can handle the complexities of medical imaging tasks with high accuracy and efficiency.

## III. Proposed Method

Fig. 1 introduces the proposed scheme for instance segmentation, which employs a comprehensive and systematic methodology that amalgamates dataset preparation, sophisticated neural network topologies, and optimization for medical image analysis. The methodology begins with the NuInsSeg dataset, a specialized dataset containing images of nuclei, which undergo preprocessing to isolate individual nuclei instances. This includes overlaying segmentation masks to enhance visual clarity and support instance segmentation. Once preprocessed, the dataset is split into training and validation subsets, ensuring a robust foundation for model training and evaluation.

At the core of the framework are the YOLOv9 and YOLOv11 architectures, fine-tuned for medical image instance segmentation tasks. YOLO models are widely recognized for their real-time object detection capabilities, which involve predicting bounding boxes, class labels, and object probabilities in a single pass. YOLOv9 and YOLOv11, as iterations of the YOLO architecture, introduce significant advancements in feature extraction, multi-scale detection, and attention mechanisms. Specifically, YOLOv9 employs an efficient backbone network for faster and more accurate feature extraction. This is achieved through the use of feature pyramids, which enhance multi-scale object detection, and the integration of convolutional layers with batch normalization to stabilize the learning process. YOLOv9 uses anchor-based bounding box predictions for effective object localization across various scales. This architecture strikes an optimal balance between speed and accuracy, making it particularly suitable for real-time applications in medical imaging. YOLOv11 builds upon the strengths of YOLOv9, introducing several architectural enhancements aimed at improving performance, especially for complex or overlapping objects such as small cells or tumors in medical images. One of the key advancements in

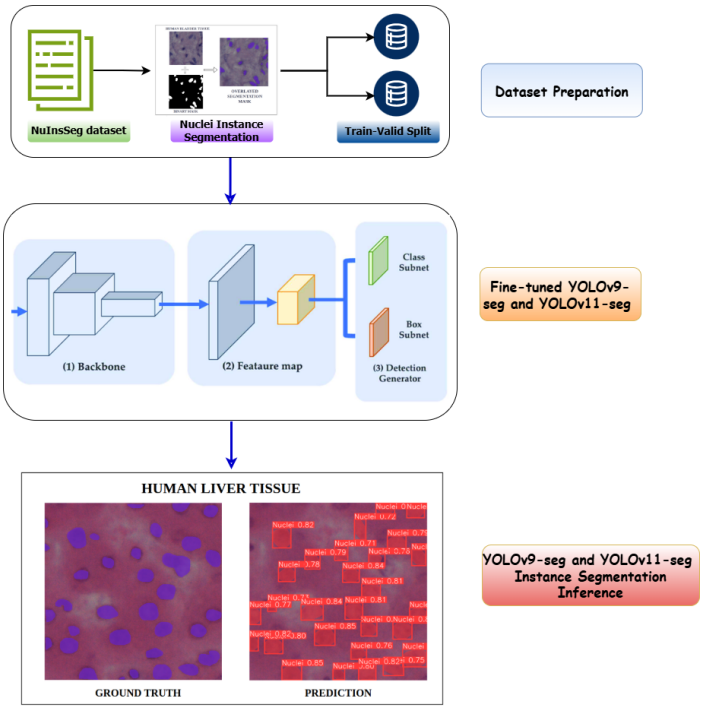

Fig. 1. Proposed framework for instance segmentation task.

YOLOv11 is the inclusion of enhanced attention mechanisms, which enable the model to focus on the most relevant parts of an image, thereby improving its ability to handle densely packed or irregularly shaped objects. Additionally, YOLOv11 features more robust feature pyramids with additional layers that capture fine-grained details, an essential capability for medical imaging tasks involving high-resolution structures like nuclei or tumors. YOLOv11 also employs an improved loss function, which better balances localization and classification errors, resulting in enhanced detection accuracy. These improvements make YOLOv11 particularly effective for tasks requiring precise object boundaries and accurate segmentation, addressing common challenges in medical image analysis.

The differences between YOLOv9 and YOLOv11 highlight the evolution of the architecture in response to the specific demands of medical image segmentation. While both models utilize feature pyramids, YOLOv11's enhanced pyramids provide superior detail capture. Moreover, the advanced attention mechanism in YOLOv11 allows it to outperform YOLOv9 when working with small, densely packed, or complex objects. YOLOv11 also optimizes the trade-off between speed and accuracy through improvements in its backbone architecture and the incorporation of advanced convolutional layers, further enhancing its utility in real-time medical imaging applications.

To adapt both YOLOv9-seg and YOLOv11-seg for instance segmentation, the framework employs fine-tuning through transfer learning strategies. Transfer learning enables the models to leverage learned features from large, general datasets, such as COCO, and adapt them to the specific requirements of medical image segmentation. The fine-tuning process involves replacing the final layers of the pre-trained models with segmentation heads designed for pixel-wise classification of object instances. This adaptation ensures that the models retain the powerful feature extraction capabilities of the original YOLO architectures while addressing the unique challenges of medical image segmentation, such as small or overlapping objects. By fine-tuning the models on the medical dataset used in this study, their ability to generalize to task-specific challenges is significantly improved, resulting in better performance in segmenting nuclei and other structures within human liver tissue.

The framework's workflow integrates these methodologies seamlessly, beginning with dataset preparation and culminating in the application of fine-tuned YOLOv9-seg and YOLOv11-seg models for instance segmentation inference. The inference stage outputs include bounding boxes, segmentation masks, and confidence scores for each detected nucleus. The results are evaluated by comparing the model's predictions with the ground truth, demonstrating the effectiveness of the framework in accurately identifying and segmenting nuclei in human liver tissue. The visualization of these results highlights the models' capability to achieve precise segmentation, even in challenging scenarios involving small or overlapping objects. This comprehensive framework represents a significant advancement in the application of deep learning for medical image analysis. By leveraging the strengths of YOLOv9-seg and YOLOv11-seg architectures, coupled with fine-tuning and transfer learning techniques, the proposed methodology achieves a robust balance between speed, accuracy, and adaptability. This makes it a valuable tool for addressing the complexities of medical image segmentation, paving the way for more accurate and efficient analysis in clinical and research settings.

### A. Dataset

The NuInsSeg dataset, utilized in this study, is a comprehensive collection of medical images designed for the task of instance segmentation. The dataset was curated specifically for the segmentation of nuclei in histological images and includes over 30,000 manually segmented nuclei across 665 image patches. These images were extracted from Hematoxylin and Eosin (H&E)-stained whole slide microscopic images, which are commonly used for tissue examination in pathology [12], [10]. The dataset features a variety of tissues and organs from both human and mouse subjects, with key organs such as the cerebellum, kidney, liver, and pancreas being included [11], [13]. These images are critical for the study of medical diagnostics, offering rich information for segmenting and analyzing the structural details of biological tissues.

The dataset consists of 665 image patches, each containing segmented nuclei, making it ideal for the instance segmentation task, where the goal is to not only detect the presence of nuclei but also delineate their exact boundaries within each image [14], [15]. This dataset's diversity—spanning multiple organ types and tissue structures—poses unique challenges for segmentation algorithms, especially due to the inherent variability in the quality and resolution of the images. Furthermore, the complexity of the tissue structures, varying shapes of nuclei, and the presence of overlapping or clustered cells introduce significant challenges for achieving precise segmentation [16], [17].

For training and validation purposes, the NuInsSeg dataset is split into an 80% training set and a 20% validation set. This

split ensures a sufficient number of samples for model training while maintaining an adequate set of images to evaluate the model's performance in real-world scenarios [18], [19]. The training set provides a large enough pool for the model to learn diverse patterns from various tissue types, while the validation set is used to assess the model's ability to generalize and make accurate predictions on unseen data. The variability in the dataset further challenges the models to maintain performance across different tissue types, image qualities, and segmentations [20], [21]. Medical image datasets, such as NuInsSeg, present several challenges due to the variability in image quality caused by differences in slide preparation, staining intensity, and imaging equipment [22], [23]. Moreover, the structural complexity of organs and tissues, along with the potential for overlapping cells, increases the difficulty of achieving accurate segmentation. These challenges emphasize the importance of developing robust instance segmentation models capable of handling such diversity and complexity [24], [25].

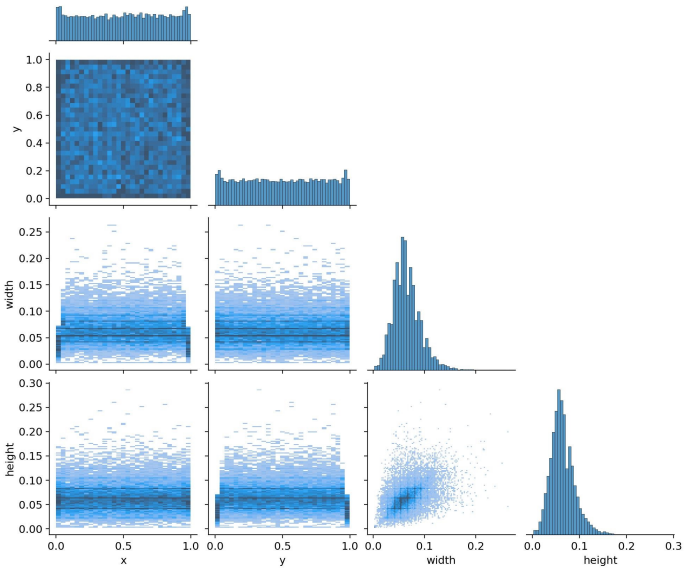

Fig. 2. Correlogram of bounding box attributes in the dataset.

Fig. 2 illustrates the distribution and relationships between bounding box attributes (x, y, width, height) in the dataset. It provides insights into the spatial placement and size variability of nuclei across the images, helping to understand patterns in object positioning and scale, which are crucial for optimizing the model's detection and segmentation performance.

### B. Performance Metrics

The performance of the instance segmentation models (YOLOv9 and YOLOv11) is evaluated using a set of commonly used quantitative metrics that are critical for assessing the effectiveness of medical image segmentation models. These metrics include Precision, Recall, Intersection over Union (IoU), Mean Average Precision (mAP), and the F1 Score.

Precision is the proportion of true positives (TP) to the sum of true positives and false positives (FP), and it measures how many of the predicted positive instances are actually correct. It is given by the Formula (1):

$$\text{Precision} = \frac{TP}{TP + FP} \tag{1}$$

Recall, on the other hand, measures the proportion of true positives (TP) to the sum of true positives and false negatives (FN), and it assesses how many of the actual positive instances are correctly identified by the model. It is calculated as Formula (2):

$$\text{Recall} = \frac{TP}{TP + FN} \tag{2}$$

To provide a balance between precision and recall, the F1 Score is used. The F1 Score is the harmonic mean of precision and recall, and is calculated by the Formula (3):

$$\text{F1 Score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{3}$$

Intersection over Union (IoU) is another critical metric, specifically for evaluating segmentation tasks. It measures the overlap between the predicted segmentation mask and the ground truth mask. IoU is given by the Formula (4):

$$\text{IoU} = \frac{\text{Area of Overlap}}{\text{Area of Union}} \tag{4}$$

The Mean Average Precision (mAP) is a common metric used in object detection and segmentation tasks, which evaluates the precision of predicted masks at different IoU thresholds. The mAP is calculated as the mean of average precision (AP) for each class, as shown below Formula (5):

$$\text{mAP} = \frac{1}{N} \sum_{i=1}^{N} \text{AP}_i \tag{5}$$

The mAP at various IoU thresholds, such as mAP@50 and mAP@75, is commonly used to assess segmentation accuracy, particularly in tasks like medical imaging where fine-grained object boundaries are critical. These metrics—Precision, Recall, IoU, mAP, and F1 Score—are used together to evaluate the model's overall performance in medical image segmentation tasks. Precision and recall help understand the trade-off between false positives and false negatives, while IoU and mAP provide insight into the quality of the segmentation boundaries. The F1 Score combines both precision and recall into a single metric to offer a comprehensive assessment of the model's performance.

### C. Training Process

The training process for the proposed YOLO-seg models was conducted over 100 epochs to ensure sufficient learning and convergence of the models. A batch size of 4 was chosen to balance computational efficiency with model performance, particularly given the high-resolution nature of the dataset images. The input image size was set to $640 \times 640$ pixels, a resolution that allows for detailed feature extraction while maintaining manageable computational demands. The learning rate was initialized at 0.001, a value selected to

provide a steady optimization process, avoiding overshooting while ensuring gradual convergence of the loss function. This configuration was designed to optimize the models for accurate instance segmentation in medical imaging tasks.

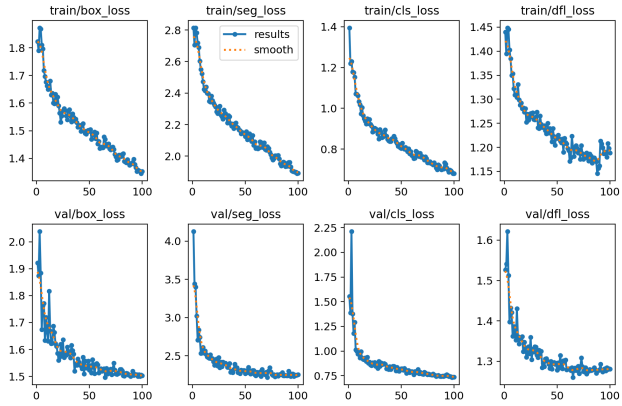
## IV. Experimental Results

### A. Complexity Analysis

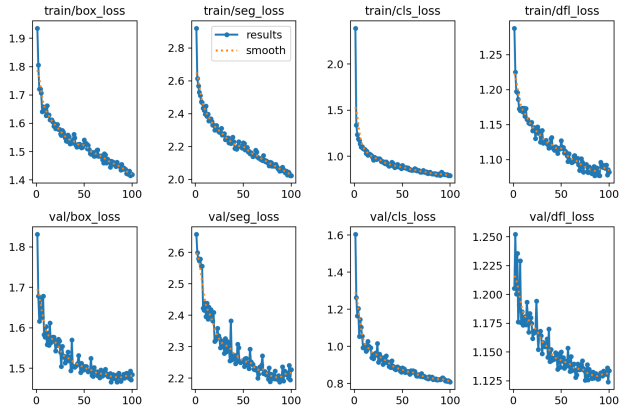
Table I provides a comparative complexity analysis of the one-stage YOLOv9c-seg and YOLOv11n-seg models, highlighting their layers, parameters, GFLOPs (billion floating-point operations), inference time per image, and post-processing time per image. YOLOv9c-seg, with 441 layers and 27,625,299 parameters, has a computational complexity of 157.6 GFLOPs, achieving an inference time of 24.2 milliseconds per image and a post-processing time of 5.5 milliseconds. This design focuses on achieving high accuracy, albeit with higher computational requirements. On the other hand, YOLOv11n-seg, a lightweight model with 265 layers and only 2,834,763 parameters, significantly reduces computational complexity to 10.2 GFLOPs, achieving an inference time of just 2.6 milliseconds per image and a post-processing time of 2.4 milliseconds. The streamlined design of YOLOv11n-seg makes it highly suitable for real-time applications where computational resources are limited, effectively balancing speed and accuracy.

TABLE I. Complexity Analysis of One-Stage Models

| Model | yolov9c-seg | yolov11n-seg |
|---|---|---|
| **Layers** | 441 | 265 |
| **Parameters (M)** | 27,625,299 | 2,834,763 |
| **GFLOPs** | 157.6 | 10.2 |
| **Inference Time(ms)** | 24.2 | 2.6 |
| **Postprocess per image (ms)** | 5.5 | 2.4 |



(a) Fine-tuned YOLOv9c-seg.



(b) Fine-tuned YOLOv11n-seg.

Fig. 3. Training and Validation loss curves.

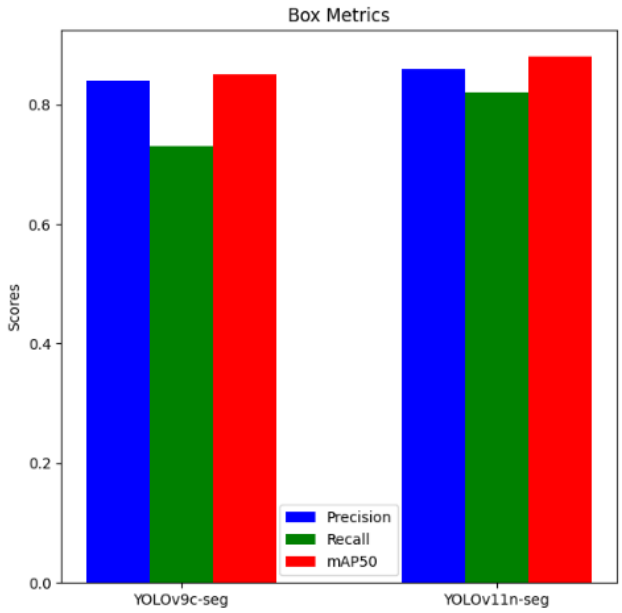
### B. Training and Validation Loss Results

Fig. 3 shows loss curves for two different instance segmentation models evaluated on the NuInsSeg dataset. Each model is assessed on training and validation losses for four categories: box loss, segmentation loss, classification loss, and distribution focal loss (DFL). The comparison between YOLOv9c-seg and YOLOv11n-seg for instance segmentation on the NuInsSeg dataset reveals that both models show a consistent downward trend in losses, indicating successful learning. However, the fine-tuned YOLOv11n-seg model demonstrates superior performance with lower initial and final losses across all metrics, including box loss, segmentation loss, classification loss, and DFL loss, on both training and validation sets. The validation losses for YOLOv11n-seg are notably smoother and lower towards the end, suggesting better optimization, generalization, and regularization compared to YOLOv9. This makes the proposed YOLOv11 model the more optimal choice for the NuInsSeg dataset.

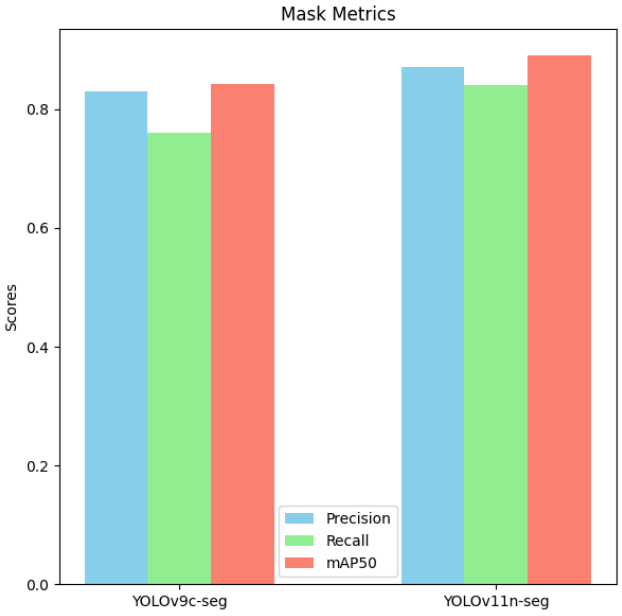
### C. Comparative Performance Evaluation

For instance segmentation in medical imaging, particularly in the context of segmenting nuclei in histopathological images using the NuInsSeg dataset, the provided metrics compare two versions of YOLO (YOLOv9c-seg and YOLOv11n-seg), as shown in Fig. 4. In the box metrics, YOLOv9c-seg achieves a precision of 0.84, recall of 0.73, and mAP50 of 0.85, indicating solid performance in detecting the nuclei. In comparison, YOLOv11n-seg demonstrates improved performance with a precision of 0.86, recall of 0.82, and mAP50 of 0.88, suggesting better accuracy in detecting and localizing the nuclei. For the mask metrics, YOLOv9c-seg shows a precision of 0.83, recall of 0.76, and mAP50 of 0.843, reflecting good segmentation of the nuclei boundaries. YOLOv11n-seg outperforms YOLOv9c-seg with a precision of 0.87, recall of 0.84, and mAP50 of 0.89, indicating superior segmentation quality and more accurate delineation of nuclei contours. Overall, YOLOv11n-seg demonstrates better detection and segmentation accuracy for nuclei from the NuInsSeg dataset.

The predicted results from YOLOv11n-seg and YOLOv9c-seg demonstrate their medical image instance segmentation capabilities, as depicted in Fig. 5. Advanced attention mechanisms and feature pyramids let YOLOv11n-seg identify tiny, densely packed nuclei in many tissue types with great accuracy. Bounding boxes with high confidence ratings (0.7–0.9) around nuclei in diverse tissue types are predicted. For overlapping or irregularly shaped nuclei, YOLOv11n-seg's bounding box placement shows its attention processes, resulting in generally constant confidence ratings even in complicated areas. YOLOv11n-seg is ideal for complex medical imaging activities

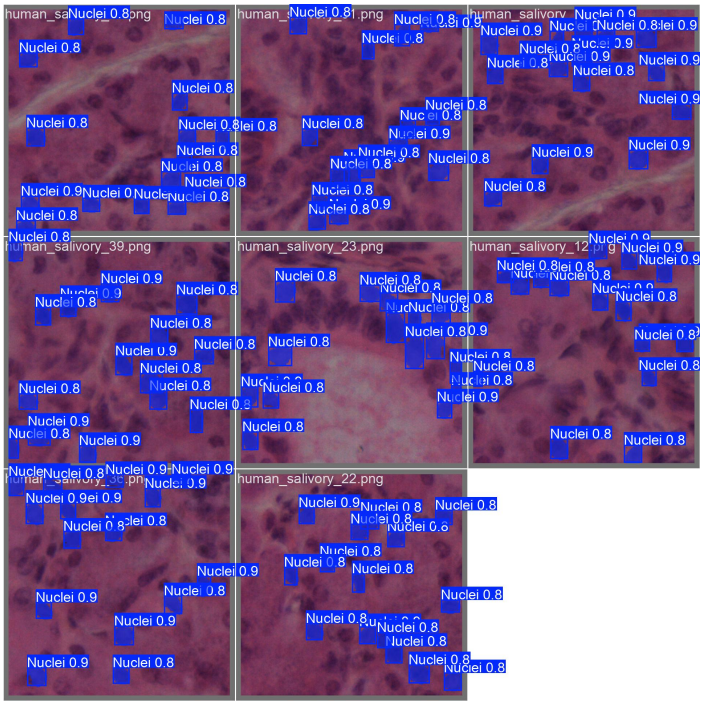


(a) Box metrics.

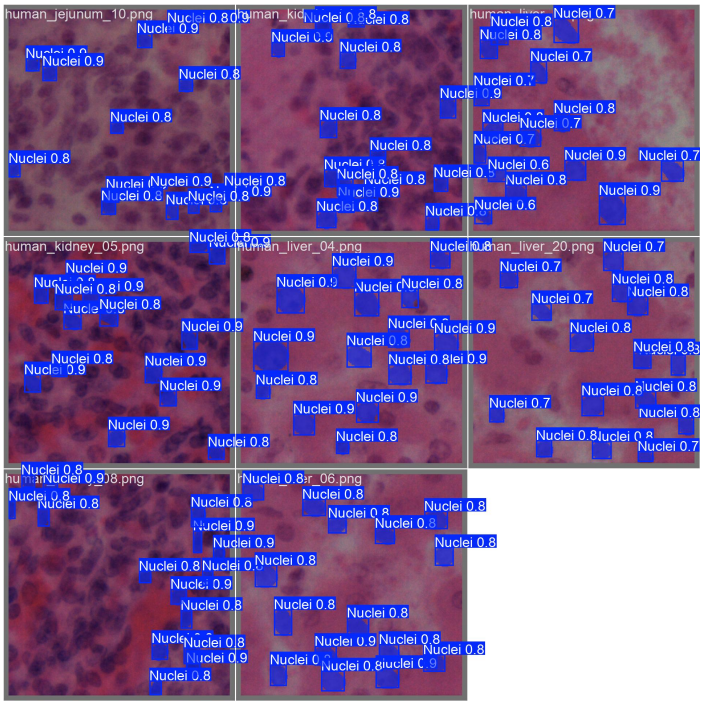


(b) Mask metrics.

Fig. 4. Performance evaluation: YOLOv11n-seg vs YOLOv9c-seg.



(a) Fine-tuned YOLOv9c-seg.



(b) Fine-tuned YOLOv11n-seg.

Fig. 5. Predicted results.

like assessing tumors or cell nuclei because to its enhanced resilience and precision.

YOLOv9c-seg also provides bounding boxes with good confidence ratings for medical image nuclei. When addressing thick or overlapping nuclei, YOLOv9c-seg is less precise than YOLOv11n-seg owing to the lack of strengthened attention mechanisms and feature pyramid enhancements. Tissue locations with complicated or subtle nucleus features may have small detection consistency differences. Despite this, YOLOv9c-seg balances speed and accuracy, making it suited for real-time applications that prioritize processing efficiency.

A performance comparison shows important differences between the two devices. YOLOv11n-seg's sophisticated attention mechanism and feature pyramids may help it identify tiny or overlapping nuclei more consistently. While both algorithms have similar confidence levels for discovered nuclei, YOLOv11n-seg has a somewhat better balance between

accuracy and false positives. YOLOv11n-seg is superior for sophisticated medical imaging tasks requiring fine-grained detail identification, whereas YOLOv9c-seg works well but may struggle with thick or complex tissue samples. The comparative analysis reveals that while YOLOv9c-seg performs adequately in standard scenarios, YOLOv11n-seg excels in complex imaging conditions, offering enhanced detection capabilities that are crucial for precise and reliable medical diagnostics.

## V. Discussion

The comparative analysis of YOLOv9c-seg and YOLOv11n-seg models for instance segmentation in medical imaging provides several important insights into their performance and practical applicability. The models were fine-tuned using transfer learning on the NuInsSeg dataset, which contains over 30,000 annotated nuclei, presenting a diverse and complex challenge for segmentation models. The experimental results clearly indicate that YOLOv11n-seg outperforms YOLOv9c-seg across multiple evaluation metrics. Notably, YOLOv11n-seg achieved higher values in precision (0.87), recall (0.84), and mAP50 (0.89), compared to YOLOv9c-seg. This suggests superior segmentation quality and a greater ability to accurately detect and delineate nuclei, particularly in complex or densely populated tissue regions. The reduced training and validation losses across all categories further affirm YOLOv11n-seg's improved generalization capabilities. The success of YOLOv11n-seg can be attributed to its architectural advancements, including enhanced attention mechanisms and deeper feature pyramids, which allow for more precise detection of small, overlapping, and irregularly shaped nuclei. Additionally, the significant reduction in parameters and computational complexity makes YOLOv11n-seg an attractive option for real-time clinical applications, achieving inference times of just 2.6 milliseconds per image. These findings support the primary objective of the study—to identify a more robust and efficient instance segmentation model for medical imaging. By demonstrating higher segmentation accuracy and faster inference with YOLOv11n-seg, the study confirms the advantages of integrating transfer learning and advanced architectural features for improving medical image analysis. These results highlight YOLOv11n-seg's strong potential for deployment in diagnostic tools and automated workflows within clinical and research settings.

## VI. Conclusion

This paper provided a detailed comparative analysis of fine-tuned one-stage object detection models for instance segmentation in medical imaging. Using the NuInsSeg dataset, which contains over 30,000 manually segmented nuclei across 665 image patches from various human and mouse organs, we presented the fine-tuned YOLOv9-seg and YOLOv11-seg architectures. The models were evaluated using key performance metrics, including precision, recall, mAP, and Intersection over Union (IoU). The experimental results demonstrate that the fine-tuned YOLOv11-seg outperforms YOLOv9-seg, with significant improvements in segmentation accuracy and mAP. YOLOv11-seg's advanced attention mechanisms and enhanced feature pyramids enable superior detection of small, densely packed, and irregularly shaped nuclei, making it a robust and efficient tool for complex medical imaging tasks.

Future studies may investigate the use of multi-modal imaging methods to provide more comprehensive contextual information, hence possibly improving segmentation accuracy. Furthermore, enhancing the computational efficiency of YOLOv11-seg for implementation in resource-limited contexts, such as mobile or embedded systems, would expand its practical use. Incorporating varied datasets and diseases into the assessment may enhance the models' resilience and scalability across numerous medical imaging contexts.

# Multitask Model with an Attention Mechanism for Sequentially Dependent Online User Behaviors to Enhance Audience Targeting

Marwa Hamdi El-Sherief, Mohamed Helmy Khafagy, Asmaa Hashem Sweidan
Faculty of Computers and Artificial Intelligence, Fayoum University, 63514 Egypt

***Abstract*—This paper proposes a multitask learning approach with an attention mechanism to predict audience behavior as sequential actions. The goal is to improve click-through and conversion rates by effectively targeting audience behavior. The proposed model introduces specific task sets designed to address the challenges specific to each prediction task. In particular, the first task, click prediction, suffers from data sparsity and a lack of prior knowledge, limiting its predictive power. To address this, a one-dimensional convolutional network (1D CNN) tower is used in the first task to learn local dependencies and temporal patterns of user activity. This design choice allows the model to better detect potential clicks, even without rich historical data. The task of conversion prediction is tackled by a fully connected convolution tower that selectively combines the corresponding features extracted from the first task using an Attention Mechanism, as well as the original shared embedding input data, enabling richer context for performing more accurate prediction. Experimental results show that the proposed multitask architecture significantly outperforms existing state-of-the-art models that do not consider tower architecture design to predict sequential online audience behavior.**

***Keywords*—Multitask learning; 1D convolution neural networks; attention mechanism; click through rate; conversion rate; audience behavioral targeting; audience behavior**

## I. Introduction

In Internet advertising, audience targeting delivers the right message to the right audience at the perfect time. It is a multifaceted process that depends on several factors and how they work together. Recently, researchers have become increasingly interested in using machine learning to improve audience targeting as the market's online advertising needs grow. Behavioral targeting (BT) [1], which considers the behavior of the online user, such as clicking links, visiting websites, submitting forms, sending messages, making purchases, etc., is one of the most efficient techniques for improving the target audience [2].

To reach the ultimate business goal of conversion, the user behavior in an advertising campaign takes a multistep path (impression $\rightarrow$ click $\rightarrow$ conversion). The terms" impression", "click", and "conversion" denote the frequency of an online advertisement's display, clicks, and conversions, which include purchases that include the number of clicks that result in an action. The ratio of clicks on an online advertisement to the times the online ad is presented is called the click-through rate, or "CTR" [3]. In contrast, the conversion rate (CVR) is the ratio of the number of people who convert to the number of clicks at first; efforts were focused on developing different models to predict the click-through rate (CTR) [4], which gauges the effectiveness of the campaign. It is difficult to capture complex interactions in advertising systems using traditional machine learning classification methods, such as linear regression, support vector classification (SVC), and decision trees, particularly when high-dimensional data are present. Furthermore, a variety of deep learning architectures are employed in advertising systems to capture interactions between high-order features, including long-short-term memory (LSTM) and convolution neural networks (CNN) [5] and [6].

However, calculating the exact return on investment (ROI) has become crucial for marketers dealing with Internet advertising. Due to the complexity of user behavior, both the CTR and CVR predictions are required. The issue of limited data and delayed feedback is the main barrier to the prediction of the conversion rate [7]. Furthermore, clicks and conversion behaviors are sequential and depend on a multi-step conversion path. Recently, multitask models have used click behavior to address the problem of sparse data in conversion behavior. Deep learning researchers are actively investigating multitask learning (MTL) [8]. Through shared information, this learning paradigm seeks to learn several related tasks to enhance performance and generalization collaboratively. MTL has been used effectively by several academics in a variety of areas recently, including recommendation systems [9], computer vision, natural language processing, and reinforcement learning.

Multitask learning has been frequently applied to improve end-to-end conversion rates in the audience's multistep conversion path. According to task relations, multitask learning is divided into parallel, cascaded, and auxiliary tasks in multitask deep recommendation systems [9]. In this instance, a sequential dependency between tasks is termed a cascading task connection, where the prior task influences the computation of the current task. Numerous cascaded task relation models have been presented in user behavior sequence prediction to address the problems of overfitting and data sparsity in training sparse conversion behavior data. The authors in [10] and [11] proposed multigate mixture of experts (MMoE) and progression-layered extraction (PLE), respectively, taking into account CTR and CVR as non-sequential tasks. To address the problem of the sequential nature of the user behavior input data, [12] proposed the mixture of sequential experts (MoSE) to represent sequential behavior using long-short-term memory (LSTM) in cutting-edge multigate mixture of expert multitask models. However, this technique lacks information sharing between the top-level towers in the model, which holds valuable information from the previous tasks to model click-through rate (CTR) and conversion rate (CVR) prediction by

two auxiliary tasks. Using an estimated conditional probability in the CVR task, the sequential dependence between user activities is taken into account in [13], [14], and [15].

To improve model performance, ESM2 [15] specifically masks conversion-related information during click prediction, therefore addressing the constraints of ESMM [13]. However, severe information loss might result from incorrect probability estimates. To overcome the difficulties of multitask learning with sequentially dependent tasks among multistep conversions, where prior tasks exchange valuable information with the subsequent task at the top of the tower [16], [17], and [18] proposed AITM, PIMM, and MNCM, respectively. Although many multitask learning models have been proposed for CTR and CVR prediction, most of them either overlook the sequential dependence across user behaviors or fail to share high-level task-specific information effectively among tasks. For example, models such as ESMM and MMoE don't explicitly model the action sequence of users or transfer informative signals from clicks to conversions using complicated mechanisms. Although recent models such as AITM, PIMM, and MNCM consider the sequential nature of user behavior, they still lack emphasis on the architectural design of task-specific towers. To the best of our knowledge, most of these models adopt simple feedforward networks as towers and overlook the potential benefits of using diverse tower structures. This is particularly crucial for the click prediction task, which suffers from a lack of prior knowledge and would greatly benefit from employing a more expressive architecture, such as a 1D convolutional network, to represent local temporal dependencies in user behavior. To address this gap, this paper proposes a novel multitask model that consists of a 1D CNN tower to improve the click prediction task and an attention-based mechanism to transfer beneficial information into the conversion prediction task. The proposed design addresses the challenges of data sparsity, sequential dependency, and task interaction of online user behavior prediction.

As a result, the following summarizes all the primary contributions in this paper:

1) Proposed a multitask model to improve audience behavioral targeting.
2) Shared embedding vector for all tasks.
3) Using 1D CNN improves the first task tower.
4) Use the attention mechanism to identify useful information from the information provided.
5) Processing of the Ali-CCP dataset.
6) Pre-processing of the Taobao dataset and feature engineering to be relevant to our work.
7) The data loader to access processed data that can be parallelized and shuffled.

Therefore, the remainder of this paper is structured as follows: Section II reviews the related work in multitask learning and user behavior modeling. Section III presents the proposed architecture in detail. Section IV explains the datasets, the preprocessing pipeline, and the experimental setup. Section V discusses the experimental results and performance evaluation. Finally, Section VI concludes the paper and suggests directions for future research.

## II. Related Work

This section reviews recent studies on online audience behavior targeting using machine learning [19]. Previous research has shown that machine learning greatly improves the online audience-targeting process. Recent research uses multitask models to improve multistep user conversion path (click $\rightarrow$ conversion) returns [9]. According to task relation, models are classified into non-sequential tasks and sequential dependence tasks, as shown in Table I.

### A. Non_Sequential Tasks

In studies [10], [11], and [12], tasks are non-sequential and are modeled separately. The multi-gate mixture of experts (MMoE) [10] uses network gates to bring together experts for various tasks, improving the model's capacity to capture complex task-specific patterns. The model AUCs are 0.6420 for purchases and 0.6047 for clicks.

The authors of study [11] presented a progressive layered extraction (PLE) model that clearly distinguishes between task-specific and task-shared experts to address the seesaw problem, which occurs when improving one task's performance may affect the performance of another task. The AUC models for click and conversion are, respectively, 0.6039 and 0.6417.

The authors of study [12] introduced MoSE. This model models user activity streams using long-short-term memory (LSTM) and offers a comprehensive sequential solution with a gated mixture of experts. After extensive testing with real-world G Suite user data, MoSE outperforms the production model with an AUC score of +4.8%.

In studies [10], [11], and [12], the mixture of experts shares expert modules across all tasks at the bottom of the multi-task model. However, the inability to exchange information between tasks in top towers, which contain richer and more useful information, may limit their ability to improve each other.

### B. Sequential Dependence Tasks

Models are created to handle dependency-based actions, which means that when the first step is completed, the subsequent step could occur due to a sequential dependency.

The authors proposed the Entire Space Multitask Model (ESMM) in [13], which takes into account the sequential dependence between tasks and the probability of transfers for various activities to calculate the click and conversion rate (CTCVR) by calculating the product of (CVR) and (CTR). The model gets AUCs of 0.6022 and 0.6291 for click and conversion, respectively.

The authors of study [15] introduced ESM$^2$ to deliberately hide conversion-related information during click prediction to overcome the shortcomings of ESMM [13]. This method enhances model performance by using conditional probability rules based on user behavior graphs to convey fundamental information. However, it ignores richer representations in vector space, which results in a severe loss of information if any probability prediction is off.

In study [16], the authors proposed an AITM (Adaptive Information Transfer Multitask) to simulate multistep conversions and sequential reliance of the audience. To improve the performance of sequentially dependent multitask learning, the suggested adaptive information transmission (AIT) module combines the behavioral expectation calculator in the loss function to acquire knowledge of what and how much information to transmit for different conversion phases. With the Ali CCP dataset, AITM achieves AUCs of 0.6043 and 0.6525 for click and purchase, respectively. The authors of study [18] proposed the multilevel network cascades model (MNCM) with two adaptive information transfer modules, the task-level information transfer module (TITM) and the expert-level information transfer module (EITM), to address the information lacking in the first task. They achieve AUCs of 72.15, 87.16, 71.06, and 86.44 on click and buy, respectively, using the AliExpress-NL and AliExpress-US datasets. The authors used the prior information merged model (PIMM) to learn sequentially dependent tasks in [17]. The PIMM combines explicit premise information (i.e., probability of previous positive reinforcement) with latent representations (specialized knowledge) to strictly describe the logical dependency among tasks as learning several sequential dependence tasks under a curriculum-structured guidance. Using a soft sampling method, PIM randomly chooses the real label information to transfer to the downstream task during training, adhering to a curriculum paradigm that ranges from basic to advanced. They obtain AUCs of 0.6075 and 0.6561 for click and buy, respectively, using the Ali CCP dataset.

Most of the reviewed literature addressed the problem of targeting online audience behavior, and current models often fail to account for the dynamic nature of user behavior, which changes over time due to different factors, including evolving interests, outside influences, and seasonal trends. To bridge these gaps, the proposed approach in this paper uses a CNN tower for the click task to handle the absence of prior information in the first task. Furthermore, the attention method is utilized to convey pertinent information from the click task to manage sparse data in the conversion task.

## III. The Proposed Model

In this paper, the methodology used to apply a multitask model with an attention mechanism [20] to anticipate the behavior of an online audience, which is intended to predict user clicks and conversion behaviors while accounting for the sequential dependency between these events; this means that the conversion event depends on the click event that occurred previously. Furthermore, as seen in Fig. 3, the shared embedding layer, the click tower, the conversion tower, the attention mechanism, and the click information extraction are the components of the proposed approach.

The approach consists of the following main phases:

### A. Preprocessing of Data

The preparation of the data phase is crucial to the proposed model. To deal with various types of characteristics in the input data and to guarantee that the input data is consistent with the nature of sequentially dependent events. The preparation step consists of the following individual stages:

*1) Data cleaning and transformation:* The data cleaning and transformation process involved several key steps in preparing the dataset for modeling. First, missing values were identified and eliminated, as they did not significantly affect the performance of large datasets. Then, low-frequency characteristics, those with fewer than ten occurrences, were removed to enhance the conciseness and relevance of the input data. The numerical features were normalized to the same scale as the variables. Categorical characteristics were encoded to convert them to a numeric form so that they could be analyzed. In addition, timestamp fields were converted into a uniform date-time format to support temporal analysis. Finally, the data were ordered by user and date time to meet the sequential input data requirements.

*2) Feature engineering:* Generate additional features based on past user behavior.

*3) Data splitting:* divide the dataset into testing, validation, and training sets based on the number of days.

### B. Data Loader

In the proposed model, the data loader plays a critical role in optimal data batching, shuffling, and loading. It begins by partitioning data and pulling associated feature names, and targets with sequential dependencies such as clicks and conversions. As an indication of process optimization, the data are batched according to a specified batch size. In addition, the data are randomized during training to improve the model's generalization capacity. Importantly, the data are dynamically loaded, which is extremely beneficial when dealing with a large dataset.

### C. Shared Embedding Layer

During this stage, the embedding methods convert all input characteristics into low-dimensional dense vectors of a given size [21]. To create a common embedding module, all embedding vectors must be concatenated. By sharing the embedding layer between all tasks, the model can benefit from rich positive samples of previous tasks, which promotes information sharing and reduces the impact of the class imbalance conversion task. Sharing the embedding layer also contributes to reducing the total number of model parameters.

### D. Click Task

This stage consists of two phases: click tower and click probability. Since the click tower, which represents the first task, has a significant impact on all subsequent tasks, as it suffers from a lack of useful information, since there are no previous tasks in this stage, this paper presents a new construction for the click tower, which addresses the representation of features using one-dimensional convolutional neural networks [22] as the tower. 1D Convolution Neural Networks are a unique kind of CNN in which the kernel analyzes one-dimensional input, such as sequential and temporal series. In CNN, the output size No is estimated as in Equation (1), the kernel size K refers to the size of the sliding kernel or the kernel filter, The number of kernels that slide before producing the output and the product points is known as the stride length S, and the size of the 0-Th frame that surrounds the input feature map $N_n$ is known as padding P [23]. The proposed

TABLE I. SUMMARY OF SURVEYED STATE-OF-THE-ART MULTITASK MODELS FOR ONLINE USER BEHAVIOR PREDICTION

| Study | Model | Dataset(s) | Model Type | Tasks | Evaluation Metric(s) | Year |
|---|---|---|---|---|---|---|
| [13] | **ESMM** | Taobao's recommender system logs | DNN | CVR, CTR, CTCVR, SPP | Multi-AUC | 2018 |
| [10] | **MMOE** | Synthetic dataset, UCI Census | Neural network (8 hidden units) | CTR, CVR | AUC | 2018 |
| [11] | **PLE** | Census-income, synthetic data, Ali CCP | LSTM | CTR, CVR | AUC | 2020 |
| [12] | **MoSE** | Generated synthetic dataset | MLP | Task1, Task2 | PR-AUC | 2020 |
| [16] | **AITM** | Ali CCP | MLP | CTR, Buy, Approval, Activation | AUC | 2021 |

| [17] | **PIMM** | Ali CCP | MLP | CTR, CVR | AUC | 2023 |

model used multiple layers of a 1D convolution network to process the shared and embedded input characteristics, varying the stride and padding for every kernel size as specified by Eq. (1). Furthermore, weight normalization is handled by ReLU activation functions, and regularization is accomplished via the dropout approach. To pass through fully connected layers, the output of the 1D convolution layers is flattened, as shown in Fig. 1. Furthermore, the second phase is the click probability, which uses a sigmoid activation function to process the output data from the click tower after passing through a linear neural network to determine the output probability.

$$\mathbf{N_o} = \left(\frac{N_n - \mathrm{K} + 2 \times \mathrm{P}}{\mathrm{S}}\right) + 1 \tag{1}$$

### E. Information Extraction

For the conversion task and other behaviors that follow, the information extraction phase is essential to improve the prediction process; learning is transferred between tasks through the attention mechanism, as shown in Fig. 2; the attention mechanism enhances the model's ability to recognize pertinent parameters required for the conversion task [24], and [25], which frequently involves sparse input. The attention mechanism that combines the information from the click information tower and the conversion tower, as shown in Fig. 3, where the feed-forward networks $Q(a)$, $K(a)$, and $V(a)$ represent the input vector to a single new vector representation, dot attention uses a dot product to determine how comparable queries $Q(a)$ and Key $K(a)$ are and scaled by dimension $\sqrt{d}$ in Eq. (2), and Eq. (3) uses a softmax function to determine attention weights $w_a$. Eq. (4) computes $z_t$, the weighted sum of the value vectors $V(a)$ using these attention weights $w_a$.

$$\mathbf{w_a} = \frac{Q(a) \cdot k(a)}{\sqrt{d}} \tag{2}$$

$$\mathbf{w_a} = \mathrm{softmax}(w_a) = \frac{\exp(w_a)}{\sum_a \exp(w_a)} \tag{3}$$

$$\mathbf{z_t} = \sum_a w_a \cdot V(a) \tag{4}$$

### F. Conversion Task

This phase handles subsequent tasks using valuable knowledge obtained from the previous task, specifically from the click tower. It begins with the conversion tower, where a fully connected neural network is used to process input coming from the shared input embedding vector. Then, an information vector is generated using a feedforward neural network that models the output of the click tower. To enhance the learning process, an attention mechanism is applied to the output of the conversion tower, which is concatenated with the information vector of the previous task. In this step, the model can successfully utilize the knowledge acquired in the earlier stages. Lastly, the probability of conversion is found by feeding the attention output into a linear neural network, then applying the sigmoid activation function to get the final prediction.

### G. Loss Calculation

The final loss function $L_f$ in our suggested model is determined by calculating the loss of cross entropy $L_c$ and the behavioral expectation calibrator $L_{bc}$ combined with a constant weighting parameter $\alpha$ that regulates the behavioral force expectation calibrator as indicated in Eq. (7). The loss is determined using the binary cross-entropy loss ($L_c$) indicated in Eq. (5), where $y$ is the label, $\hat{y}$ is the target value, T is the task, and N is the number of samples. In addition, a calibration of behavioral expectations ($L_{bc}$) indicated in Eq. (6) is added to ensure that the model result meets the actual production constraints, where the click task is expected to have a higher probability than conversion for the same user because click and conversion are sequentially dependent behaviors.

$$\mathbf{L_c}(y, \hat{y}) = -\frac{1}{N} \sum_T \sum_N \left(y \log(\hat{y}) + (1 - y) \log(1 - \hat{y})\right) \tag{5}$$

$$\mathbf{L_{bc}} = \frac{1}{N} \sum_T \sum_N \max(\hat{y}_{cl} - \hat{y}_{co}, 0) \tag{6}$$

$$\mathbf{L_f} = L_c + \alpha L_{bc} \tag{7}$$

### H. Evaluation

The proposed approach adopts the AUC, or Area Under the ROC Curve, which is a commonly used evaluation metric in

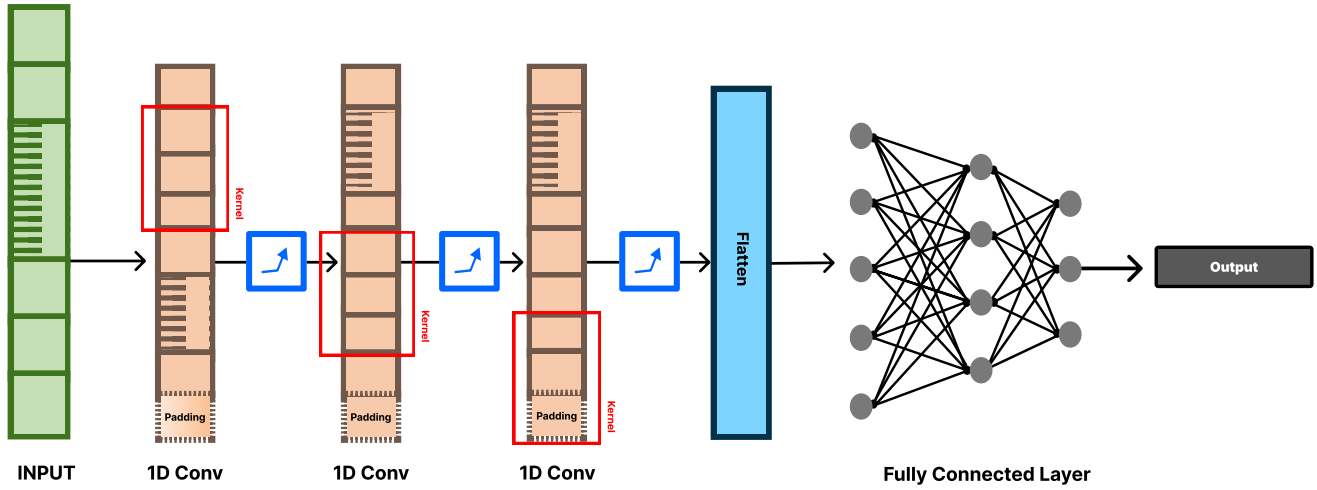

Fig. 1. 1D Convolution network.

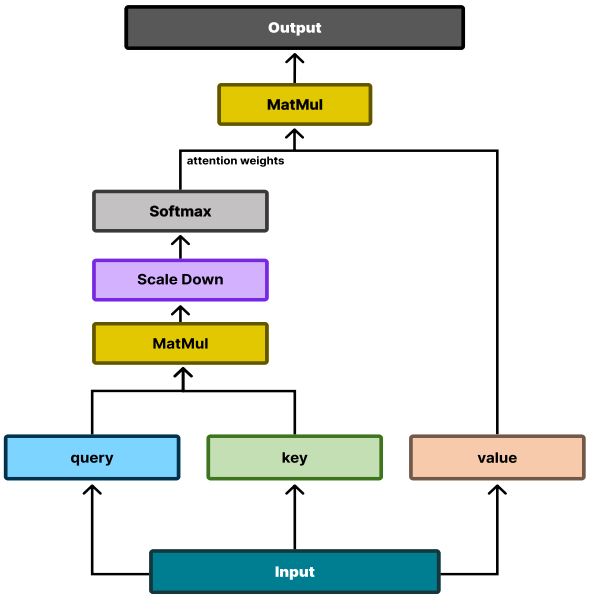

Fig. 2. Attention mechanism.

recommendation systems. Shows the probability that an item that has been clicked will rank higher than an item that has not been clicked.

## IV. Results and Discussion

### A. Datasets and Evaluation Metrics

Two public datasets were utilized in this study: Ali-CCP [13] and Taobao User Behavior for recommendation [26].

*1) Ali-CCP Dataset [13]:* This dataset is an actual traffic log from Taobao's recommendation system. The end-to-end user conversion process consists of several consecutive phases, starting from impression, moving to click, and eventually conversion (i.e., impression → click → conversion). Each observed impression is associated with a feature vector, denoted by x, representing both the user and item information. The label format is (x, y → z), where y and z are binary variables indicating whether a click (1) or no click (0), and a conversion (1) or no conversion (0), occurred, respectively. Here, as sequential tasks, the conversion can only happen if a click has occurred beforehand. The dataset exhibits significant data sparsity, as evidenced by the calculated click-through rate (CTR) and conversion rate (CVR), which are 3.89% and 0.54%, respectively, as illustrated in Fig. 4.

In the data preprocessing phase, the dataset is divided into subsets for training, validation, and testing. 50% of the data is allocated for training, 10% for validation, and the remaining 40% for testing. Low-frequency features—those with fewer than ten occurrences—are excluded, and categorical features are appropriately coded to prepare the data for input into the model. Analysis of the dataset shows that the most influential factor is the product categories the user has previously clicked on. This result demonstrates the importance of modeling user behavior history, as it has a significant impact on the prediction goal.

*2) User behavior data from Taobao for recommendation dataset [26]:* contains around 100 million user activities and serves as an essential resource for research and analysis, particularly in user behavior modeling. The dataset includes user behaviors gathered from one million randomly chosen Taobao users and records a wide range of online activities over nine days. As illustrated in Fig. 5, 846.9k users browse the items, while 6.20% add them to carts, 3.13% favorite them, and 2.27% proceed to purchase.

Regarding the preprocessing of the user behavior data from the Taobao recommendation dataset [26], the proposed approach narrowed the study to a nine-day observation period to check the fitness of the data and accelerate the processing time. It also determined the sequential dependency of the "buy"

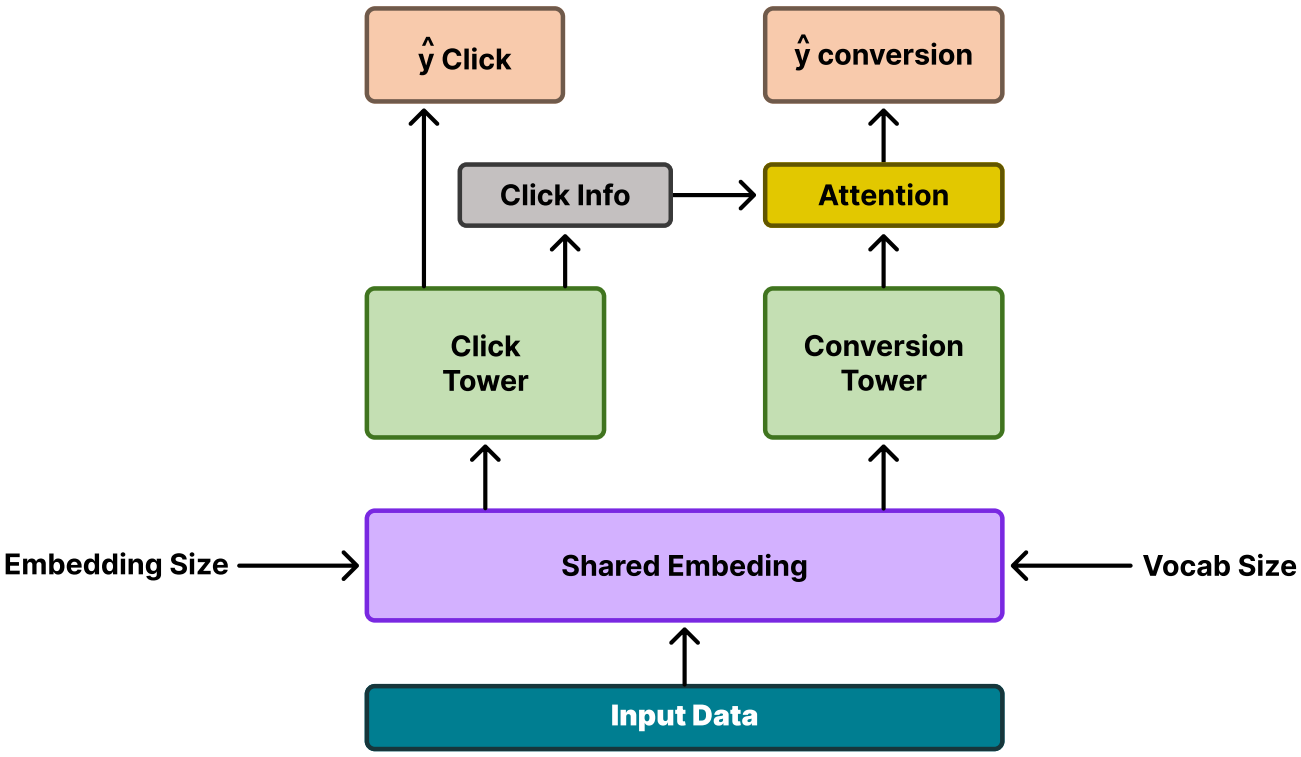

Fig. 3. Proposed model: Multitask model for sequential online user behaviors (click and conversion) with different tower architectures

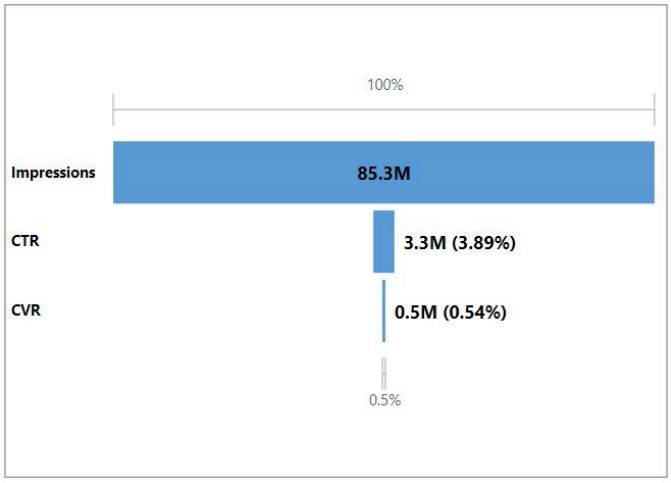

Fig. 4. Statistics of Ali_CCP dataset.

and "add-to-cart" activities, encoding the category feature "behavior" to distinguish between different activities. Data cleaning followed, excluding non-conforming products from the desired browsing-to-purchase pattern. The data preparation to supply deep learning models was ordered chronologically by user and date. This form allows the model to learn time dependencies and improve the model's ability to identify patterns and make consistent predictions. Furthermore, the presentation of the events in time-ordered sequence is consistent with the natural progression of user interactions and therefore improves the model's ability to learn meaningful information. To feature engineer the user behavior data of the Taobao recommendation dataset [26], additional historical data was incorporated, including the user's previous activities and the product categories on which the user previously clicked. This enhancement provides a contextual understanding of user behavior with more enrichment so that analysis can be deeper and more effective.

## V. Experimental Analysis

This article's studies were carried out using a PC equipped with a 16 GB GPU, 32 GB of RAM, and a 2.7 GHz Intel Core i7 CPU. The PyTorch Python libraries were used to develop our suggested strategy. Data are preprocessed using Apache Spark in Python (PySpark) to handle massive volumes of data in a distributed processing environment, especially to generate new historical characteristics that increase the size of the data. Two distinct open datasets were used to evaluate the suggested hypothesis. 4.10 GB of compressed train data and 4.68 GB of compressed test data make up the Ali CCP dataset. In comparison, the Taobao user behavior data used for the recommendation weighs 5 GB after compression.

The dictionary of vocabulary size in the embedding layer is set to the unique value of each input feature, and the embedding size is set to five. The proposed approach was experimented with different kernel sizes for the 1D Convolution

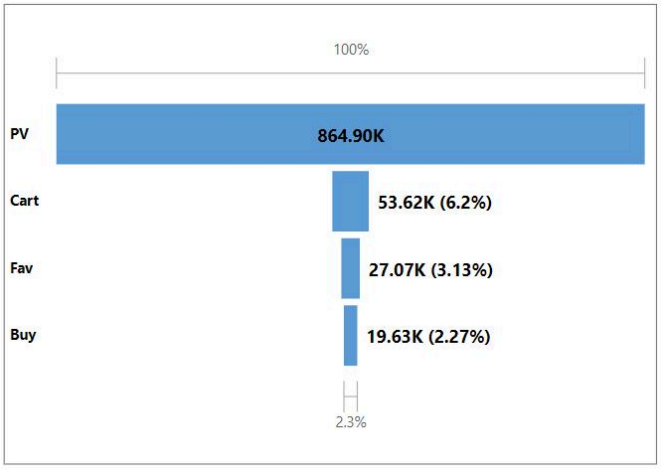

Fig. 5. Statistics of user behavior data from Taobao for recommendation dataset.

TABLE II. EVALUATION METRICS FOR CLICKS ON ALI-CCP PUBLIC DATASET FOR DIFFERENT MODELS

| Model | AUC | Accuracy | Recall | Specificity |
|---|---|---|---|---|
| AITM Model | 0.614 | 0.6 | 0.61 | 0.61 |
| Proposed Model | 0.661 | 0.64 | 0.66 | 0.66 |

tower to obtain the optimal AUC and adjusted the padding by Eq. (1). The input dimensions for the proposed approach are 128, 64, and 32 in the linear tower. The proposed approach was trained with a batch size of 1,000 samples over five epochs.

### A. Comparative Evaluation of State-of-the-Art Models

This subsection compares the performance of the suggested model with the most advanced model, AITM. The performance of the proposed model was evaluated against the AITM model using two public datasets, Ali-CCP and Taobao, using evaluation metrics such as AUC, accuracy, recall, and specificity. ROC curves are presented to visually represent the performance of the models. Fig. 6 shows the ROC curve for the AITM model in the public dataset of the Taobao recommendation. Similarly, the ROC curves for the proposed model are shown in Fig. 7 for the Ali CCP public dataset and Fig. 8 for the Taobao recommendation public dataset. These curves highlight the comparative ability of each model to distinguish between classes.

*1) Model performance on Ali CCP dataset:* In terms of model performance on the Ali CCP dataset, the click task results show that the proposed model achieved an AUC of 0.661, which was better than the AITM model with an AUC of 0.614, as presented in Table II and Fig. 9. For the conversion task, the AUC of the proposed model increased further to 0.694 compared to 0.6320 for the AITM model, demonstrating the improved performance of the proposed model, as presented in Table III and Fig. 10.

*2) Model performance on the taobao dataset:* Concerning the performance of the model in the Taobao dataset, the results of the click task show that the proposed model obtained an AUC of 0.682, compared to that of the AITM model, which

| Proposed Model | 0.725 | 0.7 | 0.73 | 0.73 |

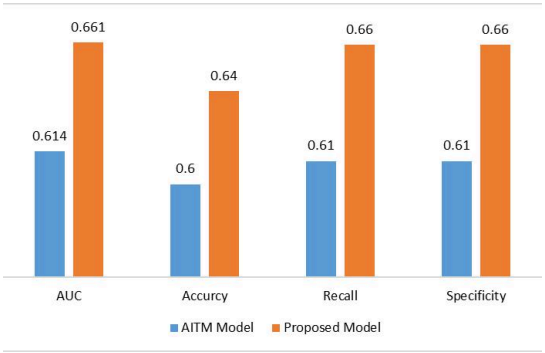

Fig. 9. Evaluation metrics for click on Ali-CCP public dataset for different models.

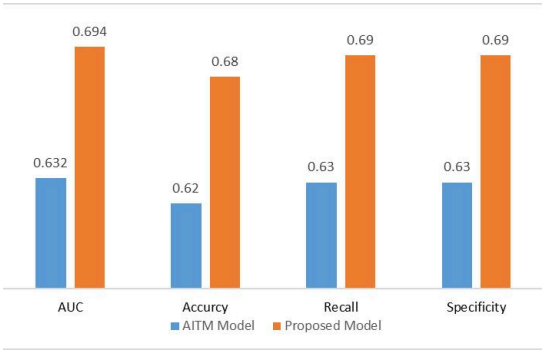

Fig. 10. Evaluation metrics for conversion on Ali-CCP public dataset for different models.

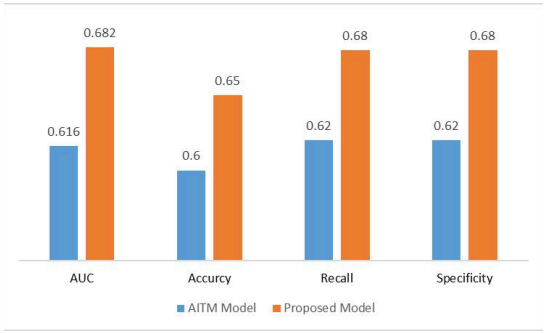

Fig. 11. Evaluation metrics for clicks on the Taobao recommendation public dataset for different models.

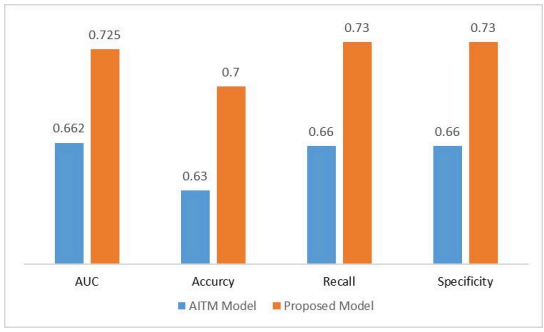

Fig. 12. Evaluation metrics for conversion on the Taobao recommendation public dataset for different models.

obtained an AUC of 0.616, as shown in Table IV and Fig. 11. As illustrated in Table V and Fig. 12, the differences were further noticeable for the conversion task, where the suggested model received an AUC of 0.725 compared to 0.662 for the AITM model.

Furthermore, the results suggest that the Taobao dataset may have slightly different structural properties than the Ali CCP dataset, resulting in marginally better model performance. This insight into the impact of the characteristics of the data set on model performance is valuable for future research.

## VI. CONCLUSION

To improve audience targeting in online advertising, this research proposes a novel multitask model to evaluate sequential user behavior online, which could help with audience targeting. The method presents a unique multitasking model with several tower architectures specific to the task. For the click task (the first task), the proposed approach uses 1D convolutional neural networks without prior knowledge to improve audience targeting by focusing on those most likely to click. In the conversion task (the subsequent task), which utilizes information from the first task, a fully connected tower is used along with an attention mechanism. The suggested method outperforms another state-of-the-art multitask model (AITM) [16] in simulating user behavior with sequential online dependencies. Future studies may need to investigate more intricate tower architectures to overcome the restrictions above.

***Abstract*—The security and efficiency of Internet of Things (IoT) networks depend on optimizing the routing protocol for low-power, lossy networks (LPNs) to manage various challenges, including expected number of transmissions (ETX), latency and energy consumption. This study proposes an advanced metaheuristic optimization framework integrating several algorithms, including Particle Swarm Optimization (PSO), Mixed Integer Linear Programming (MILP), Adaptive Random Search with two-step Adjustment (ARS2A) and Simulated Annealing (SA), to improve the performance of RPL-based IoT networks under attack scenarios. Our methodology focuses on secure routing by integrating dynamic anomaly detection and adaptive optimization mechanisms to mitigate network threats such as Blackhole, Sinkhole, and Wormhole attacks. Simulations were carried out on large-scale IoT networks with 100 and 150 nodes to evaluate the performance of the proposed algorithms. Experimental results indicate that ARS2A and MILP offer the best compromise between security and performance, achieving minimal ETX (1.28), reduced latency (0.12 ms) and optimized energy consumption (0.85 J) in dense networks. Furthermore, simulated annealing demonstrates high adaptability to mitigate routing attacks while guaranteeing stable energy efficiency. The comparative analysis highlights the strengths and weaknesses of each algorithm, underscoring the need for hybrid optimization strategies that balance computational cost and real-time adaptability. This work establishes a secure and scalable optimization framework for IoT networks, contributing to the development of intelligent, resilient and energy-efficient routing solutions.**

## I. Introduction

Mission-critical applications in fields including smart cities,industrial surveillance-health [1], and critical infrastructure management have emerged as a result of the Internet of Things (IoT) explosive growth. These networks [2], which are composed of linked sensor nodes,need to optimize energy use while guaranteeing safe and effective data transfer. However, their decentralized architecture, coupled with limited hardware resources, exposes them to major challenges, particularly in terms of reliability, energy efficiency and security against cyber-attacks. The Routing Protocol for Low-Power and Lossy [3] Networks is one of the numerous vulnerabilities in these networks are of particular concern. Numerous attacks take advantage of RPL flaws to interfere with routing and jeopardize data transfer. The most destructive of these are the Blackhole [4], Sinkhole, Wormhole and Selective Forwarding attacks, which reroute, delay, or eliminate packets moving throughout the network. These threats [5] have a direct impact on network performance, increasing the number of retransmissions required (ETX), latency and energy consumption. These degradations have the potential to cause significant system failures in critical applications,like medical and environmental networks, endangering the availability and integrity of services.

The development of sophisticated attack detection [6] and mitigation techniques that can preserve the best possible balance between security energy efficiency [7], and quality of service(QoS) is essential in light of these expanding threats. Traditional cryptography-based solutions and authentication often prove unsuitable for IoT networks [8] due to the energy and computing constraints of sensors. Therefore,a more dynamic and intelligent strategy that incorporates cutting-edge optimization techniques [9] is needed to improve routing resilience while lowering energy expenses.

In light of this,our work suggests a novel strategy that combines behavioral analysis methods with metaheuristic optimization algorithms [9], in order to secure IoT networks against attacks targeting the RPL protocol [10]. Optimizing packet routing is the goal by taking into account three fundamental metrics:

- Expected Transmission Count (ETX): Indicator of link quality, measuring the Average number of transmissions required to route a packet. A high ETX value reflects increased routing instability, often caused by attacks or interference.
- Latency: Total time required to transmit a packet from the source node to the destination node. Excessive latency is often a symptom of the presence of attacks such as Wormhole, Flooding or Selective Forwarding.
- Consumed Energy [11]: Total amount of energy consumed by nodes during transmissions. An abnormal increase in this metric is generally a sign of attack, resulting from artificially generated traffic or packet hijacking.

In order to optimize safety and network resilience, we use four sophisticated optimization algorithms [12]:

- Simulated Annealing: Enhances routing robustness by facilitating effective solution space exploration while avoiding local minima.

- Particle Swarm Optimization: Simultaneously minimizes latency and energy consumption, based on how particles behave collectively.
- Mixed Integer Linear Programming: Ensures safe and reliable routing by offering the best solution under tight restrictions.
- ARS2A (Adaptive Random Search with Two-Step Adjustment): Adaptive routing optimization is a new high-performance algorithm that allows for dynamic enhancements in IoT network performance.

By integrating these various methods, we provide a strong attack detection [13] and mitigation strategy that can dynamically adjust to threats while preserving optimal energy efficiency. By increasing network stability, our solution dramatically lessens the effect of attacks on routing, as demonstrated by our tests conducted on network with 100 and 150 nodes, reducing latency and optimizing energy consumption. These results confirm the importance of a hybrid approach combining security and metaheuristic optimization to ensure reliable, energy-efficient and resilient routing in modern IoT environments [14]. The remainder of this paper is structured as follows: Section II provides an overview of related work in the field of secure RPL-based IoT routing. Section III presents the problem formulation, detailing the key challenges and security threats addressed in this study. Section IV describes the metaheuristic algorithms employed, including PSO, MILP, ARS2A, and Simulated Annealing, and their application to secure and energy-efficient routing optimization. Section V discusses the experimental setup and performance evaluation, comparing the effectiveness of different algorithms under various network configurations and security attack scenarios. Finally, Section VI concludes the paper by summarizing key findings and suggesting future research directions to enhance the robustness and scalability of secure RPL-based IoT networks.This research aims to answer the following question: How can metaheuristic algorithms be effectively utilized to optimize secure routing in RPL-based IoT networks while minimizing ETX, latency, and energy consumption under attack conditions?

## II. Related Work

Due to the increase in cyber threats [5], a lot of research has been done recently on the security of Internet of Things networks [14], especially in relation to routing Protocol for Low-Power and lossy Networks.To address vulnerabilities in RPL-based IoT systems [15], a number of research projects have investigated the combination of machine learning [16], [17], metaheuristics algorithms [18], and security-enhancing techniques [19]. The rapid expansion of IoT networks has introduced significant challenges in energy efficiency, security, and routing optimization. Various studies have explored solutions leveraging metaheuristic algorithms and security mechanisms to mitigate threats and optimize network performance. The application of metaheuristic algorithms to improve routing effectiveness and reduce energy consumption in IoT networks has been the subject of numerous studies. Choudhary et al. [12] carried out a thorough investigation to enhance routing security and efficiency in IoT environments by merging metaheuristic approaches with convolutional Neural Networks. Their findings highlight the potential of hybrid AI-metaheuristic models in optimizing path selection while mitigating security threats. Similarly, Rahmani et al. [18] investigated the use of metaheuristic algorithms for task offloading optimization in cloud, fog, and edge computing settings. Their strategy showed increased resource allocation effectiveness and delay reduction, making it a viable technique for extensive IoT deployments.

Security is a major issue in IoT networks, especially in low-power and lossy networks (LLNs) that rely on RPL routing. Omar et al. [10] introduced UOS_IOTSH_2024, a dataset specifically designed for analyzing sinkhole attacks in RPL-based IoT networks, providing a benchmark for evaluating intrusion detection systems. Reshi et al. [20] suggested a unique defense against blackhole attacks, showing how preventative security measures can lower packet loss and improve network robustness.

Further, Yalli et al. [14] carried out a thorough analysis of IoT authentication methods,emphasizing biometric-based access restrictions,AI-driven authentication models, and lightweight cryptographic protocols as crucial ways to increase IoT security. Additionally, Kadri et al. [13] offered a thorough analysis of Dos and DDOS attack detection in Internet of Things environments, categorizing current solutions according to mitigation techniques and validation methods. Their results demonstrate that hybrid models combining anomaly detection and heuristic-based prevention offer significant benefits in securing IoT networks against large-scale attacks.

In the context of routing security, Moudni et al. [4] investigated the detection of blackhole attacks in Mobile Ad Hoc Networks (MANTEs) using machine learning. Their findings showed how adaptive learning algorithms and tailored datasets may be used to detect and stop harmful activities. Similarly, Karima et al. [19] demonstrated the promise of AI-driven adptive security frameworks by proposing a method based on SDN and AI to dynamically improve IoT security policies.

Optimizing IoT networks while maintaining security in IoT routing, the relationship between security measures and metaheuristics has drawn more attention. Yugha et al. [21] provided an extensive survey on security protocols for next-generation IoT networks, emphasizing the importance of lightweight cryptographic methods that do not compromise energy efficiency. P. M. R. et al. [11] highlighted the trade-offs between network performance, security, and energy restrictions in their analysis of energy-aware routing strategies. These studies collectively suggest that a hybrid approach, integrating metaheuristic algorithms for optimization and advanced security mechanisms, could significantly enhance the resilience and efficiency of IoT networks. Future research should focus on scalable, AI-driven security models and adaptive optimization techniques to ensure sustainable and secure IoT deployments. Although various studies have explored the use of metaheuristics and AI-based approaches for enhancing RPL-IoT routing security and efficiency, few have provided a unified solution that simultaneously addresses resilience against multiple attack types and optimization of key metrics such as ETX, latency, and energy consumption. To bridge this gap, our study proposes a novel hybrid metaheuristic framework integrating ARS2A, MILP, PSO, and Simulated Annealing, which collectively aim to enhance security and performance under realistic attack scenarios.

## III. Problem Statement

In the section we formulate the RPL-based IoT networks optimization problem considering the following metrics:$ETX$, the latency ($LT$) and the energy consumption ($EC$). The objective function integrating these criteria is defined as follows [15],

$$Minimize\ F = \ w_1.ETX + \ w_2.LT + \ w_3.EC \quad (1)$$

Where $w_1$, $w_2$ and $w_3$ are weights assigned to $ETX$, $LT$ and $EC$ respectively.

### A. Define the Metrics

$ETX$ measures the number of expected transmissions, including retransmissions, required to successfully deliver a packet over a link.

$$ETX_{ij} = \frac{1}{P_{ij}.P_{ji}}$$

Where $P_{ij}$ is the probability of successful packet transmission from node $i$ to node $j$, and $P_{ji}$ is the probability of successful acknowledgment.
$LT$ represents the time required for a packet to travel from the source to the destination.

$$LT_{ij} = \ d_{ij} + \sum_k ProcessingTime_k$$

Where $d_{ij}$ is the propagation delay between nodes $i$ and $j$, and the sum represents the processing delays at intermediate nodes.
$EC$ is the of energy consumed to transmit a packet from the source to the destination.

$$EC_{ij} = \ TE_{ij} + \sum_k ProcessingEnergy_k$$

Where $TE_{ij}$ is the energy consumed for transmission between nodes $i$ and $j$, and the sum represents the energy consumed at intermediate nodes for processing.

### B. Formulate the Constraints

The connectivity constraint ensures that the selected path maintains network connectivity [15].

$$\sum_{j \in N} x_{ij} = 1, \ \ \forall\ i \ \in \ N$$

Where $xij$ is a binary variable indicating whether the link between nodes $i$ and $j$ is part of the path (1) or not (0). The Loop-Free constraint ensures that routing path does not exceed the available energy at any node.

$$\sum_{j \in N} x_{ij} = 1, \ \ \forall\ i \ \in \ N$$

The energy constraint ensures that the energy consumption does not exceed the available energy at any node.

$$EC_{ij} \ \leq \ E_i, \ \ \forall\ i \ \in \ N$$

Where $E_i$ is the available energy at node $i$.

### C. Optimization Problem Formulation

$$Minimize\ F = \sum_{i,j \in E} (w_1.ETX_{ij} + w_2.LT_{ij} + w_3.EC_{ij}).x_{ij}$$

Subject to:

$$\sum_{j \in N} x_{ij} = 1, \ \ \forall\ i \ \in \ N$$

$$x_{ij} \ + \ x_{ji} \ \leq \ 1, \ \ \forall\ i, j \ \in \ N$$

$$EC_{ij} \ \leq \ E_i, \ \ \forall\ i \ \in \ N$$

$$x_{ij} \in 0, 1$$

## IV. Security-Aware Optimization Formulation

We apply security-aware constraints to the routing optimization problem in order to improve security in IoT networks [14]. The following is the definition of the objective function that combines network performance and security.

$$Minimize\ F = \ w_1.ETX + \ w_2.LT + \ w_3.EC - w_4.SI \quad (2)$$

Where $w_1$, $w_2$, $w_3$, and $w_4$ are the respective weights assigned to $ETX$, $LT$, $EC$, and the security index ($SI$), which quantifies the resilience of the network against attacks.

### A. Security and Attack Analysis

IoT networks are extremely susceptible to different kinds of cyberattacks [13] that take advantage of resource constraints and routing flaws. Specifically, by absorbing all packets and preventing them from reaching their destination, Blackhole attacks [20] interfere with communication. Wormhole attacks cause significant route diversion by establishing a tunnel between two malevolent nodes in order to intercept and after communications. By deceiving trustworthy nodes into sending packets via a compromised node, sinkhole [10] attacks dramatically raise network latency and energy usage. Selective forwarding attacks make it more difficult to identify them by dropping important packets while forwarding others. By increasing the Expected Transmission Count, Latency and Energy Consumption, these attacks collectively degrade network performance.

Our architecture has anomaly detection methods that continuously track changes in routing behavior in order to combat these attacks. The security-aware optimization ensures routing pathways do not include compromised nodes, and energy-efficient, low-latency routes are prioritized.

### B. Security Index (SI)

We define a Security Index ($SI$) that takes into account the likelihood of attack detection ($D_A$) and the effect of the attack on routing reliability in order to guarantee secure routing.

$$SI = \sum_{i,j \in E} (D_{A_{ij}} \times R_{ij}) \quad (3)$$

Where:

- $D_{A_{ij}}$ indicated the likelihood of finding a link attack $(i, j)$, calculated based on anomaly detection methods .
- $R_{ij}$ represents the routing reliability of link $(i, j)$, which is inversely proportional to the number of compromised nodes.

### C. Security-Aware Constraints

To mitigate routing attacks, we introduce additional constraints:

**Attack Avoidance Constraint**

$$\sum_{(i,j)\in E} x_{ij} \cdot C_{ij} \leq T_{max} \tag{4}$$

Where: - $C_{ij}$ is a binary variable indicating whether a node $(i, j)$ is identified as compromised (1) or safe (0). - $T_{max}$ is a predefined threshold limiting the number of compromised nodes in the path.

**Secure Energy Constraint**

$$EC_{ij} + \sum_{k} ProcessingEnergy_k \leq E_i - E_{safe}, \quad \forall i \in N \tag{5}$$

Where:

- $E_{safe}$ is an energy buffer set aside to guard against malicious energy depletion.
- This limitation prevents attack-induced routing changes from causing nodes to prematurely exhaust their energy.

### D. Final Optimization Problem Formulation

Integrating security considerations, the final optimization model is formulated as:

$$\begin{aligned} Minimize \quad F = \sum_{i,j\in E} \Big( & w_1 \cdot ETX_{ij} + w_2 \cdot LT_{ij} \\ & + w_3 \cdot EC_{ij} - w_4 \cdot SI_{ij} \Big) \cdot x_{ij} \end{aligned} \tag{6}$$

Subject to:

$$\sum_{j\in N} x_{ij} = 1, \quad \forall i \in N \tag{7}$$

$$x_{ij} + x_{ji} \leq 1, \quad \forall i, j \in N \tag{8}$$

$$EC_{ij} \leq E_i - E_{safe}, \quad \forall i \in N \tag{9}$$

$$\sum_{(i,j)\in E} x_{ij} \cdot C_{ij} \leq T_{max} \tag{10}$$

$$x_{ij} \in \{0, 1\} \tag{11}$$

## V. Metaheuristic Methods for Routing Optimization in IoT Networks

Optimization methods that draw inspiration from physical, biological,or natural phenomena are known as metaheuristic algorithms [18]. They are employed to resolve complicated issues when precise methods are not feasible because of computational complexity. Metaheuristics [12] as opposed to exact algorithms produce high-quality approximations in a reasonable amount of time but do not ensure global optimality. Among the most popular algorithms in the field of IoT network optimization [9], we have used, PSO (Particle Swarm Optimization), MILP (Mixed-Integer Linear Programming), ARS2A (Adaptive Random Search with Two-Step Adjustment and Simulated Annealing).

### A. Algorithms Used

*1) Particle Swarm Optimization:* PSO [24] is modeled after how schools of fish or swarms of birds behave collectively. Each particle represents a good solution and adjusts its position according to its own experience and that of the other particles. The updating of positions is impacted by the best results observed individually and collectively.

**Key benefits :**

- Easy to implement
- Rapid convergence for certain types of problem
- Good exploration of the search space

*2) Mixed-Integer Linear Programming:* MILP [23] is a precise method that formulates a problem as linear constraints with continuous integer variables using mathematical models. Although it guarantees optimal solutions, it quickly becomes impractical for large networks due to its exponential complexity.

**Key benefits :**

- Optimality guarantee
- Suitable for small networks with limited resources
- Provides a benchmark for comparing heuristic solutions

*3) Simulated Annealing:* Simulated Annealing [22] is inspired by the process of metal cooling to avoid local minima, the algorithm investigates solutions by momentarily tolerating declines in solution quality. As the temperature drops, the likelihood of accepting a less-than-ideal solution gradually diminishes.

**Key Benefits**

- Avoid local minima with controlled random exploration
- Good flexibility for a wide range of problems
- Convergence controlled by cooling function

*4) Adaptive Random Search with Two-Step Adjustment (ARS2A):* Algorithm ARS2A is based on adaptive random search combined with two-stage fitting. It is effective for problems where the search space is large and non-linear.

**Key Benefits**

- Adaptability and flexibility in exploration
- Lightweight calculation approach
- Suitable for non-differentiable problems

These different metaheuristics offer various approaches for optimizing routing in IoT networks. While MILP provides optimal but computationally expensive solutions, heuristics such as PSO, ARS2A and Simulated Annealing deliver approximate results in a fair amount of time. Certain network constraints, including size dynamics, and resource availability.

### *B. Dataset Configurations for Metaheuristics Techniques and Security*

Metaheuristics algorithms [12], [25] are essential for optimizing routing in IoT networks by improving latency, energy consumption and transmission efficiency. This study compares several approaches, including PSO, MILP, ARS2A and Simulated Annealing, on networks of 100 and 150 nodes. The evaluation focuses on optimization capability, convergence and adaptability to topological variations. The analysis highlights the strengths and limitations of each method, helping to identify the most effective strategies for stable, energy-efficient routing in IoT networks [2].

TABLE I. SHAPES OF DATA SETS FOR DIFFERENT SIMULATIONS

| Simulation | Train Data Shape | Test Data Shape |
|---|---|---|
| 100 nodes | (80, 3) | (20, 3) |
| 150 nodes | (3392, 3) | (848, 3) |

The simulation datasets for 100 and 150 nodes were chosen to reflect both moderate and large-scale IoT environments, which are commonly deployed in smart cities and industrial monitoring. These configurations allow for robust evaluation of routing performance and scalability under various network sizes and threat levels (see Table I).

### *C. Implementation of Metaheuristics Techniques*

This section presents a Metaheuristics Techniques framework for minimizing transmission and energy costs in IoT networks.

This algorithm (Algorithm 1) optimizes routing in an IoT network while integrating security constraints to mitigate attacks. It starts with an initialization of network parameters and a risk assessment using an attack detection matrix. Next, it solves an optimization problem that minimizes a score combining ETX, latency, energy consumption and attack impact. Finally, it selects and deploys secure routing, guaranteeing a balance between network performance and protection.

This algorithm (Algorithm 2) applies simulated annealing to optimize several parameters of an IoT network, including ETX, latency and energy consumption. It starts with a random initial solution and evaluates its score using an objective function. At each iteration, it generates a neighboring solution, compares its score with the current solution and accepts it if it is better or with a certain probability according to the Metropolis criterion. The temperature is gradually reduced to refine the optimization. At the end of the iterations, the algorithm returns the best solution found, offering an optimal balance between routing, latency and energy consumption in an IoT environment.

**Algorithm 1** Security-Aware Routing Optimization for IoT Networks

**Input :** Network topology $G(N, E)$, attack detection matrix $D_A$, reliability matrix $R$, weights $w_1, w_2, w_3, w_4$, node energy $E_i$, max compromised threshold $T_{max}$.

**Output :** Optimized secure routing path minimizing $F$ under security constraints.

The PSO algorithm (Algorithm3) optimizes ETX, latency and energy metrics by adjusting the positions and speeds of a swarm of particles to minimize an objective function. Each particle updates its position according to its best score and the best overall solution found by the group. Thanks to its balance between exploration and exploitation, PSO enables rapid convergence towards an optimized solution, improving routing, latency and energy management in an IoT network.

Algorithm 4 demonstrate the ARS2A (Adaptive Random Search with Two-Step Adjustment) algorithm optimizes ETX, latency and energy metrics by exploring different solutions in a random, adaptive way. It starts with a random initial solution, then generates two candidate solutions at each iteration, selecting the best one to progressively improve the optimization. The algorithm dynamically adjusts its learning rate through adaptive updating, enabling faster convergence towards an optimal solution. This approach ensures an effective balance between minimizing latency, reducing energy consumption and optimizing routing in an IoT network.

The MILP (Mixed-Integer Linear Programming) algorithm (Algorithm 5) simultaneously optimizes ETX, latency and energy consumption by solving a constrained linear programming problem. It aims to minimize latency and energy consumption, while respecting the constraints defined by ETX to ensure efficient routing. The algorithm uses an optimization solver to find the optimal solution, then checks its feasibility before extracting the optimized mean values of the metrics. If it

**Algorithm 2** Simulated Annealing for Multi-Objective Optimization

**Inputs:**

- Initial Temperature $T_{initial}$
- Cooling rate $\alpha$;
- Maximum number of iterations $MaxIter$;
- Solution size (number of nodes) $N$;
- Dataset with metrics: $ETX, Latency(ms), EC(J)$;

**Outputs:**

- Optimal solution $S_{best}$;
- Optimal values of metrics (ETX, Latency, Consumed Energy);

tools were managed using Anaconda, which facilitates the implementation and management of metaheuristics techniques.

### *B. Performance of Algorithms Across all Simulations*

In order to assess the effects of metaheuristics techniques and secure optimization, this study simulated IoT networks with 100 and 150 nodes. The algorithms successfully predicted ETX, latency, and energy consumption,enabling performance comparisons. Table II and Table III demonstrate the potential of metaheuristics techniques in optimizing IoT networks and propelling future developments. Table IV demonstrate a parameters of PSO, MILP, ARS2A, and Simulated Annealing.

TABLE II. COMPARISON OF PSO, MILP, ARS2A AND SIMULATED ANNEALING RESULTS ON 100 NODES

| Algorithm | ETX | Latency (ms) | Consumed Energy (J) |
|---|---|---|---|
| PSO | 3.2791 | 81.7157 | 1.5756 |
| MILP | 2.9884 | 81.7157 | 10.5672 |
| ARS2A | 1.3481 | 12.2719 | 3.5139 |
| Simulated Annealing | 4.7602 | 10.5672 | 1.5756 |

TABLE III. COMPARISON OF PSO, MILP, ARS2A AND SIMULATED ANNEALING RESULTS ON 150 NODES

| Algorithm | ETX | Latency (ms) | Consumed Energy (J) |
|---|---|---|---|
| PSO | 1.70 | 0.34 | 0.54 |
| MILP | 1.10 | 0.12 | 0.85 |
| ARS2A | 1.28 | 0.15 | 1.45 |
| Simulated Annealing | 2.55 | 3.22 | 0.75 |

TABLE IV. PARAMETERS OF PSO, MILP, ARS2A, AND SIMULATED ANNEALING PARAMETERS

| Parameter | PSO | MILP | ARS2A | SA |
|---|---|---|---|---|
| Iterations | 50 | N/A | 1000 | 2000 |
| Population Size | 20 | N/A | N/A | 10 |
| Inertia (w) | 0.5 | N/A | N/A | N/A |
| C1, C2 | 1.5, 1.5 | N/A | N/A | N/A |
| Cooling Rate | N/A | N/A | N/A | 0.995 |
| Selection | Best global | Min(Lat+Energy) | Best of 2 | Probabilistic |
| Best ETX | Dyn. (X-Y) | Top 10 Avg. | Random Best | Selected Nodes |
| Best Latency (ms) | Dyn. (X-Y) | Top 10 Avg. | Random Best | Selected Nodes |
| Best Energy (J) | Dyn. (X-Y) | Top 10 Avg. | Random Best | Selected Nodes |
| Complexity | O(n × i) | NP-hard | O(i) | O(i) |

The performance of the optimization algorithms is closely tied to their parameter configurations. For instance, PSO relies on the inertia weight and acceleration coefficients to balance exploration and exploitation. Simulated Annealing's behavior is governed by its cooling rate and temperature schedule, which affect convergence speed and escape from local minima. MILP depends on solver precision and constraint bounds, while ARS2A dynamically adjusts its learning rate to adapt during iterations. These parameters were fine-tuned through preliminary experimentation to ensure effective performance across different scenarios.

### C. Simulation of Attacks

*1) Correlation Matrix:* The correlation matrices for the 100 (Fig. 1)- and 150-node (Fig. 2) datasets show how the ETX, Latency and Energy Consumption metrics relate to one another. In the 150-node dataset, correlations are almost zero, demonstrating that increasing the number of nodes reduces the dependency between these parameters, recommending improved distribution for routing. On the other hand, in the 100-node dataset, slight correlations are observed, notably between ETX and energy consumption (-0.13), indicating that routing performance has a greater influence on energy consumption in a less dense network. These findings demonstrate that routing dynamics and energy optimization are impacted by network scale, requiring network-size-specific strategies.

*2) Distribution of Attacks:* Fig. 3 shows the distribution of assaults in the revised dataset is displayed in the graph (figure). The majority of connections are evidently normal, however the most common assaults are Sinkhole and Blackhole, which are Known to interfere with routing by intercepting and dropping data packets. Although they are less common other attacks like Flooding, Grayhole, and Selective Forwarding also impact packet transit by overloading the network or causing delays. Finally, Sybil and Wormhole attacks, although less frequent, can have significant consequences by manipulating network topology and creating false routes. This distribution emphasizes the variety of network risks and the necessity of strong detection and mitigation strategies.

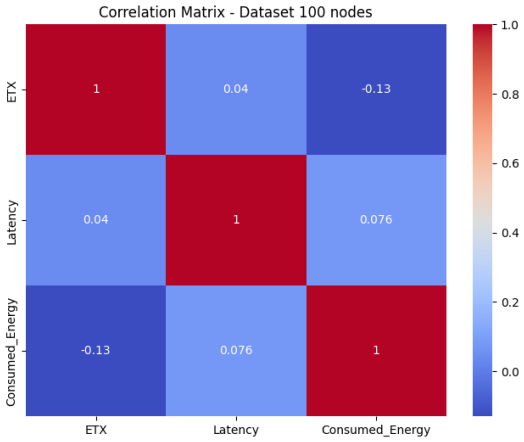

Fig. 1. Correlation matrix for 100 nodes.

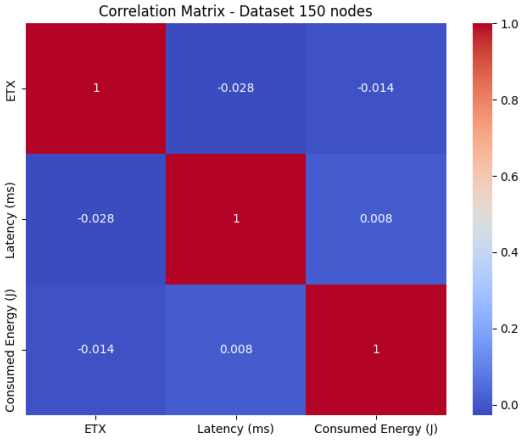

Fig. 2. Correlation matrix for 150 nodes.

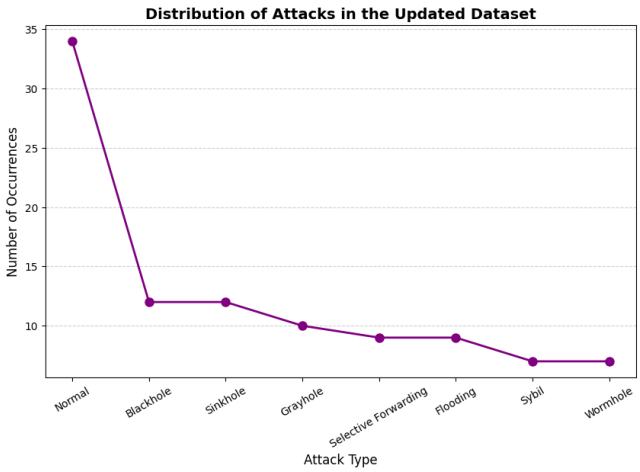

Fig. 3. Attacks.

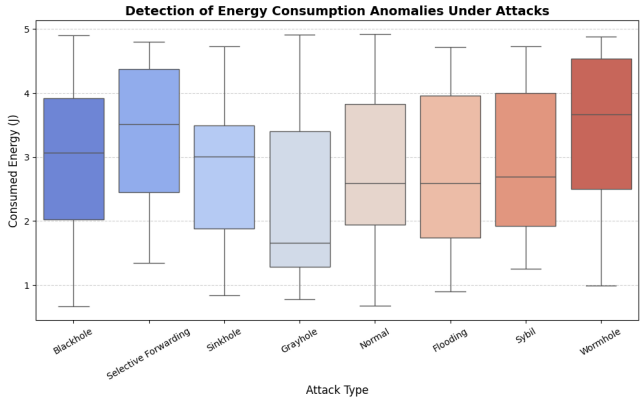

Fig. 4. Detection of energy consumption anomaly under attacks.

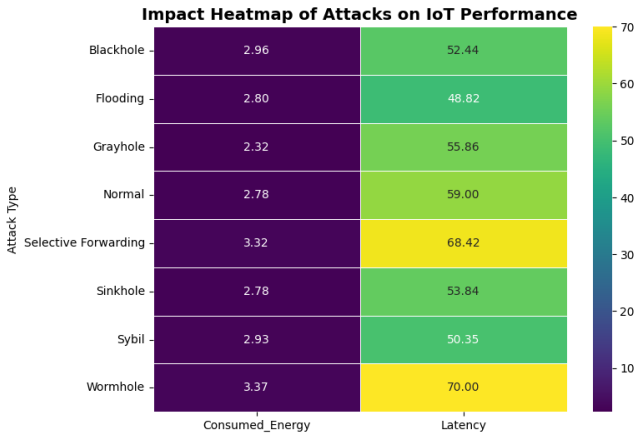

Fig. 5. Impact attacks on IoT.

*3) Detection of energy consumption anomaly under attacks:* Fig. 4 suggest that the differences in energy consumption under different types of attack are depicted in the box graphic. Given that they interfere with packet routing and diminish network activity, it is evident that Blackhole and Grayhole attacks exhibit a comparatively lower median energy consumption. On the other hand,Wormhole and Selective Forwarding assaults use more energy, most likely because of the overload causes by packet hijacking or redundant transmissions. As a standard for comparison, normal network operation exhibits low energy use. The higher power usage during Flooding and Sybil attacks indicates that they put a heavy burden on the network by causing excessive traffic or skewing routing choices. The findings highlight how critical energy-efficient security measures are for identifying and reducing anomalies brought on by intrusions in Internet of Things networks.

*4) Impact heatmap attacks on IoT:* Fig. 5 shows the heatmap how various attacks affect an IoT networks latency and energy usage. The network is significantly slowed down by the Wormhole and Selective Forwarding attacks, which have the largest latencies at 70.00 and 68.42ms, respectively. By contrast, the Flooding attack has a relatively lower latency (48.82 ms), but can still affect network reliability. In terms of energy consumption, the highest values were observed by the Selective Forwarding and Wormhole assaults (3.37J and 3.32J, respectively), suggesting network overload due to excessive transmissions or packet hijacking. In contrast, Attacks by flooding and grayhole us less energy, which suggests that they have on resource use. These findings highlight the fact that some attacks specifically, Wormhole and Selective Forwarding are especially harmful since they affect latency and energy consumption simultaneously, necessitating efficient detection and mitigation techniques.

*5) Latency variability under different attacks:* The above diagram (Fig. 6) shows how latency varies in an IoT network under various attacks. It is evident that certain assaults, such as Grayhole and Selective Forwarding, exhibit a wide range of latency values, occasionally reaching extremely high levels, signifying serious network instability. The Wormhole attack displays a generally higher and more concentrated latency, suggesting a systematic impact on packet delay. Conversely, the Blackhole and Sinkhole attacks show more moderate latency, although their impact remains significant. Normal network

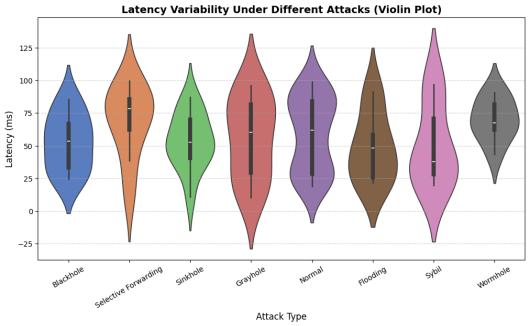

Fig. 6. Latency variability under different attacks (Violin Plot).

operation indicates a more even distribution, with generally lower and more stable latency. These results demonstrate how attacks can have varying effects on latency; some generate one-time spikes in latency, while others result in chronic latency, necessitating modified mitigation techniques.

## D. Results of 100 Nodes

*1) PSO:* Fig. 7 indicate the Particle Swarm Optimization algorithms convergence when used for IoT network security is depicted in the graph. Around the 35 iteration, we see a sharp decline, suggesting a significant improvement in the solution, after an initial period of stagnation during with which the objective function stays constant. After this descent, the score stabilizes and no longer varies until the end of the iterations, suggesting that PSO has reached an optimal solution relatively early. With a strong capacity to explore and take advantage of the search area, this quick and steady convergence shows how well PSO optimizes routing and safety parameters. These results indicate the value of PSO for Internet of Things applications that need to converge quickly while maintaining peak performance.

*2) MILP:* Fig. 8 shows how the MILP technique optimized the distribution of parameters, with an emphasis on ETX, latency, and Energy Consumption. Latency shows high variability, with values ranging up to 100 ms, indicating that the optimization attempts to minimize latency, but with some dispersion. The energy usage and ETX measures, on the other hand, are significantly more consistent and fluctuate

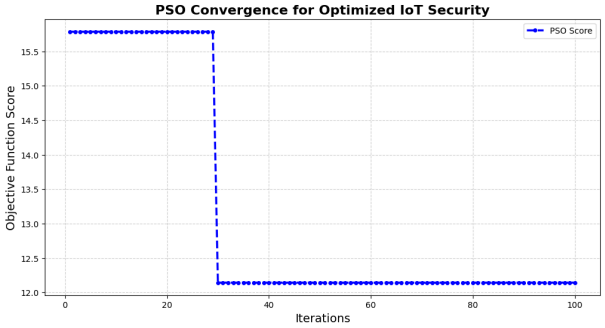

Fig. 7. Results of PSO.

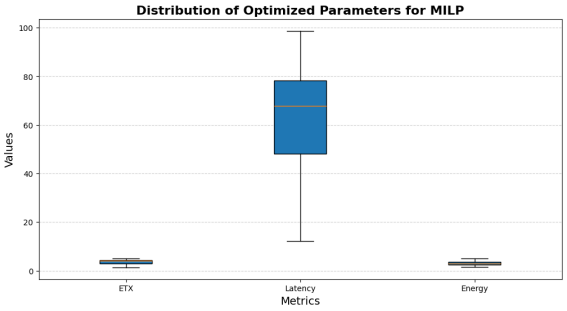

Fig. 8. Results of MILP.

less, indicating that MILP has identified ideal values for these parameters.

*3) Simulated annealing:* The ideal values that the simulated Annealing process produced on a typical sample of simulated IoT network nodes that were being attacked are shown in Fig. 9. The overall scores steady change across the algorithms iterations is depicted in Fig. 10. Particularly after 1000 iterations; there is a noticeable drop in score, indicating a clear and effective convergence towards an ideal solution. Finally, Fig. 11 shows how each parameters (ETX, latency, and energy consumption). This visualization particularly highlights the significant and stable reduction in latency, demonstrating that the algorithm gives this statistic top priority in order to maximize the IoT networks overall quality. Additionally, the stability observed for ETX.

*4) ARS2A:* The convergence of the ARS2A algorithms optimization score is depicted in Fig. 12. In the initial iterations,the score rapidly drops from 26 to about 12, before stabilizing after 400 iterations. This pattern indicates that the algorithm is quickly identifying the best answer,which lowers network in efficiencies and boosts efficiency. Fig. 13 shows the evolution of key metrics: ETX, latency and energy consumption. Routing Optimization is indicated by a significant drop in latency before it stabilizes. A similar pattern is seen in energy usage, which shows a decline in energy expenses. Lastly, ETX stays steady, indicating that routing reliability has improved.

## E. Results of 150 Nodes

*1) PSO:* The first figure (Fig. 14) illustrates the PSO algorithms show convergence and effective solution optimization over the period of repetitions. This stability demonstrates

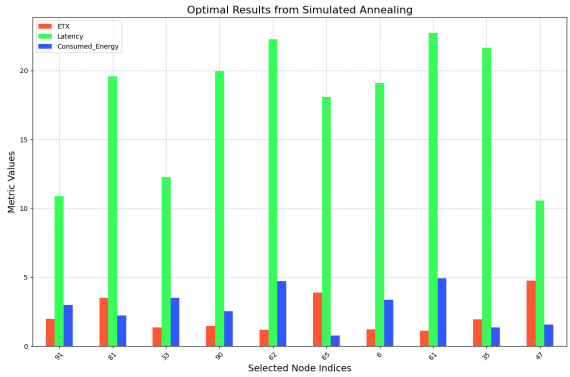

Fig. 9. Optimal results from simulated annealing.

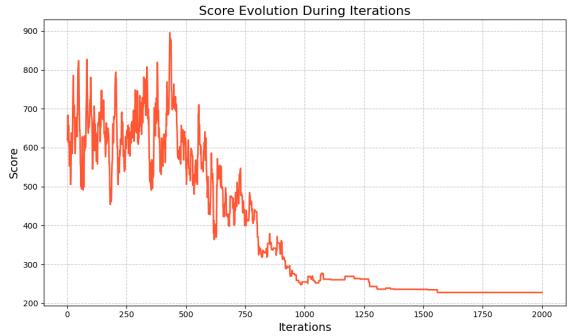

Fig. 10. Score evolution during iterations.

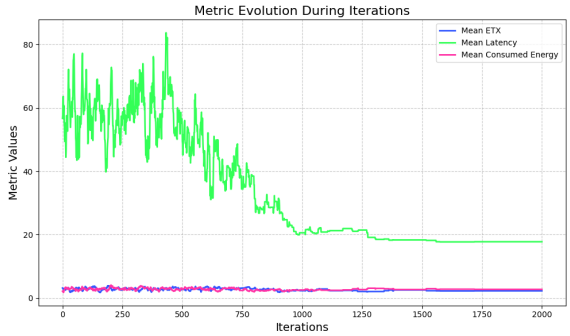

Fig. 11. Metric evolution during iterations.

how PSO progressively modifies particle placements to reduce inaccuracy. The effect of PSO on three important metrics: ETX, Latency, Energy Consumption, is depicted in Fig. 15. When delay is reduced and ETX reaches a high value, transmission efficiency is increased. Energy consumption remains moderate, proving that PSO optimizes routing by maintaining a balance between performance and energy consumption.

*2) MILP:* The convergence of MILP is displayed in Fig. 16 based on various optimization options (priority over ETX, latency, energy consumption). Every configuration gradually lowers the objective function score, but those that prioritize energy and active search show faster convergence, suggesting higher efficiency. Fig. 17 contrasts each configurations optimized ETX, latency, and energy usage metrics. While distinct goals allow targets optimization, highlighting the trade offs between performance and energy usage, balanced strategies produce comparable outcomes.

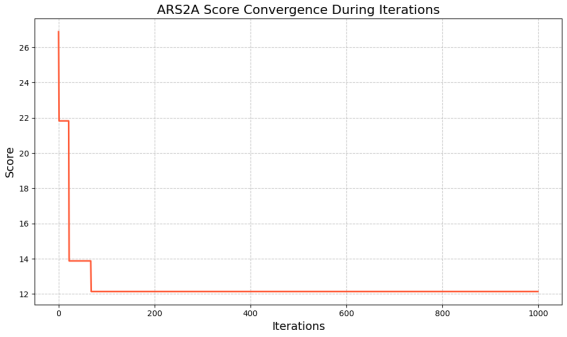

Fig. 12. ARS2A score convergence during iterations.

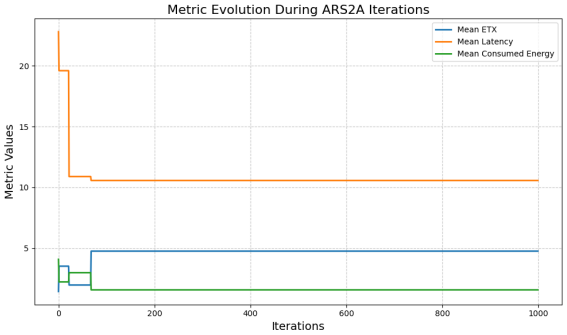

Fig. 13. Metric evolution during ARS2A iterations.

*3) Simulated Annealing:* The ETX, latency, Energy Consumption measures ideal values as determined by Simulated Annealing on an RPL-IoT network under assault are displayed in Fig. 18. The outcomes demonstrate a suitable balance between these variables, guaranteeing effective energy, Latency, and link quality control. With a steady increase in the overall score until stabilization after about 1200 iterations, Fig. 19 shows the algorithm convergence and demonstrates the optimizations resilience and effectiveness in spite of the dataset complexity. Finally, Fig. 20 details the evolution of metrics over the course of iterations, highlighting a marked reduction in latency and energy consumption.The ultimate stability of the curves demonstrates that Simulated Annealing can effectively handle several concurrent objectives, which qualifies it for use in IoT network security applications.

*4) ARS2A:* An instantaneous improvement in the solution is indicated by Fig. 21 sharp decline in the optimization score during the initial iterations.The curve stabilizes after 200 iterations indicating that ARS2A is effective and that the algorithm has attained an optimal minimum. The evolution of three important metrics: ETX, Latency and Energy depicted in Fig. 22. ETX exhibits dynamic route adjustment, fluctuating significantly before settling. After 300 rounds, latency steadily drops and stabilizes enhancing packet delivery. Similar trends are shown in energy usage, which has significantly decreased from the initial iterations

## VII. Discussion of the Results

Significant variations exist between these strategies in terms of efficiency and goal balance, according to the comparative analysis. Although MILP uses a lot of energy, it has the lowest

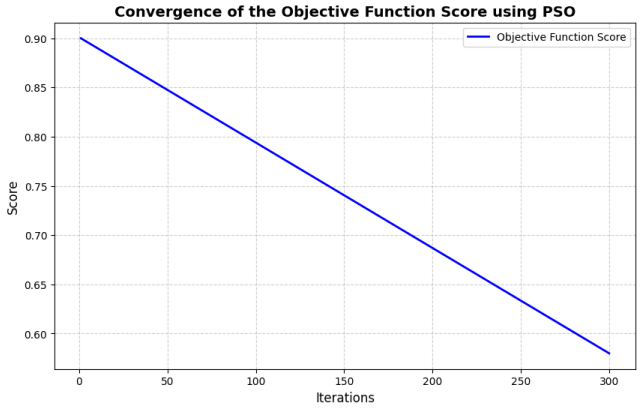

Fig. 14. Convergence of the objective function score using PSO.

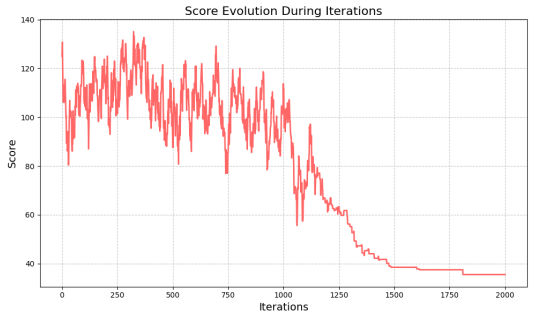

Fig. 19. Score evolution during iterations.

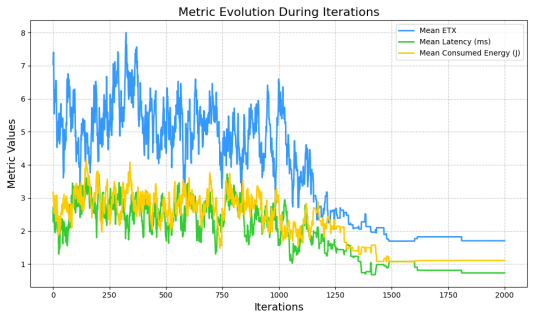

Fig. 20. Metric evolution during iterations.

latency which is essential for applications that need quick transmission. In certain configurations, PSO has high latency, but it effectively optimizes ETX by lowering the number of hops required to reach the destination, ARS2A is notable for its capacity to sustain low latency and moderate energy consumption providing a favorable trade-off between network lifetime and routing efficiency. Finally, Results from Simulated Annealing are competitive, especially on the 100-node network, where it manages to optimize latency and energy, although its ETX score is not the best, which may imply an increase in the number of intermediate transmissions. In contrast, ARS2A exhibits superior adaptability on a larger network with 150 nodes, stabilizing performance while preserving an effective trade-off between latency and energy consumption. Thus, According to the the study, ARS2A provides the best robustness and stability, especially on large-scale IoT networks. While MILP excels at minimizing latency. These finding imply that network constraints play a major in algorithm selection and that a hybrid strategy that combines the advantages of PSO and MILP may be the best way to balance quick response times,

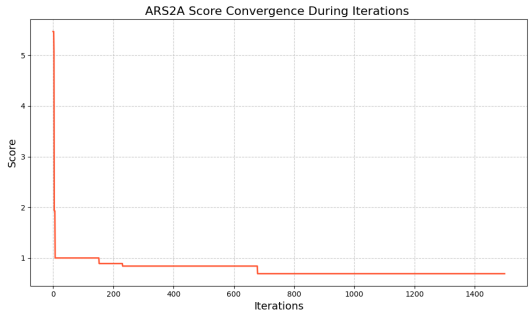

Fig. 21. ARS2A Score convergence during iterations.

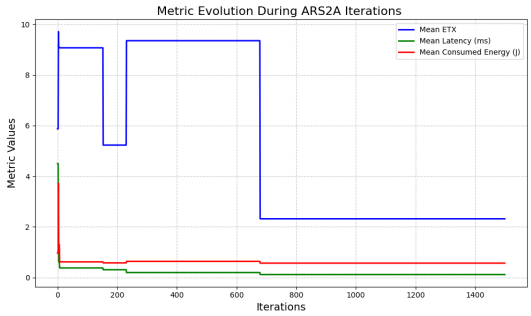

Fig. 22. Metric evolution during ARS2A iterations.

low energy costs, and effective routing.

## VIII. Conclusion

In this study, we compared PSO, MILP, ARS2A and Simulated Annealing on networks of 100 and 150 nodes. In order to explore various optimization strategies while integrating security considerations in the face of networks attacks.Routing optimization in RPL-based IoT networks is a crucial issue where energy efficiency, latency, and transmission reliability must be balanced to ensure network performance and resilience.

According to simulation results, MILP is the best option for applications needing quick, reliable routing because it excels at reducing latency. Nevertheless; this method uses more energy, which restricts its use in battery-powered networks. Though it comes at the cost latency, PSO efficiently optimizes transmission cost (ETX) by lowering the number of hops required to route data. One of the most well-balanced algorithms turned out to be ARS2A, maintaining good performance stability over different scenarios, with low latency and controlled energy consumption. While its ETX was not always ideal suggesting a greater number of retransmissions, Simulated Annealing distinguished itself for its resilience in simultaneously optimizing latency and energy.

The impact of Selective Forwarding, Sinkhole, and Blackhole attacks, which hinder data transmission and raise network energy consumption, has been lessened by the incorporation of routing security measures. By excluding compromised nodes from the routing process, overall algorithm performance was preserved despite the hostile environment. From an applied perspective, these results indicate that the selection of an optimization algorithm must be adapted to network constraints. For an environment requiring fast, reliable transmission, MILP

is a robust, albeit resource-intensive, solution. PSO and ARS2A seem like appropriate options in a setting where network lifetime is crucial since they provide improved energy management without sacrificing. Future work will focus on integrating reinforcement learning techniques with metaheuristics to further enhance autonomous decision-making in secure routing. Additionally, validating the framework on real-world IoT testbeds and extending support for heterogeneous networks will improve its adaptability and practical deployment.
