The study's findings show that CSFs do not carry the same weight throughout the ERPP. Their priority shifts according to the specific requirements of each implementation phase. Strategic factors dominate the analysis phase, while project management and technological factors become more important during the design and implementation phases. Finally, organizational factors take on major importance during the final preparation and system deployment phases.

TABLE XVI. CHANGES IN CSFS ACROSS ERPI PHASES

	Analysis	Design	Realization	Final preparation	Commissioning and support
Management support and involvement	23 %	17 %	9 %	5 %	14 %
Involvement of end users and stakeholders	18 %	20 %	—	15 %	23 %
Project management	20 %	27 %	21 %	12 %	17 %
Process reengineering	18 %	—	—	—	—
Project team competence	12 %	22 %	19 %	8 %	19 %
Change management	9 %	14 %	12 %	18 %	27 %
Minimal customization	—	—	15 %	—	—
Configuration	—	—	24 %	—	—
User training	—	—	—	22 %	—
Tests	—	—	—	20 %	—

VI. DISCUSSION

To provide a deeper understanding of the results obtained, this section discusses them in relation to previous research on the CSFs of ERPI projects. The analysis highlights both areas of agreement with the existing literature and specific contributions related to the phased approach adopted in this study.

First, the results confirm the importance of strategic factors during the ERPP analysis phase. In particular, the support and involvement of senior management emerge as a determining factor for the project's success. This finding aligns with the conclusions of several previous studies that emphasize the central role of management commitment in defining the project vision, allocating the necessary resources, and aligning the ERP with the company's overall strategy [19,28,46].

Furthermore, the results show that factors related to project management and technological factors become increasingly important during the design and implementation phases. Efficient project management, the project team competence, and the configuration of the ERP emerge as essential elements for transforming organizational needs into appropriate functional and technical solutions. These conclusions are consistent with the studies by [18,33,38], who highlight the key role of project planning, the team's technical skills, and proper system configuration in the success of ERPI.

Furthermore, the study highlights the growing importance of organizational factors in the final phases of the project, particularly during the final preparation phase and the implementation and support phase. User training, change management, and end-user involvement appear to be essential conditions for promoting system adoption and ensuring its continued use. These results confirm the findings of several

studies emphasizing that the success of an ERPP depends not only on technical aspects but also on the organization's ability to support the organizational transformations brought about by the system's implementation [47,48].

Overall, the main contribution of this research lies in highlighting how CSFs evolve over the course of an ERPP lifecycle. Unlike many studies that analyze CSFs in a general manner, this research shows that their relative importance varies across the different phases of the implementation process. This phase-based approach provides a more nuanced understanding of the conditions for ERPP success and offers practical guidance to decision-makers and consultants involved in the implementation of ERP within Moroccan SMEs.

VII. Research Contributions and Limitations

This work makes several contributions, both theoretical and practical.

From a theoretical standpoint, this research:

- Complements the existing literature, which generally analyzes CSFs in a broad sense, by introducing a phase-based analysis of the ERPP.
- Offers a dynamic approach to CSFs by demonstrating that their relative importance changes across the different phases of the ERPI process.
- Contributes to an improved understanding of the ERPI process by highlighting the specific role of strategic, organizational, project management, and technological factors at each phase of the project.

From a practical standpoint, this research:

- Provides ERP consultants and project managers with a clear overview of the factors to prioritize at each stage of the project.
- Helps ERP consultants and project managers better tailor their support strategies to the specific requirements of each implementation phase.
- Contributes to reducing the risk of ERPP failure by identifying the CSFs that ensure a successful system deployment.

Our research has certain limitations:

- It was limited to Moroccan SMEs.
- The action research method is used in only two enterprises.

VIII. Conclusion and Future Works

The objective of this study is to identify the CSFs associated with each phase of the ERPI process, as well as to determine their relative importance in each of these phases within Moroccan SMEs.

In this research, we adopted a mixed-methods approach. The action research method was used to identify the CSFs associated with each phase of the ERPI process within Moroccan SMEs. Additionally, we used the Fuzzy AHP method to determine their relative importance in each of these phases.

The results indicate that the importance of CSFs varies across the different phases of ERPI. During the analysis phase, strategic factors are paramount, while those related to project management and technology gain importance during the design and implementation phases. Finally, organizational factors play a crucial role during the final preparation phase, as well as during the implementation and support phase.

This work provides numerous themes for future research:

- Expand this study to include a larger number of Moroccan SMEs.
- Expand this study to include enterprises of other sizes and other countries.
- Examine the importance of CSFs after the ERPI.
- Examine the challenges that hinder the success of ERPI in the context of Moroccan SMEs.

***Abstract*—The explosive growth of online education platforms has led to increased exposure to cybersecurity threats, which makes secure Learning Management Systems (LMS) a critical requirement. However, the current methods often can't capture user behavior risk and network-level attack patterns at the same time, which causes the threat to be incomplete. This study presents a dynamic cyber risk prediction model by fusing log information of LMS behavior with network intrusion information in the CICIDS2017 dataset. The goal is to create an AI-based model that is able to perform real-time risk assessment using a Dynamic Risk Index (DRI). The methodology includes the combination of feature engineering, hybrid data fusion, machine learning, deep learning (LSTM, DNN), and anomaly detection methods. Experimental results demonstrate that the proposed model achieves an accuracy of 97.6%, an F1-score of 96.9%, and an AUC of 98.5%, outperforming state-of-the-art methods. The robustness and significance of the framework are confirmed by ablation and statistical analyses. The overall study concludes that combining behavioral and network intelligence with dynamic risk scoring improves cyber threat detection and proactive security management in e-learning environments.**

Keywords*—Cybersecurity; Dynamic Risk Index (DRI); e-learning security; behavioral analytics; intrusion detection; hybrid deep learning; LMS logs; CICIDS2017 dataset; anomaly detection; risk prediction

I. Introduction

The rapid digital transformation of education has resulted in the widespread use of online learning platforms. Specifically, online learning platforms called Learning Management Systems (LMS) enable remote education types to assist in assessing, as well as in involving different educators, students, or learners in online learning[1]. While these platforms offer flexibility and accessibility, they also introduce some intense cybersecurity challenges. The growing amount of sensitive information such as student records, academic content, and institutional information makes LMS environments appealing targets in cyberattacks such as phishing, brute-force attacks, and unauthorized access[2]. As online education continues to grow, robust cybersecurity mechanisms must be in place to support institutions around the world.

Traditional cybersecurity approaches in the e-learning environments are mainly based on rule-based systems or network-level intrusion detection mechanisms. While the above methods work well in detecting known attack patterns, they are often poor at detecting subtle behavioral anomalies displayed by users [3]. Conversely, behavioral analytics techniques are focused on the activity patterns of users but may not be aware of the underlying threat at the network level[4]. This separation between behavioral and network perspectives means that not all risks are measured, and limits the effectiveness of the security solutions in place. Some recent research has been carried out into the application of machine learning and deep learning intrusion detection techniques based on datasets such as the CICIDS2017 dataset [5]. However, most of the research is focused on network traffic analysis and fails to integrate real-world LMS behavioural data, making its applicability in the practical setting of e-learning minimal.

The motivation behind this research is linked to the necessity of having a general and dynamic cybersecurity model that involves the incorporation of behavioral and network-based information [6]. As the nature of cyber threats advances, this is no longer a sufficient method of detection[7]. The need to use smart systems that can constantly monitor is increasing, along with demand for systems capable of dynamically evaluating risk and proactively preventing threats. The level of accuracy in detection may be increased, and the views of the overall scope of cyber risks may be taken with the use of LMS log data and benchmarking intrusion detection sets. Moreover, the global introduction of a Dynamic Risk Index (DRI) provides an uninterrupted and descriptive indication of the user risk that enables real-time decision-makers to implement such things as personalized security intervention.

On the foundation of the challenges and the motivations, the following research question is suggested for the study: How can the behavioral analytics data and network intrusion data successfully be integrated so that they become a dynamic and precise cyber risk prediction model in online education settings? The problem with the case is that it does not have a single framework that connects the heterogeneous information sources of user activity to real-time risk scoring. The current solutions are either very fixed classification or inadaptable to a dynamic threat environment.

A. Objectives of the Study

- To propose a hybrid model of cyber risk prediction based on integration of LMS behavioral data and network intrusion data.
- To propose a Dynamic Risk Index (DRI) for real-time user risk assessment as well as detection of anomalies.
- To test the effectiveness of the proposed framework based on advanced machine learning and deep learning techniques.

B. Contributions of the Study

The major contributions of this study are as follows.

- The proposed novel hybrid cyber risk prediction framework is achieved by integrating LMS behavioral analytics with the CICIDS2017 network intrusion data for the complete cybersecurity analysis of e-learning systems.
- To enhance the representation of multi-source threats, fusion strategies at the feature level and decision level are proposed for fusing behavioral log and network traffic features. A multi-source threat representation is developed by combining a feature-level and decision-level fusion strategy for behavioral logs and network traffic features.
- This will allow for a real-time, continuous, and meaningful cyber risk score through Dynamic Risk Index (DRI), which is designed to integrate the results of the behavior, network, and anomaly detection scores.
- Hence, an LSTM-DNN-ensemble-learning-anomaly-detector deep learning-based hybrid architecture is proposed, which is suitable for the hybridity of this challenge. To address this hybrid nature of the problem, a hybrid deep learning system, which combines LSTM, DNN, ensemble learning, and anomaly detection techniques, is introduced to capture the temporal user behaviour characteristics and network-level intrusive characteristics.
- Establishing an adaptive risk assessment and risk decision support system to support real-time risk monitoring, risk classification based on thresholds, and automatic risk intervention measures.
- The superiority and robustness of the proposed framework over the existing state-of-the-art methods are demonstrated through a set of comparative analyses, ablation studies, statistical significance testing, and temporal risk analysis studies, which are conducted experimentally.

The study is organized as follows: Section II reviews related work, Section III presents the proposed methodology, Section IV describes experimental setup and datasets, Section V discusses results and analysis, and Section VI concludes the study with future research directions.

II. Related Works

The section on related works reviews the recent research on adaptive cybersecurity in e-learning, learning behavior analytics, risk assessment models, and AI-based educational intelligence. These publications point to progress in the field of anomaly detection, student performance prediction, and security improvement, as well as to shortcomings in the field of data integration, real-time flexibility, and generalization among heterogeneous learning conditions.

Hernandez et al. (2026) suggest the use of an adaptive security model that integrates multi-layer detection of anomalies with a context-sensitive risk evaluation of e-learning platforms. The work successfully incorporates behavioral profiling and a hybrid ML model, and it provides good results for detection. Nevertheless, the use of simulated session-level data restricts applicability to the real world. The framework is also not explainable regarding decision-making and does not address scalability issues in large, diverse educational ecosystems with changing patterns of attacks[8].

Mudawi et al. (2023) use predictive analytics to analyze student behavior in the e-learning environment to enhance educational outcomes. The study emphasizes the significance of behavioral knowledge in improving the learning processes. Nevertheless, it is more of a descriptive analysis, as opposed to strong predictive modelling. The lack of more sophisticated deep learning methods and the lack of handling temporal behavioral dynamics make it less generalizable across a wide range of e-learning platforms and the complicated dynamics of interaction between students[9].

Yuan et al. (2024) suggest a unified system of behavioral analysis and machine learning to predict online learning performance better. The research is sufficient to indicate that behavioral segmentation using clustering has a greater predictive accuracy. Nonetheless, the method relies on systematic datasets such as edX, which restricts real-life flexibility. Also, the framework does not have rich multimodal integration and does not thoroughly investigate variations of learning behavior in real time or cross-platform generalization issues[10].

The article by Zine et al. (2023) presents a machine-learning-enabled system of e-learning readiness measurement based on the dimensions of the ADKAR model. The research is able to determine the major readiness factors such as ability and knowledge with the help of RF and DT models. Nonetheless, it is limited in dynamics by using survey-based static data. Another weakness of this model is its inability to scale, as well as the fact that it does not integrate behavioral or temporal learning analytics, which are crucial in the ever-changing digital learning context[11].

According to Qiu et al. (2022), there is a self-adaptive feature integration plan that can be applied to improve e-learning performance prediction with the assistance of behavioral classification. The predictive accuracy of the study is good on the OULAD dataset. However, it can also make more complicated interactions among learners easier, as it relies on predetermined types of behavior. The model also lacks deep neuralization and real-time scalability; hence, it is

not so flexible for dynamic online learning systems with volatile user participation dynamics[12].

The awareness of cybersecurity and e-learning engagement is tested by Oroni et al. (2025) using structural equation modeling. The essay highlights the significance of demographics in cyberspace behavioral designs. However, it heavily relies on an SEM analysis that is based on surveys, and this does not make it as scalable or as applicable in real time. Its application to a modern-day e-learning environment is reduced by the absence of AI-based detector models and behavioural anomaly detectors, which restricts its application further in reacting to evolving cyber threats in the e-learning environment[13].

The vulnerability analysis of e-learning platforms (Moodle, Chamilo, and Ilias) is offered by Akacha and Awad (2023). The study provides valuable data on susceptibility to security threats and security measures. It is largely, however, descriptive in nature and lacks predictive modelling skills. Nor does it include the adaptive AI-driven security features, which limit its functions to the aggressive identification of any emerging threats in dynamic and distributed e-learning environments[14].

The authors Sadiqzade and Alisoy (2025) discuss the risks of cybersecurity in online education and suggest solutions such as MFA and AI-based threat recognition. The study successfully points out areas of weakness and measures to improve. Nevertheless, it is a conceptual one with little empirical support. It is less practical in practice, due to the absence of implementation-level experimentation and dataset-based evaluation in real-life large-scale e-learning systems [15].

One of the proposed solutions is the real-time decision support system for identifying at-risk students based on the LMS interaction data offered by Eli et al. (2025). The framework depicts encouraging initial warning possibilities. Nonetheless, the complexity of the behavioral patterns is restricted by its rule-based organization. The lack of deep learning integration and the limited personalization limit its effectiveness in heterogeneous learning settings where student engagement behavior changes [16].

Mi et al. (2022) produce an analytical risk evaluation framework of early warning in educational systems. The research is effective in enhancing the early identification of learning risks through the structured indicators. But it is based on predetermined factors of evaluation and is not adaptive to learning. The model also lacks real-time behavioral analytics and predictive mechanisms based on AI, which also restricts its scalability and responsiveness [17].

Kepuska and Tomasevic (2024) suggest a simple cybersecurity framework for higher education institutions that is based on vulnerability detection. The study gives useful details regarding the active security measures. Nevertheless, it does not have a deep-learning interface and sophisticated anomaly identification. It is too light to be used effectively in the context of a complex cyber threat, and it is not concerned with real-time adaptive risk scoring or multimodal behavioral analysis [18].

The current literature of e-learning analytics and cybersecurity mainly emphasizes one of the two approaches to behavioral analysis and security assessment, yet it seldom involves both to create an adaptive strategy. The majority of these methods are based on fixed datasets, survey-based assessments, or rule-based systems and restrict real-time adaptability and generalization. Multimodal fusion and cross-domain behavioral-security integration via deep learning have not been well studied. Moreover, most of the models are not explainable, scalable, and resistant to changing cyber threats. Transformer-based architectures are also not widely used to model sequential behavior. These are the gaps that lead to the necessity of an integrated, AI-based system to incorporate behavioral intelligence, anomaly detection, and adaptive risk assessment in safe and customized e-learning platforms.

Table I provides an in-depth comparative analysis of the recent research studies that can be dedicated to e-learning analytics, cybersecurity frameworks, behavioral modeling, and risk assessment methods. It provides an overview of every study regarding the proposed methodology, the data used, the strengths, and limitations identified.

TABLE I. COMPARATIVE ANALYSIS OF EXISTING STUDIES ON E-LEARNING ANALYTICS, CYBERSECURITY, AND RISK ASSESSMENT MODELS

Author (et al., Year)	Method	Dataset	Strengths	Limitations
Hernández et al., 2026	Multi-layer anomaly detection + context-aware risk assessment (RF, LSTM, Isolation Forest)	135,687 e-learning sessions (synthetic/collected LMS logs)	High detection accuracy; hybrid deep-learning + ML fusion; strong anomaly detection performance	Limited real-world validation; weak explainability; scalability concerns
Mudawi et al., 2023	Predictive behavior analytics	E-learning behavior datasets (various LMS sources)	Provides insights into student behavior patterns; supports learning improvement strategies	Lacks deep learning models; mainly descriptive; limited predictive robustness
Yuan et al., 2024	Behavior clustering + ML prediction framework (XGBoost, RF)	edX dataset	Improves prediction using behavioral segmentation; better accuracy than baseline ML	Limited generalization; lacks multimodal learning; no real-time adaptation
Zine et al., 2023	ML-based readiness assessment (RF, DT, SHAP analysis)	Survey dataset (ADKAR-based data from university students/faculty)	Identifies key readiness factors; interpretable ML using SHAP	Static survey data; lacks temporal learning dynamics; poor scalability
Qiu et al., 2022	Adaptive feature fusion + behavior classification model	OULAD dataset	High prediction accuracy; effective feature selection strategy	Simplified behavioral modeling; no deep temporal modeling; limited adaptability

Oroni et al., 2025	SEM-based cyber awareness model	Survey data from e-learning students	Considers demographic moderation (gender, experience); strong behavioral insights	No AI-based detection; not real-time; limited scalability
Akacha & Awad, 2023	Vulnerability analysis of LMS platforms	Moodle, Chamilo, ILIAS	Practical security insights; identifies system vulnerabilities across platforms	Descriptive only; no predictive AI; lacks experimental ML validation
Sadiqzade & Alisoy, 2025	Conceptual cybersecurity framework (MFA, AI-based detection)	Literature-based analysis	Broad coverage of cyber threats; proposes modern mitigation strategies	No experimental evaluation; lacks dataset-based validation
Eli et al., 2025	Real-time rule-based early warning system	OULAD dataset (32,000+ students)	Real-time monitoring; lightweight system; early risk detection	Rule-based limitations; lacks deep learning; low personalization
Mi et al., 2022	Data-driven risk assessment and early warning model	University learning data	Structured risk prediction framework; improves early warning systems	Static indicators; no deep learning; limited real-time adaptability
Kepuska & Tomasevic, 2024	Lightweight cyber risk framework for HEIs	Western Balkan HEIs systems	Practical deployment focus; proactive control mechanisms	No AI/ML depth; lacks anomaly detection; limited accuracy for complex attacks

III. METHODOLOGY

The general structure of the proposed hybrid cyber risk prediction framework is displayed in Fig. 1. It is initiated using data sources like LMS behavioral logs and the CICIDS dataset, which is the data of user activity and network traffic. These inputs are passed to the feature extraction and fusion layer, where network and behavioral features are obtained and fused. The combined aspects are then fed into the hybrid risk prediction model that employs machine learning and deep learning algorithms, including LSTM, DNN, Anomaly detection, and Ensemble learning to uncover potential threats or threats. It is then translated into a so-called Dynamic Risk Index (DRI), providing real-time risk scoring. Lastly, the risk analysis and response module interprets the DRI and carries out the risk distribution analysis, threshold tuning, alert generation, and mitigation activities. The framework includes the process of monitoring and proactive intervention, which can ensure better cybersecurity for online education systems.

A. Multi-Source Acquisition

The step entails the collection of non-homogeneous data in the Learning Management Systems (LMS) and CICIDS2017 dataset to guarantee that the process of cyber risk modeling is complete. LMS logs will give real-time information on user behavior such as login patterns, time spent in the session, use of the device, navigation behavior, and so on. Simultaneously, the CICIDS dataset avails of labeled network traffic with both benign and malicious processes, including DoS, DDoS, and brute force attacks. Suppose that the two data sources are LMS behavioral data and CICIDS network data, denoted by the two equations, Eq. (1) and (2), respectively.

$$D^L=\{x_i^L\}_{i=1}^N,\ x_i^L \in R^{d_L} \quad (1)$$

$$D^c = \{(x_j^C, y_j)\}_{j=1}^M,\ \ x_j^c \epsilon R^{d_c}, y_j \epsilon \{0,1\} \quad (2)$$

The Combined dataset is

$$D=D^L \cup D^C \quad (3)$$

The combination of real-world behavioural data and benchmark intrusion data improves the ability of the model to generalize across a range of cyber threat scenarios and improves the detection accuracy in dynamic e-learning environments.

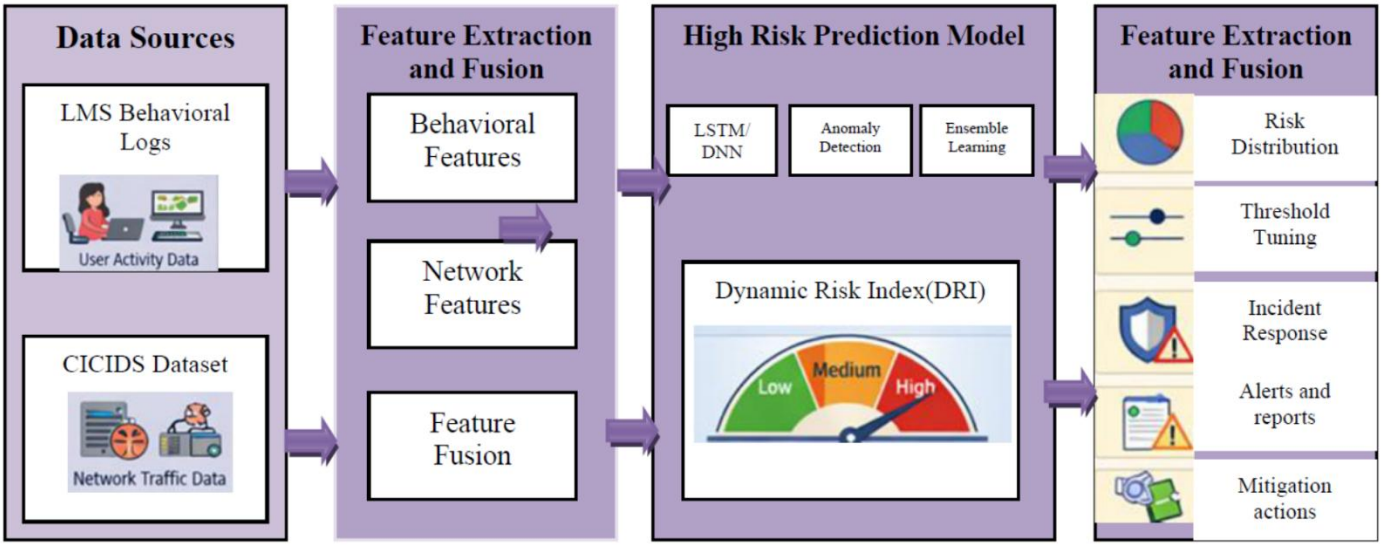

Fig. 1. Architecture of the hybrid cyber risk prediction framework for e-learning environments.

B. Harmonization of Data & Data Preprocessing

In this phase, the data of LMS and CICIDS are preprocessed and standardised for unified analysis. Data cleaning is done to eliminate missing values, duplicates, and noise. Numerical attributes are normalized, while categorical attributes, e.g., user's role, protocol type, etc., are encoded. Since the datasets have different structures, feature alignment is followed in order to align the behavioral patterns to network features, such as correlating repeated login attempts to brute force attack characteristics. In addition, data in LMS is semi-labeled on the basis of inferred risk, whereas in CICIDS the data is fully labeled and can be used for supervised learning.

The missing value handling is given by Eq. (4)

$$x_{ij} = \begin{cases} \frac{1}{K}\sum_{k=1}^{k} x_{kj} \\ x_{ij} \end{cases} \text{, f missing otherwise} \quad (4)$$

The normalization is denoted by Eq. (5)

$$x' = \frac{x-\mu}{\sigma} \quad (5)$$

The encoding of categorical variables is represented by Eq. (6)

$$x_{cat} \longrightarrow e_k \epsilon \{0,1\}^K \quad (6)$$

The feature alignment is given by Eq. (7)

$$\emptyset: \mathbb{R}^{d_L} \rightarrow \mathbb{R}^{d_c} \quad (7)$$

The semi -labeling LMS is performed using Eq. (8)

$$y_i^L = \begin{cases} 1, \\ 0, \end{cases} \downarrow f(x_i^L) > \tau \quad (8)$$

This harmonization allows for compatibility of the data and helps in the preparation of the data to be truly useful in the blocks used for feature extraction and data modeling.

Dataset Integration and Temporal Alignment Strategy

A structured integration and preprocessing pipeline is used to make the LMS behavioral log data and network intrusion data at CICIDS2017 temporally and feature-level compatible. The data in the LMS dataset are session-based records of users' interactions within a specific session, and the data in CICIDS2017 is flow-based, with each one representing a user interaction in the network within a flow. Both are automatically converted into a common format of fixed-length sliding time windows, such that they are all synchronized to time and provide consistent temporal granularity—both behaviorally and in network measures—within the context of a behavioral session.

Next, using features that are semantically related to each other from both sources, feature alignment is performed, mapping the features within a common feature representation space. These, in terms of behavioral features, are correlated using the so-called transformation function, a function derived by mapping heterogeneous features to a network feature vector space, with features such as network flow duration, packet rate, or packet connection attempts. This enables efficient cross-domain fusion of behavioural and intrusion information, giving rise to a successful system.

The unification of the labels is facilitated by maintaining a direct label for CICIDS2017, whereas semi-labeled LMS logs are given a label based on deviation thresholding with a risk scale mechanism. This will make doing supervised learning with both sets of data consistent.

In order to alleviate the domain mismatch problem, a transfer learning approach is followed, meaning that models are first trained on the data from the CICIDS2017 dataset and then fine-tuned with the LMS behavioural data. In this way, the differences between data available at each level of the network (or network-level information) and data available from the behavior level (or behavior-level information) are minimized. All the preprocessing, alignment, and fusion operations are executed through the same pipeline implemented in Python, with modularity (scikit-learn and TensorFlow), thereby ensuring future reproducibility and the extendability of the proposed framework.

C. Feature Engineering

Feature engineering is about the conversion of raw data to meaningful indicators of cyber risk to predict. Behavioral features obtained from LMS logs include the irregularity of the login, session deviation, access frequency anomaly, and the usage of role-based privileges. From the CICIDS dataset, the network-level features such as flow duration, no of packets, and traffic pattern are extracted. The behavioral, network features are given by Eq. (9) and (10)

$$F_b = \{f_1, f_2, \ldots . f_p\} \quad (9)$$

$$F_n = \{g_1, g_2, \ldots . g_q\} \quad (10)$$

Hybrid features are then constructed in order to poach cross-domain threat signals using a combination of behavior deviations and anomalies in the network, and it is denoted but he Eq. (11)

$$F_h = F_b \oplus F_n \quad (11)$$

Temporal features are also generated to represent the sequential activity of the user. The temporal modeling is denoted by Eq. (12)

$$x_1 = \{x_{t-k}, \ldots, x_t\} \quad (12)$$

This set of features is very complete; this increases the effectiveness of the model in distinguishing good behavior and bad behavior, and makes the model more predictive and robust.

D. Data Fusion Strategy

This step has combined the LMS behavioural features with those of CICIDS network features using the fusion methods. Feature-level fusion combines both data sets into one feature vector, and model-level fusion combines the predictions from individually trained models. The feature-level and model-level fusion is given by Eq. (13)

$$x^{fusion} = [x^L || x^C] \quad (13)$$

$$\hat{y} = \sum_{k=1}^{k} w_k . f_k(x) \quad (14)$$

Domain adaptation techniques are employed, for example, transfer learning techniques, which provide the means of training the models using CICIDS data and fine-tuning them

using LMS data to minimize distribution dissimilarities. The transfer learning approach is given by Eq. (15)

$$\theta^{*}=\arg\min_{\theta} L_{CICIDS}(\theta) \quad (15)$$

$$\theta^{sdapt} = \arg\min_{\theta} L_{LMS}(\theta|\theta^{*}) \quad (16)$$

This hybrid fusion approach ensures that both behavioral and network-level insights are effectively utilized and increases the ability of the model to detect sophisticated cyber threats that will manifest in multiple dimensions in the e-learning environments.

E. Behavioral Profiling and Baseline Modeling

Behavioral profiling builds the base for normal user behavior as behavioral clustering is applied to cluster similar behavioral patterns together by applying clustering algorithms, such as K-Means or DBSCAN. Each user/group is assigned a profile of behavioural activities based on the typical times of day that they logged in, session times, and navigation patterns. Deviations from what are considered baselines are calculated by such measures of distance and time. These deviation scores are used for the detection of abnormal user activities that may lead to cyber risks. The clustering is given by Eq. (17)

$$\min\sum_{i=1}^{N} ||x_i-\mu_k||^2 \quad (17)$$

The baseline profile is given by Eq. (18)

$$B_u = E[x_u] \quad (18)$$

The deviation score is given by Eq. (19)

$$D_u = ||x_u - B_u|| \quad (19)$$

The temporal deviation is denoted by Eq. (20)

$$D_t = \sum_{t=1}^{T} ||x_t - \hat{x}_t|| \quad (20)$$

This constant update of these profiles is what allows the system to be adapted to changing user behavior, which ensures the system is able to detect anomalies accurately and limits false postings in dynamic online learning environments.

F. Development of the Predictive Model

In this phase, machine learning and deep learning models are developed to predict the cyber risk. Supervised models (Random Forest and XGBoost) are trained based on labelled CICIDS data, while the sequential models (LSTM) are trained to understand the temporal patterns of LMS behavioral data. The supervised learning is given by Eq. (21)

$$\hat{y}=f(X;\theta) \quad (21)$$

As well, the unsupervised technique such as autoencoders is used for the purpose of anomaly detection. The idea behind the hybrid modeling approach is the utilization of both labeled data and unlabeled data in order to provide better prediction results. The loss function is given by Eq. (22)

$$L= -\sum y \log(\hat{y}) +(1-y) \log(1-\hat{y}) \quad (22)$$

The LSTM modeling and the autoencoder are given by Eq. (23)

$$h_t = LSTM(x_t, h_{t-1}) \quad (23)$$

$$\hat{x} = g(f(x)) \quad (24)$$

The reconstruction error is denoted by Eq. (24)

$$L_{AE} = ||x - \hat{x}||^2 \quad (25)$$

G. Dynamically Risk Scoring Mechanism

A Dynamic Risk Index (DRI) is calculated to measure the risk for each user/session. The score is a combination of behavioral risk, network-based risk, and anomaly detection score using weighted combining. The weights are changed in an adaptive manner so that they represent the relative importance of each of the components. The resulting score is normalized on a range of 0 to 1 and is divided into low, medium, and high risk categories. This dynamic scoring mechanism allows continuous monitoring of the behaviour of the user and provides real-time risk assessment to timely intervene in order to mitigate the potential cyber threats in the e-learning systems. The DRI is computed using Eq. (26).

$$DRI = w_1 . BRS + w_2 . NRS + w_3 . ADS \quad (26)$$

where, BRS is the behavioral risk Score (LMS) , NRS is the network Risk Score (CICIDS–trained model), ADs is the Anomaly detection score, and w_1, w_2 are the adaptive weights.

The proposed Dynamic Risk Index (DRI) intends to be a single risk quantification mechanism to assimilate various and diverse outputs of behavioral analytics modules, network intrusion detection modules, and anomaly detection modules. While it is actually a weighted formulation, what is unique about this formulation is that it does not combine risks in a linear fashion, but instead is adaptive and context-aware. The proposed framework allows to globally reweight the weights depending on the different levels of behavioural risks and network risk, in which way considering temporal variations of user behaviour and network risk. The DRI will constantly incorporate Behavioral Risk Score (BRS), Network Risk Score (NRS), and Anomaly Detection Score (ADS) into an updated risk score, which will be easily monitored throughout the session as risk levels change. This formulation enables the outputs of the classification process to be mapped in a continuous risk space, enabling it for fine-grained monitoring, warnings, and interventions. So DRI is not an approach of a simple weighted sum – it is an adaptive risk inference mechanism integrated within the proposed cyber risk prediction framework. The classification is performed based on the risk level, and it is given by (27)

$$\text{Risk level}=\begin{cases} \text{Low}, & 0 \le DRI < 0.3 \\ \text{Medium}, & 0.3 \le DRI < 0.7 \\ \text{High DRI} & \ge 0.7 \end{cases} \quad (27)$$

H. Real-Time Anomaly Detection

This step is to identify anomalies, unusual activities in real-time with the help of algorithms such as Isolation Forest, autoencoders, etc. The scope of monitoring the system can be evidenced by monitoring the behavior and network patterns of people, and identifying anomalies such as unusual login times, spikes in activity, or attempts to steal access. Alerts are raised when the anomalies are out of preset limits. This preventive security system is important because it enables the attackers to note early any possible cyber threat that will reduce the

response time and mitigate the damage. The actual implementation of real-time analytics can be used to achieve continuous surveillance and fortification of the entire security posture of that online education platform.

I. Model Evaluation

The performance of the predictive model is evaluated using a large number of measures such as accuracy, precision, recall, F1-score, ROC-AUC, etc. Moreover, the false alarm rate and detection rate are also studied to ascertain how well the model has detected cyber threats without false alarms. The validation is cross-dataset, carried out by training the data of CICIDS and testing on the patterns of LMS to test the generalisability. This is a holistic assessment plan that fosters consistency and well-being of the model prior to its implementation in the actual real-life e-learning settings.

J. Deployment in the LMS Environment

The LMS integrates the authenticated model through APIs in order to provide on-time risk monitoring. An interface in the form of a dashboard is developed that will give users a visual interpretation of the user risk scores, anomaly alerts, and system activity. The inputs and risk scores are constantly dynamically processed through the system. Automated alert systems are useful in alerting the administrators about risky users or suspicious activities. The deployment guarantees that it can integrate with the existing e-learning platform with ease and also enable the management of cybersecurity proactively without disrupting the normal operations of the system.

To maintain the effectiveness of the model, ongoing learning occurs due to the contribution of new LMS data and new patterns of attacks that emerge. Regular retraining assists in the updating of model parameters and making it more accurate over time. The weighting applied in the Dynamic Risk Index is also revised based on the feedback, as well as the evolving danger scenarios. This dynamic system ensures that the system is robust to new and advanced cyber threats; this offers security to an online learning setting in the long term.

IV. Results and Findings

Experiments were run in Python with the aid of TensorFlow, Scikit-learn, and Pandas libraries, with the system consisting of an Intel i7 processor, 16GB RAM, and an Nvidia GPU (8GB). It is implemented with the help of Jupyter Notebook; the LMS environment is simulated with the assistance of real log data, and the API based testing is included.

A. Dataset Description

LMS log data and the CICIDS2017 dataset are the two datasets that will be used in the study. The LMS logs reflect the real-life educational experiences in terms of user behavior like their login behaviors, the time of sessions, patterns of navigation, and information about devices. CICIDS 2017 is a set of labeled network traffic information with both normal and malicious activities that include DDoS attacks, brute force, and web attacks. Unlike in CICIDS, where there are orderly patterns of attack, in LMS, data anomalies of behavior are being reflected.

The two sets of data are utilized to deliver a more detailed modeling through integrating behavioral and network-level threat intelligence to make quality predictions of cyber risk [19, 20].

For this study, the LMS behaviour data was obtained from an open-source educational interaction repository as a proxy for LMS use in the realistic context of education. The data set includes about 2,845 registered learners and 186,742 interaction sessions during a six-month time frame, collected during actual online learning activities by the users and reported by the original provider of the data set. The courses are made up of sessions, which are continuous engagement of the user in the LMS environment. It includes elements of behavior such as logins, time spent, page navigation, access to resources, assignment activities, quiz activities, login time, IP access characteristics, and device information. A total of 24 behavioural attributes were identified and grouped into 6 categories: authentication features, navigation behaviour indicators, engagement metrics, temporal activity features, access-pattern features, and more. The dataset doesn't have any cybersecurity labels provided, so a semi-supervised labeling strategy was used, where anomalous behavioral sessions were identified by statistical deviation analysis and the anomaly scoring methods of Isolation Forest. The individual sessions were divided into low-risk and medium-high risk groups, according to the scores of the anomaly type of the sessions generated, for risk prediction modeling. The data is anonymized, meaning that personally identifiable information (PII) is not included, thus providing privacy protection and compliance with the data. The LMS behavioral dataset was then combined with the CICIDS2017 benchmark intrusion dataset to allow for combined analysis of behavioral and network-level cyber risk factors in e-learning environments.

B. Experimental Design and Validation Protocol

To make sure that the results were reliable and could be reproduced, the studies used a strict testing protocol for experiments. The LMS-CICIDS dataset was divided into 3 parts that were balanced for both benign and malicious traffic, i.e., 70% of the data would go to training, 15% would go to validation, and 15% would go to testing. The training set was also used in a 5-fold cross-validation to provide greater stability in the models produced and to reduce the variance of the models created from a single train/test split.

The data processing steps (normalization, feature scaling, and categorical encoding) only used the training set data, which eliminated the potential for data leakage. Because of the way in which the LMS behavioral data was arranged, user sessions were assigned to specific partitions, and there were no overlapping sessions between training, validation, and test partitions. In addition, the separate parts of the dataset retained the chronological order in which they were originally collected; so earlier sessions were used to train the models, while later sessions were used to validate and test the models. By retaining the timing of sessions, there was no way for data from the future to find its way into models that had been trained.

It addresses the class imbalances with the use of the SMOTE technique, which was applied only to the training partition of the data. Both the validation and test datasets remained in their original distributions in order to allow for an unbiased evaluation of model performance in a realistic operational environment. The hyperparameter optimization was completed through grid search on the validation set. The following hyperparameter configurations were included within the search: LSTM unit numbers (32, 64, 128), hidden layer size (64, 128, 256), learning rate (0.001, 0.0005, 0.0001), batch size (32, 64, 128), dropout rate (0.2, 0.3, 0.5), and the different weights applied when using an ensemble of models. The best configuration was chosen based on validation AUC.

Additionally, to assess generalization capability, we executed an independent validation experiment where the network intrusion components were trained on CICIDS2017 data and the intrusion components were adapted to work with LMS behavioural data after transfer learning/knowledge. This cross-domain validation strategy ensured that the results represented true performance and were not the result of any characteristics that were dataset-specific. Through the use of stratified partitioning, user-level isolation, temporal distance, cross-validation, class imbalance correction techniques, and independent validation, we believe the generated performance results provide a high level of confidence that they reflect true predictive capability vs. being the result of data leakage or overfitting.

C. Quantitative Evaluation

Table II shows the quantitative comparison of different state-of-the-art machine learning and deep learning methods on the combined LMS logs and CICIDS2017 hybrid dataset.

The results show that the ensemble and deep learning models are better at the task than traditional approaches because of their capacity to capture complex behavior and network patterns. The proposed hybrid model shows the best performance as per all the evaluation metrics with an accuracy of 97.6% and AUC of 98.5%. This points to its effectiveness of incorporating data from multiple sources for strong cyber risk prediction as well as better generalization in e-learning environments.

Fig. 2 illustrates the comparative performance of different machine learning and deep learning models, including traditional classifiers (SVM, Random Forest, XGBoost, KNN, Naive Bayes, AdaBoost, LightGBM, CatBoost), DL models (DNN, Bi-LSTM, Transformer-based model), ensemble stacking methods, and the proposed hybrid model across four evaluation metrics: Accuracy, Precision, F1-score, and AUC.

The findings clearly demonstrate that classical machine learning models like Naive Bayes and KNN would have relatively low performance on all measures, and they have the weakness of learning more complex relationships between features. Conversely, models that are based on deep learning, like DNN, Bi-LSTM models, and Transformer models, have better and more consistent performance as they are capable of learning hierarchical and sequential feature representations.

Among all the considered methods, the proposed hybrid model shows the best performance with the best results of about 97.6% Accuracy, 97.6% Precision, 96.9% F1-score, and 98.5% AUC. This shows that ensemble learning that incorporates deep feature extraction has great potential in improving classification. The findings affirm that hybrid and attention-enhanced frameworks are better in terms of discriminative strength and resilience than independent machine learning or deep learning frameworks.

TABLE II. QUANTITATIVE COMPARISON OF STATE-OF-THE-ART METHODS ON COMBINED LMS LOGS + CICIDS2017 DATASET (HYBRID DATASET)

Method	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC (%)
SVM[21]	92.8	92.1	91.6	91.8	93.4
Random Forest[22]	94.9	94.2	93.7	93.9	95.2
XGBoost[23]	95.8	95.3	94.6	94.9	96.3
KNN[24]	91.2	90.5	90.1	90.3	91.8
Naïve Bayes[25]	89.7	88.9	88.5	88.7	90.2
AdaBoost[26]	94.1	93.5	92.7	93.1	95.0
LightGBM[27]	96.2	95.7	95.0	95.3	97.1
CatBoost[28]	96.5	96.0	95.4	95.7	97.5
Deep Neural Network (DNN)[29]	97.0	96.6	96.0	96.3	97.9
Bi-LSTM[30]	97.2	97.0	96.5	96.7	98.1
Transformer-based Model[31]	97.4	97.2	96.8	97.0	98.3
Ensemble (Stacking)[32]	97.5	97.4	97.0	97.2	98.4
Proposed Hybrid Model	97.6	97.6	97.1	96.9	98.5

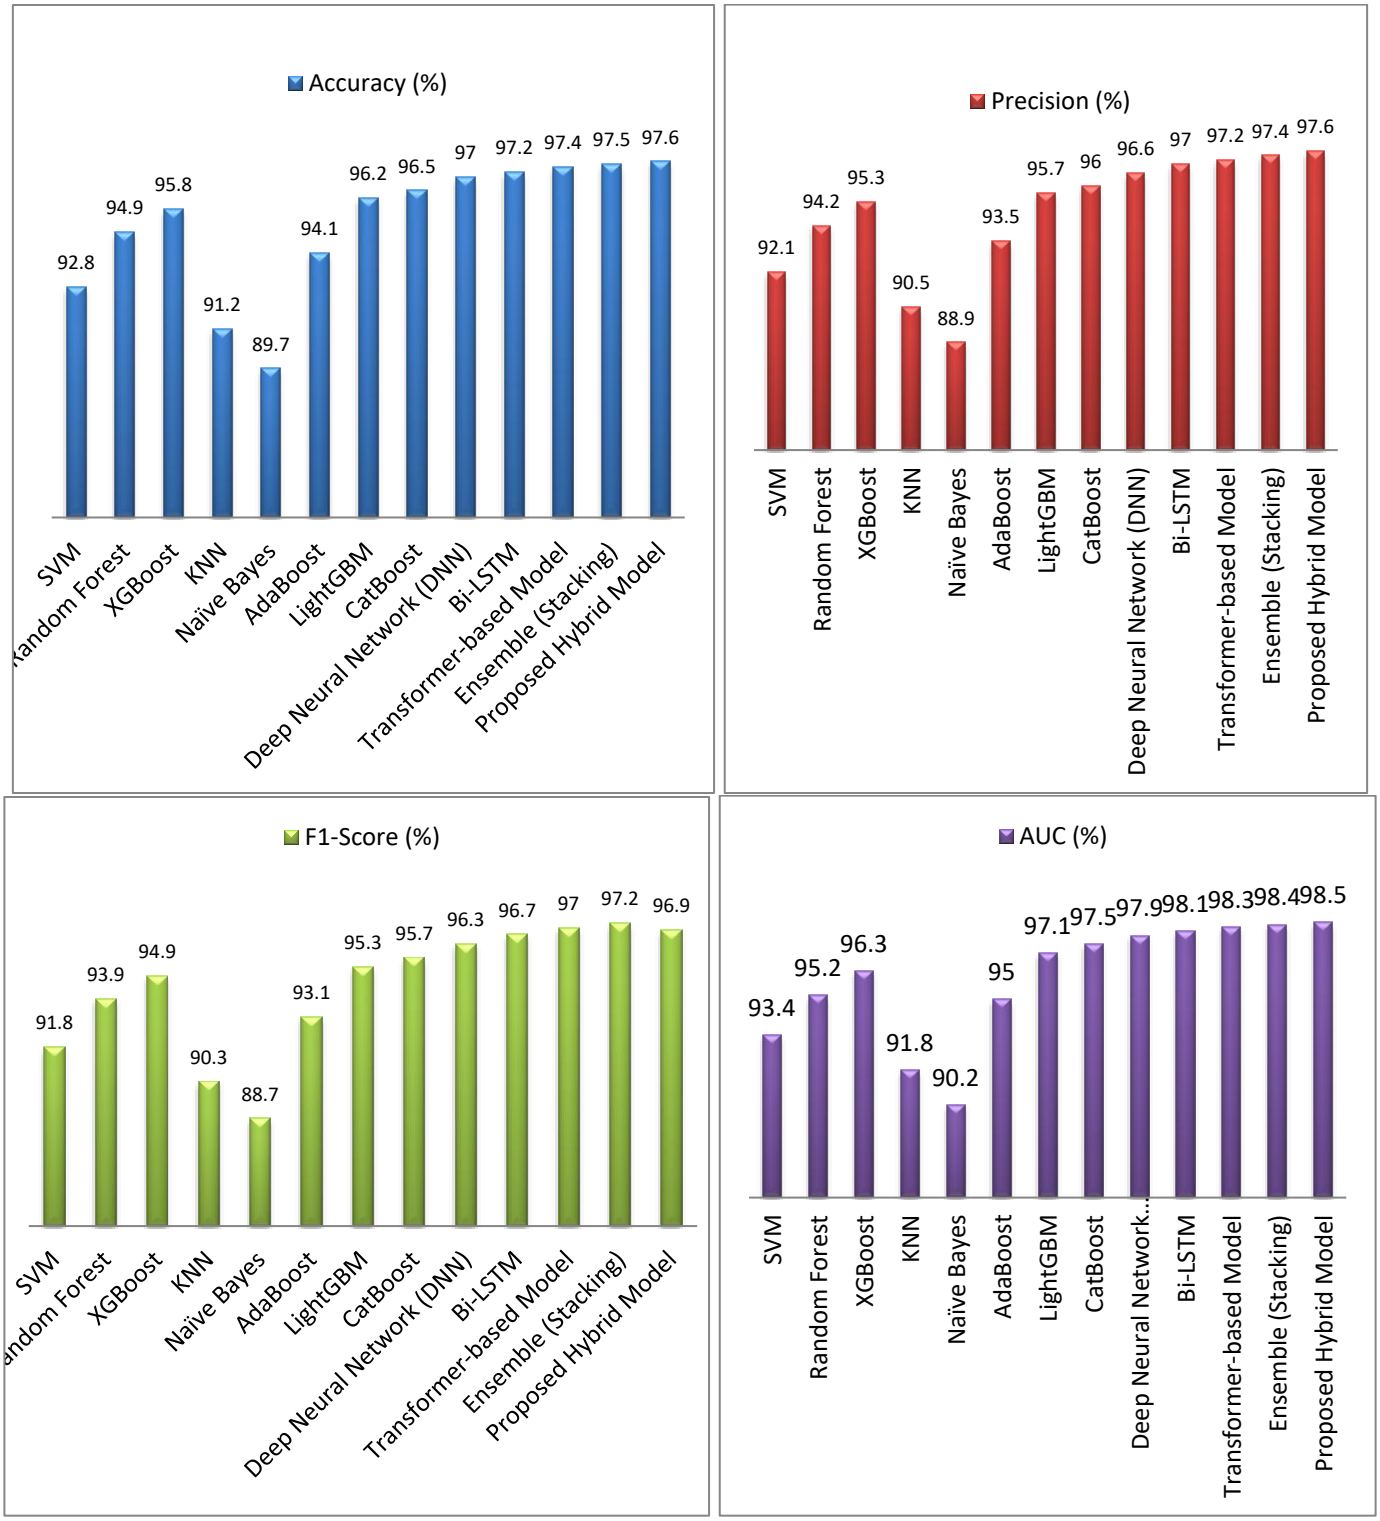

Fig. 2. Performance comparison of machine learning for e-learning environments.

D. Ablation Study

The ablation study of the proposed hybrid model tested on the combined LMS + CICIDS data is provided in Table III. It examines the role played by each of the key elements, such as the behavioral feature, network traffic feature, anomaly detection feature, temporal modeling (LSTM), and feature fusion strategy. The study systematically eliminates the elements of the architectural framework and measures the effect of each module on overall performance to show the significance of each architectural element in the proposed framework.

TABLE III. ABLATION ANALYSIS OF PROPOSED HYBRID MODEL ON COMBINED LMS + CICIDS DATASET

Configuration	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)	AUC (%)
Full Model (All Components)	97.6	97.6	97.1	96.9	98.5
Without Behavioral Features (LMS Removed)	95.1	94.6	94.2	94.4	96.8
Without Network Features	94.3	93.7	93.1	93.4	96.1
Without Anomaly Detection Module	95.6	95.1	94.5	94.8	97.2
Without Temporal Modeling (No LSTM/Sequence)	96.2	95.7	95.0	95.3	97.6
Without Feature Fusion Strategy	95.4	94.9	94.3	94.6	97.0

The performance of the model based on ablation shows that the entire model presents the highest performance in all the assessment factors, which shows the efficacy of incorporating all components. Users of behavioral features of LMS experience a significant performance decline when these features are eliminated, which underscores the significance of user behavior analytics in predicting risks. On the same note, omission of CICIDS network features will result in further deterioration, which proves that network-level information is fundamental in the detection of cyber threats.

The loss of the anomaly detection module lowers the performance of the model in identifying abnormal patterns, whereas removing temporal modeling (LSTM-based sequence learning) worsens the performance as the sequential behaviour is important in capturing changing attack patterns. Also, the elimination of the feature fusion strategy will lead to lower overall performance, which demonstrates that multimodal feature integration is vital. All in all, the findings confirm that individual components are significant, and the hybrid architecture is giving effective and balanced predictive performance.

E. Statistical Significance Analysis

A statistical significance analysis of the proposed model is done against various baseline machine learning and deep learning models, namely, SVM, Random Forest, XGBoost, LightGBM, a standalone Transformer model, and Ensemble (Stacking) approach, as shown in Table IV.

In submitting results on improved performance of their model, a detailed statistical procedure was followed in order to confirm the reliability of the data being reported. Each experiment was run independently 10 times using a unique random initialization seed for each run, with the training, validation, and testing partitions being identical for all runs. These results reflect the mean of all 10 runs' resultant accuracy values and will provide standard deviations that reflect variability in the results and stability of the model; therefore, before conducting significance testing, we used the Shapiro-Wilk test to assess if there was a normal distribution of performance across each model, which provided a basis for using parametric testing techniques ($p > 0.05$). Next, for the proposed model, we used paired two-tailed t-tests to compare its five-fold cross-validated performance against all baseline methods using the average of the five-fold cross-validated performance scores on the various models.

Evaluating the statistical significance consisted of using 95% confidence intervals ($p < 0.05$) or 99.9% confidence intervals ($p < 0.001$). In addition to looking at the p-values, we computed 95% confidence intervals to further examine the reliability of the differences in performance observed. The next step in our evaluation of the model was to conduct effect size analysis using Cohen's d to evaluate practical significance. Although some of the methods we employed performed comparably (e.g., Ensemble Stacking vs. Proposed Model) based solely on the mean accuracy, the Proposed Model consistently showed more stability, lower variability, better overall performance, higher AUC values, and superior risk predictions than Ensemble Stacking across all experiment runs. Therefore, we utilized statistical significance in conjunction with practical performance characteristics when making comparisons for superiority to one another.

TABLE IV. STATISTICAL SIGNIFICANCE COMPARISON (PROPOSED VS BASELINES)

Model Compared	Mean Accuracy (%)	Std Dev	t-value	p-value	Significance
SVM	92.8	0.85	8.21	<0.001	Significant
Random Forest	94.9	0.72	6.45	<0.001	Significant
XGBoost	95.8	0.64	5.38	<0.001	Significant
LightGBM	96.2	0.59	4.92	<0.001	Significant
Transformer Model	97.4	0.48	2.67	0.012	Significant
Ensemble (Stacking)	97.5	0.45	2.11	0.031	Significant
Proposed Model	97.6	0.41	—	—	—

The proposed model has a high mean accuracy of 97.6% and the lowest standard deviation (0.41), which signifies high stability in the evaluation of experimental runs as well as high performance. All the models in the baseline indicate statistically significant dissimilarities with the proposed model, as the p-values are less than 0.05.

The classical models of machine learning, including SVM (92.8%) and Random Forest (94.9%), are relatively less accurate and more variable, which can be explained by the fact that they are not very capable of detecting intricate data trends. XGBoost and LightGBM approaches yield a higher performance (95.8% and 96.2%), but nevertheless, they remain lower than the proposed approach, which proves the superiority of more sophisticated feature learning algorithms.

Models based on deep learning, such as the Transformer (97.4% and Ensemble stacking (97.5%), are closer to the proposed model, although they have higher t-values and statistically significant p-values (0.012 and 0.031), meaning that even they are significantly underperforming. These enhanced baselines have relatively lower t-values, which implies that there are fewer performance differences but still indicates that the proposed model is robust. In general, statistical analysis confirms that the proposed model is the best

predictor that has statistically significant improvement and better consistency compared to all other comparison methods.

Even though the absolute accuracy gain over the strongest baseline is small (0.1%), the development of this new framework achieves that increase in accuracy while at the same time providing the ability to dynamically score risk, track evolution of risk temporally, predict anomalous events, and provide greater stability in execution across multiple iterations. Hence, this framework presents users with further practical uses beyond simply improved classification accuracy.

F. DRI-Based Analysis

The analysis based on the Dynamic Risk Index (DRI) provides a holistic way of measuring cyber risk by constantly monitoring the activities of users and systems within the online learning system. As opposed to the conventional static methods of making the classification, DRI allows dynamic and real-time analysis of the risk levels and has the opportunity to measure deviations in their behavior as well as network anomalies. Such analysis helps to elaborate more comprehensive data regarding risk allocation, time-consecutive changes, and behavioral patterns for users as well as in detecting and alleviating dangers in a proactive mode. DRI is a potent decision support mechanism, and with a combination of many analysis views such as correlation, threshold optimization, and intervention effectiveness, it can be applied. Altogether, the DRI-based analysis contributes to a new dimension of better interpretability, flexibility, and responsiveness to e-learning systems; therefore, it is a vital attribute of intelligent and resilient cybersecurity systems in a contemporary e-learning environment.

1) Risk distribution analysis: The risk distribution analysis using DRI is divided into users with low risk (0-0.3), medium risk (0.3-0.7), and high risk (0.7-1).

TABLE V. DRI-BASED RISK DISTRIBUTION

Risk Level	DRI Range	Percentage of Users (%)
Low Risk	0 – 0.3	62.4
Medium Risk	0.3 – 0.7	28.7
High Risk	0.7 – 1	8.9

Based on the results of Table V, we have observed that 62.4 percent of user has low risk level, 28.7 percent under medium level of risk, and 8.9 percent under high level of risk. The distribution indicates that the majority of users are normal (have normal behavior); however, the percentage of users who significantly affect the possible security threat is lower. It has a skewed distribution, which provides weight on the need to prioritize security resource allocation on high-risk users. Besides, the analysis assists in developing a rudimentary knowledge of the system risk in totality and designing specific mitigation measures to address the vulnerable user groups.

2) Temporal risk evolution analysis: DRI temporal analysis is used to measure the changes in user risk score throughout time or between time intervals. Trends of the gradual increase of risks can be established by plotting the DRI values with time.

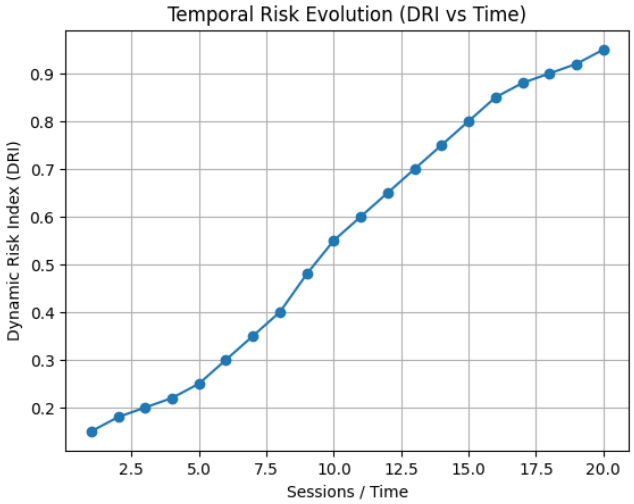

Fig. 3. Evolution plot of the temporal DRI that demonstrates that risk is increasing with sessions.

Fig. 3 demonstrates that the disclosure of high-risk users is based on a consistent increment in DRI before the emergence of anomalies or attacks. This is a developing trend, hence the fact that evil acts do not mostly crop out of thin air but are likely to develop with time. These insights would be useful to identify and creatively act to prevent decisive events before they occur. As such, temporal DRI monitoring is significant to enhance security in predicting and reducing the response time in an e-learning setup.

3) Risk vs attack correlation analysis: This discussion examines the correlation between the DRI scores and the real incidences of an attack with the use of statistical correlation scales. The Pearson correlation coefficient of 0.87 and Spearman rank correlation value of 0.84 demonstrate that the predicted risk has a very high correlation with the actual attack labels in a positive relationship.

TABLE VI. CORRELATION ANALYSIS

Metric	Value
Pearson Correlation (DRI vs Attack Label)	0.87
Spearman Rank Correlation	0.84

Table VI results substantiate the findings that the value of DRI is highly correlated with malicious behavior at high levels. The degree of correlation is high, which proves to support the reliability and effectiveness of DRI as a predictive risk indicator. Based on this analysis, therefore, the risk scoring mechanism presented in this study has been revealed as a true reflection of the threat conditions in real life, which can be trusted in making a decision.

4) Threshold sensitivity analysis: Threshold sensitivity analysis is used to determine the effect of various DRI thresholds on performance in the classification.

Table VII reveals that the optimal balance between the precision (96.3%), recall (95.1%), and F1-score (95.7) is attained with a threshold of 0.6. The lower thresholds give

more recalls but probably more false positive whereas the higher thresholds will give more precision but will not detect as many things. In this analysis, it is noted that there is a need to establish a level of success on the balance between detection versus false alarm. The identified threshold would facilitate successful risk classification, and the suggested framework will become more practical regarding usability.

TABLE VII. THRESHOLD OPTIMIZATION

Threshold	Precision (%)	Recall (%)	F1 (%)
0.5	94.8	96.2	95.5
0.6	96.3	95.1	95.7
0.7	97.6	93.8	95.6

5) Risk escalation detection analysis: This test is an assessment of DRI's ability to identify threats before they occur.

TABLE VIII. EARLY DETECTION CAPABILITY

Metric	Value
Avg. Detection Lead Time	2.3 sessions
Early Detection Rate (%)	91.4

Table VIII results indicate that the mean detection lead time is 2.3 sessions and the early detection rate is 91.4. These results demonstrate that the suggested system will be able to identify the suspicious activity early enough to eliminate the actual attacks. Early detection- this is so because those who administer may take preventive measures, which reduce the destruction and compromise of the system. The advantages of the DRI-based framework include this proactive capability since it transforms the approach to cybersecurity from reactive defense strategies to prediction-driven defense strategies.

6) User behavior segmentation based on DRI: The separation of the population based on the DRI into steady low-risk, oscillating medium, and steady high-risk groups is user segmentation. This method of clustering enables users to learn more about the user behavior patterns and risk dynamics. The behavior of a stable user is predictable, and that of a user with fluctuations is infrequent and might require monitoring. Such abnormal patterns are always exhibited by high-risk users, and this demonstrates the potential danger. The segmentation can facilitate personalized security policies, which in turn give the institutions the opportunity to institute certain user group interventions like additional checks of authentication, or user group surveillance amongst other activities to enhance the overall security and efficiency of the system. The segmentation of behavioral and DRI risk scores into low, medium, and high risk cluster are segmented into user behavior in Fig. 4 using the scatter plot to segment them based on the risk scores.

7) Component contribution analysis (DRI weights): This analysis assesses the relative contribution of each component to this DRI calculation. The results indicate that network-based features are the most important features, accounting for 41.2%, followed by behavioral features (38.5%) and anomaly detection (20.3%).

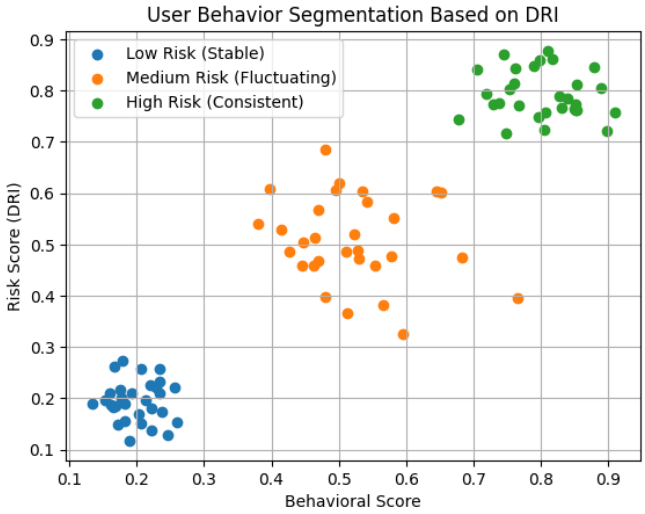

Fig. 4. User behavior segmentation based on DRI.

TABLE IX. COMPONENT CONTRIBUTION ANALYSIS

Component	Weight Contribution (%)
Behavioral Score	38.5
Network Score	41.2
Anomaly Score	20.3

The results in Table IX suggest that both behavioral information and network information are dominant sources for risk prediction, although anomaly detection offers further enhancement to risk prediction. The balanced contribution is a confirmation of the effectiveness of the hybrid approach in capturing the multi-dimensional threat characteristics.

8) Risk transition matrix: The movement of users between the various risk levels over time is analysed in the risk transition matrix.

From \ To	Low	Medium	High
Low	91%	8%	1%
Medium	12%	78%	10%
High	3%	15%	82%

Fig. 5. Risk transition matrix.

The findings in Fig. 5 indicate that 91 percent of the low-risk users stay at the same level, and 8 percent of the risk group move towards the medium-risk level. Out of the medium-risk users, 10 percent progress to the high-risk group and high risk users are so much persistent and were found to be 82 percent still at the same level. The results of these studies can lead to

the conclusion that once users have been put in the high-risk state, they are prone to remain in that state unless something is done about them. This discussion therefore shows the need to detect the issue early enough and ensure mitigation to prevent the escalation of the risk and ensure that the system remains secure.

G. Discussion

The proposed study puts forward an expansive framework for dynamic cyber risk prediction in the online education environment by amalgamation of behavioural analytics from LMS logs and network intrusion data from the CICIDS2017 dataset. The results demonstrate that the use of a multi-source data combination provides a much better detection capability than one dataset. Machine learning and deep learning models are good at capturing both static and temporal features, whereas the mechanism for anomaly detection gets better in the case of previously unseen threats. The introduction of the DRI provides a continuous and interpretable measure of user risk, which can be used to monitor user risk in real-time and mitigate it as proactively as possible. According to the comparative analysis, the proposed hybrid model is consistently superior compared to the state-of-the-art techniques in all the evaluation metrics. Ablation studies highlight the importance of individual components, especially feature fusion and behavioural modelling. Statistical significance analysis is another way of validating the robustness of the model. In addition, DRI-based analyses provide important information about user risk distribution, threshold optimization, and early detection of threats. Overall, the research holds the success in harnessing the intelligence at the behavioral and network level for the development of scalable, adaptive, and resilient cybersecurity solutions for modern E-learning platforms.

H. Limitations

The proposed framework also has some limitations even though it performs well. The LMS logs coupled with the CICIDS2017 data give rise to heterogeneity of the domain that could possibly affect generalization to various institutional settings. The use of historical and semi-labeled LMS data could be used as a factor of limitation in limiting the detection of zero-day attacks. Moreover, the deep learning components of these functions are a complication in the calculations and may pose a difficulty in having real-time systems that are constrained by the resources of the system. Moreover, variations in LMS platforms and patterns of user actions can require more customization of the platforms in order to guarantee optimal performance.

I. Practical Implications

The suggested framework possesses a high degree of practical advantages in enhancing cybersecurity in e-learning systems. Using the opportunity of the Dynamic Risk Index (DRI), the institution is able to track the activity of users in real time; the activity of high-risk members can be discovered beforehand. The incorporation with LMS platforms guarantees the facilitation of the ease of installation without disrupting an existing operation. Its model assisted in automated alert generation, making security administrators' work easier and enabling quicker reaction to an incident. As well, behavioral analytics will be useful in targeting cybersecurity awareness programs, as well as improving policies through the insights obtained using the methods of behavioral analytics.

V. Conclusion

This work proposes a novel hybrid framework for dynamic cyber risk prediction in online education environments using both LMS behavioral data and network intrusion information from the CICIDS2017 dataset. The proposed approach essentially combines the techniques of machine learning, deep learning, and anomaly detection to pick up on behavioral as well as network-level threat patterns. Experimental results show that the model has better performance as compared to the current methods with better accuracy, robustness and generalization. The integration of the Dynamic Risk Index (DRI) provides for constant surveillance of the risk and helps to prevent threats. Future research can focus on introducing federated learning to overcome the data privacy issues and facilitate joint learning between institutions. The combination of explainable AI techniques can help to increase transparency and trust in the model predictions. Additionally, expanding the framework for processing streaming data in real-time as well as the deployment of the framework at the edge can make the system more scalable and responsive. Exploring greater unsupervised and reinforcement learning techniques could also enhance zero-day attack detection. Overall, the proposed framework provides a firm basis to develop intelligent and adaptive cybersecurity solutions in a changing e-learning ecosystem.

Adaptive Honey Badger Optimization with Bernoulli Chaotic Mapping and Decreasing Neighborhood for Efficient Cloud Task Scheduling

Yanfang XING
School of Media Technology, Communication University of China Nanjing,
Nanjing City, Jiangsu Province, 211172, China

***Abstract*—One of the most important challenges in optimizing task scheduling in cloud computing is the dynamic nature of resources, the heterogeneity of tasks, and conflicting optimization criteria, such as minimizing task completion period, optimizing resource utilization, and shortening task migration time. Meta-heuristics such as the Honey Badger Algorithm (MBA) often converge on suboptimal solutions and may not strike the perfect balance between exploitation and exploration in task scheduling optimization. To address the problems associated with traditional HBA and similar algorithms, this research introduces a novel optimization technique called the Multi-strategy Honey Badger Algorithm (MHBA). The proposed MHBA integrates three optimization strategies: horizontal crossing coupled with adaptation, an optimum decreasing neighborhood, and a Bernoulli shift scheme. The MHBA is simulated using CloudSim and compared with other advanced techniques. The experimental findings confirm MHBA's efficacy in reducing makespan by up to 25.6%, increasing resource utilization by up to 16.7%, and decreasing migration time by up to 27.5% when applied to the HPC2N dataset. The same was evident in the NASA dataset, where MHBA achieved reductions in makespan of up to 25.9%, improvements in resource utilization of up to 21.6%, and reductions in migration time of up to 24.1%.**

I. Introduction

Cloud computing is a revolutionary technological shift towards a new paradigm for scalable and on-demand provision of various services through virtualization [1]. Today, organizations increasingly use cloud computing to process large volumes of data, run distributed applications, and offer elastic computing services to users worldwide [2]. In this context, task scheduling is a fundamental issue for mapping various computational tasks to a set of Virtual Machines (VMs) [3]. This factor is crucial to determining a system's performance. In a heterogeneous environment with changing scenarios, scheduling mechanisms must effectively handle multiple tasks while ensuring optimal resource allocation [4]. Therefore, the development of intelligent scheduling algorithms is a prominent issue for cloud computing systems, as it affects the efficiency and cost-effectiveness of a cloud infrastructure [5].

However, scheduling in cloud computing remains a complex optimization problem, as many tasks must be allocated to heterogeneous VMs while optimizing multiple conflicting objectives [6]. Some common scheduling objectives in cloud computing include minimizing makespan, maximizing resource utilization, and diminishing task migration overhead. These objectives are conflicting, and it is really hard to achieve optimal performance across all of them. In addition, as the number of tasks and resources increases, the scheduling process becomes increasingly complex. In cloud computing, task scheduling is known to be an NP-complete problem. In addition, the dynamic nature of the cloud computing environment, particularly in resource provisioning, makes it a complex task that requires adaptive optimization techniques to achieve near-optimal performance.

Several strategies have been proposed to overcome these issues, including heuristics and more sophisticated techniques known as metaheuristics, inspired by natural processes. In fact, algorithms such as Differential Evolution (DE) [7], Genetic Algorithm (GA) [8], Particle Swarm Optimization (PSO) [9], and Ant Colony Optimization (ACO) [10] have proven effective for optimization problems. Nevertheless, many of them possess severe limitations in solving large-scale scheduling problems in cloud computing environments. For instance, traditional metaheuristics may suffer from premature convergence, in which a local optimum is found before a global one. Furthermore, many existing approaches may struggle to establish an appropriate equilibrium between exploration and exploitation throughout the search process.

These limitations emphasize the importance of developing more powerful and flexible optimization strategies to effectively explore the search domain and possess strong local search capabilities. Recently, various advances in swarm-based optimization methodologies have been proposed to improve the efficiency of optimization algorithms by combining multiple improvement strategies. Among such strategies, the Honey Badger Algorithm (HBA) has been found to possess strong global search capabilities and simplicity [11]. However, like other metaheuristic optimization techniques, the traditional HBA may face limitations, such as insufficient population diversity and low adaptability in the later stages of optimization. Hence, motivated by such limitations, this research aims to introduce a novel enhanced version of the Multi-strategy Honey Badger Algorithm (MHBA) to improve diversity, maintain adaptive exploration–exploitation strategies, and efficiently solve multi-target task scheduling problems in a cloud

computing setting. The main contribution of this research can be summarized as follows:

- Proposing MHBA to address the multi-target task scheduling issue in cloud computing.
- Introducing the Bernoulli chaotic mapping to optimize the population diversity in the initialization phase.
- Suggesting the Optimum Decreasing Neighborhood (ODN) approach to optimize search space exploration.
- Incorporating the Horizontal Crossing coupled with Adaptation (HCA) mechanism to maintain a balanced exploration–exploitation process.

The remaining part of this study is presented as follows. Section II reviews recent research on cloud task scheduling and optimization algorithms. Section III describes the system model and mathematical description of the multi-target task scheduling problem. Section IV introduces the proposed algorithm and its application to a cloud task scheduling system. Section V presents the experimental evidence and compares the proposed method with other algorithms. Finally, in Section VI, the study is summarized, and future research directions for intelligent cloud task scheduling are proposed.

II. Related Work

Task scheduling is a major concern in cloud computing due to its effects on system performance, resource allocation, and quality of service. Several heuristics and metaheuristic methods have been developed to address the task scheduling problem due to its inherent NP-hard nature. Some of the works include the following. In their study, Pirozmand, et al. [12] present the Improved Particle Swarm Optimization (IPSO) as a scheduling algorithm in cloud computing. The proposed IPSO algorithm uses a multi-adaptive learning approach, with two particle types: ordinary particles and locally best particles, to ensure efficient convergence.

In another work, Gong, et al. [13] proposed the Enhanced Marine Predator Algorithm (EMPA) as a cloud computing task scheduler. The EMPA algorithm develops a scheduling model that optimizes for both minimum makespan and maximum resource utilization. The algorithm employs Whale Optimization operators, a nonlinear inertia-weight coefficient, and a golden sine strategy to enhance search capabilities and convergence performance. In a different study, Pabitha, et al. [14] developed Chameleon and the Remora Search Optimization Algorithm (CRSOA) as a multistage cloud computing task scheduler.

Selselejoo and Ahmadifar [15] introduce the DT-GWO, a hybrid scheduling technique that integrates the Decision Tree (DT) classifier with the Grey Wolf Optimization (GWO). Emara, et al. [16] suggest a novel adaptive task scheduling approach that uses the enhanced Harris Hawks Optimization (HHO) method. The method incorporates several enhancements, including selecting the best solution rather than a random one in the exploration phase and introducing mutation operations in the exploitation phase to prevent convergence to local optima.

Du, et al. [17] enhance the Reptile Search Algorithm (RSA) by proposing the ACRL-RSA, where adaptive chaotic reverse learning strategies are utilized. Population diversity is improved by adopting chaotic mapping and enhanced exploration capabilities in the optimization process. Experimentation conducted using the CloudSim toolkit revealed that ACRL-RSA performs better in minimizing makespan, computation cost, and energy expenditure. Kathole, et al. [18] introduce the HL-GOA as an optimization technique for task scheduling and VM placement in cloud computing. The HL-GOA model considers several factors, including cost, time, throughput, resource utilization, and makespan.

Awad, et al. [19] suggest a combined PSO-GWO-based scheduling approach for workflow management in fog and cloud computing systems. Tawfeek, et al. [20] introduce a novel artificial bee colony-genetic algorithm-based framework for multi-objective cloud workflow scheduling. The push-pull algorithm for task scheduling in cloud computing is introduced by Rajeshwari and Namratha [21]. This scheduling approach assigns arriving tasks to VMs using the push-pull model.

TABLE I. An Overview of Existing Approaches

Algorithm	Key technique	Objectives	Advantages	Limitations
IPSO [12]	Multi-adaptive PSO learning strategy	Makespan and load balancing	Faster convergence than PSO	Risk of local optimum
EMPA [13]	Improved marine predator algorithm with WOA operators	Makespan and resource utilization	Improved exploration capability	Parameter sensitivity
CRSOA [14]	Chameleon and remora hybrid optimization	Makespan, cost, and load balancing	Handles uncertainty factors	Increased computational complexity
DT-GWO [15]	Decision tree and grey wolf optimization	Makespan, cost, and resource utilization	Improved task classification	Limited scalability
Enhanced HHO [16]	Adaptive Harris hawks optimization	Throughput and makespan	Better exploration and exploitation	Mutation tuning required
RSA-ACRL [17]	Chaotic reverse learning in RSA	Makespan, energy, and cost	Increased population diversity	Higher computational overhead
HL-GOA [18]	Lemur-gannet hybrid optimization	Cost, throughput, and makespan	Multi-constraint optimization	Algorithm complexity
IPSO-GWO [19]	Hybrid PSO-GWO	Cost, energy, and makespan	Balanced search strategy	Limited adaptability
ABC-GA [20]	Artificial bee colony and genetic algorithm	Time, cost, and energy	Strong hybrid search capability	Computational cost
LPP [21]	Linked list push-pull scheduling	SLA and response time	Effective load balancing	Limited global optimization ability

Despite the development of several metaheuristic algorithms for effective task scheduling in cloud computing environments, several limitations remain to be addressed. For example, as shown in Table I, most algorithms are designed to optimize specific aspects of the problem, while the multi-objective nature is not adequately addressed. In addition, some algorithms suffer from early convergence and insufficient population diversity, making it difficult to explore the solution space. It is because of such challenges that hybrid algorithms were developed to address weaknesses in other algorithms.

Another major limitation evident in most algorithms is the lack of an effective trade-off between exploration and exploitation in the optimization process. Most optimization algorithms have strong exploratory capabilities but fail to adequately explore the search space because of poor local search refinement strategies. However, optimization algorithms with effective local search strategies tend to converge to poor-quality solutions. Moreover, most optimization algorithms used in multi-objective optimization problems fail to incorporate adaptive search strategies that can change their behavior at different stages of the optimization process. To address this issue in multi-objective cloud task scheduling problems, this study proposes MHBA, which improves population diversity and adapts the crossover strategy during search.

III. Problem Formulation

A. Cloud Computing System Architecture

Cloud computing is a computing model that allows users to access shared computing resources over the internet without owning their own infrastructure. Service providers offer users computing resources, such as storage capacity, software applications, databases, and data analysis capabilities, through a network-based computing model known as the cloud. Benefits of cloud computing include elasticity, availability, scalability, and reliability, among others. Cloud systems can take various forms based on operational requirements and security considerations. These include public, private, and hybrid clouds. Furthermore, cloud computing services are typically provided through a layered architecture comprising infrastructure-as-a-service, platform-as-a-service, and software-as-a-service. As shown in Fig. 1, the layers include infrastructure as a service, which provides the bottom layer of basic computing infrastructure; platform as a service; and software as a service.

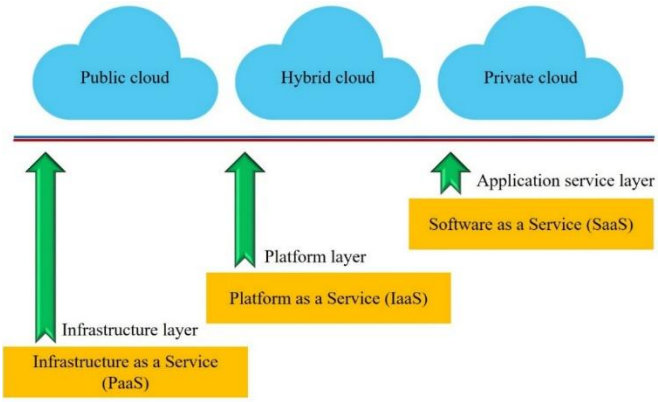

Fig. 1. Layered service architecture for cloud environments.

In practical cloud systems, task scheduling involves migrating computational workloads from user devices to large-scale cloud data centers. The objective is to ensure that tasks are processed efficiently while meeting user requirements for performance and service quality. Due to continuously changing workloads and resource conditions, scheduling mechanisms must be highly adaptable and capable of dynamically adjusting allocation strategies. Consequently, an effective scheduling system must consider factors such as system performance, resource constraints, task priorities, and user requirements to achieve efficient resource utilization. The architecture for service delivery in a cloud computing model is shown in Fig. 2 below. The architecture has several layers that process user requests and manage computational resources. At the user end, several clients simultaneously submit their work requests to the cloud computing system. These requests are handled by the task management layer.

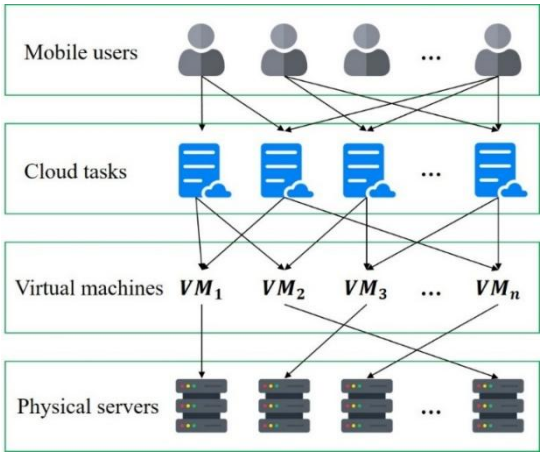

Fig. 2. Layered service delivery architecture in cloud computing.

To achieve this objective, the scheduling algorithm must consider these characteristics when allocating resources. The cloud computing architecture typically consists of multiple VMs running on physical computers. Computing resources can be allocated according to the system's needs. The resource manager keeps track of the current state of each computing resource, whether it is busy, idle, or faulty. Given the above facts and the chosen scheduling algorithm, the jobs are allocated to VMs. The performance analysis of the job, like its execution time, will be delivered to the user. Task scheduling is an important process in a cloud computing system. As shown in Fig. 3, the scheduling process typically comprises two main layers: the scheduling control layer and the task execution layer. First, users' submitted jobs are divided into individual tasks. Then, the scheduler evaluates all tasks to determine their relationships with computing resources. Resource allocation is then performed based on the task's needs.

Once the scheduling process is complete, the execution process is sent to the task-processing layer, where computing nodes perform the operations. While executing, the scheduler continuously monitors task status and adjusts allocations as needed. At the end of the execution process, the computation results are then returned to the user. Effective scheduling processes enable the cloud computing environment to work effectively.

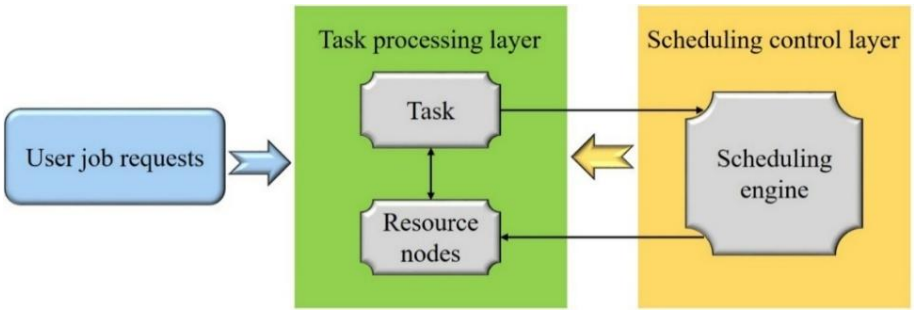

Fig. 3. Conceptual workflow of the cloud task scheduling mechanism.

B. Task and Resource Modeling

In cloud computing task scheduling optimization, the primary objective is to determine an optimal mapping between computational tasks and available computing resources. To formally describe the scheduling process, a mathematical model is constructed that captures the relationship between tasks and computing nodes. Let the cloud environment consist of a set of computing nodes $R = \{R_1, R_2, \dots, R_m\}$ and a set of tasks $T = \{T_1, T_2, \dots, T_n\}$, where m denotes the number of VMs, and n represents the number of submitted tasks, typically satisfying $n > m$. The scheduling decision can be represented using an assignment matrix as follows:

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & a_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{bmatrix} \quad (1)$$

where, a_{ij} is a binary decision variable indicating whether the task T_i is assigned to the resource R_j. If $a_{ij} = 1$, task T_i is executed on the j^{th} VM; otherwise, the value is zero. To accurately describe scheduling performance, three fundamental metrics are considered: makespan, resource utilization, and migration time. Makespan represents the completion time of the final task in the scheduling sequence, calculated using Eq. (2).

$$M = \max_{i \in \{1,\dots,m\}} C_i \quad (2)$$

where, C_i signifies the finishing time of the task T_i. Resource utilization quantifies the proportion of computational resources effectively used by scheduled tasks, defined as follows:

$$U = \frac{\sum_{j=1}^{n} \sum_{i=1}^{m} R_{ij} \cdot y_{ij}}{\sum_{j=1}^{n} R_j} \quad (3)$$

where, R_{ij} denotes the resource requirement of the task T_i on VM j, y_{ij} is a binary decision variable indicating whether the task T_i is assigned to VM j, and R_j represents the total capacity of VM j. Migration time captures the overhead incurred when tasks are transferred between VMs, expressed by Eq. (4).

$$T_{mig} = \sum_{i=1}^{m} \sum_{j=1}^{n} y_{ij} \cdot o_{ij} \quad (4)$$

where, o_{ij} denotes the migration duration required for the task T_i to move to VM j. To evaluate scheduling quality, a composite fitness function is formulated by combining the three metrics. The overall optimization objective is defined by Eq. (5).

$$F = \omega_1 \left(\frac{1}{M}\right) + \omega_2 U - \omega_3 T_{mig} \quad (5)$$

where, ω_1, ω_2, and ω_3 represent the weighting coefficients that determine the importance of each objective.

IV. Proposed Algorithm

HBA operates on a population and mimics honey badger behavior when hunting in the wild. This algorithm consists of two main predation phases: the digging and honey phases. The latter allows the search technique to perform both exploration and exploitation to solve problems effectively. In nature, honey badgers collaborate with honey-guiding birds, as the latter are responsible for detecting bees' nests. Honey guides find the nest; however, honey badgers break open the hive with their claws. This cooperation forms the foundation for the algorithm. During the search process, potential solutions mimic honey badgers' prey-hunting behavior by scent-tracking and following clues.

A. Population Initialization

As with any other population-based algorithm, the search procedure begins with an initialization stage that generates candidate solutions. Let us assume that there are N_p honey badgers in the population. The location of the k^{th} badger is randomly generated from the search space using Eq. (6).

$$Y_k = L_b + (U_b - L_b) \cdot \rho, \quad k = 1,2, \dots, N_p \quad (6)$$

where, L_b and U_b represent the lower and upper bounds of the search space, respectively, while ρ is a uniformly distributed random number in the range [0,1]. The initialization process ensures that candidate solutions are uniformly distributed across the search space.

B. Digging Phase (Exploration)

During the digging phase, honey badgers detect prey using their powerful olfactory capabilities. This phase promotes global search, enabling the algorithm to find prey across extensive areas. The position updating equation used in this phase is given by Eq. (7).

$$y_i = y^* + G \cdot \kappa \cdot \Psi \cdot y^* + G \cdot r_2 \cdot \delta \cdot \Delta_i |\cos(2\pi r_3)[1 - \cos(2\pi r_4)]| \quad (7)$$

where, y^* represents the current optimal solution in the population, κ is a constant with a minimum value of 1, r_2, r_3,

and r_4 represent randomly generated numbers within [0,1], Δ_i denotes the distance between the current solution and the current optimal solution, and G serves as the directional parameter, regulating the search orientation. The digging phase includes an intensity operator that calculates the honey badger's attraction to the prey. This intensity is determined using Eq. (8).

$$\Psi = \rho_1 \cdot \frac{Q}{4\pi\Delta_i^2} \tag{8}$$

where, ρ_1 is a random number within [0,1] and Q represents the source strength. The source strength and distance term are computed as follows:

$$\mathrm{Q} = (y_i - y_{i+1})^2 \tag{9}$$

$$\Delta_i = y^* - y_i \tag{10}$$

To control the search direction, a directional control parameter is employed during the digging phase and is defined by Eq. (11).

$$G = \begin{cases} 1, & r_5 \le 0.5 \\ -1, & \text{otherwise} \end{cases} \tag{11}$$

where, r_5 represents a randomly generated number within the interval of [0,1]. If G is positive, the direction of movement will be towards the best solution; otherwise, it will be away from it. Moreover, a density parameter is used to control the gradual shift of the search mode from exploration to exploitation, decreasing nonlinearly with time and given by Eq. (12).

$$\delta = \theta \cdot \exp\left(-\frac{t}{T_{max}}\right) \tag{12}$$

where, θ is a constant usually set to 2, t is the current iteration number, and T_{max} denotes the maximum number of iterations. The adaptive parameter enables the algorithm to smoothly transition between global search and local refinement.

C. Honey Phase (Exploitation)

The next step of the algorithm models the interaction between the two species as cooperation. At this stage, the honey guides help locate the hive, and then the honey badger goes to the site to exploit the resources. The updating process at the honey stage can be mathematically defined by Eq. (13). It shows that the candidates approach the best-known location in a controlled random manner.

$$y_i = y^* + G \cdot r_6 \cdot \delta \cdot \Delta_i \tag{13}$$

D. Multi-Strategy Honey Badger Algorithm

While HBA shows excellent exploratory ability, it may be prone to an imbalance between exploration and exploitation. To address this drawback of the initial HBA, an improved approach, MHBA, will be introduced in this research. As the name suggests, this algorithm uses three improvement strategies: chaotic Bernoulli initialization, an optimal piecewise decrease strategy, and horizontal crossover. Chaotic maps produce deterministic sequences with high randomness, thereby enhancing population diversity during initialization. In the MHBA algorithm, instead of random initialization, the chaotic Bernoulli map is used. Eq. (14) defines the Bernoulli map.

$$z_{t+1} = \begin{cases} \frac{z_t}{1-\varepsilon}, & 0 \le z_t < 1-\varepsilon \\ \frac{z_t - (1-\varepsilon)}{\varepsilon}, & 1-\varepsilon \le z_t \le 1 \end{cases} \tag{14}$$

where, ε is a control parameter within the range [0,1]. A commonly used simplified form of the Bernoulli map is $z_{t+1} = 2z_t \bmod 1$ that generates a chaotic sequence used for initializing candidate solutions. To improve the adaptability of search behavior, MHBA employs the ODN technique. It controls the neighborhood search radius throughout the optimization process. The ODN parameter is expressed as:

$$ODN = \begin{cases} 1 + \tau_1 \cdot \eta_1 \cdot U(0,1), & 0 \le t \le \frac{T_{max}}{3} \\ 1 + \tau_2 \cdot \eta_2 \cdot U(0,1), & \frac{T_{max}}{3} < t \le \frac{2T_{max}}{3} \\ 1 + \tau_3 \cdot \eta_3 \cdot U(0,1), & \frac{2T_{max}}{3} < t \le T_{max} \end{cases} \tag{15}$$

Three nonlinear decline functions regulate the neighborhood size as follows:

$$w_1 = w_{max} - (w_{max} - w_{min})\left(\frac{t}{T_{max}}\right)^2 \tag{16}$$

$$w_2 = w_{max} - (w_{max} - w_{min})\frac{t}{T_{max}} \tag{17}$$

$$w_3 = w_{max} - (w_{max} - w_{min})\left[\frac{2t}{T_{max}} - \left(\frac{t}{T_{max}}\right)^2\right] \tag{18}$$

Early iterations emphasize exploration while later iterations focus on exploitation. By integrating ODN, the updated position in the digging phase becomes:

$$y_i = y^* \cdot ODN + G \cdot \kappa \cdot \Psi \cdot y^* + G \cdot r_2 \cdot \delta \cdot \Delta_i |\cos(2\pi r_3)(1 - \cos(2\pi r_4))| \tag{19}$$

Similarly, the honey stage is modified as follows:

$$y_i = y^* + ODN + G \cdot r_6 \cdot \delta \cdot \Delta_i \tag{20}$$

To enhance the exploration process, MHBA uses a crossover technique based on a swarm intelligence algorithm. This crossover creates new candidates by merging the two parents' information to create children's solutions using Eq.

(21) and (22).

$$y_{new}(i) = \begin{cases} c_1 y_i + (1-c_1)y_j + c_2(y_i - y_j), & \text{CSO/rand/1} \\ y_i + c_3(y_i - y_j), & \text{DE/rand/1} \\ y^* + c_4(y_i - y_j), & \text{DE/best/1} \\ y_i + c_5(y^* - y_i) + c_6(y_i - y_j), & DE/rand - to - best/1 \end{cases} \tag{21}$$

$$y_{new}(j) = \begin{cases} c_1 y_i + (1-c_1)y_j + c_2(y_j - y_i), & \text{CSO/rand/1} \\ y_j + c_3(y_j - y_i), & \text{DE/rand/1} \\ y^* + c_4(y_j - y_i), & \text{DE/best/1} \\ y_j + c_5(y^* - y_j) + c_6(y_j - y_i), & DE/rand - to - best/1 \end{cases} \quad (22)$$

The success ratio of each crossover technique is recorded, and the probability of selecting each technique is adaptively adjusted during the search process. The flowchart of the MHBA is depicted in Fig. 4. The MHBA algorithm begins by initializing a population using the Bernoulli chaotic mapping. During the search process, the algorithm alternates between the digging and honey stages using the PDN neighborhood approach. A horizontal crossover with adaptive selection of crossover techniques is employed to improve exploration. The search process stops when the stopping criterion is met; the optimal solution is yielded as the optimal schedule.

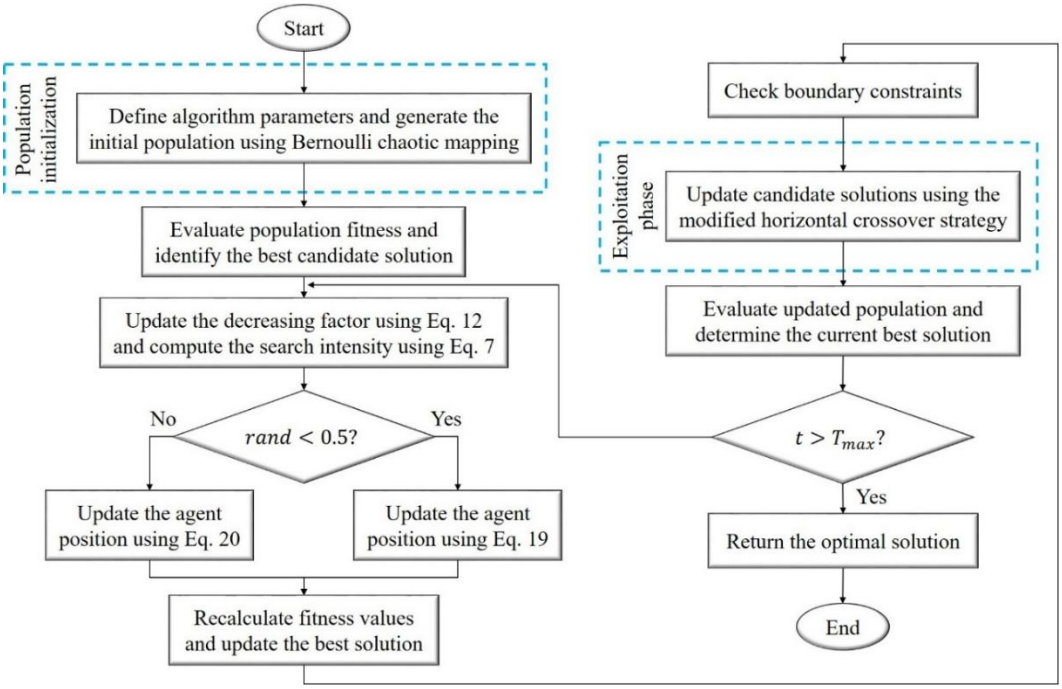

Fig. 4. Flowchart of the proposed algorithm.

V. Results and Discussion

To test the efficacy of the proposed MHBA for task scheduling in cloud computing, three critical parameters are used: makespan, resource utilization, and migration time. These parameters give a complete picture of how effective a task scheduling algorithm is in cloud computing. Makespan is defined as the total time required to execute all tasks scheduled in a system. A low makespan indicates that tasks are executed efficiently and that the task scheduling algorithm is effective. Resource utilization is the ratio of computational resources used to execute tasks to the total computational resources available in a system. If resource utilization is high, it indicates that a task scheduling algorithm is effective and that computational resources are being used efficiently in the system. Migration time is the total time required to migrate tasks from one VM to another within a system that executes tasks using a task scheduling algorithm. A low migration time implies that a task scheduling algorithm is effective.

The performance of the proposed MHBA-based scheduling framework is evaluated through simulation experiments using the CloudSim toolkit, which models and simulates the cloud computing environment. CloudSim provides a simulation framework for emulating complex cloud computing environments, including VMs, hosts, data centers, and task workloads, without requiring actual hardware. The simulation framework provides a wide range of cloud computing components, such as VM allocation, scheduling policies, and resource provisioning mechanisms. This provides a wide range of analysis capabilities for scheduling strategies in various cloud computing environments. To improve simulation reliability and realistic workload modeling, two workload traces, namely HPC2N and NASA, were used in simulation experiments. These workload traces contain detailed workload information regarding the execution behavior of jobs.

The HPC2N dataset is derived from a high-performance computing environment and comprises a heterogeneous workload analogous to large-scale scientific computing activities in a distributed computing environment. NASA is another dataset derived from scientific workflows executed in real computing environments. It comprises details on task execution time, task dependencies, and computational requirements. Using these datasets in the simulation enables the evaluation mechanism to capture realistic scheduling scenarios and workload diversity, which are common in cloud computing environments. By using the HPC2N and NASA datasets in the experiments, the MHBA algorithm is validated for its ability to handle diverse and dynamic task-scheduling scenarios. The configuration parameters utilized in the simulation environment for the cloud computing system are presented in Table II.

TABLE II. CONFIGURATION PARAMETERS USED IN THE CLOUD SIMULATION ENVIRONMENT

Simulation parameter	Assigned value
Total virtual machine instances	50
Processing capability of each VM	100 – 1000
Memory allocated per VM	1024 MB
Virtual machine memory capacity	9192 MB
Number of cloud data centers	2
Total number of submitted tasks	100 – 1000
Task workload size (instruction length)	1500 – 10,000
Virtualization platform	Xen

The makespan performance of MHBA has been tested against two popular swarm-based optimization techniques: PSO and Cat Swarm Optimization (CSO). Fig. 5 presents a visual representation of the results, and Table III summarizes the results for the HPC2N workload set. From 100 to 1000 cloudlets, all makespan values increase, indicating increased computational complexity. MHBA has been found to possess lower makespan values than the other techniques. When scheduling 100 cloudlets, MHBA achieves a makespan of 36.85, which is reduced by 25.5%, 34.57%, and 21.57% compared with PSO, CSO, and HBA, respectively. When the workload is increased to 500 cloudlets, MHBA still achieves the best performance, with a makespan of 135.18, which is reduced by 12.15%, 20.66%, and 8.9% compared with PSO, CSO, and HBA, respectively. When the workload is increased to 1000 cloudlets, MHBA still outperforms the other algorithms, achieving a makespan time of 247.25, which is reduced by 9.75%, 17.54%, and 7.34. Various parts of MHBA contribute to this improvement. For instance, the random initialization process enhances population diversity, ensuring the algorithm can explore all feasible scheduling options from the start.

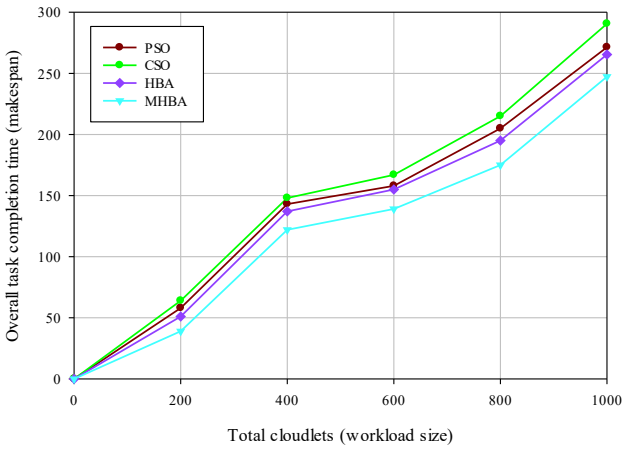

Fig. 5. Comparison of makespan for different scheduling algorithms under the HPC2N workload with varying numbers of cloud tasks.

The resource utilization comparison is shown in Fig. 6 and summarized in Table IV. As the number of tasks increases, the utilization rates of all algorithms decrease slightly. This is because the number of tasks is distributed among the available resources. Though MHBA has lower utilization for 100 cloudlets, the performance is still acceptable. This is because MHBA has strong exploration capabilities during the initial search phase. For smaller-scale tasks, the search space is relatively simple, and other algorithms, such as PSO and CSO, can achieve convergence.

TABLE III. COMPARISON OF MAKESPAN ACROSS SCHEDULING ALGORITHMS USING THE HPC2N DATASET

Workload size (Cloudlets)	PSO	CSO	HBA	MHBA
100	46.25	49.59	41.80	36.85
500	151.61	163.11	147.22	135.18
1000	271.38	290.63	265.42	247.25

MHBA has to spend some extra time exploring the possible scheduling configurations. MHBA outperforms other algorithms on complex tasks. For example, when the number of cloudlets is 500, MHBA has a better value, i.e., 2.42, for the resource utilization. This is because MHBA outperforms PSO, CSO, and HBA by 16.52%, 7.02%, and 8.67%, respectively. For 1000 cloudlets, MHBA outperforms other algorithms, achieving a resource utilization of 2.15. This is because MHBA outperforms PSO, CSO, and HBA by 16.74%, 13.95%, and 12.09%, respectively.

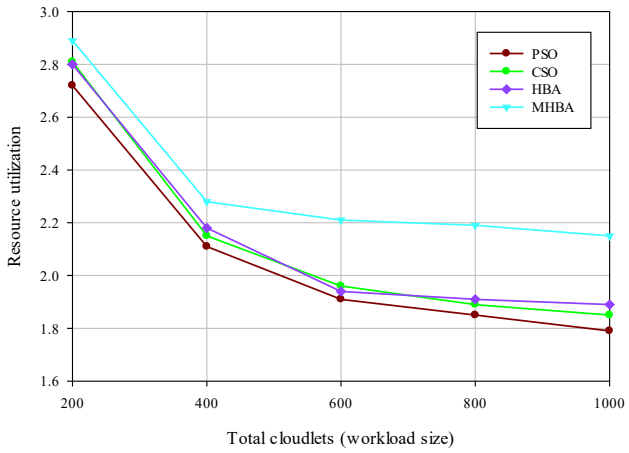

Fig. 6. Comparison of resource utilization for different scheduling algorithms under the HPC2N workload with varying numbers of cloud tasks.

TABLE IV. COMPARISON OF RESOURCE UTILIZATION ACROSS SCHEDULING ALGORITHMS USING THE HPC2N DATASET

Workload size (Cloudlets)	PSO	CSO	HBA	MHBA
100	2.94	3.03	2.97	3.15
500	2.02	2.25	2.21	2.42
1000	1.79	1.85	1.89	2.15

Fig. 7 and Table V show the migration time results. As the number of cloudlets increases (i.e., as system load increases), migration time increases for all algorithms. However, MHBA outperforms PSO, CSO, and HBA in terms of migration time. At 100 cloudlets, MHBA attains a migration time of 29.83, which is 28.76% lower than PSO, 38.08% lower than CSO, and 17.49% lower than HBA. At 500 cloudlets, MHBA attains 112.65, outperforming PSO and CSO by 11.2% and 20.6%, respectively. At 1000 cloudlets, MHBA again outperforms PSO, CSO, and HBA in terms of migration time, achieving 235.87, which is 15.16% lower than PSO, 27.89% lower than CSO, and 11.21% lower than HBA. This is because MHBA can identify

effective scheduling configurations early in the optimization process. Chaotic population initialization, dynamic search strategies, and strategy-based crossover in MHBA enable it to converge to effective task assignments early in the optimization process.

In addition to the HPC2N dataset, the proposed MHBA algorithm was further evaluated using the NASA workload traces. The performance results obtained using this dataset are shown in Fig. 8-10 and Table VI-VIII. Based on experimental analysis across various datasets, it is verified that the proposed MHBA algorithm achieves better scheduling efficiency across multiple performance metrics. In particular, the algorithm maintains a stable performance with heterogeneous tasks and varying resource requirements.

500	13.06	13.67	13.02	11.20
1000	19.37	21.25	19.35	16.11

VI. CONCLUSION

In this study, a novel algorithm, MHBA, was proposed for the multi-target task scheduling issue in a cloud computing context. Firstly, a chaotic Bernoulli initialization strategy was adopted to improve the diversity of the initial population and expand the search area. In this way, the algorithm's randomness is enhanced, and its convergence is improved. The second contribution of this study is the development of a piecewise optimum decreasing neighborhood model. In this way, the algorithm's search space is optimized, thereby improving its convergence to the solution. The efficiency of the MHBA algorithm has been validated using experimental results. It can be observed that, compared with the other baseline algorithms, MHBA outperforms them across various metrics at different workloads. The advantages of MHBA become more pronounced as the workload increases. MHBA is better suited to large-scale scheduling problems. In addition, the significance test results indicate that MHBA's advantages are statistically significant.

MHBA's better performance can be attributed to the synergy among its three enhancement strategies. The chaotic initialization mechanism enhances the algorithm's global search, the adaptive neighborhood strategy balances exploration and exploitation, and the horizontal crossover mechanism improves population diversity and information sharing. These mechanisms enable MHBA to have outstanding optimization ability. As for future research, several avenues are outlined. Firstly, it is possible to propose adaptive parameter control mechanisms that can improve the algorithm's robustness in dynamic environments. Secondly, it is possible to incorporate energy/cost constraints into the scheduling process, thereby improving the algorithm's applicability to green computing. Thirdly, it is possible to extend the MHBA framework to collaborative environments and real-time task scheduling, and to improve the algorithm's applicability to emerging/developing distributed computing environments, e.g., the Internet of Things and edge computing.

***Abstract*—To address the limitations of existing line art colorization methods in structural preservation, color mapping accuracy, and semantic consistency, this study proposes a structure-aware multi-instance constrained line art colorization method based on latent diffusion. Built upon the latent diffusion framework, the proposed method introduces a structure-aware constraint mechanism to enhance the preservation of line contours and edge details during generation. Meanwhile, instance-level semantic modeling and feature fusion strategies are incorporated to achieve coherent local color representation and optimize global semantic consistency. In addition, a unified optimization objective is constructed by jointly integrating structural constraints, color consistency constraints, and regularization terms, thereby improving the visual quality and naturalness of the generated results through collaborative multi-constraint learning. Experimental results on public datasets demonstrate that the proposed method outperforms comparative approaches in terms of FID, PSNR, SSIM, and LPIPS, producing high-quality colorization results with clear structures, natural colors, and strong semantic consistency, which verifies its effectiveness and superiority.**

***Keywords*—Line art colorization; latent diffusion; structure-aware modeling; instance-level semantic modeling; feature fusion; image generation**

I. Introduction

In modern electronic measurement and intelligent vision systems, high-precision image acquisition and processing play a crucial role in automated inspection, analysis, and visualization tasks [1], [2]. In applications such as electronic component detection, industrial visual monitoring, and intelligent measurement instruments, the accurate interpretation of image information directly affects the reliability and precision of measurement results [3], [4]. In recent years, with the widespread adoption of animation-style visual content and line art representations in education, electronic displays, digital media, and intelligent human–computer interaction systems, efficient automatic line art colorization has gradually emerged as an important research topic in image processing and electronic information systems [5], [6].

Traditional manual colorization methods are labor-intensive and time-consuming, and they often suffer from inconsistent color representation and structural ambiguity when handling multiple object instances [7], [8], [9]. These limitations can significantly degrade visualization quality and affect observation accuracy in practical applications [10]. With the rapid development of deep generative models, diffusion models have demonstrated remarkable performance in image synthesis and restoration tasks owing to their strong generative capability and latent-space representation learning ability [5], [11]. Nevertheless, existing diffusion-based line art colorization methods still face several challenges in multi-instance scenarios, including insufficient instance-level semantic understanding, inadequate exploitation of structural contour information, and excessive reliance on complex conditional guidance strategies in latent space [12], [13].

To address the above issues, this study proposes a structure-constrained multi-instance line art colorization framework based on latent diffusion, termed SC-MILC (*Structure-Constrained Multi-Instance Line Art Colorization*). Specifically, the proposed framework consists of three key components: a latent generative backbone (LGB), a structure-aware guidance module (SGM), and an instance semantic modeling and feature fusion module (ISMFF). The latent generative backbone performs efficient color generation in latent space, while the structure-aware guidance module enhances contour preservation and structural consistency by exploiting line art edge information. Furthermore, the instance semantic modeling and feature fusion module enables accurate semantic representation and adaptive feature interaction among multiple instances. On this basis, a unified optimization objective is constructed to jointly model diffusion reconstruction loss, structural consistency constraints, color consistency supervision, and instance fusion regularization, thereby achieving high-quality and controllable multi-instance line art colorization.

The main contributions of this work are summarized as follows:

- A latent diffusion-based generation framework for multi-instance line art colorization is proposed, which improves generation stability and computational efficiency.
- A structure-aware guidance module is introduced to enhance structural consistency and edge fidelity by effectively utilizing line art contour information.

II. Problem Definition

The objective of multi-instance line art colorization is to transform an input line art image into a high-quality color image while achieving accurate color control under multiple object instances. Let the input line art image be defined as:

$$S \in \mathbb{R}^{H \times W}, \tag{1}$$

where, H and W denote the height and width of the image, respectively. The reference instance set is represented as:

$$\mathcal{R} = \{I_i\}_{i=1}^{N}, \quad I_i \in \mathbb{R}^{H \times W \times 3}, \tag{2}$$

where, N denotes the number of object instances and each reference image I_i provides the target color information for the corresponding instance. The spatial mask set associated with the reference instances is defined as:

$$\mathcal{M} = \{M_i\}_{i=1}^{N}, \quad M_i \in \{0,1\}^{H \times W}, \tag{3}$$

where, M_i is a binary mask indicating the spatial region occupied by the i-th instance. The goal of the proposed framework is to learn a conditional mapping function:

$$\mathcal{F} : (S, \mathcal{R}, \mathcal{M}) \mapsto \hat{X}, \quad \hat{X} \in \mathbb{R}^{H \times W \times 3}, \tag{4}$$

such that the generated image $\hat{X}$ satisfies the following constraints.

A. Structural Consistency

The generated result should preserve the contour structures and geometric layout of the input line art image, which can be formulated as:

$$\mathcal{F}_{edge}(\hat{X}) \approx \mathcal{F}_{edge}(S), \tag{5}$$

where, $\mathcal{F}_{edge}(\cdot)$ denotes the edge extraction operator.

B. Instance-Level Color Consistency

For each instance region M_i, the generated colors should remain consistent with those of the corresponding reference instance I_i, which is expressed as:

$$\mathrm{Pool}_{M_i}(\hat{X}) \approx \mathrm{Pool}_{M_i}(I_i), \tag{6}$$

where, $\mathrm{Pool}_{M_i}(\cdot)$ represents the average pooling or feature extraction operation within the masked region M_i.

C. Multi-Instance Semantic Consistency

Under multi-instance conditions, the framework should maintain a balance between local instance-level representations and global semantic information, thereby ensuring natural color distributions and avoiding color conflicts among different instances.

Based on the above constraints, the entire task can be formulated as a conditional generation problem in latent space. Let the latent representation of the input line art image be:

$$z_0 = \mathcal{E}(S), \tag{7}$$

where, $\mathcal{E}(\cdot)$ denotes the encoder. The final generated image is obtained by:

$$\hat{X} = \mathcal{D}\left(\mathcal{F}_{diff}\left(z_0, \{f_i, M_i\}_{i=1}^{N}, F_{struct}\right)\right), \tag{8}$$

where, $\mathcal{D}(\cdot)$ denotes the decoder, $\mathcal{F}_{diff}$ represents the latent diffusion generation backbone, f_i denotes the semantic feature of the i-th instance, and F_{struct} represents the structure-aware feature representation.

Through the above formulation, the multi-instance line art colorization task can be uniformly modeled as an optimization problem under a latent conditional generation framework, jointly constrained by structural consistency, instance-level color supervision, and semantic coherence. This formulation provides a unified theoretical foundation for the subsequent network architecture and optimization strategy design.

III. Methodology

The overall architecture of the proposed SC-MILC framework is illustrated in Fig. 1. The framework consists of four major components: a latent-space generation backbone, a structure-aware guidance branch, an instance semantic modeling module, and a reference feature fusion module. The framework takes a line art image together with multiple reference instance images as conditional inputs and performs progressive denoising generation in latent space, thereby achieving automatic multi-instance colorization and consistent color control.

Specifically, a pre-trained variational autoencoder (VAE) is first employed to project the target image into a low-dimensional latent space, where the diffusion process is conducted to reduce computational complexity and memory consumption. Subsequently, the input line art image is fed into the structure-aware guidance branch to extract contour and edge representations. These structural features are further utilized to construct structure-aware constraints, which enhance spatial consistency during the generation process.

Meanwhile, multiple reference instance images are processed by the semantic encoding module to extract high-level semantic representations. Combined with the corresponding instance region masks, the extracted features form region-aware reference representations with instance-level perception capability. Based on these representations, the reference feature fusion module adaptively integrates global semantic information and local instance features to generate unified conditional control signals.

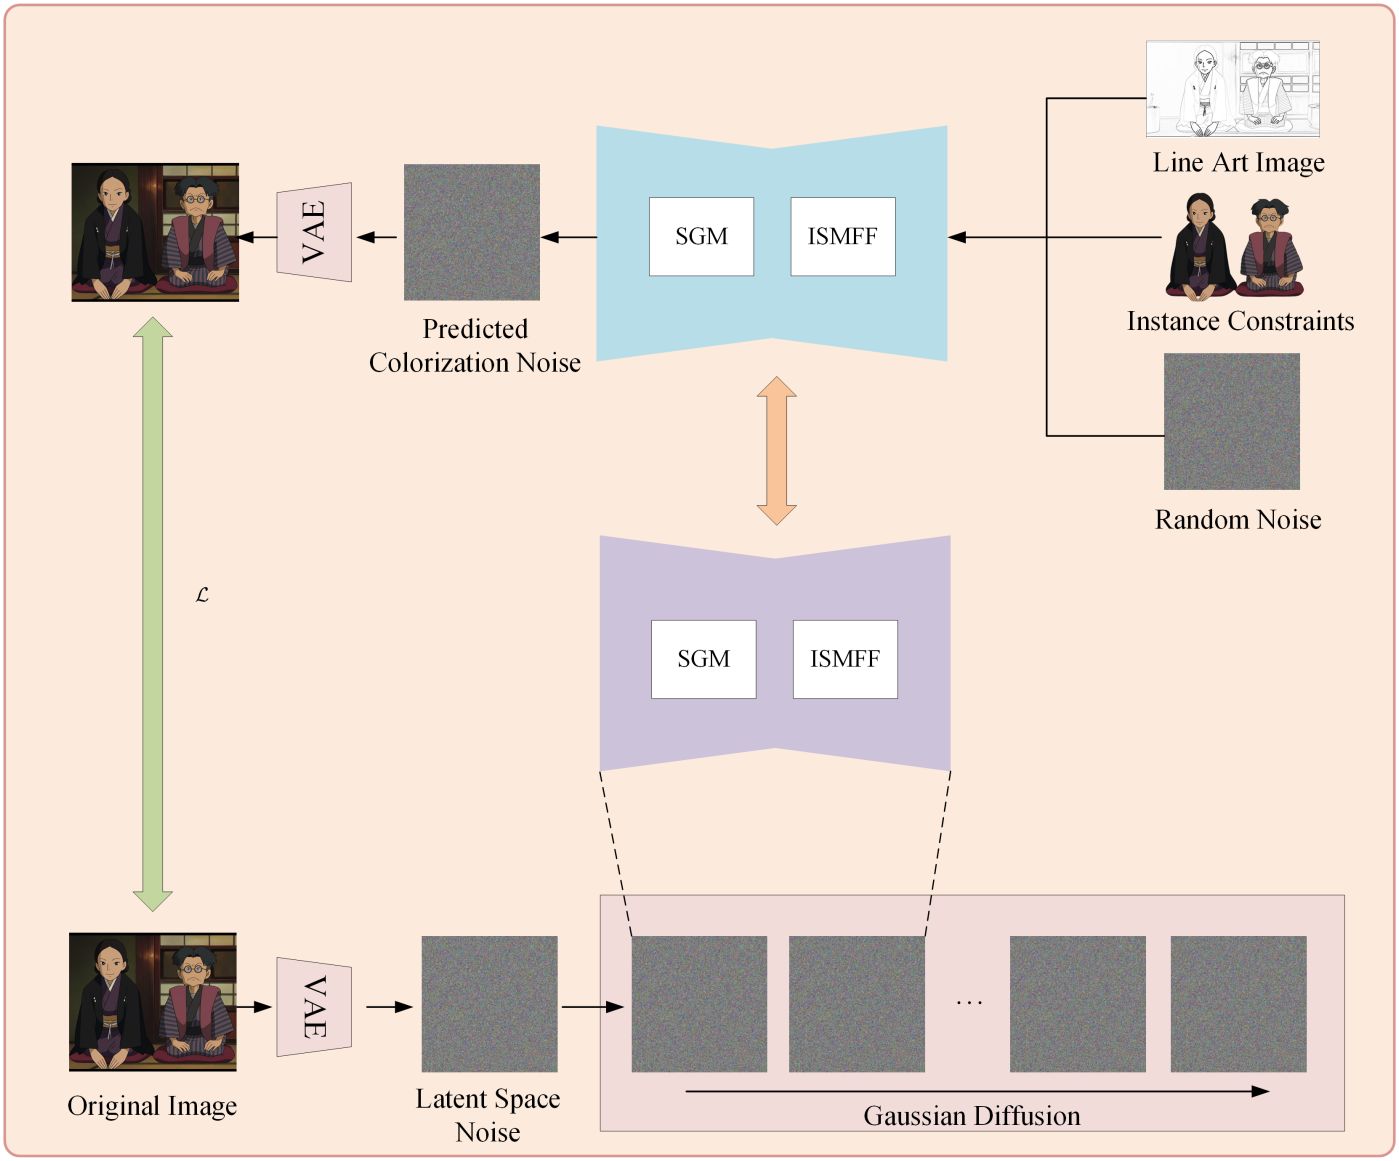

Fig. 1. Overall architecture of the proposed SC-MILC framework. The framework consists of a latent-space diffusion generation backbone, a structure-aware guidance branch, an instance semantic modeling module, and a reference feature fusion module for multi-instance line art colorization.

During the diffusion denoising process, latent features are progressively restored into clear representations under the joint constraints of multiple conditional signals. Among them, structural information constrains the spatial layout and contour consistency of the generated results, while reference semantic information guides color distributions and texture details. Finally, the generated latent representations are decoded into color images through the decoder, producing high-quality multi-instance line art colorization results.

A. Latent Generative Backbone (LGB)

To achieve efficient image generation modeling, a latent-space diffusion generation backbone is constructed in the proposed framework. Let the input image be denoted as $x \in \mathbb{R}^{H\times W\times 3}$. A pre-trained variational autoencoder (VAE) encoder $\mathcal{E}(\cdot)$ is first employed to project the image into a compact latent representation:

$$z_0 = \mathcal{E}(x), \quad z_0 \in \mathbb{R}^{C\times H'\times W'}, \tag{9}$$

where, $H' = \frac{H}{s}$ and $W' = \frac{W}{s}$ denote the latent spatial resolution, and s represents the spatial downsampling factor.

In the latent space, a forward diffusion process is defined by progressively injecting Gaussian noise into z_0 to construct a sequence of latent variables $\{z_t\}_{t=1}^{T}$,

$$q(z_t|z_0) = \mathcal{N}\left(z_t; \sqrt{\bar{\alpha}_t}z_0, (1-\bar{\alpha}_t)\mathbf{I}\right), \tag{10}$$

where, $\alpha_t = 1-\beta_t$, $\beta_t \in (0,1)$ denotes the predefined noise scheduling parameter, and $\bar{\alpha}_t = \prod_{i=1}^{t}\alpha_i$. The above process can be equivalently reformulated as:

$$z_t = \sqrt{\bar{\alpha}_t}z_0 + \sqrt{1-\bar{\alpha}_t}\epsilon, \quad \epsilon \sim \mathcal{N}(0,\mathbf{I}), \tag{11}$$

which enables direct sampling of noisy latent representations at arbitrary diffusion steps.

Based on the above formulation, a parameterized noise prediction model ϵ_θ is introduced to estimate the injected noise and progressively recover the latent distribution through the reverse diffusion process. The conditional reverse transition probability is defined as:

$$p_\theta(z_{t-1}|z_t, c) = \mathcal{N}\left(z_{t-1}; \mu_\theta(z_t, t, c), \sigma_t^2 \mathbf{I}\right), \tag{12}$$

where, c denotes external conditional information, and the mean parameter μ_θ is estimated by the noise prediction network:

$$\mu_\theta(z_t, t, c) = \frac{1}{\sqrt{\alpha_t}}\left(z_t - \frac{1-\alpha_t}{\sqrt{1-\bar{\alpha}_t}}\epsilon_\theta(z_t, t, c)\right). \tag{13}$$

Consequently, the latent-space generation process can be uniformly formulated as a learning problem for the noise prediction function $\epsilon_\theta(z_t, t, c)$. The optimization objective is constructed by minimizing the mean squared error between the predicted noise and the ground-truth Gaussian noise:

$$\mathcal{L}_{diff} = \mathbb{E}_{z_0,\epsilon,t}\left[\|\epsilon - \epsilon_\theta(z_t, t, c)\|_2^2\right]. \tag{14}$$

Under the above modeling framework, the latent variables progressively converge from the noise distribution toward the latent representation corresponding to the real data distribution under the guidance of conditional information c. Finally, the generated latent representation is mapped back to the image space through the decoder $\mathcal{D}(\cdot)$:

$$\hat{x} = \mathcal{D}(z_0). \tag{15}$$

The proposed latent generative backbone provides a compact and unified formulation for modeling the transformation from the data distribution to the noise distribution and subsequently to the generated distribution. This formulation further establishes a unified conditional generation foundation for integrating structural guidance and instance-level semantic information in the subsequent modules.

B. Structure-Aware Guidance Module (SGM)

To enhance the structural consistency of the generated results, a structure-aware guidance mechanism is introduced to explicitly incorporate geometric contour information from line art images into the diffusion modeling process. Let the input line art image be denoted as $S \in \mathbb{R}^{H\times W}$. Its structural response is first extracted using an edge operator:

$$E = \mathcal{F}_{edge}(S), \tag{16}$$

where, $\mathcal{F}_{edge}(\cdot)$ denotes the structure extraction operator, and $E \in \mathbb{R}^{H\times W}$ represents the normalized edge intensity map.

To align the structural representation with latent-space features, the extracted edge map is further projected to the latent spatial resolution:

$$E' = \mathcal{R}(E), \quad E' \in \mathbb{R}^{H'\times W'}, \tag{17}$$

where, $\mathcal{R}(\cdot)$ denotes the spatial rescaling operation.

During the diffusion denoising process, let the intermediate latent feature representation be denoted as $F_t \in \mathbb{R}^{C\times H'\times W'}$. The conventional attention operation is formulated as:

$$\mathrm{Attn}(Q, K, V) = \mathrm{Softmax}\left(\frac{QK^\top}{\sqrt{d}}\right)V, \tag{18}$$

where, Q, K, and V denote the query, key, and value feature mappings, respectively, and d represents the feature dimension.

To introduce structural constraints into the attention mechanism, a structure-aware modulation term A_s is constructed as:

$$A_s = \gamma \cdot \mathrm{Norm}(E'), \tag{19}$$

where, $\mathrm{Norm}(\cdot)$ denotes the normalization operation and γ is a learnable modulation parameter.

The structure-aware attention operation is then formulated as:

$$\mathrm{Attn}_s(Q, K, V) = \mathrm{Softmax}\left(\frac{QK^\top}{\sqrt{d}} + A_s\right)V, \tag{20}$$

which enables the attention distribution to adaptively focus on structurally important regions.

Furthermore, to strengthen feature representation in edge regions, an element-wise modulation strategy is introduced for intermediate latent features:

$$\tilde{F}_t = F_t \odot (1 + \alpha E'), \tag{21}$$

where, $\odot$ denotes element-wise multiplication and α represents the modulation coefficient. This operation assigns higher response weights to structural edge regions, thereby suppressing color overflow and structural ambiguity during generation.

Through the above mechanisms, structural information is jointly incorporated into the diffusion process via attention bias modulation and feature-level enhancement. Consequently, the proposed structure-aware guidance module enables the diffusion model to preserve clear structural boundaries and stable spatial layouts during latent-space denoising, thereby improving the structural consistency between the input line art image and the generated colorized result.

C. Instance Semantic Modeling and Feature Fusion Module (ISMFF)

To achieve accurate color control under multi-instance conditions, a unified instance semantic modeling and feature fusion mechanism is constructed in the proposed framework. Let the reference image set be denoted as $\mathcal{R} = \{I_i\}_{i=1}^{N}$, and the corresponding instance mask set be represented as $\mathcal{M} = \{M_i\}_{i=1}^{N}$, where $I_i \in \mathbb{R}^{H\times W\times 3}$ and $M_i \in \{0,1\}^{H\times W}$.

First, each reference instance image is processed by a semantic encoder $\mathcal{F}_{enc}(\cdot)$ to extract high-level semantic representations:

$$f_i = \mathcal{F}_{enc}(I_i), \quad f_i \in \mathbb{R}^{C\times H'\times W'}, \tag{22}$$

where, f_i denotes the semantic feature representation of the i-th reference instance.

To establish spatial correspondence between semantic features and instance regions, the instance masks are projected to the latent-space resolution:

$$M_i' = \mathcal{R}(M_i), \quad M_i' \in \mathbb{R}^{H'\times W'}, \tag{23}$$

where, $\mathcal{R}(\cdot)$ denotes the spatial rescaling operation.

Based on the projected masks, instance-aware semantic features are defined as:

$$\hat{f}_i = f_i \odot M_i', \tag{24}$$

where, $\odot$ denotes element-wise multiplication. This operation explicitly constrains semantic features within the corresponding instance regions.

To further enhance global semantic perception, a global semantic representation is introduced as:

$$f_g = \frac{1}{N}\sum_{i=1}^{N} \mathrm{Pool}(f_i), \tag{25}$$

where, $\mathrm{Pool}(\cdot)$ denotes the global pooling operation.

Furthermore, an adaptive feature fusion mechanism is designed to integrate local instance features with global semantic information. The gating function is formulated as:

$$g_i = \sigma\left(W_1 f_g + W_2 \mathrm{Pool}(\hat{f}_i)\right), \tag{26}$$

where, $\sigma(\cdot)$ denotes the Sigmoid activation function, and W_1 and W_2 represent learnable parameters.

Based on the obtained gating weights, the fused instance feature representation is defined as:

$$\tilde{f}_i = g_i \cdot \hat{f}_i + (1 - g_i)\cdot f_g, \tag{27}$$

which enables adaptive balancing between local instance-specific information and global semantic consistency.

Finally, all fused instance features are aggregated to construct a unified instance-aware conditional representation:

$$F_{inst} = \sum_{i=1}^{N} \tilde{f}_i, \tag{28}$$

which is incorporated into the diffusion generation framework as part of the conditional guidance signal:

$$c = \{F_{inst}, F_{struct}\}, \tag{29}$$

where, F_{struct} denotes the structure-aware feature representation generated by the structure-aware guidance module.

Through the above formulation, instance-level semantic alignment is explicitly achieved by introducing mask-based spatial constraints, while the proposed gating mechanism adaptively balances local instance features and global semantic information. Consequently, the proposed ISMFF module enables stable and semantically consistent color mapping in multi-instance scenarios. Compared with conventional methods relying on strict spatial feature alignment, the proposed strategy effectively reduces feature alignment complexity while improving semantic representation capability and model generalization performance.

D. Optimization Objective and Constraint Functions

Under the unified framework of the latent generative backbone, the structure-aware guidance module, and the instance semantic fusion module, an overall optimization objective is constructed to ensure structural consistency and color fidelity in the generated images.

Let $\epsilon_\theta(z_t, t, c)$ denote the predicted noise in latent space and ϵ represent the ground-truth Gaussian noise. The basic diffusion optimization objective is defined as:

$$\mathcal{L}_{diff} = \mathbb{E}_{z_0,\epsilon,t}\left[\|\epsilon - \epsilon_\theta(z_t, t, c)\|_2^2\right]. \tag{30}$$

To enhance structural fidelity, a structure-aware loss based on edge consistency is introduced:

$$\mathcal{L}_{struct} = \mathbb{E}_{z_0}\left[\|\mathcal{F}_{edge}(\mathcal{D}(z_0)) - E\|_2^2\right], \tag{31}$$

where, $\mathcal{D}(\cdot)$ denotes the latent-space decoder, E represents the edge map extracted from the input line art image, and $\mathcal{F}_{edge}(\cdot)$ denotes the edge extraction operator.

To achieve instance-level color consistency, an instance-aware color matching loss is further defined as:

$$\mathcal{L}_{color} = \frac{1}{N}\sum_{i=1}^{N} \|\mathrm{Pool}_{M_i}(\mathcal{D}(z_0)) - \mathrm{Pool}_{M_i}(I_i)\|_2^2, \tag{32}$$

where, $\mathrm{Pool}_{M_i}(\cdot)$ denotes masked average feature extraction within the instance region specified by M_i, and I_i denotes the corresponding reference instance image.

To prevent the gating mechanism from collapsing toward either the local instance branch or the global semantic branch, a gated regularization term is introduced:

$$\mathcal{L}_{gate} = \frac{1}{N}\sum_{i=1}^{N} \|g_i - 0.5\|_2^2, \tag{33}$$

which encourages the gating coefficients to maintain a balanced contribution from both local instance features and global semantic representations during feature fusion. By avoiding extreme gate values, the proposed regularization improves the stability of feature integration and facilitates more effective exploitation of complementary information across different semantic levels.

By combining the above objectives, the final overall optimization function is formulated as:

$$\mathcal{L} = \mathcal{L}_{diff} + \lambda_s \mathcal{L}_{struct} + \lambda_c \mathcal{L}_{color} + \lambda_g \mathcal{L}_{gate}, \tag{34}$$

where, λ_s, λ_c, and λ_g denote balancing hyperparameters used to control the contributions of structural consistency, color supervision, and feature fusion regularization, respectively.

Through the above optimization strategy, the proposed framework enables the diffusion model to simultaneously satisfy the following objectives during latent-space denoising: preserving clear structural contours and spatial layouts from the input line art image, maintaining color consistency between generated instances and reference images, and balancing local instance semantics with global contextual representations to produce visually natural and semantically coherent colorization results.

IV. Dataset and Preprocessing

In this study, two publicly available anime line art datasets, *Sakuga* [14] and *ATD-12K* [15], are adopted to evaluate the performance of the proposed framework on multi-instance line art colorization tasks.

The Sakuga dataset contains high-quality animation frame sequences with rich motion variations and diverse character poses, making it suitable for training and evaluating multi-instance colorization models. In contrast, the ATD-12K dataset provides well-annotated line art and color image pairs covering various character categories and artistic styles, thereby offering reliable references for instance-level color learning.

As illustrated in Fig. 2, both datasets are uniformly processed to construct the final training and testing sets. During preprocessing, samples with excessively low resolution or incomplete line art structures are removed to ensure data quality. For each image pair, the line art image S and the corresponding color reference image I are jointly utilized to establish the conditional colorization relationship. Furthermore, instance masks are extracted as auxiliary conditional inputs for multi-instance semantic modeling.

Specifically, an open-source segmentation tool is first employed to segment characters and key objects in the reference images, thereby generating binary instance masks to support instance-level semantic modeling. Subsequently, both the line art images and the color reference images are uniformly resized to a fixed spatial resolution while preserving the original aspect ratio to maintain latent-space feature alignment.

Fig. 2. Dataset preprocessing and instance mask construction pipeline. The line art images, reference color images, and corresponding instance masks are jointly utilized for multi-instance conditional colorization training.

To improve the generalization capability of the model under varying viewpoints and illumination conditions, data augmentation strategies including random horizontal flipping and brightness perturbation are further applied to the reference images. These augmentation operations effectively enhance the robustness of the proposed framework in modeling instance-level color distributions and structural representations.

The above dataset partitioning and preprocessing strategies ensure the reproducibility of the experiments and provide sufficient multi-instance conditional information for validating the effectiveness of the latent generative backbone, the structure-aware guidance module, and the instance semantic fusion mechanism.

A. Experimental Environment and Parameter Settings

All experiments were implemented using the PyTorch deep learning framework. The detailed experimental environment configuration is summarized in Table I.

TABLE I. Experimental Environment Settings

Environment	Configuration
CPU	Xeon(R) Gold 6348
GPU	NVIDIA A800 80GB
Memory	120 GB
Programming Language	Python 3.9
Deep Learning Framework	PyTorch 2.6.0 + cu118

During the training stage, in order to ensure the stability and convergence of the latent generative backbone and the instance semantic fusion module, the proposed framework was trained for a total of 100,000 optimization iterations. A batch size of 1 was adopted for single-sample training to fully preserve instance-level conditional information during the diffusion learning process.

The initial learning rate was set to 1×10^{-4} and remained fixed throughout the training process to maintain stable latent-space noise prediction and conditional feature optimization. The AdamW optimizer was employed for parameter optimization with momentum coefficients $\beta_1 = 0.9$ and $\beta_2 = 0.999$.

In the diffusion process, the total number of diffusion steps was set to $T = 1000$, and a linear noise scheduling strategy was adopted for Gaussian noise injection. The latent-space downsampling factor was set to $s = 8$, which effectively reduced computational complexity while preserving essential semantic and structural information.

For all experiments, the model parameters were initialized using pre-trained latent diffusion weights, and mixed-precision training was adopted to further improve training efficiency and GPU memory utilization.

B. Evaluation Metrics

To comprehensively evaluate the performance of the proposed multi-instance line art colorization framework, four widely used image quality assessment metrics are adopted, including Fréchet Inception Distance (FID), Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index Measure (SSIM), and Learned Perceptual Image Patch Similarity (LPIPS).

FID is employed to measure the distribution discrepancy between generated images and real images in a high-dimensional feature space. A lower FID value indicates that the generated image distribution is closer to the real image distribution, implying higher generation quality and better visual realism.

PSNR is utilized to evaluate the pixel-level similarity between the generated image and the reference image, which is defined as:

$$\mathrm{PSNR} = 10 \cdot \log_{10} \frac{L^2}{\mathrm{MSE}}, \tag{35}$$

where, L denotes the maximum possible pixel intensity value and MSE represents the mean squared error between the generated image and the reference image. Higher PSNR values indicate better reconstruction fidelity and lower pixel-level distortion.

SSIM is adopted to measure structural consistency between generated images and reference images in terms of luminance, contrast, and structural information. It is formulated as:

$$\mathrm{SSIM} = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)}, \tag{36}$$

where, μ_x and μ_y denote the mean intensities of two images, σ_x^2 and σ_y^2 represent the variances, σ_{xy} denotes the covariance, and C_1 and C_2 are stability constants. An SSIM value closer to 1 indicates better structural preservation and visual consistency.

LPIPS is introduced to evaluate perceptual similarity between generated images and reference images based on deep feature representations extracted from neural networks. It is defined as:

$$\mathrm{LPIPS} = \sum_l \frac{1}{H_l W_l} \sum_{h,w} \left\| w_l \odot (\hat{y}^l_{hw} - \hat{x}^l_{hw}) \right\|_2^2, \tag{37}$$

where, l denotes different network layers, $\hat{x}^l$ and $\hat{y}^l$ represent normalized feature maps, w_l denotes the learned layer weight, and H_l and W_l correspond to the spatial dimensions of the feature maps. Lower LPIPS values indicate higher perceptual similarity and better visual quality.

In summary, lower FID and LPIPS values together with higher PSNR and SSIM values indicate that the generated images are closer to the reference images in terms of distribution consistency, pixel-level reconstruction accuracy, structural preservation, and perceptual quality. These metrics collectively provide a comprehensive evaluation of the proposed method for multi-instance line art colorization tasks.

C. Comparative Experimental Results

To validate the effectiveness of the proposed framework, extensive comparisons were conducted against several representative line art colorization methods. In all comparison methods, the complete reference image was directly used as the conditional input, whereas the proposed framework utilized instance-level information extracted from the same reference image for multi-instance conditional guidance.

For GAN-based approaches, RSIC [16] and SGA [17] were selected as representative comparison methods. Both approaches employ generative adversarial networks for line art colorization, while adopting different network architectures and training strategies. In addition, for diffusion-based methods, AnimeDiffusion [18], ColorizeDiffusion [19], and MangaNinja [20] were adopted for comparison. These methods represent recent advances in diffusion-based line art colorization and provide strong baselines for evaluating color consistency, structural fidelity, and detail restoration under multi-instance conditions.

The quantitative comparison results on the Sakuga and ATD-12K datasets are summarized in Table II.

As shown in Table II, the proposed structure-aware multi-instance line art colorization framework achieves significant performance improvements on both the Sakuga and ATD-12K datasets.

Among the GAN-based approaches, RSIC and SGA obtain relatively high FID values and moderate PSNR and SSIM scores, while their LPIPS values remain comparatively large. These results indicate that GAN-based methods still suffer from color inconsistency and structural distortion, especially in multi-instance scenes or regions containing complex color distributions. In many cases, color overflow occurs around instance boundaries, leading to loss of structural details and degraded visual coherence.

Compared with GAN-based methods, diffusion-based approaches demonstrate clear improvements in image quality and structural preservation. AnimeDiffusion, ColorizeDiffusion, and MangaNinja achieve lower FID values ranging from 25.7 to 22.8 on the Sakuga dataset and from 28.5 to 25.3 on the ATD-12K dataset. Meanwhile, PSNR and SSIM values are improved to the ranges of 24.8–25.4 and 0.801–0.817, respectively, while LPIPS values decrease to 0.165–0.176. These results demonstrate the superiority of diffusion models in maintaining global color consistency and structural fidelity. However, existing diffusion-based methods still exhibit

TABLE II. COMPARATIVE EXPERIMENTAL RESULTS ON THE SAKUGA AND ATD-12K DATASETS. THE BEST RESULTS ARE HIGHLIGHTED IN BOLD.

Methods	Sakuga				ATD-12K			
	FID ↓	PSNR ↑	SSIM ↑	LPIPS ↓	FID ↓	PSNR ↑	SSIM ↑	LPIPS ↓
RSIC	42.5	21.3	0.732	0.241	48.7	20.9	0.715	0.257
SGA	38.9	22.1	0.749	0.227	44.3	21.7	0.731	0.243
AnimeDiffusion	25.7	24.8	0.801	0.176	28.5	24.1	0.788	0.189
ColorizeDiffusion	23.4	25.2	0.813	0.169	26.1	24.6	0.798	0.181
MangaNinja	22.8	25.4	0.817	0.165	25.3	24.8	0.802	0.178
Proposed Method	**15.2**	**27.1**	**0.856**	**0.121**	**17.4**	**26.3**	**0.841**	**0.135**

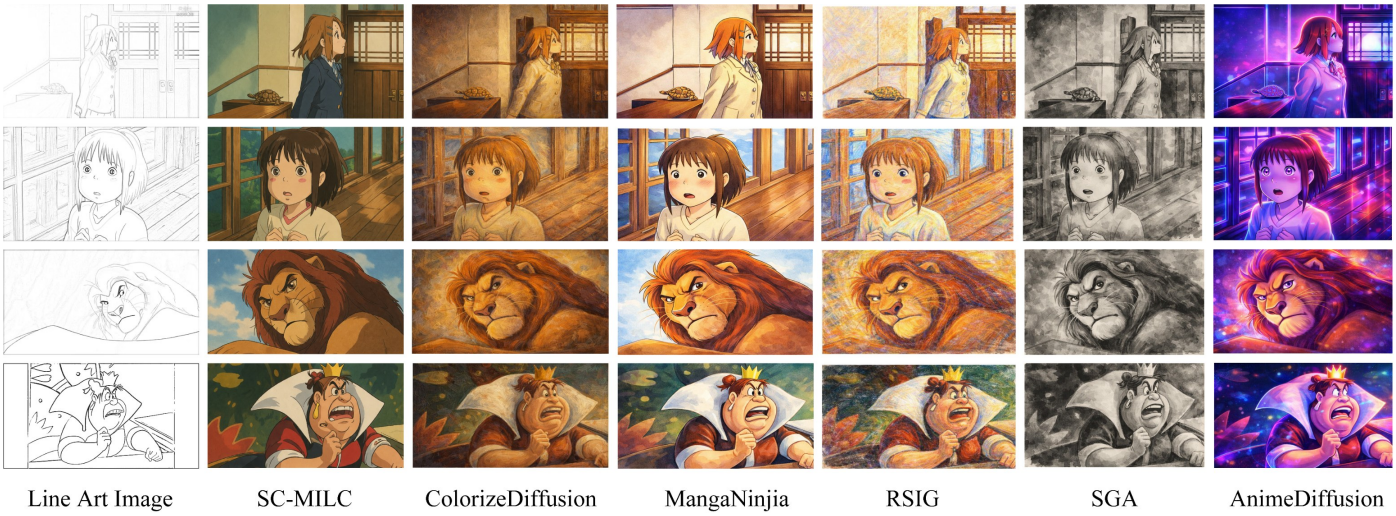

Fig. 3. Qualitative comparison results of different line art colorization methods. The proposed method achieves superior structural consistency, color fidelity, and instance-level detail restoration compared with existing GAN-based and diffusion-based approaches.

limitations in instance-level color mapping, particularly for small-scale details and complex multi-instance scenarios.

In contrast, the proposed method achieves the best performance across all evaluation metrics on both datasets. On the Sakuga dataset, the proposed framework reduces the FID score to 15.2, while improving PSNR and SSIM to 27.1 and 0.856, respectively, with LPIPS further reduced to 0.121. Similarly, on the ATD-12K dataset, the proposed framework achieves FID, PSNR, SSIM, and LPIPS values of 17.4, 26.3, 0.841, and 0.135, respectively. These results indicate that the proposed framework effectively preserves structural details while achieving more accurate instance-level color mapping.

In particular, the collaborative interaction between the latent generative backbone and the instance semantic fusion module enables the generated images to maintain high perceptual similarity to the reference images, especially in regions containing small-scale instances or complex color distributions. The proposed structure-aware guidance mechanism further improves edge sharpness and spatial consistency during the diffusion denoising process.

Furthermore, the qualitative comparison results shown in Fig. 3 provide intuitive visual evidence of the performance differences among various methods.

GAN-based methods can generate basic color regions; however, they often exhibit noticeable color overflow and inconsistent color distributions around instance boundaries and small-scale regions. For example, colors from clothing or accessories frequently bleed into adjacent regions, resulting in poor global visual consistency and insufficient detail restoration.

Diffusion-based methods achieve more natural global color distributions and better structural preservation compared with GAN-based methods. Nevertheless, they still encounter difficulties in accurately restoring local color details in complex multi-instance scenarios, and color inconsistencies among different instances remain observable in some cases.

By contrast, the proposed framework demonstrates clear visual advantages. Through the integration of the latent generative backbone, structure-aware guidance, and instance semantic fusion mechanisms, the generated images preserve fine line structures while achieving accurate instance-level color mapping. Particularly in multi-instance scenes containing complex color regions and small objects, the proposed method produces natural color distributions, sharp structural boundaries, and highly consistent color representations across instances.

Moreover, the proposed framework effectively suppresses color bleeding and feature interference among neighboring instances, thereby exhibiting stronger controllability and superior detail restoration capability in multi-instance line art colorization tasks.

Overall, both quantitative and qualitative results demonstrate that the proposed framework significantly improves instance-level controllability, structural fidelity, and overall color consistency, highlighting its effectiveness and practical

value for multi-instance line art colorization applications.

D. Ablation Experiments

To verify the effectiveness of each core component and the unified optimization objective in the proposed framework, a series of ablation experiments were conducted on the Sakuga and ATD-12K datasets. The experiments were designed as follows:

- Experiment A: The structure-aware guidance module (SGM) was removed while retaining the latent generative backbone (LGB) and the instance semantic modeling and feature fusion module (ISMFF). This experiment evaluates the contribution of structural guidance to contour preservation and edge fidelity.
- Experiment B: The ISMFF module was removed while retaining the LGB and SGM modules. In this setting, only global reference information was utilized without instance-level semantic modeling and feature fusion. This experiment evaluates the effectiveness of instance-level semantic guidance for precise multi-instance color control.
- Experiment C: The LGB module was removed while retaining SGM and ISMFF. In this case, latent-space diffusion generation was not employed, and the framework directly performed color mapping based on structural and semantic guidance. This experiment evaluates the importance of latent-space generation for overall image quality and generation stability.
- Experiment D: The complete framework was adopted, including LGB, SGM, ISMFF, and the unified optimization objective. This configuration was used to evaluate the collaborative effectiveness of all proposed modules.

As shown in Table III and Table IV, each module contributes significantly to the overall performance of the proposed framework.

On the Sakuga dataset, Experiment A removes the SGM module while retaining LGB and ISMFF. Without structural guidance, the generated images exhibit blurred edge structures and insufficient contour consistency, resulting in an FID score of 28.5, a PSNR of 24.3, an SSIM of 0.790, and an LPIPS value of 0.182. These results demonstrate that structural information plays an important role in preserving edge sharpness and structural fidelity.

Experiment B removes the ISMFF module while retaining LGB and SGM. Although the overall colorization results remain visually reasonable, obvious color deviations appear in multi-instance regions. The obtained FID, PSNR, and SSIM values indicate that instance-level semantic modeling is crucial for precise multi-instance color control and semantic consistency.

Experiment C removes the latent generative backbone and only retains SGM and ISMFF. In this setting, the overall generation capability deteriorates significantly, with the FID score increasing to 36.8 and LPIPS increasing to 0.215, while PSNR and SSIM decrease substantially. These results demonstrate that the latent diffusion generation backbone provides the fundamental generation capability and stability for the proposed framework.

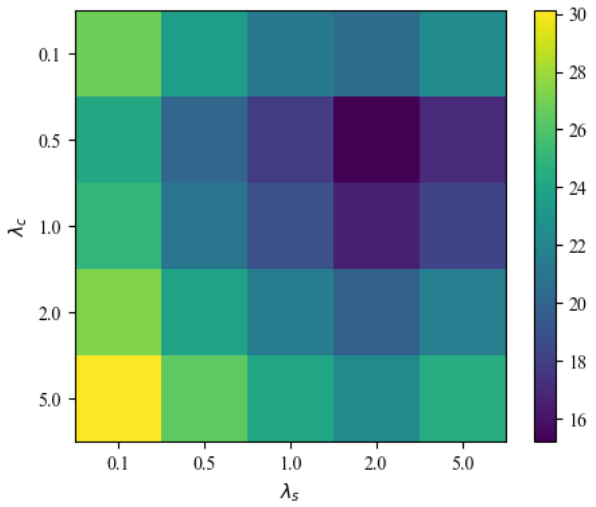

Fig. 4. FID heatmap under different λ_s and λ_c with a fixed λ_g.

Experiment D adopts the complete framework and achieves the best performance across all evaluation metrics. The generated images exhibit clear structural boundaries, accurate color mapping, and high visual consistency, demonstrating the effectiveness of the collaborative interaction among all proposed modules.

Similar trends can also be observed on the ATD-12K dataset. Removing SGM in Experiment A leads to weaker structural preservation and degraded edge quality. Removing ISMFF in Experiment B results in noticeable color inconsistencies among different instances. Meanwhile, removing LGB in Experiment C causes the most severe performance degradation in overall image quality and generation stability. By contrast, the complete framework in Experiment D achieves the best quantitative performance, further validating the effectiveness of the proposed module collaboration strategy.

Overall, the ablation experiments demonstrate that the LGB module provides stable latent-space generation capability and robust color representation, the SGM module enhances structural consistency and edge fidelity, and the ISMFF module enables accurate multi-instance semantic alignment and color control. Moreover, the unified optimization objective further improves high-frequency detail restoration and overall visual quality. These results comprehensively verify the necessity and effectiveness of each proposed component for high-quality and controllable multi-instance line art colorization.

E. Parameter Sensitivity Analysis

To further analyze the coupling relationship among different constraint terms in the proposed optimization objective, a two-dimensional grid search was conducted for λ_s and λ_c while fixing λ_g. The corresponding FID heatmap is illustrated in Fig. 4.

It can be observed that the model performance exhibits a distinct asymmetric distribution in the parameter space, and

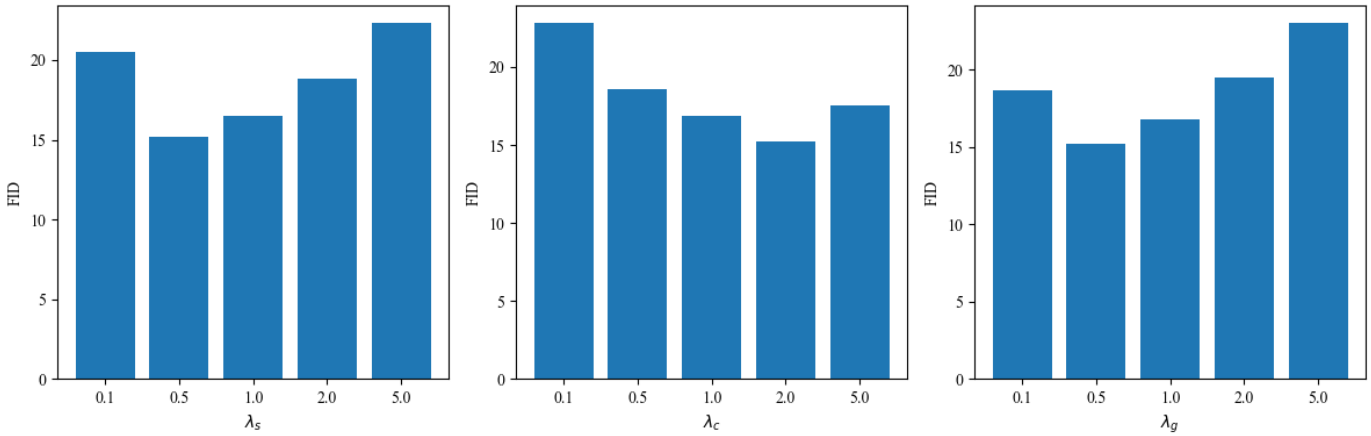

Fig. 5. Results of the univariate sensitivity analysis for different constraint weights.

the optimal performance is achieved around specific non-uniform parameter combinations rather than simple equal-weight settings. This phenomenon indicates that different constraint terms contribute unequally during the optimization process.

Specifically, moderately increasing λ_c helps improve color consistency, enabling the generated images to better match the reference instances. In contrast, λ_s should be controlled within a relatively small range to avoid excessive structural constraints that may suppress detail flexibility. When λ_s becomes overly large, the model excessively emphasizes sketch structures and weakens color representation capability. Conversely, excessively large λ_c values tend to produce overly concentrated color distributions, thereby reducing visual naturalness.

These results demonstrate that a significant trade-off exists between structural preservation and color consistency. Meanwhile, the instance fusion regularization term λ_g achieves the best performance within a moderate range, effectively balancing local instance features and global semantic representations. Overall, the three constraint terms do not contribute equally but instead cooperate through non-uniform weighting strategies, thereby validating the necessity and rationality of the proposed unified optimization objective.

To further investigate the influence of each constraint weight individually, univariate sensitivity experiments were conducted for λ_s, λ_c, and λ_g, while fixing the remaining parameters to their optimal settings. The experimental results are shown in Fig. 5.

It can be observed that all three parameters exhibit a similar trend in which the performance first improves and then deteriorates as the parameter value increases. However, the optimal ranges differ significantly among the three parameters.

The optimal value of λ_s is relatively small, indicating that moderate structural constraints are beneficial for preserving edge clarity, whereas excessive structural guidance suppresses fine-detail generation. In contrast, the optimal value of λ_c is comparatively larger, demonstrating that color consistency plays a more important role in multi-instance line art colorization tasks. Meanwhile, λ_g achieves the best performance within a moderate range. Excessively large fusion regularization tends to over-smooth semantic features and weakens local detail representation.

These results further confirm that different constraint terms play distinct roles during optimization. Therefore, the three constraints should be collaboratively adjusted through non-uniform weighting in order to achieve an effective balance

among structural fidelity, color consistency, and semantic fusion capability.

V. Conclusion and Future Work

This study proposes a structure-aware line art colorization framework based on latent diffusion to address the challenges of insufficient structural preservation, inaccurate color mapping, and semantic inconsistency in line art colorization tasks. The proposed framework introduces a structure-aware constraint mechanism to enhance contour fidelity and spatial consistency during the diffusion generation process. Meanwhile, an instance semantic modeling and feature fusion strategy is designed to improve local color consistency and instance-level controllability. Furthermore, a unified optimization objective is constructed to collaboratively optimize structural constraints, color consistency, and semantic fusion regularization within a unified latent-space generation framework.

Experimental results on publicly available datasets demonstrate that the proposed method achieves superior performance compared with existing approaches in terms of FID, PSNR, SSIM, and LPIPS metrics. The generated colorization results exhibit clearer structural details, more natural color distributions, and stronger semantic consistency. In particular, the proposed framework effectively improves color controllability and detail restoration capability in complex multi-instance scenarios.

Overall, the proposed framework provides an effective solution for high-quality and controllable line art colorization, and offers a feasible technical reference for related image generation tasks and electronic measurement vision applications.

In future work, the proposed framework can be further extended in several directions. First, introducing temporal consistency modeling may improve color stability in animation sequence generation tasks. Second, incorporating multimodal conditional guidance, such as text descriptions or style priors, could further enhance controllability and diversity in color generation. In addition, lightweight diffusion architectures and efficient inference strategies may be explored to improve computational efficiency and facilitate practical deployment in real-time intelligent visual systems.

***Abstract*—Speech Emotion Recognition (SER) in low-resource languages deals with the scarcity of labeled corpora and the instability of learned representations when transferred across diverse recording conditions and speaker demographics. This study introduces Conditional Tri-Factor Low-Rank Adaptation (C-TRILORA), a multi-task architecture that jointly performs automatic speech recognition (ASR) and SER on Kazakh speech while generalizing reliably across corpora. The proposed model extends a pre-trained Whisper encoder–decoder backbone through three primary innovations: a Tri-LoRA routing module that disentangles lexical, emotional, and speaker latent factors; CORAL domain alignment that matches second-order statistics between source and target domains without target labels; and a gradient reversal layer (GRL) that suppresses speaker-identity information. Experimental evaluations on the KazEmoTTS and ENU KEMO datasets demonstrate that C-TRILORA achieves a competitive in-domain Macro-F1 of 86.09% and significantly outperforms standard baselines in cross-corpus conditions (41.44% Macro-F1 versus 37.34% for the Shared-Head baseline). McNemar and Wilcoxon signed-rank tests confirm that explicit factor disentanglement is essential for cross-corpus robustness. These results show that separating speech components effectively mitigates negative transfer, making C-TRILORA a practical approach for low-resource SER deployment.**

***Keywords*—Speech emotion recognition; low-resource languages; parameter-efficient fine-tuning; domain adaptation; multi-task learning; disentangled representations**

I. Introduction

Over the past decade, deep learning has transformed speech emotion recognition, yet most of this progress has concentrated on a handful of well-resourced languages such as English and Mandarin [1], [2]. Languages with limited data infrastructure remain largely overlooked. Kazakh is one such case: a Turkic language with around 18 million speakers whose emotional speech has received little systematic attention, partly because publicly available, labeled corpora for it are scarce [3]. Without adequate training data, building SER systems that work reliably in Kazakh is difficult from the outset.

Beyond data scarcity, a pervasive challenge in deploying SER systems is corpus dependency, commonly referred to as the cross-corpus generalization problem. Acoustic representations learned by deep neural networks are notoriously brittle; they tend to conflate paralinguistic affective cues with domain-specific artifacts such as recording conditions, background noise, and speaker demographics [4], [5]. When a model trained on a specific source dataset is evaluated on an unseen target dataset, performance typically degrades significantly due to this covariate shift. Existing approaches to mitigate domain shift, such as adversarial domain adaptation and self-supervised learning, often treat the acoustic signal as a monolithic entity [6], [7], [8]. They generally fail to explicitly disentangle the underlying factors of speech, namely, lexical content, emotional prosody, and speaker identity, which limits their effectiveness in highly variable, cross-corpus scenarios.

To address these limitations, recent advancements have increasingly focused on mitigating the computational costs of large pre-trained models and the performance degradation caused by domain shifts in data-scarce environments. For instance, parameter-efficient fine-tuning (PEFT) techniques, particularly Low-Rank Adaptation (LoRA), have been successfully applied to foundation models like Whisper to extract robust emotional representations with minimal trainable parameters [9]. Furthermore, researchers have recently leveraged transfer learning and transformer-based paradigms to enhance cross-lingual and cross-corpus generalization [10]. However, aligning the feature distributions between mismatched source and target datasets remains a critical bottleneck. Consequently, contemporary cross-corpus SER frameworks are increasingly adopting advanced domain adaptation strategies, such as adversarial domain generalization [11] and classification inconsistency alignment [12]. These ongoing trajectories underscore the necessity of synergizing PEFT with unsupervised domain alignment and explicit factor disentanglement.

Within speech emotion recognition specifically, self-supervised transformer representations combined with lightweight fine-tuning have improved robustness in data-scarce conditions [13], and multi-task learning coupled with subdomain adaptation has been used to bridge the feature-distribution gap between mismatched corpora [14].

Motivated by these findings, this study develops C-TRILORA, a multi-task architecture for cross-corpus Kazakh SER. Rather than applying standard fine-tuning to a pre-trained Whisper backbone [15], we introduce a Tri-LoRA routing module that splits the shared speech representation into three separate streams:lexical, emotional, and speaker; each processed by its own low-rank adapter. This separation is the core design choice, aimed directly at the corpus dependency problem. The three main contributions of the work are:

- Architectural innovation: A Tri-LoRA routing module is integrated into a pre-trained Whisper backbone, explicitly decomposing shared representations into disentangled lexical, emotional, and speaker latent

*Corresponding author

factors.

- Unsupervised domain alignment: Correlation Alignment (CORAL) is integrated directly into the emotional latent space, successfully matching second-order statistics between source (KazEmoTTS) and target (ENU KEMO) domains without requiring labeled target data [3], [15]. This is coupled with a gradient reversal layer (GRL) to suppress speaker-identity leakage.
- Validation in a low-resource context: The efficacy of this approach is demonstrated on Kazakh speech, showing that explicit factor disentanglement significantly mitigates negative transfer and outperforms standard baseline models in cross-corpus SER tasks.

II. Related Work

A. Speech Emotion Recognition in Low-Resource Languages

Modern SER systems achieve strong results on richly resourced languages, supported by large corpora and by two decades of feature-engineering and benchmark work [1], [2]. For low-resourced languages, including Kazakh, progress is constrained by the absence of large labeled emotional corpora. The KazEmoTTS corpus [3] was released primarily for emotional text-to-speech rather than recognition, and recent multimodal efforts target low-resource settings explicitly [20]. A complementary direction reduces the labelled-data requirement through transfer learning and transformer architectures [10], [8]. These studies establish that low-resource SER is feasible, but remains sensitive to the conditions under which the training data were collected.

B. Cross-Corpus SER and Unsupervised Domain Adaptation

Cross-corpus SER addresses the realistic case in which training and test data are taken from different corpora with mismatched recording environments, speakers, languages, and elicitation styles. Classical solutions align feature distributions through subspace learning or transfer factorization, while deep approaches minimise an explicit domain discrepancy. Domain-adversarial training (DANN) [7] learns domain-invariant features through a gradient reversal layer, and Deep CORAL [16] aligns the second-order statistics of source and target representations. Self-supervised adversarial domain adaptation has further been applied jointly to cross-corpus and cross-language SER [25]. Recent transformer-based methods push this further: adversarial domain-generalised transformers [11], classification inconsistency alignment networks [12], multitask transformers that jointly model auxiliary tasks for cross-corpus transfer [22], source-free contrastive adaptation networks [27], and the mining of corpus-invariant emotional acoustic features [26]. A separate line of work disentangles speaker identity from affect through adversarial speaker-invariant representation learning [28], which directly motivates the speaker-suppression component used in this work. A recurring limitation of most of these methods is that they treat the acoustic embedding as a single monolithic vector and align it as a whole, without separating the lexical, affective, and speaker components that respond differently to domain shift.

C. Parameter-Efficient Fine-Tuning of Speech Foundation Models

Large self-supervised and weakly-supervised speech models such as wav2vec 2.0 [6], HuBERT [24], WavLM [23], and Whisper [17] provide powerful general-purpose representations, but full fine-tuning is expensive and prone to catastrophic forgetting in data-scarce regimes. Compact task-adapted variants such as Vesper [29], and parameter-efficient fine-tuning: Low-Rank Adaptation (LoRA) [18] in particular – instead update a small number of parameters while freezing the backbone, and have been shown effective for SER [9]. Existing PEFT-for-SER work, however, adapts the backbone with a single shared adapter and does not couple PEFT with explicit factor disentanglement or unsupervised cross-corpus alignment.

D. Research Gap

In summary, prior cross-corpus SER methods align a monolithic embedding, PEFT-SER methods use a single shared adapter without domain alignment, and low-resource SER work rarely evaluates cross-corpus transfer at all. The present work closes this gap by combining, within a single parameter-efficient model, three elements:

- A Tri-LoRA router that explicitly disentangles lexical, emotional, and speaker factors;
- CORAL alignment applied selectively to the emotional factor;
- Adversarial speaker suppression.

The resulting combination is validated on a genuinely low-resource language (Kazakh) under cross-corpus evaluation.

III. Methods

A. Problem Formulation

The fundamental objective of this study is to learn a robust emotion classifier capable of generalizing across different speech corpora without requiring target-domain labels during training. Let Eq. (1) denote the source corpus, where x_i represents a raw speech waveform, $y_i^e \in \{0, \ldots, E-1\}$ is the emotion label, y_i^t is the word-level transcript, and y_i^s is the speaker identity. Concurrently, let Eq. (2) denote the unlabelled target corpus utilized exclusively for domain alignment. The goal is to optimize a classification function, Eq. (3), that maintains high predictive accuracy on both the source domain D_S and the unseen test partition of the target domain D_T.

$$D_S = \{(x_i, y_i^e, y_i^t, y_i^s)\}_{i=1}^{N} \tag{1}$$

$$D_T = \{x_j\}_{j=1}^{M} \tag{2}$$

$$f : x \longmapsto y^e \tag{3}$$

B. Backbone Architecture: Kazakh Whisper

The proposed Conditional Tri-Factor Low-Rank Adaptation (C-TRILORA) architecture, as shown in Fig. 1, utilizes a pre-trained encoder–decoder backbone based on the Whisper architecture, which was originally developed as a robust, large-scale multilingual speech recognition system trained on weakly

supervised data [17]. Specifically for this study, the model is initialized using a Kazakh-adapted Whisper-small checkpoint [15], which was previously fine-tuned on 335 hours of Kazakh read speech. The encoder module, denoted as $\mathcal{E}$, maps an input log-Mel spectrogram $X \in \mathbb{R}^{80\times T}$ into a sequence of hidden states $H = \mathcal{E}(X) \in \mathbb{R}^{T'\times d}$, where the hidden dimension $d = 768$. To interface with the subsequent routing modules, a mean-pooled representation $\bar{h}$ is computed across the temporal dimension, as in Eq. (4):

$$\bar{h} = \frac{1}{T'}\sum_{t=1}^{T'} H_t \tag{4}$$

Whisper was chosen over encoder-only self-supervised models such as wav2vec 2.0 [6], HuBERT [24], and WavLM [23] for three reasons. First, it is an encoder–decoder model, so it natively supports the auxiliary ASR objective that grounds the lexical factor; encoder-only backbones would require an externally attached decoder for sequence-to-sequence transcription. Second, Whisper is trained on large-scale weakly-supervised, multi-condition data [17], which yields representations that are comparatively robust to the channel and noise variation that characterises cross-corpus evaluation. Third, and decisively for the low-resource setting, a Kazakh-adapted Whisper-small checkpoint fine-tuned on 335 hours of Kazakh speech is publicly available [15]; no comparable in-language checkpoint exists for the alternative backbones, so initialising from Whisper provides a substantially stronger starting point for Kazakh.

C. Parameter-Efficient Fine-Tuning and Tri-LoRA Routing

To adapt the Whisper backbone efficiently without catastrophic forgetting or excessive computational overhead, Low-Rank Adaptation (LoRA) is applied to all attention projection matrices (W_Q, W_K, W_V, W_O) in both the encoder and the decoder [18]. For any given frozen pre-trained weight matrix W_0, the adapted weight W' is computed as in Eq. (5):

$$W' = W_0 + \Delta W = W_0 + \frac{\alpha}{r} BA \tag{5}$$

where, $A \in \mathbb{R}^{r\times d}$ and $B \in \mathbb{R}^{d\times r}$ are trainable low-rank matrices, $r = 16$ is the rank, and $\alpha = 32$ is a scaling factor. This parameter-efficient strategy reduces the trainable parameter count to approximately 0.31% of the total backbone. The routing module and the three auxiliary heads add only a small number of further trainable parameters on top of the LoRA adapters; a detailed profiling of the additional training-time and inference overhead they introduce is identified as a direction for future work.

The core architectural innovation of this framework is the Tri-LoRA Routing Module. Instead of relying on a single shared embedding, this module decomposes the pooled representation $\bar{h}$ into three semantically specialized, disentangled latent factors: the lexical factor z_{lex}, the emotional factor z_{emo}, and the speaker factor z_{spk}. Each factor is processed through an independent low-rank adapter stream gated by learned soft routing weights, ensuring that the model explicitly isolates affective cues from confounding linguistic and demographic variables.

D. Unsupervised Domain Alignment and Optimization

To directly mitigate corpus dependency and domain shift, Correlation Alignment (CORAL) is integrated into the emotional latent space [16]. The CORAL objective minimizes the Frobenius-norm distance between the covariance matrices (second-order statistics) of the source and target z_{emo} distributions. Furthermore, to suppress the leakage of speaker-identity information into the emotion representations, a Gradient Reversal Layer (GRL) is applied to z_{emo} during adversarial training [7].

The total training objective $\mathcal{L}$ is formulated as a weighted sum of five distinct loss components:

- Automatic Speech Recognition Loss ($\mathcal{L}_{\text{ASR}}$): Cross-entropy loss from the Whisper decoder to ground z_{lex} in lexical semantics.
- Speech Emotion Recognition Loss ($\mathcal{L}_{\text{SER}}$): Weighted cross-entropy for emotion classification.
- Speaker Classification Loss ($\mathcal{L}_{\text{SPK}}$): Cross-entropy to explicitly capture speaker traits in z_{spk}.
- Counterfactual Loss ($\mathcal{L}_{\text{CF}}$): A margin-based penalty enforcing the separation of lexical and emotional variations for in-batch pairs sharing transcripts but differing in emotion.
- CORAL Loss ($\mathcal{L}_{\text{CORAL}}$): The unsupervised covariance alignment term.

After training, post-hoc temperature scaling is applied to the output logits to optimize probabilistic calibration and reduce the Expected Calibration Error (ECE) [19].

E. Speech Emotion Datasets

To evaluate the proposed C-TRILORA architecture, particularly its cross-corpus generalization capabilities, this study utilizes two distinct Kazakh speech emotion corpora:

- KazEmoTTS (Source Domain): This dataset serves as the primary labeled source domain (D_S) for training. It consists of high-quality, studio-recorded Kazakh emotional speech originally developed for text-to-speech applications [3], and comprises six emotion categories (neutral, angry, happy, sad, fear/scared, and surprise).
- ENU KEMO (Target Domain): This dataset serves as the unlabeled target domain (D_T) for the unsupervised Correlation Alignment (CORAL) and is subsequently used to evaluate cross-corpus performance. ENU KEMO features different acoustic conditions and speaker demographics compared to KazEmoTTS, providing a robust testbed for covariate shift [20].

F. Experimental Setup and Evaluation Metrics

All acoustic inputs were standardized. Raw audio waveforms were resampled to 16 kHz, and 80-dimensional log-Mel spectrograms were extracted using a 25 ms window and a 10 ms hop size to match the input requirements of the Whisper encoder.

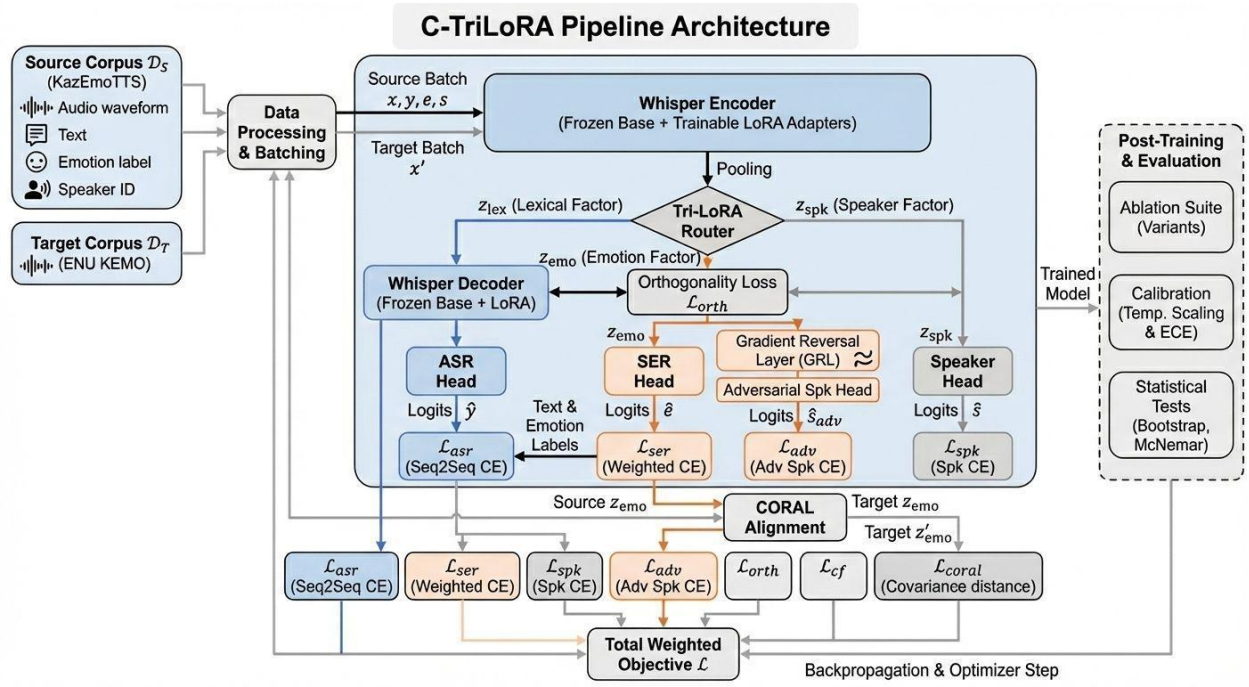

Fig. 1. The proposed C-TRILORA architecture illustrating the Tri-LoRA routing module for factor disentanglement and the CORAL module for domain alignment.

To rigorously assess the performance of the emotion classification, the primary evaluation metric used is Unweighted Average Recall (UAR). UAR is standard in speech emotion recognition tasks because it prevents majority-class bias in imbalanced datasets by calculating the accuracy independently for each emotion class and then averaging the results. Macro-F1 is reported alongside UAR throughout, as it likewise weights all emotion classes equally while being sensitive to false positives.

Additionally, to validate the statistical significance of the performance improvements yielded by the Tri-LoRA routing and CORAL components, two statistical tests were employed: *McNemar's test*, used to assess the statistical significance of differences in classification outcomes between the baseline and proposed models; and the *Wilcoxon signed-rank test*, applied to compare the paired differences in model performance across different experimental folds [21].

All models were trained using the AdamW optimizer with a learning rate of 1×10^{-4}, linear warmup over the first 10% of steps, and weight decay of 0.01, for 5 epochs with a batch size of 16 on a single NVIDIA A100 GPU (40 GB) using mixed-precision (fp16). The LoRA rank was $r = 16$ with scaling factor $\alpha = 32$. Multi-task loss weights were set empirically: $\lambda_{\text{ASR}} = 0.3$, $\lambda_{\text{SER}} = 1.0$, $\lambda_{\text{SPK}} = 0.5$, $\lambda_{\text{CF}} = 0.2$, and $\lambda_{\text{CORAL}} = 0.1$. KazEmoTTS was split 80/10/10 for training, validation, and testing; ENU KEMO was used exclusively for unsupervised domain alignment and cross-corpus evaluation.

IV. Results and Discussion

A. In-Domain and Cross-Corpus Classification Performance

The primary objective of this study was to evaluate the efficacy of the proposed C-TRILORA architecture under cross-corpus evaluation scenarios, where the model is tested on unseen target data (ENU KEMO) after being trained exclusively on the source domain (KazEmoTTS). Table I presents the classification performance across all model variants. Furthermore, the overall training stability and the convergence of the distinct multi-task loss components over the five epochs are illustrated in Fig. 2.

On the in-domain KazEmoTTS test set, the C-TRILORA model achieved strong performance with a Macro-F1 score of 86.09%. While the standard Shared Head baseline slightly outperformed the proposed model in-domain (Macro-F1 $=$ 89.69%), this is a well-documented phenomenon in representation learning. The Shared Head overfits to the joint statistics of the source domain's recording conditions and actor pool. Consequently, its representations are optimal for in-domain discrimination but highly fragile under distributional shift. Conversely, in the cross-corpus evaluation on ENU KEMO, C-TRILORA demonstrated superior robustness, achieving a Macro-F1 of 41.44% and significantly outperforming the Shared Head baseline (37.34%).

This confirms that explicitly disentangling the lexical, emotional, and speaker factors sacrifices a marginal amount of in-domain specificity in exchange for a substantial increase in cross-domain transferability. This preservation of class separability and domain-invariant clustering under covariate shift is visually corroborated by the t-SNE projections of the emotional latent space (z_{emo}) presented in Fig. 3.

B. Ablation Study and the Role of Domain Alignment

To isolate the contribution of each architectural component, an extensive ablation study was conducted. As illustrated in Fig. 4, the removal of any single component resulted

TABLE I. MACRO-F1 CLASSIFICATION PERFORMANCE OF THE C-TRILORA ARCHITECTURE AND ITS ABLATION VARIANTS.

Model Configuration	KazEmoTTS (In-Domain)	ENU KEMO (Cross-Corpus)
Shared Head (Baseline)	0.897	0.374
Full C-TRILORA (Proposed)	0.861	0.414
SER Only	0.722	0.255
No Orthogonality	0.638	0.264
No CORAL	0.615	0.211
No GRL	0.606	0.256
No Counterfactual	0.603	0.264
CORAL Only	0.578	0.239
ASR Only	0.057	0.051

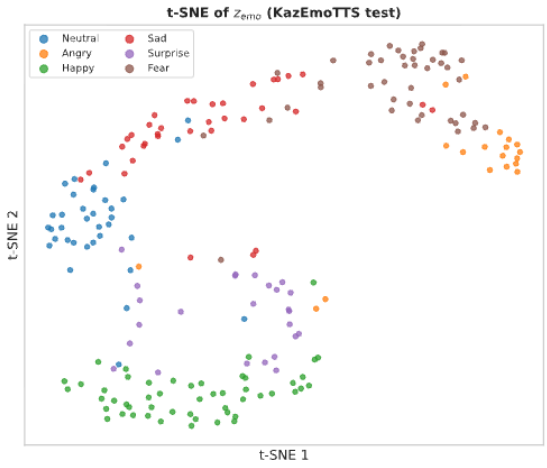
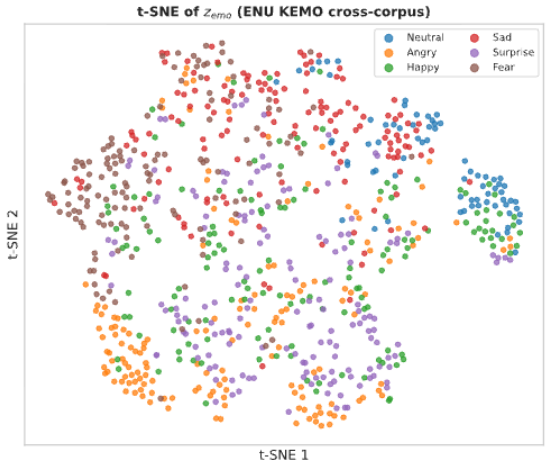
in a degradation of cross-corpus performance. To rigorously validate these performance drops, statistical significance was assessed using McNemar's test. As shown in the heatmap in Fig. 5, the cross-corpus performance degradation observed in all ablation variants is statistically significant ($p < 0.05$) when compared to the full C-TRILORA architecture.

Most notably, as visualized in the waterfall chart in Fig. 6, the removal of the Correlation Alignment (CORAL) objective caused a dramatic 17.5 to 19.3 percentage point absolute drop



(a) In-domain (KazEmoTTS test)



(b) Cross-corpus (ENU KEMO)

in Macro-F1 on the ENU KEMO dataset depending on the specific configuration. This finding underscores the centrality of second-order distribution matching for cross-corpus Speech Emotion Recognition (SER). This empirical result strongly aligns with established domain adaptation theory, which posits that minimizing the discrepancy in the covariance structure of source and target distributions provides a mathematical upper bound reduction on target-domain generalization error [4].

Furthermore, the CORAL-only variant only achieved a 23.91% Macro-F1. This indicates that unsupervised domain alignment alone is insufficient. It must be synergistically paired with explicit factor disentanglement to prevent negative transfer. We further note that two of these ablation configurations double as implicit comparisons to standard domain-adaptation baselines: the CORAL-only variant instantiates Deep CORAL [16], and the gradient-reversal component corresponds to domain-adversarial training (DANN) [7]. The full C-TRILORA surpasses both, indicating that explicit factor disentanglement adds value beyond these established alignment strategies; a broader empirical comparison against further

published cross-corpus systems [11], [12], [22], [27], [26] re-implemented under an identical Kazakh protocol is identified as future work.

studies on the "valence bottleneck" in SER [5]. The confusion matrices in Fig. 7 demonstrate that high-arousal emotions with unambiguous, biologically driven prosodic signatures such as fear and neutral affect generalized relatively well across the two Kazakh corpora.

However, as highlighted by the per-class distribution in the radar plot (Fig. 8), mid-valence emotions like happiness and sadness suffered the most severe performance drops. The model exhibited systematic over-prediction of sadness and confusion between happy and sad states when tested on ENU KEMO. This aligns with broader SER literature indicating that the acoustic realizations of mid-valence emotions vary substantially across different speaker demographics, recording setups, and elicitation styles (e.g., read speech versus acted speech). Explicitly mapping these nuanced valence differences without target-domain labels remains a fundamental challenge.

D. Probabilistic Calibration

Finally, the probabilistic calibration of the network was assessed using the Expected Calibration Error (ECE). As shown

in Fig. 9, before calibration, the model exhibited slight overconfidence in-domain (ECE $= 6.44\%$). Post-hoc temperature scaling successfully reduced this to 5.15%. However, under cross-corpus domain shift, the raw ECE rose substantially to 19.44%, reflecting systematic overconfidence on out-of-distribution data.

Crucially, applying the optimal in-domain temperature parameter actually worsened the cross-corpus ECE to 23.12%, confirming that standard temperature scaling does not seamlessly transfer across domains. This highlights a critical area for future research in domain-adaptive calibration for affective computing architectures.

V. Conclusion

This study successfully addressed the challenge of cross-corpus covariate shift in low-resource speech emotion recognition through the development of the C-TRILORA architecture for Kazakh speech. The integration of a Tri-LoRA routing module separated lexical, emotional, and speaker representations, which, when combined with unsupervised CORAL domain alignment, reduced the fragility of standard acoustic models. Experimental results confirmed that this parameter-efficient approach significantly outperforms baseline models on unseen target domains by preserving domain-invariant affective features. Taken together, the results support the value of both feature disentanglement and second-order distribution matching for deploying reliable affective computing systems in low-data settings.

This study nevertheless has several limitations, which in turn define clear directions for future work. First, the evaluation is currently restricted to two Kazakh corpora; extending it to additional Kazakh datasets and, importantly, to other low-resource languages is a priority for establishing broader generality. Because the Tri-LoRA router, the CORAL alignment, and the gradient reversal layer make no language-specific assumptions (only the Whisper backbone checkpoint is language-dependent, and multilingual Whisper checkpoints are readily available), the architecture is expected to transfer to other languages, and a cross-lingual evaluation is planned. Second, beyond the internal Shared-Head baseline and the ablation variants two of which, the CORAL-only and gradient-reversal configurations, already correspond to the established Deep CORAL and DANN baselines - a comprehensive empirical comparison against the recent published cross-corpus systems surveyed in Section II, re-implemented under an identical Kazakh protocol, is an important next step. Third, the multi-task loss weights were set empirically; a systematic sensitivity analysis and joint optimisation of these weights remain to be carried out. Fourth, a detailed profiling of the computational cost: the additional training time, FLOPs, peak memory, and inference latency introduced by the routing module relative to the baseline is left for future work. Finally, the cross-corpus gains, while statistically significant, are not large in absolute terms, and the valence bottleneck for mid-arousal emotions together with domain-adaptive probabilistic calibration remain open problems for affective computing in low-data settings.

Query Recovery Attack Based on Multi-Source Leakage and Semantic Embedding in Searchable Symmetric Encryption

Xiaogang Yuan, Xinle Yang, Dezhi An
School of Cyber Security, Gansu University of Political Science and Law, Lanzhou 730070, China

***Abstract*—With the rapid development of cloud computing and big data technologies, searchable encryption has become a research hotspot. To improve search efficiency, searchable encryption algorithms may leak redundant information, allowing adversaries to launch query recovery attacks by exploiting pattern leakage in searchable symmetric encryption and infer the underlying keywords of user queries. Existing query recovery attack methods only perform query recovery under multi-source leakage patterns, without considering the semantic level; they simulate user queries with plaintext rather than ciphertext and rarely take frequency as auxiliary leakage for attacks. Meanwhile, the weights between volume and frequency mostly rely on manual configuration, without dynamic allocation of the weights for volume and frequency. Therefore, this study proposes a novel attack method named refine_atk. First, a multi-layer perceptron is used to learn the weights of volume and frequency to accurately identify and recover distinctive queries. Next, co-occurrence information is employed to correct the queries recovered in the previous step. Finally, a cost matrix is constructed using the weighted co-occurrence matrix and the semantic embedding matrix obtained by the pre-trained language model MiniLM-L6, and the remaining queries are recovered in one pass via greedy graph matching. The proposed attack achieves an attack accuracy of 95% on the Enron and Lucene datasets. The attack performance remains robust even after removing part of the similar data. The attack execution efficiency of the proposed method is significantly superior to that of the traditional schemes, yielding better performance when attacking concrete searchable symmetric encryption schemes or evaluating their security. This work provides a reference for the security evaluation and defense mechanism design of searchable symmetric encryption.**

***Keywords*—Searchable symmetric encryption; query recovery attack; pattern leakage; multi-layer perceptron (MLP)**

I. Introduction

Searchable symmetric encryption (SSE) query recovery attacks mainly utilize the queries observed by the server and the returned results to infer the keywords of the user query. It is divided into active attack and passive attack. Active attack [1], is also known as injection attack. Suppose an attacker can upload a small number of malicious files, which will leak the content of encrypted queries, allowing the attacker to obtain the client query privacy. The file injection attack proposed by Zhang Y et al. [1] only requires the injection of a small amount of files. Even in the face of the SE scheme with less leakage, the query content of the client can be completely inferred. The attack proposed by Poddar et al. [2] can be recovered with just one query issued by the user. The attack exploits file injection and automatic query replay, combined with volume leakage, to recover user queries. Zhang X et al. [3] proposed two binary-based volume injection attacks, BVA and BVMA, which reduce the number of injected files by using known keywords and infer the query content by observing the query volume. Zhang L et al. [4] proposed a volume injection attack with the optimal injection size. By using the response length and size patterns, only O(logn) injection files are required, and the total size is O(nlogn).

Passive attacks can be classified into known data attacks and similar data attacks. A known data attack refers to an attacker who has full or partial knowledge of the documents stored on the server. This study focuses on the SSE solution for single-keyword query. Cash et al. [5] proposed a counting attack, which requires the number of identical files matched by any two keywords in a known document to recover the query based on the response volume (length of the access pattern). The IKK attack [6] uses access pattern leakage to recover user queries. It assumes that the attacker has some known queries and knows the probability that any two keywords appear in the same known document. The core principle is the simulated annealing algorithm. Blackstone et al. [7] proposed a subgraph attack that exploits the document volume pattern (the number of bytes each document occupies) to recover queries. The attack proposed by Ning et al. [8] simultaneously recovers user queries and databases.

Similar data attack refers to the situation where the attacker has documents with keyword distributions similar to the user real data, and the documents in the similar data do not need to be indexed. For example, public threat intelligence datasets [9] and knowledge graphs [10] can serve as sources of similar data. The attack proposed by Liu et al. [11] only relies on the leakage of search patterns. By comparing the search frequency of each keyword on known documents with the search frequency of user queries on real documents, the underlying keywords are recovered. Oya et al. [12] pointed out that by simultaneously utilizing the access pattern and the search pattern and using the optimal solver [13], the problem of linear allocation of keywords can be solved.Damie et al.[14] proposed a similar data attack that utilizes a small number of known queries as prior knowledge. Xu et al. [16] proposed an attack in a dynamic scenario, which utilizes the update volume and query response volume of the same keyword before and after the update, and combines query equality to recover the query. Gui et al. [17] redefined leakage from the perspective of SSE systems and pointed out that the vast majority of literature only considers the leakage of encrypted search indexes throughout the SSE system and does not take into account the leakage of encrypted documents. Attacks remain effective

against some SSE schemes that suppress leaks. Wang et al. [18] proposed a machine learning enhancement framework for real-time risk assessment in searchable encryption. In other fields of cybersecurity, machine learning is also widely applied to malware detection [19], [20] and threat detection [21]. In [12], [24], the authors indicate that similar data attacks can bypass the defense of pattern randomization [35], [15]. Additionally, active learning techniques [36] can be utilized to enhance entity recognition, which may be related to keyword extraction in such attacks.

Damie et al. [14] indicated that accuracy is related to query volume (the number of documents matched by the query). Oya et al. [12] pointed out that high-frequency queries are more likely to be accurately recovered. In [7], the authors emphasize that high-volume queries are easier to recover. Nie et al. [22] pointed out that high-volume and high-frequency queries are easier to recover than other queries. Based on these queries, almost all remaining queries can be recovered. The volume and frequency of keywords in the database follow Zipf's law [23], that is, the lower the ranking of a keyword, the smaller its volume and frequency. The similar data attack RSA proposed by Damie et al. [14] can recover all queries by using only 10 known queries. Passive query recovery attacks are classified into two types based on the prior knowledge utilized by the attacks: known data attacks and similar data attacks. Table I lists several known data attacks and similar data attacks.

Inspired by Nie et al.[22], prioritizing the recovery of high-volume and high-frequency queries brings significant advantages to subsequent query recovery. Fig. 1 shows the overview of the refine_atk (Ours) operation pipeline.The main contributions of this study are as follows:

- Most existing query recovery attacks simulate user queries using plaintext queries, whereas this study employs ciphertext queries for user query simulation. The statistical features used throughout the attack are modeled based on ciphertext queries. The volume, frequency, and co-occurrence information of ciphertext queries remain consistent with those in the plaintext state. Since the indices of the underlying semantic embeddings of queries are fixed, semantic vectors can still be extracted via these indices, enabling effective ciphertext query recovery and facilitating better analysis and validation of attack performance.
- This study uses a multi-layer perceptron (MLP) to dynamically allocate weights for volume and frequency. The weights learned by the MLP cannot be directly applied to distinctive query recovery; instead, a coefficient α for distinctive query recovery is derived with the help of a small number of known queries. The weights assigned to volume and frequency, as well as coefficient α vary in each simulated attack.
- This study constructs a TF-IDF weighted co-occurrence matrix from unrecovered queries and unpaired keywords. The pre-trained language model MiniLM-L6 is used to encode unrecovered queries and unpaired keywords to obtain a semantic embedding submatrix. These two components form a cost matrix, and the remaining queries are recovered in one pass via greedy graph matching.
- The proposed method (Ours) remains robust even when the attacker possesses limited auxiliary knowledge. The first module of the proposed attack achieves promising Top-10 performance, meaning that the top 10 candidates in the attack results all correspond to the recovery of distinctive queries, which is critical to the overall effectiveness of our method.

II. SSE Scheme and Attack Model

A. SSE

Searchable encryption schemes are divided into five steps. Generate key: Enter a security parameter and output the system key. The data owner encrypts the file with a key and uploads it to the cloud server. Index establishment: Extract keywords from the database, encrypt as user document indexes, and upload to the cloud server. Generate trapdoor: The data owner uses the key pair to generate trapdoors for the keywords and send to the cloud server. Search: The cloud server matches the search trapdoor with the encrypted index stored locally. If the match is successful, the cloud server will send the ciphertext document mapped by the encrypted index to the user. File decryption: Legitimate users decrypt ciphertext documents.

Bost et al. [25] proposed a forward-privacy SSE scheme named Sophos, which only relies on trapdoor permutation and does not require a structure similar to ORAM. Subsequently, Bost [26] proposed a framework for constructing forward privacy using range-constrained pseudo-random functions. Cash and Tessaro[27] discussed the balance issue between "server storage size" and "memory access locality" in SSE. The size of the encrypted index is O(NlogN), and only O(logN) reads are required during search. Chamani et al. [28] proposed three DSSE schemes, addressing the balance between "security and performance" in backward privacy and providing efficient solutions for strong privacy requirements. Kamara and Moataz [29] proposed a non-interactive and efficient SSE scheme that can handle arbitrary disjunctive queries and boolean queries. It features sublinear search efficiency in the worst-case scenario and optimal communication complexity. Patel et al. [30] proposed a scheme that supports dynamic sharing and unsharing of documents among users, with small cross-user leakage and slow growth as queries increase. Sun et al. [31] proposed the cryptographic primitive of symmetric deletable encryption, which features fast search speed and low server storage cost. Xu et al. [32] introduced the "key-updatable pseudo-random function" to construct the ROSE scheme, which simultaneously satisfies robustness, forward privacy, backward privacy and practical performance.

B. Pattern Leakage

Searchable encryption can leak the document identifier (access pattern) returned by the query. By observing and analyzing the access patterns, attackers attempt to infer the private information queried by users. The search pattern refers to which two queries in a query sequence are equal. SSE using deterministic encryption algorithms will expose the same access pattern when repeatedly searching for the same keyword. Taking advantage of this, attackers can infer whether two queries correspond to the same keyword. The volume pattern refers to the number of documents returned by each query.

TABLE I. COMPARISON OF THE EXISTING PASSIVE ATTACKS[1]

Attack	Leak	KPK		SPK		ACC
		Doc	Query	Doc	Fre	
IKK[6]	AP	■	▲	□	□	∼80%
Count[5]	AP,VP	■	□	□	□	∼90%
SubgraphID[7]	AP	▲	□	□	□	∼90%
LEAP[8]	AP	▲	□	□	□	∼100%
RSA[14]	AP	□	▲	■	□	∼85%
IHOP[24]	AP,SP	□	□	■	■	∼90%
Jigsaw[22]	AP,SP,VP	□	□	■	▲	∼90%
Ours(refine_atk)	AP,SP,VP	□	▲	■	▲	**∼ 95%**

[1] "AP" stands for access pattern, "SP" for search pattern, "VP" for volume pattern, "KPK" for known prior knowledge, "SPK" for similar prior knowledge. "Doc" stands for document, "Query" for known query, and "Fre" for frequency. "■" indicates that the attacker requires all known data or highly depends on similar data. "▲" indicates that the attacker requires some known data or relatively depends on similar data. "□" indicates that the attacker does not need known data or similar data. The first four are known data attacks, and the last four are similar data attacks. Although our attack requires some known queries to assist in attacks, in actual scenarios, it is "treated as" not knowing any known queries.

Searchable encryption can reveal the number of documents returned by the server.

C. Attacker

Honest, yet curious servers follow the SSE protocol, but attempt to recover user queries by exploiting leaks and prior knowledge. The server can access all encrypted documents. In searchable symmetric encryption, only the document contents and indexes are encrypted, while the semantic information of keywords (e.g., word meaning, contextual relations) naturally exists in plaintext space. Although an attacker cannot directly obtain the plaintext of user queries, they can extract the keyword space W_s from auxiliary data documents and independently perform semantic embedding on these keywords. Since semantic embedding relies solely on public corpora and pre-trained models and does not require any user private data, the attacker is fully capable of incorporating this information into the attack process. Relying solely on volume, frequency, and co-occurrence matrices, the attacker struggles to distinguish between queries with similar statistical features (e.g., two low-frequency, low-volume keywords may have nearly identical volume and frequency values). This fully demonstrates the ambiguity inherent in statistical information, whereas semantic embedding provides orthogonal discriminative capability. Query recovery essentially aligns observed ciphertext queries (with observable volume, frequency, and co-occurrence patterns) with plaintext keywords. Semantically similar words often exhibit similar document occurrence patterns (e.g., "apple" and "fruit" may appear in similar document contexts). Therefore, semantic embedding and co-occurrence-based statistical features are naturally complementary.

Attackers use leaks to infer the frequency, volume and co-occurrence information of queries. Suppose a user issues s queries, represented as Q^s, and l different queries are identified by using the search frequency. Mark the query list identified by the attacker as $Q_r = [q_1, q_2,..., q_l]$. The attacker observed the documents returned by the query $[D(q_1), D(q_2),..., D(q_l)]$. The server knows the total number of documents and records it as $|D|$. For each query q, normalize the query volume: $v_{qi} = |D(q_i)| / |D|$, $V_r = [v_{q1}, v_{q2},..., v_{ql}]$ is the volume vector for all queries in the Q_r, with the component numerator being the number of documents matched by the query. The attacker uses the search pattern to know the frequency of q in Q^s. The frequency of q is: $f_q = Cnt(q)/|Q^s|$, where $Cnt(q)$ is the number of q in Q^s. $F_r = [f_{q1}, f_{q2},..., f_{ql}]$ is the frequency vector for all queries in Q_r. Based on the access pattern, an attacker can construct an $l \times |D|$ matrix ID_r, where the rows are queries and the columns are documents. If the search results of q_i include d_j, then $ID_r[i, j] = 1$; otherwise 0. Finally, construct the $l \times l$ co-occurrence matrix $C_r = ID_r ID_r^T / |D|$.

Suppose the attacker has a list of similar documents $D_s = [d_1, d_2,..., d_k]$, and uses the same algorithm to extract the keywords. Attackers can easily obtain a keyword space similar to the user's document[3], denoted as $W_s = [w_1, w_2,..., w_m]$, and construct a volume vector $V_s = [v_{w1}, v_{w2},..., v_{wm}]$, with $v_{wi} = |D_s(w_i)| / |D_s|$, where $|D_s(w_i)|$ is the number of documents containing the keyword w_i in D_s. The attacker constructs an ID_s from W_s and D_s, with the co-occurrence matrix $C_s = ID_s ID_s^T / |D_s|$. For W_s, the attacker obtained the similar search frequency $F_s = [f_{w1}, f_{w2},..., f_{wm}]$ through Google Trends [37], which is used to display the keyword trends and changes searched by users in various regions around the world on the Google search engine.

III. REFINE_ATK

A. Partition Query

Fewer keywords in the database have high volume and frequency. Users may frequently query these keywords, so it is necessary to first distinguish between high-volume and high-frequency queries. Fig. 2 and Fig. 3 shows the results of the queries ranked by volume and frequency. This study selects the top 1000 keywords without stopping words as W. The query is divided into four quadrants: HVHF, HVLF, LVHF and LVLF. "L" and "H" represent "low" and "high", while "V" and "F" represent "volume" and "frequency". High-volume (frequency) queries refer to those ranking in the top 10% in terms of volume (frequency), while low-volume (frequency) queries account for the remaining 90%.

Rank the queries based on volume and frequency, and display the queries in different quadrants according to the ranking. The HVHF query ranking in the upper right corner is high, but the quantity is small. The ranking of the LVLF query in the lower left corner is low, but the number is large.

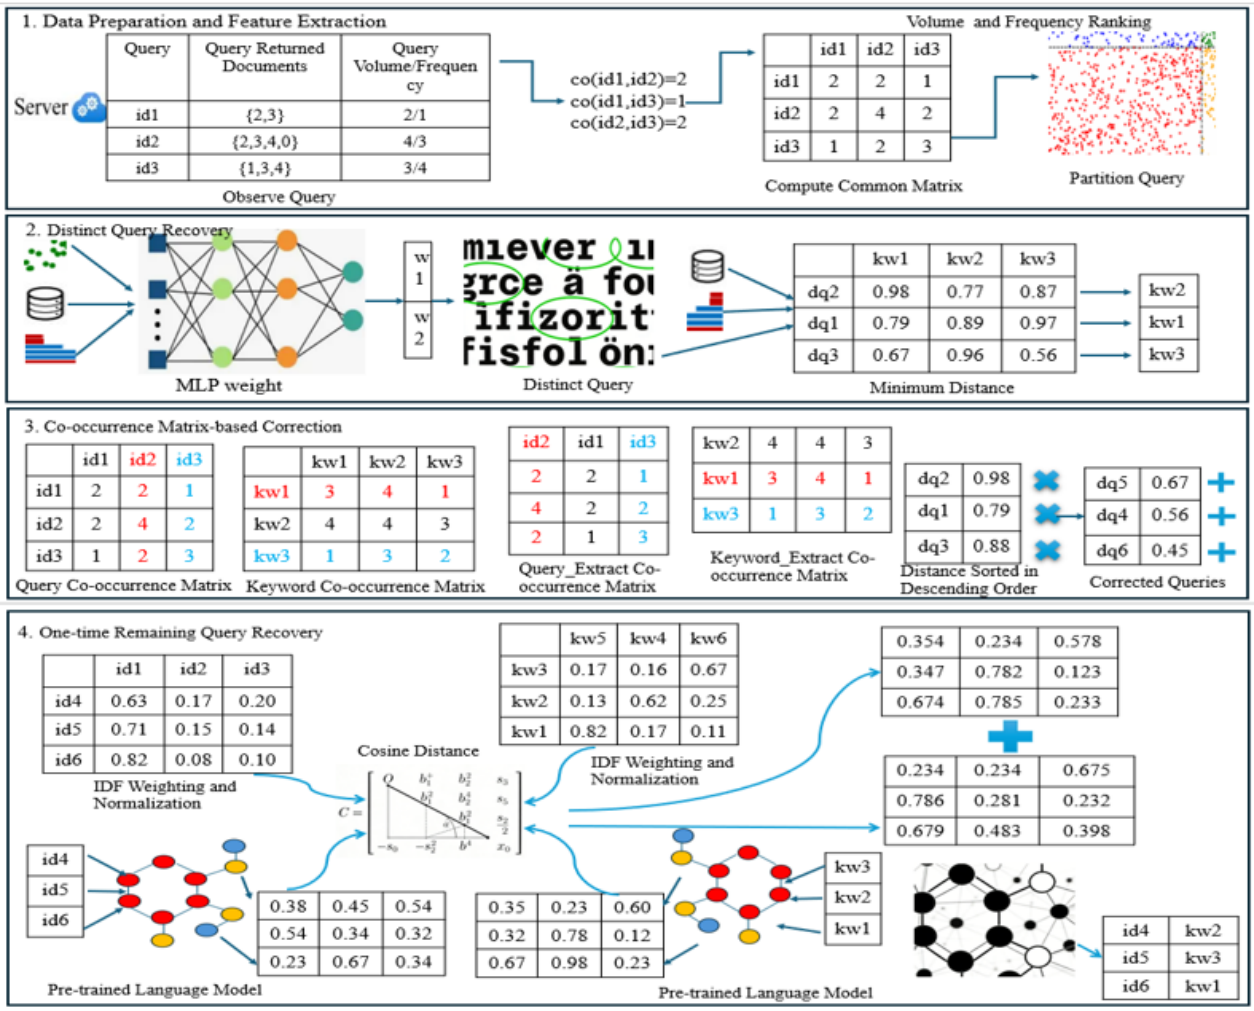

Fig. 1. An overview of the refine_atk (Ours) operation pipeline.

The attack accuracy rates in the HVLF quadrant in Enron and Lucene were 63% and 86%, respectively, 84% and 72% for LVHF, 26% and 34% for LVLF, and all were over 90% for HVHF. It indicates that the LVLF query is difficult to recover.

B. Identify and Recover Distinctive Queries

Algorithm 1 inputs the Td_r, V_r, F_r of the leaked exported data in the SSE query and similar data W_s, V_s, V_s. Output the *BaseRec* predictions. *BaseRec* refers to the number of queries recovered by this module. The *BaseRec* should not be too large. If the *BaseRec* is too large, there will be more predictions for non-HVHF queries, and the accuracy rate will decline.

First, the HVHF, HVLF, LVHF, and LVLF queries are divided. MLP uses the HVHF query, F_r and V_r learn the weights of volume and frequency, which are respectively denoted as w_V and w_F. Transpose F_r and V_r into column vectors and perform a logarithmic transformation (The frequency is processed in the same manner) [see Eq. (1)]:

$$\log V = \ln(V + \epsilon) \tag{1}$$

Element-by-element multiplication and division [see Eq. (2)]:

$$V \times F = V \odot F \tag{2}$$

$$V_{divF} = \frac{V + \epsilon}{F + \epsilon} \tag{3}$$

Calculate the ascending ranking for F_r and V_r, respectively. The smallest element ranks 0, the second smallest ranks 1, and so on. The largest ranking is n-1, where n is the total number of queries. Normalize the ranking vector to the interval [0,1]:

$$\text{ranks}_V = \frac{\text{argsort}(\text{argsort}(V))}{n-1} \tag{4}$$

Concatenate the features V, F, $logV$, $logF$, $V \times F$, V_{divF}, F_{divV} [Swap the numerator and denominator, see Eq. (3)], $ranks_V$ and $ranks_F$ [Replace the numerator with the frequency see Eq. (4)] by column. If the query $\in$ HVHF, the label is marked as 1; otherwise 0. If the number of HVHF queries

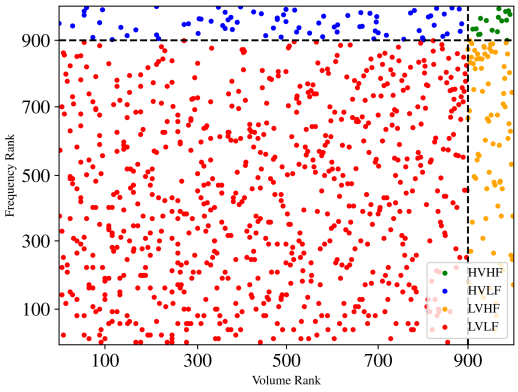

Fig. 2. Query distribution divided into different quadrants based on volume and frequency rank in Enron.

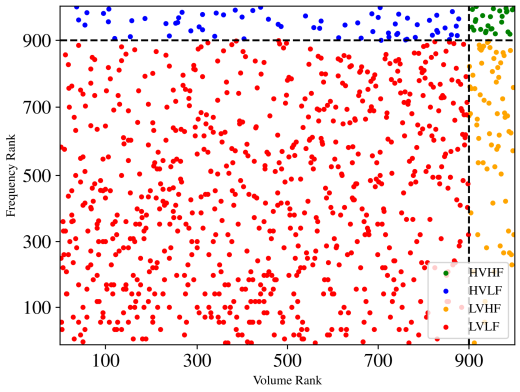

Fig. 3. Query distribution divided into different quadrants based on volume and frequency rank in Lucene.

Algorithm 1 Locate and recover distinctive queries

procedure LocRecDQ($\mathrm{Td}_r, \mathrm{V}_r, \mathrm{F}_r, \mathrm{W}_s, \mathrm{V}_s, \mathrm{F}_s$, params)
// Outline: learn weights using MLP, compute the differential distance, select the distinctive queries, and then perform recovery.Params include: BaseRec, nb_queries.
// 1. Partition the quadrants and take HFHV (or another subset) as the training set.
$(\mathrm{HFHV}, \mathrm{HFLV}, \mathrm{LFHV}, \mathrm{LFLV}) \leftarrow$ plot_histogram_and_classify($\mathrm{F}_r, \mathrm{V}_r$)
// 2. Use MLP to learn the weight vector on the selected subset (output denoted w).
TrainSet $\leftarrow$ HFHV
w $\leftarrow$ learn_weight_mlp(TrainSet, $\mathrm{F}_r, \mathrm{V}_r$)
// 3. Compute the differential distance vector with the learned weights and select the distinctive queries.
$\mathrm{D_{FV}} \leftarrow$ calculate_dVF(w)
// 4. Obtain known query pairs and learn the recovery coefficient α.
known_pairs $\leftarrow$ get_known_queries(nb_queries = params.nb_queries)
$\alpha \leftarrow$ learn_recover_weight_alpha(known_pairs)
// 5. Perform recovery mapping on the distinctive queries.
Pred $\leftarrow$ RecoverByVF(HFHV, $\mathrm{W}_s, \mathrm{V}_s, \mathrm{F}_s, \alpha$)
return Pred
end procedure

is less than 5% of the total number of queries, oversampling is performed. Specifically, the query index for HVHF is pos_idx, and the query index for the rest is neg_idx. The number of HVHF queries is the maximum value between 50 and 10% of the total number of queries. The number of repetitions, repeat_times, is the number of HVHF queries divided by the length of pos_idx, repeat the HVHF query features and labels repeat_times, and concatenate them with the remaining queries. Finally, shuffle the order. Divide the training set and the validation set (80% training and 20% validation). Use StandardScaler (The validation set is treated in the same way) [see Eq. (5)]:

$$X_{\mathrm{train}_r} = \frac{X_{\mathrm{train}} - \mu_{\mathrm{train}}}{\sigma_{\mathrm{train}}} \tag{5}$$

The hidden layer size of MLPClassifier is (64, 32), the activation function is relu, the solver is adam, an early stop strategy is set, and the maximum iteration is 500 times. Repeatedly shuffle a certain feature column on the validation set to see how much the model performance drops. The more the performance drops, the more important this feature is. Each feature is shuffled 20 times and the average is taken. Each feature has an importance score. Aggregate feature importance to *V* and *F*. For each feature *i*, its importance is I_i, and it is assigned according to the feature name (Apply the same processing to the frequency) [see Eq. (6)]:

$$\mathrm{imp}_V = \sum_{\text{only } V} I_i + \sum_{V \text{ and } F} \frac{I_i}{2} + \sum_{\text{others}} \frac{I_i}{2} \tag{6}$$

Only *V* refers to a feature *i*, where the feature name contains only *V*, with an importance of I_i. *V* and *F* indicates that the feature name includes both *V* and *F*, with an importance of $\frac{I_i}{2}$. Others refers to all other features, with an importance of $\frac{I_i}{2}$. The weight calculation for volume and frequency is simplified as follows [see Eq. (7) to Eq. (9)]:

$$w = \left[\frac{\mathrm{imp}_V}{|\mathrm{imp}_V| + |\mathrm{imp}_F|}, \frac{\mathrm{imp}_F}{|\mathrm{imp}_V| + |\mathrm{imp}_F|} \right] \tag{7}$$

$$w_V = \frac{\mathrm{imp}_V}{|\mathrm{imp}_V| + |\mathrm{imp}_F|} \tag{8}$$

$$w_F = \frac{\mathrm{imp}_F}{|\mathrm{imp}_V| + |\mathrm{imp}_F|} \tag{9}$$

Calculate the differential distance to identify unique queries from all the queries. The differential distance d_{qi} of query q_i is [see Eq. (10)]:

$$d_{q_i} = \min_{q_j \in Q_r \wedge j \neq i} w_V \cdot |v_{q_i} - v_{q_j}| + w_F \cdot |f_{q_i} - f_{q_j}| \tag{10}$$

w_V and w_F denote the weights associated with volume and frequency, respectively. The queries are sorted in descending order based on their differential distance. The top *BaseRec* queries constitute the distinctive queries. A small set of known queries is utilized to learn the weight parameter α, which is used to recover distinctive queries. The specific value of α is determined by the statistical characteristics (volume and frequency) of the known queries and their correspondence with keywords in the auxiliary data. Known queries are used solely as a tool for internal parameter estimation and are not directly leveraged as prior knowledge for computing the final attack accuracy, thereby ensuring fairness in comparison with other baseline attacks (e.g., RSA, Jigsaw). This study experimentally validates (see Fig. 20) that with a small number of known queries (1, 2, 5), Algorithm 1 can still achieve relatively stable accuracy (although accuracy fluctuates more significantly when the number is extremely small). This demonstrates that the assumption is reasonable and feasible in practice. Attacker only needs a very small number of random known queries to effectively estimate α.

Following the definition of distance between queries and keywords from[22], each query is paired with its nearest keyword. The distance $s(q_i, w_j)$ between a true query q_i and a keyword $w_j \in W_s$ is defined as Eq. (11):

$$s(q_i, w_j) = \alpha \cdot |v_{q_i} - v_{w_j}| + (1 - \alpha)|f_{q_i} - f_{w_j}| \tag{11}$$

recovery the query q_i as Eq. (12):

$$\text{Pred}(q_i) = \arg \min_{w_j \in W_s} s(q_i, w_j) \tag{12}$$

By dynamically allocating the weights of volume and frequency, this module is capable of recovering unique queries.

C. Correction Through Co-occurrence Matrix

The query-keyword pairs output by the co-occurrence matrix correction of Algorithm 1 is given. The accurate recovery of HVHF queries is crucial for the recovery of subsequent queries.

The input of Algorithm 2 is the co-occurrence matrices C'_r and C'_s, corresponding respectively to the query and keyword in *Pred*, *BaseRec*, and *Pred* recovered by Algorithm 1. That is, in *Pred*, the columns of the query index in the co-occurrence matrix C_r are taken as C'_r, and the rows of the keyword index in the co-occurrence matrix C_s are taken as C'_s. Then, each row of C'_r and C'_s is divided by the sum of the rows to normalize. *ConfRec*($\leq$ *BaseRec*) refers to the number of queries correctly recovered in *Pred*. The smaller the *ConfRec* is, the higher the accuracy rate will be and the fewer queries can be recovered. For the correct prediction (q_i, w_i) in *Pred*, C'_r*[i]* and C'_s*[i]* are similar, and their volume and frequency are similar; Conversely, q_i and w_i are only similar in volume and frequency. The reverse confidence revconf of (q_i, w_i) is Eq. (13):

$$\text{revconf} = \|C'_r[i] - C'_s[i]\| \tag{13}$$

Algorithm 2 Verification based on co-occurrence matrix

procedure VERIFY($Pred, C'_r, C'_s, BaseRec, ConfRec$) //
// Extract the columns and rows corresponding to the queries and keywords in the co-occurrence matrices C_r and C_s of Algorithm 1 $Pred$, respectively, to construct C'_r and C'_s.
  $TempPred \leftarrow Pred$
  $Td' \leftarrow Pred.td$
  $Revconf \leftarrow \emptyset$
  for $i \in [0, |Td'| - 1]$ **do**
    revconf $\leftarrow \|C'_r[i] - C'_s[i]\|$
    append($Td'[i]$, revconf) to $Revconf$
  end for
  sort $Revconf$ in descending order by the revconf value;
  for $i \in [0, BaseRec - ConfRec - 1]$ **do**
    $(td, revconf) \leftarrow Revconf[i]$
    remove the prediction for td from $TempPred$
  end for
  return $TempPred$
end procedure

The greater the *revconf*, less reliable it is for q_i to predict w_i, that is, the plaintext keywords at the bottom of q_i are very likely not w_i. Calculate the *revconf* of each query in *Pred* and add it to the *Revconf*. Sort the *Revconf* in descending order. Remove the first *BaseRec-ConfRec* queries from *Pred*. Return *ConfRec* query predictions.

D. Recovering the Remaining Queries Globally

The input of Algorithm 3 include: the query-keyword pair *Pred* recovered by Algorithm 2, the co-occurrence matrix C_r between the unrecovered and recovered query, all queries T_r, the similar keyword space W_s, and the co-occurrence matrix C_s between the unpaired and paired keyword. U_{td} stands for unrecovered queries, and U_{kw} stands for unpaired keywords.

Calculate TF-IDF weight to each row of $\widetilde{C}_r$ and $\widetilde{C}_s$ [see Eq. (14) and Eq. (15)]:

$$idf(j) = \log \frac{N}{df(j) + 1} \tag{14}$$

$$r_w[j] = r[j] \times idf(j) \tag{15}$$

N represents the number of unrecovered queries, *df* is the number of non-zero elements in each column of the $\widetilde{C}_r$ matrix, *j* is the index, and *r* is the $\widetilde{C}_r$ matrix. Calculate the cosine distance between the two weighted co-occurrence matrices [see Eq. (16)]:

$$D_{co}[i, j] = 1 - \frac{\tilde{C}_r[U_{td}[i]] \cdot \tilde{C}_s[U_{kw}[j]]^T}{\|\tilde{C}_r[U_{td}[i]]\| \cdot \|\tilde{C}_s[U_{kw}[j]]\|} \tag{16}$$

The MiniLM-L6 pre-trained language model has 6 hidden layers and 12 attention heads. The dimension of the hidden layer is 384 dimensions, the maximum sequence length is 128 tokens, and mean pooling is adopted. MiniLM is a

lightweight variant of BERT, with fewer parameters and a more streamlined structure than the standard BERT. Encode the unrecovered queries and unpaired keywords using MiniLM-L6, normalize the generated embedding vectors, and convert them into numpy matrices. In this matrix, the embedding vectors of unrecovered queries and unpaired keywords are concatenated column-wise, respectively, and their indices remain fixed throughout the entire attack process, which is critical to query recovery. For the indexes of unrecovered queries and unpaired keywords, extract the corresponding embedding matrix row vectors to form new embedding submatrices, and calculate the cosine distance between the two embedding submatrices [see Eq. (17)]:

$$D_{emb}[i,j] = 1 - \frac{E_{td}[i] \cdot E_{kw}[j]^T}{\|E_{td}[i]\| \cdot \|E_{kw}[j]^T\|} \tag{17}$$

E_{td} and E_{kw} are embedding submatrices for unrecovered queries and unpaired keywords. The cost matrix is a linear combination of D_{co} and D_{emb} [see Eq. (18)]:

$$M[i,j] = \beta \cdot D_{co}[i,j] + (1-\beta) \cdot D_{emb}[i,j] \tag{18}$$

M is the cost matrix, β is the weight of $D_{co}[i, j]$, and 1-β is the weight of $D_{emb}[i, j]$. This study uses a greedy graph to match unrecovered queries and unpaired keywords. M_{td} and M_{kw} are two empty sets. The row index and column index of matric *M* element, as well as the element values, are added to flat as tuples to sort each element of *M* in ascending order. For each tuple's row index and column index, if neither is in M_{td} or M_{kw}, take the value of the row index in U_{td}, denoted as *td*, and take the value of the column index in U_{kw}, denoted as *kw*. (*td*, *kw*) is added as a matching pair in P_{final} [see Eq. (19)]:

$$P_{final}[td] = kw \tag{19}$$

The M_{td} and M_{kw} collections, respectively add row index and column index [see Eq. (20)]:

$$\begin{cases} M_{td} \leftarrow M_{td} \cup \{i\}, & i \notin M_{td},\ j \notin M_{kw} \\ M_{kw} \leftarrow M_{kw} \cup \{j\}, & j \notin M_{kw},\ i \notin M_{td} \end{cases} \tag{20}$$

The known queries in Algorithm 1 are not the high-volume known queries in RSA [14], but are randomly extracted from the user query sequence and the keyword space.

E. Experimental Data and Evaluation Metrics

The experimental dataset consists of Enron and Lucene. The Enron email Corpus [33] was collected from 2000 to 2002, containing a total of 30,109 emails. The Lucene mailing list consists of 66,491 emails from 2001 to 2020 [34]. This study uses the preprocessed version provided in reference [12].

The search frequency of keywords in Enron and Lucene is generated using Google Trends, which contains Google search trends for approximately 260 weeks from October 2016 to October 2021. The attacker auxiliary knowledge is the sum of the search frequency for each keyword within 1 to 50 weeks. Divide by the total to normalize the frequency of each keyword, denoted as F_s. The user query is simulated and generated based on the total frequency *F* from 1 + τ to 50 + τ. τ is the time gap between the attacker auxiliary knowledge and the user query.

Randomly shuffle all the documents and divide them into two disjoint subsets of equal size. One subset serves as the user's encrypted database D_r, and the other subset as similar data D_s. The attacker generates W_s, V_s and C_s based on D_s, and observes all user queries to obtain Q_r, V_r, F_r and C_r. Each

end procedure

combination of experimental parameters was independently simulated 30 times. Each simulation randomly selects half of the documents as D_s and generates queries based on the frequency F.

Aggressiveness can be evaluated by accuracy rate, recovery rate and attack time. The recovery rate is the proportion of queries that have been recovered among all queries. Accuracy refers to the queries that have been correctly recovered among the recovered queries. The attack time is the time spent executing Algorithm 1 to Algorithm 3, excluding the time for generating the co-occurrence matrix, query generation, generating the keyword-document matrix, and loading the pre-trained language model [see Eq. (21) to Eq. (23)]:

$$\mathrm{ACC} = \frac{|\mathrm{Recovered}(Q^s)|}{|Q^s|} \tag{21}$$

$$\mathrm{QRR} = \frac{|\mathrm{CorrectRec}(Q^s)|}{|\mathrm{Recovered}(Q^s)|} \tag{22}$$

$$\mathrm{Atk_time} = \mathrm{Alg1.time} + \mathrm{Alg2.time} + \mathrm{Alg3.time} \tag{23}$$

F. Performance of Algorithm 1 and Algorithm 2

In Table II, the parameter experiments are conducted, showing the accuracy, recovery rate and the number of correct recovery of Algorithm 1 and Algorithm 2 in Enron and Lucene when *BaseRec* $\in \{25, 50, 100, 200, 400\}$ and *ConfRec*/*BaseRec* $\in \{1, 0.5, 0.2\}$. part = 1 indicates that Algorithm 2 retains all recovery results of Algorithm 1. The first two columns of data under *ConfRec*/*BaseRec* $\in \{1, 0.5, 0.2\}$ are represented as decimals.

The accuracy rate of various parameter combinations exceeds 65%. As *BaseRec* and *ConfRec*/*BaseRec* decrease, the number of queries recovered by Algorithm 2 decreases, the recovery rate drops, but the accuracy rate increases. In Lucene, when *BaseRec* = 50 and *ConfRec*/*BaseRec* = 0.2, the accuracy rate drops by 1%. When *BaseRec* = 25 and *ConfRec*/*BaseRec* = 0.2, Algorithm 2 achieved recovery rates of approximately 0.66% and 2.04% in Enron and Lucene, respectively, but with extremely high accuracy. The attack proposed in this study outperforms the accuracy and the number of correct recovery achieved in reference [22]. *BaseRec* = 400, *ConfRec*/*BaseRec* = 1, the accuracy rate increased by 23% and 17%, respectively, the number of correct recovery increased by 63 and 57.

Algorithm 1 mainly involves MLP learning the weight of volume and frequency through HVHF query, calculating the differential distance, and identifying unique queries. A coefficient α for recovering unique queries is obtained by using a small number of known queries, and finally the unique queries are recovered by volume and frequency. The attack parameter *BaseRec* represents the total number of queries $|Q_r|$. Each dataset independently simulates 30 experiments, collecting the weights, α , accuracy of Algorithm 1, and attack time of each experiment. The collected weight and α array are divided into buckets with a width of 0.05. The mean and standard deviation of the accuracy within each bucket are calculated. The bucking is done to ensure that all values in both arrays are covered and to average the attack processing time. Test the influence of different weights and α on the accuracy and attack time of Algorithm 1.

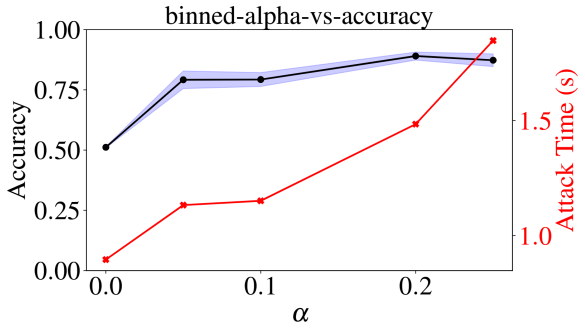

Fig. 4. Accuracy and attack time of Algorithm 1 with different weights and α in Enron.

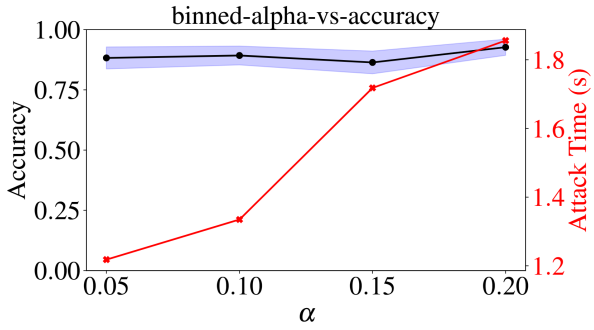

Fig. 5. Accuracy and attack time of Algorithm 1 with different weights and α in Lucene.

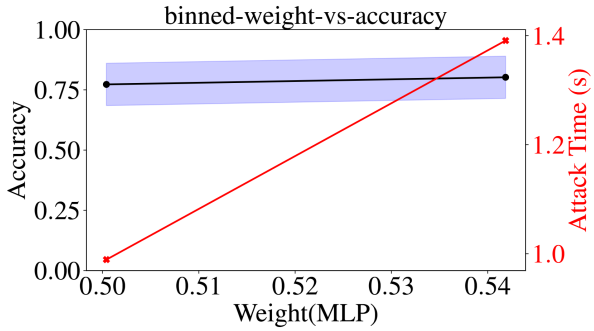

Fig. 6. Accuracy and attack time of Algorithm 1 with different weights and accuracy in Enron.

Fig. 4 shows the results in Enron, where α is 0.2, the accuracy rate is the highest, approximately 87%, and the attack time is about 1.5 seconds. α was selected as 0.05. Fig. 5 shows the results in Lucene, α is selected as 0.05, the attack time is approximately 1.3 seconds, and the accuracy rate is about 87%. In Fig. 6, when the weight keeps changing, the accuracy rate remains basically unchanged. The weight is selected as 0.5, with an accuracy rate of approximately 77% and an attack time of about 1.0 seconds. In Fig. 7, the weight is 0.55, with the highest accuracy rate of approximately 90%, and the

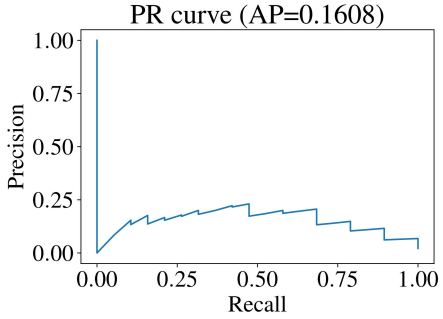

Fig. 9. Result of AP for Algorithm 1 using grid search for weights in Enron

attack time is about 1.8 seconds. The MLP can model the relationship between volume and frequency statistical features, thereby better adapting to the distribution discrepancy between the auxiliary dataset and the target dataset. The learned weights can dynamically adjust the contribution proportions of volume and frequency features, thus improving the generalization performance of the attack under different query distributions. In practical attack scenarios where the attacker only possesses incomplete auxiliary knowledge — for example, when the scale of the auxiliary document set is only half that of the target set — the MLP can mine latent correlations from limited data and maintain high query recovery accuracy.

Algorithm 1 conducts a comparative experiment of grid search and MLP learning volume and frequency weight to identify and recover unique queries. *BaseRec* is 45. Collect the differential distance. Manually divided HVHF queries are the actual queries to be recovered, as well as the prediction results of Algorithm 1 and F_r, V_r. Test the influence of grid search weight and MLP learning weight on Algorithm 1.

Fig. 8 and Fig. 11 are the Precision@K result graphs of the grid search weights of Algorithm 1 in Enron and Lucene. Algorithm 1, which only utilizes the grid search weight to recover the results of unique queries in Top-K, is indicated to be not ideal. Algorithm 1 focuses on how many of the top K of its prediction results are correct recoveries for unique queries. Because Algorithm 1 has a poor ability to recover unique queries, it will affect the performance of the entire attack algorithm. Algorithms with high classification accuracy but low Top-K accuracy are of no use to attacks. Fig. 9 and Fig. 12 show the PR curves in Enron and Lucene respectively. The average precision AP in Enron is 0.1608, and that in Lucene is 0.4058. Fig. 10 and Fig. 13 show the ROC curves in Enron and Lucene. The AUC value in Enron is 0.9204, and that in Lucene is 0.9712. In [22], the authors indicate that the keyword universe size is 1000, and the number of unique queries is approximately 18. Positive samples (unique queries) are extremely unbalanced, while PR and ROC curves are more sensitive and meaningful to the problem of sample imbalance.

Fig. 14 and Fig. 17 are the Precision@K result graphs

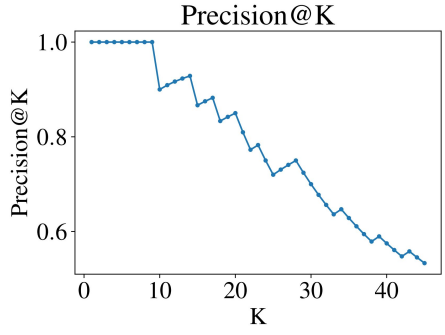

Fig. 17. Result of P_K for Algorithm 1 using MLP to learn weight in Lucene

of Algorithm 1 using MLP to learn the weights of volume and frequency in Enron and Lucene. In Enron and Lucene,

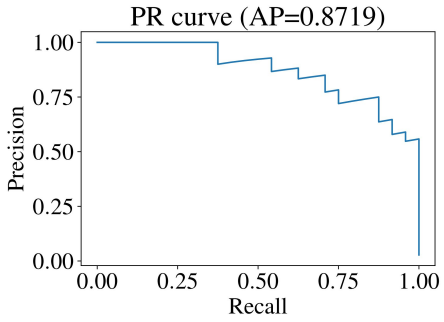

Fig. 18. Result of AP for Algorithm 1 using MLP to learn weight in Lucene

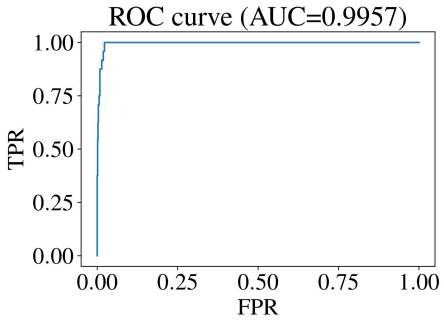

Fig. 19. Result of AUC for Algorithm 1 using MLP to learn weight in Lucene

the accuracy of K at 10 is nearly 1, Under Lucene, when K is between 0 and 10, the highest accuracy of the grid search method is only 0.6 (Fig. 11), while the accuracy of the MLP method is nearly 1 (Fig. 17). By comparing, it can be concluded that, regardless of which dataset, when K is any value within the interval, the MLP method is much more accurate than the grid search method. The accuracy of the MLP method in the Top-10 is nearly 1, significantly revealing that the Top 10 recovery results of Algorithm 1 are all recoveries of unique queries. The AP values in Enron and Lucene are 0.9364 (Fig. 15) and 0.8719 (Fig. 18), respectively. The AUC values are 0.9957 (Fig. 19) and 0.9984 (Fig. 16). In terms of AP values, the MLP method outperformed the grid search method by 83% and 53%, respectively, AUC values were 8% and 2% higher.

Algorithm 1 uses a small number of known queries to obtain a coefficient α for recovering the target query, and finally recovers the target query using volume and frequency. Test the impact of the known number of queries on the accuracy and attack time of Algorithm 1. Collect the accuracy rate and attack time of Algorithm 1 for each experiment under different known query numbers.

Fig. 20, when it is known that the number of queries is 1 and 2, the accuracy of Algorithm 1 is not stable. The lower quartile differs significantly from the upper quartile, and the data is highly dispersed and fluctuates greatly. Excluding outliers, the highest accuracy rate is 92%. In Fig. 21, when the number of known queries is small, the main reason for the unstable accuracy is that the selection of the Algorithm 1 coefficient α depends on the known queries. When the number

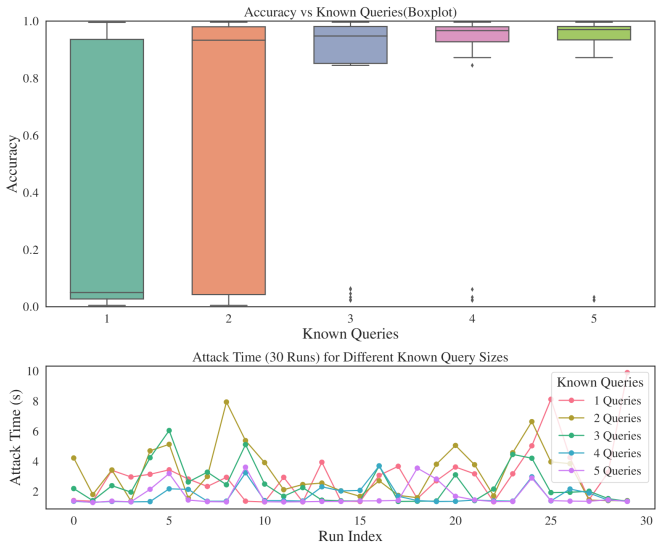

Fig. 20. Accuracy and per-attack time of Algorithm 1 with different known queries in Enron.

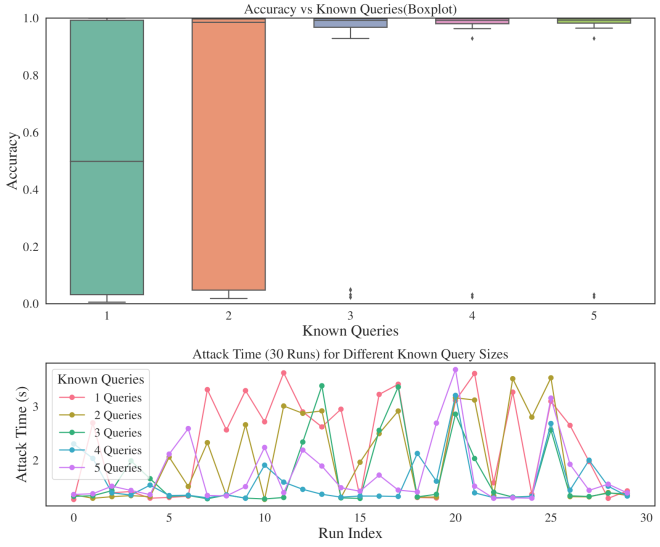

Fig. 21. Accuracy and per-attack time of Algorithm 1 with different known queries in Lucene.

is small, it is insufficient to support the selection of coefficients, resulting in unstable accuracy of Algorithm 1. The specific coefficients are shown in Fig. 4 and Fig. 5.

G. Attack Results and Durability

The following are the attack results of the entire algorithm and the impact of β on accuracy. *BaseRec* is 100 and *ConfRec* is 50. The size of the keyword space is 1000, the number of queries observed each week is 2000, and the total observation period is 50 weeks.

When $\beta = 0$, query recovery only relies on the embedding sub-matrix. Although it has a relatively high accuracy rate, in order to utilize the knowledge of weighted co-occurrence

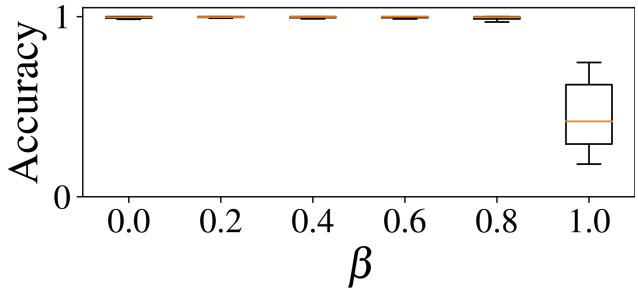

Fig. 22. Accuracy of the refine_atk under different β with embedding matrices in Enron.

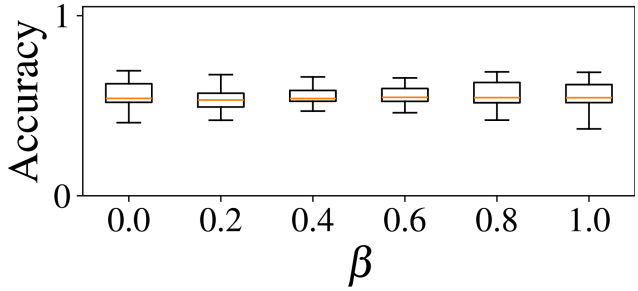

Fig. 23. Accuracy of the refine_atk under different β without embedding matrices in Enron.

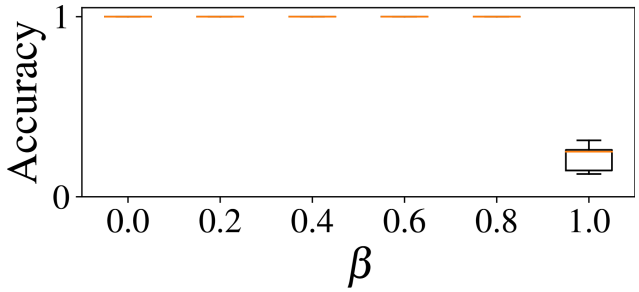

Fig. 24. Accuracy of the refine_atk under different β with embedding matrices in Lucene.

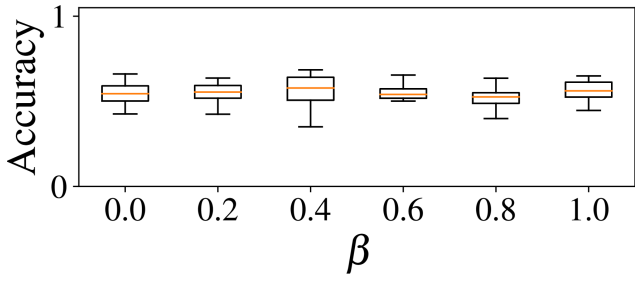

Fig. 25. Accuracy of the refine_atk under different β without embedding matrices in Lucene.

matrices, β is not set to 0. This indirectly reflects the significance of embedding sub-matrices for query recovery. Fig. 22 and Fig. 24 show the experimental results of the β value in Algorithm 3. When β = 1, query recovery only relies on the weighted co-occurrence matrix, with accuracy rates of 40% and 30% in Enron and Lucene, respectively. As β is reduced, by introducing an embedding sub-matrix, the accuracy rate is improved. The accuracy rate in Enron and Lucene is as high as 98%. This indicates that the embedding sub-matrix is crucial to Algorithm 3 and significantly enhances the attack performance. Without the embedding sub-matrix, the attack accuracy rate drops to around 50% [Fig. 23 and Fig. 25].

The embedding sub-matrix was introduced in Algorithm 3. The absence of an embedding sub-matrix will not affect the performance of Algorithm 1 and Algorithm 2, and unique queries can still be identified and recovered with high accuracy.

TABLE III. RESULT OF ATTACK ACCURACY FOR OUTDATED FREQUENCY UNDER DIFFERENT τ VALUES (IN WEEKS).

Dataset	τ (in weeks)			
	$\tau = 10$w	$\tau = 50$w	$\tau = 100$w	$\tau = 150$w
Enron	0.9879	0.9581	0.9272	0.9273
Lucene	0.9995	0.9774	0.9991	0.9890

The impact of "outdated" frequency on attack accuracy. "Outdated" refers to the time difference between the auxiliary frequency and the actual frequency. If the frequency information of the two overlaps less, the attack may fail. Durability refers to whether an attack can recover future queries by leveraging "outdated" frequency. Table III presents the experimental results for measuring the durability of attacks. The experiment used the frequency of Google Trends [37] from 1 to 50 weeks as the auxiliary information for attackers, and the frequency of 1 + τ to 50 + τ weeks was used to simulate the generation of user queries.

When τ is 10 and 50, the attack accuracy rates in Enron and Lucene decrease by 3% and 2%, respectively. When τ is 50 and 100, Enron drops by 3% and Lucene rises by 2%. When τ is 100 and 150, the attack accuracy rate in Enron remains basically unchanged, while it decreases by 1% in Lucene. The results show that the attack proposed in this study can still successfully recover future queries by leveraging the auxiliary frequency from a long time ago.

H. User Query Distribution

The impact of different query distribution on attack accuracy. The distribution for simulating the generation of user queries is "real", "poisson", "uniform", and "zipfian". "real" refers to the simulation of user query generation using the frequency of 1 + τ to 50 + τ weeks in Google Trends. "poisson" refers to generating query records that follow a Poisson distribution, simulating the random characteristic of "the number of times a keyword is queried within a unit of time". "uniform" refers to a uniform probability distribution, meaning that the probability of all keywords being queried is exactly the same, simulating the ideal situation where "users pay the same attention to all keywords". "zipfian" refers to generating queries that follow the Zipf distribution, which conforms to the practical rule that "a few keywords are frequently queried while the majority are infrequently queried". The attack parameters *BaseRec* is 45, *ConfRec* is 35, and β is 0.5. The size of the experimental parameter keyword space is 1000, the number of queries observed each week is 500, the observation period is 50, τ is 50, and the number of known queries is 15. The distribution of user queries generated

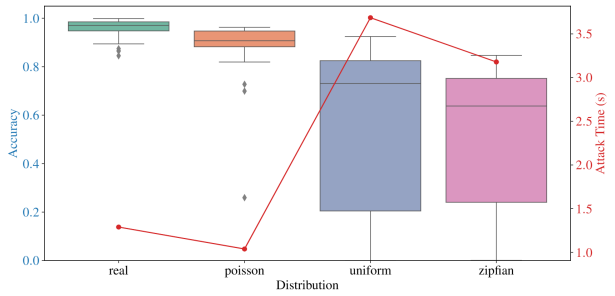

Fig. 26. Accuracy and average attack time of refine_atk under different distributions in Enron.

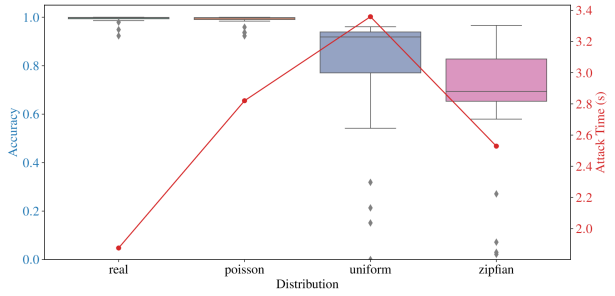

Fig. 27. Accuracy and average attack time of refine_atk under different distributions in Lucene.

is "real", "poisson", "uniform", and "zipfian". The following shows the results of the entire algorithm in Enron and Lucene.

In Fig. 26, the accuracy rate of the "real" distribution is as high as 97%. The average attack time of the "poisson" distribution is the shortest, at 1.1 seconds. The accuracy of "uniform" and "zipfian" is unstable because the queries generated by these two distributions contain a large number of difficult-to-recover LVLF queries. The average attack time of the "uniform" distribution is the longest, at 3.7 seconds. Fig. 27, the accuracy rates of the "real" and "poisson" distributions are 99%. The accuracy rates of "uniform" and "zipfian" are unstable, but perform better than Enron, with the lowest accuracy rate exceeding 60%. This is because the contents of the Lucene and Enron datasets are not related. Additionally, Lucene has a relatively large proportion of HVHF queries. The average attack time of the "uniform" distribution is the longest. The distribution that generates user queries has a certain impact on accuracy.

Table IV presents the results of paired t-tests, which compare the attack accuracy of the proposed refine_atk and the baseline Jigsaw Attack across two datasets (Enron and Lucene) under two keyword distributions (uniform and Zipfian). The core metrics include mean value, standard deviation, mean difference, p-value, Cohen's d effect size, and 95% confidence interval (CI).

Under the uniform distribution on the Enron dataset, refine_atk achieves an average accuracy of 0.9587, which is significantly higher than 0.8521 of Jigsaw Attack, with a mean improvement of 0.1067. Statistical tests confirm that the difference is statistically significant (p = 0.0012 $<$ 0.05), with a Cohen's d of 0.6548, indicating a medium-to-large effect size. The 95% CI [0.0458, 0.1675] does not contain zero, which further verifies the significance of the difference. The standard deviation of refine_atk is only 0.0074, much lower than 0.1620 of Jigsaw Attack, demonstrating that the attack results of refine_atk are extremely stable with negligible fluctuation across repeated experiments in this scenario.

The refine_atk achieves an average accuracy of 0.9678, substantially outperforming Jigsaw Attack (0.7261) with a mean improvement of 0.2417 under the uniform distribution on Lucene. The difference is highly statistically significant (p $<$ 0.0001), with a Cohen's d of 1.0842, which corresponds to a large effect size and indicates a pronounced performance gap between the two attacks. The 95% CI [0.1584,0.3249] does not contain zero, validating the statistical significance. Meanwhile, the standard deviation of refine_atk is only 0.0112, while that of Jigsaw Attack reaches 0.2261, highlighting the remarkable robustness advantage of the proposed method.

Jigsaw Attack achieves an average accuracy of 0.7894, which is significantly higher than 0.6370 of refine atk under the Zipfian distribution on Enron, with a mean difference of -0.1524. The difference is highly statistically significant (p $<$ 0.0001), with a Cohen's d of -0.8897, representing a large effect size. The 95% CI [-0.2163, -0.0884] does not contain zero, confirming the significance of the difference. The standard deviation of refine atk is 0.1706, much higher than 0.0593 of Jigsaw Attack, indicating that the attack results of refine atk fluctuate greatly in this scenario and its stability is inferior to the baseline method.

The accuracy of the two methods is nearly comparable under Zipfian distribution on Lucene: with a mean difference of only -0.0049. Statistical tests show that $p = 0.8438$, which is far greater than 0.05, indicating no statistically significant difference between the two methods. The Cohen's d is -0.0363, representing a negligible effect size, which means the performance of the two attacks is essentially equivalent in this scenario. With the exception of the Lucene-Zipfian combination, the remaining groups of comparisons reach statistical significance with effect sizes of medium level or above. This result demonstrates that the observed performance differences are not caused by random errors, but are genuine gaps derived from the inherent characteristics of the algorithms.

IV. Attack Experiment and Performance Analysis

This study will compare the performance of the refine_atk (Ours) attack with the Jigsaw attack [22], RSA attack [14], and IHOP attack [24].

A. Experimental Settings and Attack Parameters

The keyword space is the top $|W|$ keywords in terms of volume ranking. Evaluate the above attacks for different $|W|$ values (500, 1000, 2000). Suppose the attacker knows the frequency of each keyword in the keyword space in the first 50 weeks. By leveraging the frequency of 50 to 100 weeks in Google Trends, generate η queries per week, with τ = 50. η is 100, 500 and 2500.

Briefly introduce the attack parameters required for the above-mentioned attack and the reasons for their values. The

TABLE IV. STATISTICAL RESULTS OF ATTACK ACCURACY COMPARISON[1]

Dataset	Distribution	Refine_atk		Jigsaw Attack		Mean Diff.	p-value	Cohen's d	95% CI	
		Mean	Std	Mean	Std				Lower	Upper
Lucene	zipfian	0.6904	0.1242	0.6953	0.0534	-0.0049	0.8438	-0.0363	-0.0553	0.0455
Lucene	uniform	0.9678	0.0112	0.7261	0.2261	0.2417	< 0.0001	1.0842	0.1584	0.3249
Enron	zipfian	0.6370	0.1706	0.7894	0.0593	-0.1524	< 0.0001	-0.8897	-0.2163	-0.0884
Enron	uniform	0.9587	0.0074	0.8521	0.1620	0.1067	0.0012	0.6548	0.0458	0.1675

[1] All experiments are conducted with a keyword universe size of 1000 and 30 iterations.

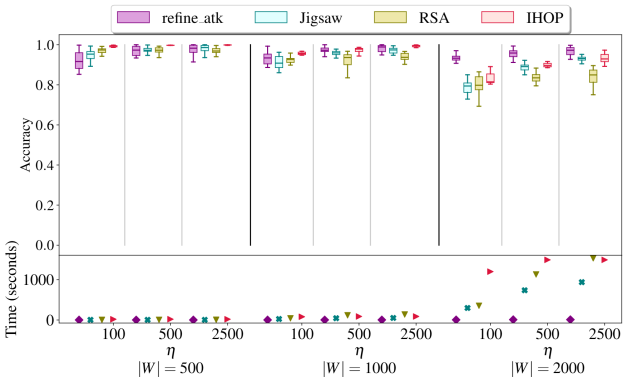

Fig. 28. Comparison of accuracy and time under different attacks in Enron.

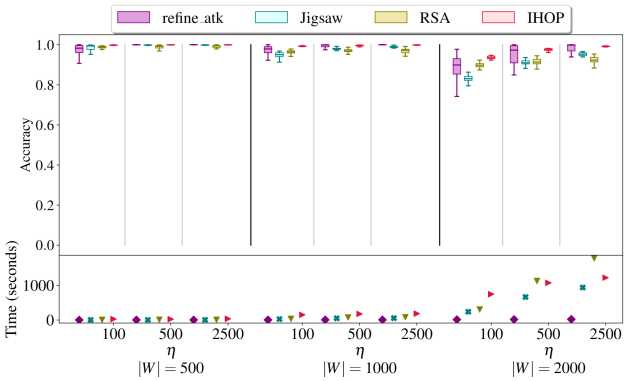

Fig. 29. Comparison of accuracy and time under different attacks in Lucene.

selection of β, *BaseRec* and *ConfRec* significantly affects the accuracy of refine_atk attacks. For β, select a value between 0.2 and 0.8 (Fig. 22). Fig. 6 has shown that without the embedding sub-matrix, the attack accuracy rate drops to 50%. Consider embedding sub-matrices and choose a relatively β, such as 0.5. The minimum *ConfRec* of Jigsaw [22] is 5. If *ConfRec* < 5, Algorithm 2 only correctly recovers < 5 queries, so that Algorithm 3 almost has to recover all user queries. Algorithm 1 and Algorithm 2 do not offer any favorable conditions for the query recovery task, which goes against the original design intention of the entire algorithm. *BaseRec* and *ConfRec* are 45 and 35, respectively, consistent with Jigsaw [22]. The refine_atk is known to have 15 queries. However, during the experiment, these queries are still regarded as "unknown".

For other attack parameters, for Jigsaw attack [22], α is 0.3, β is 0.9. *RefSpeed* controls the number of queries recovered in each iteration. If there are defense measures, increase the *RefSpeed* to reduce the attack time and improve the accuracy. RSA is known to have 10 queries, that is, it randomly selects 10 queries and reveals the underlying plaintext keywords. $|W| \leq 2000$, *RefSpeed* is 10; $|W| > 2000$, *RefSpeed* is 50 [22]. The *RefSpeed* parameter setting strategy for RSA is consistent with that of Jigsaw. The p_{free} of IHOP is 0.25 and that of n_{iters} is 500.

In Fig. 28, the attack accuracy of refine_atk(Ours) is comparable to that of Jigsaw and IHOP. when $|W|$ increases, the attack accuracy rates of Jigsaw, RSA and IHOP decline, but the refine_atk can still remain $> 90\%$. This is because a larger $|W|$ will introduce more low-volume queries that are difficult to recover. The attack time of refine_atk does not fluctuate too much with the changes of $|W|$ and η, and always remains stable. $|W| = 2000$, the attack time of Jigsaw is greater than 500 seconds, and RSA and IHOP are greater than 1000 seconds. This is disadvantageous in some cases because when the attack lasts too long, some databases or systems will record such attack behaviors and issue alerts.

In Fig. 29, when $|W| = 2000$ and $\eta = 100$, the attack accuracy of IHOP is even higher than the refine_atk. The fundamental reason is the extreme sparsity of statistical information. In this case, IHOP's global iterative Hungarian algorithm recovers the global structure from sparse co-occurrence more effectively than refine_atk stagewise greedy strategy, and refine_atk suffers from a severe shortage of HVHF seeds. However, in practical application scenarios, refine_atk outperforms IHOP and other existing attacks by leveraging semantic embeddings, efficient stagewise recovery, and strong robustness. The experimental results in the study confirm this (in Fig. 29, under the vast majority of parameter combinations, refine_atk achieves an accuracy of $\geq 90\%$, and its attack time is far lower than that of IHOP).

B. Refine_atk Ablation Study

1) Known queries ablation experiment: Algorithm 1 recovers unique queries with the aid of known queries. This study now investigates the impact of known queries on the attack performance of Algorithm 1, as shown in Fig. 30. We conducted 30 independent attack simulations on the Enron and Lucene datasets. The keyword space size is $|W|$=1000, *BaseRec*=1000, *ConfRec*= None, the number of observed queries per week $\eta = 5000$, the observation period is 30 weeks, $\tau = 0$, and the user query distribution is "real". In Fig. 30, "enron-kq" denotes the experiment on the Enron dataset with the aid of known queries, while "enron" denotes the experiment without known queries.

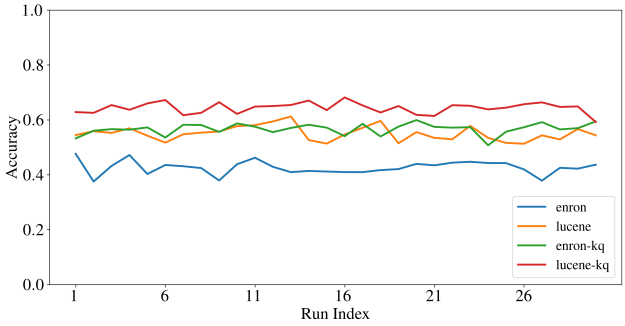

Fig. 30. Ablation study of the known queries component in Algorithm 1.

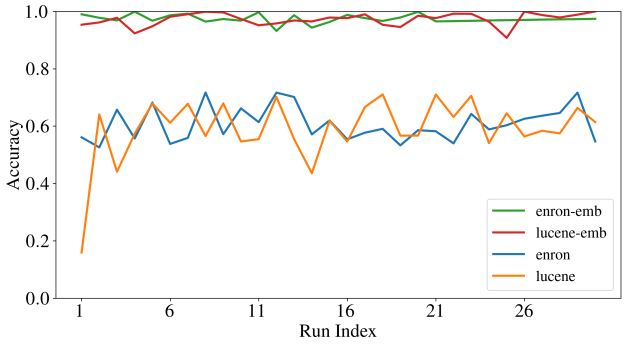

Fig. 31. Ablation study of the semantic embedding component in Algorithm 3.

The accuracy of enron-kq improved by approximately 0.1–0.15 over enron, increasing from 0.4–0.5 to 0.5–0.6, while lucene-kq improved by about 0.1 over lucene, from 0.5–0.6 to 0.6–0.7. It can be observed that the accuracy achieved with known queries is not very high. This is because when *BaseRec*=1000, Algorithm 1 recovers 1000 queries as unique queries, whereas in practice, for a keyword space size of 1000, there are only about 18 unique queries [22].*BaseRec*=1000 far exceeds the actual number of unique queries, leading to the low accuracy of Algorithm 1. Therefore, a lower *BaseRec* value can be set to improve accuracy; please refer to Section III-F for the value of *BaseRec*.

2) Semantic ablation experiment: As shown in Fig. 31, Algorithm 3 in Section III-D recovers the remaining queries at one time with the help of semantic embedding. This section investigates the impact of semantic embedding on the overall attack algorithm. We conducted 30 independent attack experiments on the Enron and Lucene datasets, respectively. The experimental settings are as follows: the keyword space size $|W| = 1000$, $\beta = 0.5$, *BaseRec*=100, *ConfRec*=25, the number of observed queries per week $\eta = 5000$, the number of observed weeks is 30, $\tau = 0$, the number of known queries is 15, and the user query distribution is "real". In Fig. 31, "enron-emb" denotes the experiment with semantic embedding on the Enron dataset, and "enron" denotes the experiment without semantic embedding.

After introducing semantic embedding, the accuracy of "enron-emb" and "lucene-emb" is almost stable between 0.95 and 1.0, while the attack accuracy without semantic embedding is only between 0.4 and 0.7, which is much lower than that

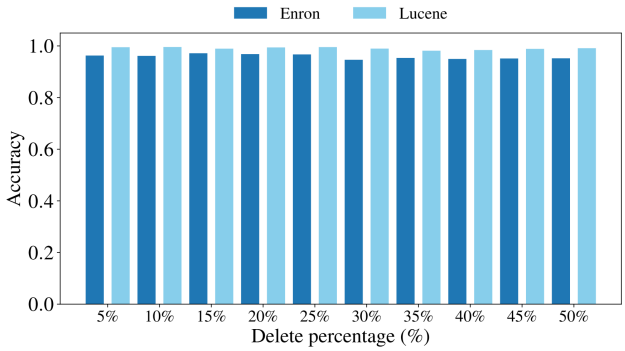

Fig. 32. Comparison of accuracy and delete percentage in Enron and Lucene.

of the attack with semantic embedding. Semantic embedding is a key factor to improve attack accuracy, as it provides additional semantic information for query recovery. The attack performances of the Enron and Lucene datasets show almost no difference, indicating that the attack method with semantic embedding has good generalization to different datasets. The initial fluctuation of Lucene is obvious, which is related to the keyword distribution of the dataset.

C. Delete Similar Data

An experiment on the impact of deleting some similar data on attack accuracy and the recovery of the top 10 high-frequency queries under the partial deletion ratio of Algorithm 1. Deleting partially similar data refers to the assumption that the size of similar data documents is 50 and the deletion ratio is 50%, that is, 50% of the similar data documents are retained, which is 25 documents. The attacker only used these 25 documents to generate the keyword-document matrix, while the real data documents always maintained the size after division. Under the partial deletion ratio, record the number of occurrences of each query in all pellations in the recovery results of Algorithm 1. Each query is sorted in descending order of its occurrence frequency as a list of high-frequency queries. Filter out the pairings that "the query is not on the high-frequency list" or "the predicted keyword is not on the high-frequency list", and retain the top 10 valid pairings where both parties belong to the high-frequency list. The deletion ratio is 5%, ..., 50%. Thirty experiments were independently simulated under each dataset and deletion ratio, and the accuracy of each experiment was collected. Each round of the simulated attack is conducted independently, and there is no mutual interference between different test runs.

When the deletion ratio is 5%, 10%, 15%, 20% and 25%, the attack accuracy rate is slightly higher than that of other ratios. This rule is reflected in both datasets [Fig. 32]. The accuracy rate of the deletion ratio of 5%, 10%, 15%, 20% and 25% in Enron was 96%. The accuracy rate of deletion ratios of 30%, 35%, 40%, 45% and 50% in Lucene is 97%. Regardless of the deletion ratio, the attack accuracy rate is all $>$ 95%. The number of auxiliary documents used by the attacker to recover the query is only half of the user's real documents. Under such unfavorable circumstances, the refine_atk attack can still achieve an accuracy rate of $>$ 90%. In practical scenarios, attackers typically have only limited

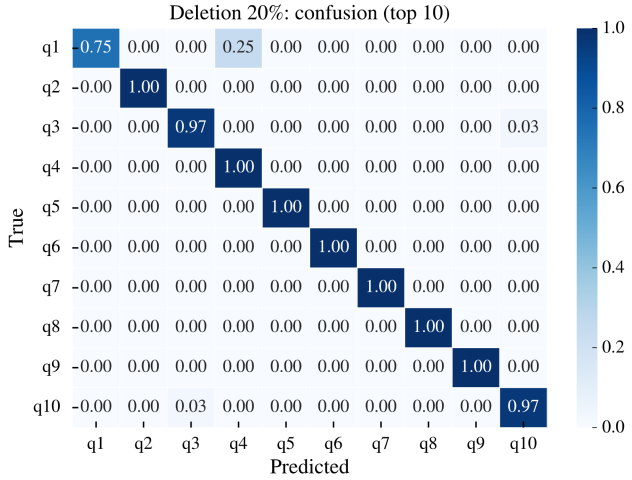

Fig. 33. Recovery results of the top 10 high-frequency queries by Algorithm 1 under 20% ratio. The vertical axis represents the labels of real queries.The horizontal axis represents the labels of the corresponding predicted keywords. (q1, q3) indicates that the real label q3 is predicted as q1.

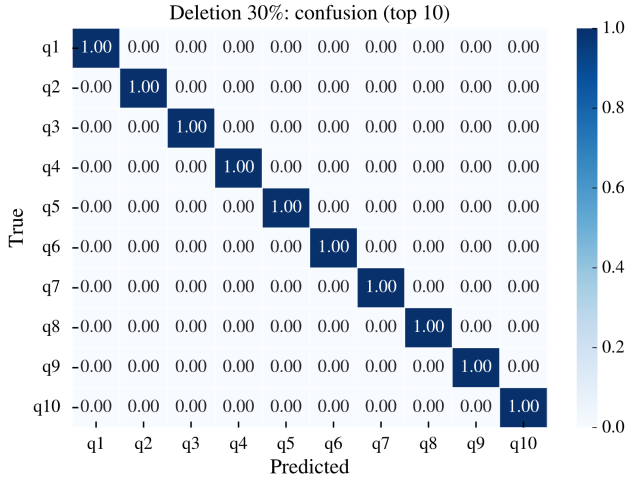

Fig. 34. Recovery results of the top 10 high-frequency queries by Algorithm 1 under ratio 30%.

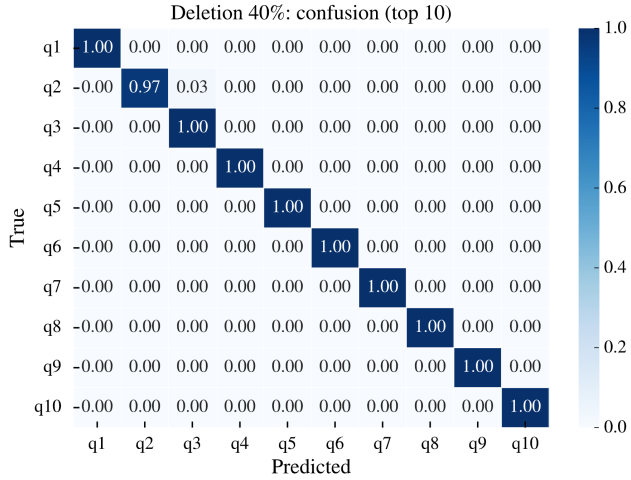

Fig. 35. Recovery results of the top 10 high-frequency queries by Algorithm 1 under ratio 40%.

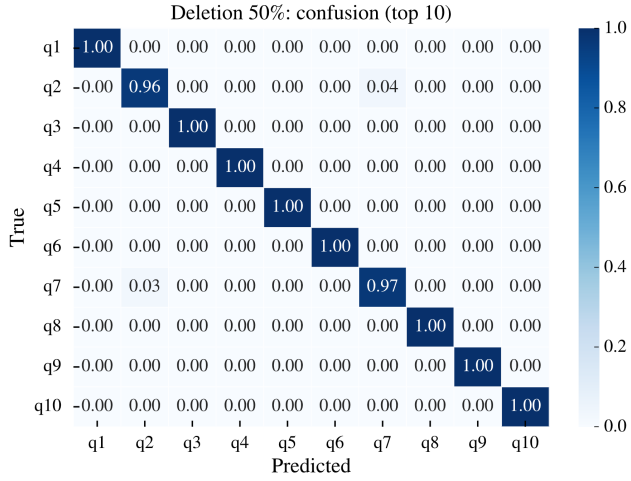

Fig. 36. Recovery results of the top 10 high-frequency queries by Algorithm 1 under ratio 50%.

auxiliary knowledge. Even under this restrictive condition, the proposed attack can still successfully recover users' underlying keywords, which alerts users that their query behaviors entail potential privacy leakage risks.

This shows the recovery of the top 10 high-frequency queries under the partial deletion ratio of Algorithm 1. Fig. 33 shows that the probability of correct recovery for query q1 is relatively low, at 0.75. Recover to q4 with a probability of 0.25. q3 and q10 were correctly recovered with a probability of 0.97. Fig. 34 shows that the probability of correct recovery for query q1-q10 is relatively high, nearly 1. Fig. 35 shows that the probability of correct recovery for query q2 is 0.97. Fig. 36 shows that queries q2 and q7 were correctly recovered with probabilities of 0.96 and 0.97 respectively. This proves the experimental conclusion in Fig. 32, that is, when the attacker auxiliary knowledge is relatively limited, the attack proposed in this study can still correctly recover high-frequency queries with a probability of nearly 1. This suffices to demonstrate the robustness of Algorithm 1 and its sensitivity to HVHF queries. Algorithm 1 exhibits sound generalization performance on both datasets.

V. Conclusion

The proposed attack, refine_atk, performs excellently in most cases. The Algorithm 3 encodes unrecovered queries and unpaired keywords with the help of a pre-trained language model. The refine_atk is tested on different datasets, and the attack accuracy is around 95%. The attack time is much lower than other attacks. Compared with Jigsaw [22], under different datasets and parameters of *BaseRec* and *ConfRec*, the refine_atk achieves higher attack accuracy, more correctly recovered queries, and a recovery rate comparable to that in [22].Algorithm 1, in this study can significantly improve the attack accuracy in Top-10, and can even utilize the weights of query learning capacity and frequency such as LVLF (HVLF, LVHF). The attack performance remains robust when auxiliary

knowledge is limited. In defense evaluation, more advanced defense mechanisms such as semantic obfuscation or synonym expansion should be considered.

The query recovery attack can be extended to dynamic searchable symmetric encryption (DSSE) scenarios. Most existing query recovery attacks are modeled on static document collections, whereas dynamic update operations, such as document addition, deletion and modification, are ubiquitous in practical cloud storage environments and introduce additional novel leakage sources, including update patterns and temporal access correlations. Future work can leverage the leakage characteristics inherent in the dynamic update process to evaluate the query privacy leakage risks of state-of-the-art DSSE schemes in dynamic scenarios. Therefore, it is crucial to develop a secure and practical SSE scheme that can resist semantic-level attacks to protect user data security.

ACKNOWLEDGMENT

This study was supported by the Key Project of the University-Level Scientific Research Innovation Project of Gansu University of Political Science and Law (Grant No. GZF2025XZD27). The authors would like to express their sincere gratitude to the funding organization for its support of this research.

Multiplicative Gate State Space Models with Skip-Net for High Accuracy COVID-19 Time-Series Prediction

Krung Sinapiromsaran, Supakit Sroynam
Faculty of Science-Department of Mathematics and Computer Science,
Chulalongkorn University, Bangkok, Thailand

***Abstract*—The rapid propagation of the COVID-19 pandemic has placed unprecedented strain on global healthcare systems, creating an urgent need for accurate forecasting to optimize resource allocation and policy implementation. However, the highly non-linear and chaotic behavior of infection rates poses significant challenges for traditional statistical and standard deep learning models. This study proposes the Multiplicative Gating State Space Model with skip connection (MG-SSM-s), a novel architecture designed to capture complex temporal dependencies in epidemiological time series. Drawing inspiration from partial autocorrelation, the model extends modern State Space Models (SSMs) by incorporating a learnable multiplicative side channel to dynamically modulating input processing. We evaluated the efficacy of MG-SSM-s using the Google COVID-19 Open Data repository, analyzing daily confirmed cases across 40 countries, including major epicenters such as the USA, India, and Brazil. Using a 30-day look-back window, the proposed model was benchmarked against four baseline architectures: LSTM, Bi-LSTM, GRU, and standard SSM. Performance verification based on Mean Squared Error (MSE) demonstrates that MG-SSM-s outperforms all deep learning baselines and achieves competitive accuracy with a tuned ARIMA model, demonstrating comparable statistical performance to the latter. These results highlight the framework's robustness and potential as a versatile tool for time-series forecasting.**

Keywords*—State Space Model; COVID-19; time-series forecast; univariate time-series

I. Introduction

The COVID-19 pandemic exposed critical vulnerabilities in public health forecasting infrastructure. As infection rates accelerated, healthcare systems faced severe resource constraints, particularly in managing hospital bed capacity, ventilator supplies, and staffing shortages. A primary barrier to effective management was the volatility of daily case counts, which severely hindered proactive capacity planning. Consequently, developing robust methods to forecast epidemiological time-series has become essential for long-term pandemic preparedness.

COVID-19 transmission dynamics exhibit highly non-linear, non-stationary behaviors that challenge traditional statistical modeling. Infection rates rely on multiplicative interactions between transmission rates, susceptible population densities, and contact frequencies [1]. Moreover, sudden shocks, including policy interventions, viral variants, and behavioral shifts, trigger abrupt regime changes that standard time-series models often misclassify as noise [2]. While machine learning architectures have advanced time-series forecasting, simultaneously capturing non-linear multiplicative dynamics, high-frequency volatility, and long-range temporal dependencies remains an open challenge. To address these limitations, we propose the Multiplicative Gating State Space Model with skip connection (MG-SSM-s), an architecture designed specifically for volatile epidemiological data.

MG-SSM-s extends modern State Space Models with a learnable multiplicative gating mechanism and skip connections, achieving a separation between global trends and volatility. The design is inspired by autocorrelation concepts, where multiplicative product interactions enable the model to capture dependencies across multiple temporal lags. This process is similar to how partial autocorrelation identifies significant historical correlations, while skip connections preserve sudden shocks that linear state transitions would otherwise attenuate. By maintaining parallel pathways for trend and volatility, MG-SSM-s retains both long-range awareness and sensitivity to sudden shifts critical for pandemic forecasting.

A. Contributions

The primary contributions of this research are fourfold:

- Novel Hybrid Architecture: MG-SSM-s extends standard State Space Models by incorporating a learnable multiplicative gating mechanism and skip connection, enabling non-linear expression of temporal dependencies.
- Theoretically-Inspired Design: The multiplicative gate is inspired by autocorrelation concepts, enabling the model to dynamically identify and weight relevant temporal patterns, with an explicit skip connection preserving immediate input shocks.
- Comprehensive Evaluation: We evaluate MG-SSM-s on COVID-19 case forecasting datasets from 40 countries against established baselines, including LSTM, Bi-LSTM, GRU, and vanilla SSMs, demonstrating superior performance on non-stationary epidemic data.
- Practical Applicability for Epidemic Forecasting: The architecture is designed for univariate time series forecasting with linear computational complexity, making it suitable for real-time deployment across diverse healthcare systems during active pandemics.

The remainder of this study is organized as follows: Section II reviews related literature in epidemiological forecasting and State Space Models, highlighting the research gaps motivating MG-SSM-s. Section III defines the Autocorrelation Function (ACF) and Partial Autocorrelation Function (PACF). Section IV details the architectural design of the proposed model, and Section V evaluates its performance on COVID-19 datasets. Finally, Section VI concludes the study and outlines future research directions.

II. Related Work

A. Traditional Statistical Methods in Epidemic Forecasting

Early COVID-19 forecasting efforts relied heavily on statistical linear models, most notably the Autoregressive Integrated Moving Average (ARIMA) and its variants [3]. ARIMA models operate by transforming non-stationary data into a stationary series through differencing, then predicting future values based on a linear combination of past errors and past values. While ARIMA provides mathematical interpretability and works well for simple linear trends, it fundamentally struggles with the chaotic volatility and non-linear dynamics of pandemic data. Its reliance on linear assumptions and stationarity makes it ill-suited for capturing the abrupt infection waves and complex environmental interactions characteristic of COVID-19 propagation.

In a comprehensive analysis, it was demonstrated that meteorological factors, such as temperature, relative humidity, and wind speed, exhibit nonlinear correlations with daily new COVID-19 cases across different regions [4]. This nonlinearity persists even when controlling for confounding factors, indicating that pandemic transmission follows non-linear mechanistic principles that linear statistical models cannot express.

B. Deep Learning Approaches for Epidemic Time-Series Forecasting

To address ARIMA's limitations, Deep Learning (DL) approaches were widely adopted for COVID-19 prediction [5], with the Long Short-Term Memory (LSTM) network developed by [6] emerging as a standard baseline. LSTMs overcome limitations of standard RNNs through a memory cell state modulated by three distinct gates (input, forget, output), allowing selective retention or discarding of information over long sequences [7]. In COVID-19 forecasting, LSTMs have demonstrated the ability to learn non-linear infection trends that ARIMA misses [8]; however, they often struggle to capture very sharp, high-frequency changes (sudden spikes from variants or policy shifts) due to the slow adaptation of recurrent cell states.

1) Bidirectional LSTMs (Bi-LSTM): Bidirectional LSTM architectures, such as those introduced by [9], enhance context awareness by processing data bidirectionally. By concatenating hidden states from both directions, the model gains temporal features surrounding each time step. While bidirectional flow improves interpolation and noise smoothing, it substantially increases computational costs and does not fundamentally solve the modeling of immediate, shock-like volatility in real-time forecasting scenarios where future data is unavailable.

2) Gated Recurrent Units (GRU): The Gated Recurrent Unit, proposed by [10], offers a more computationally efficient alternative by merging the cell state and hidden state and combining input and forget gates into a single update gate. This simplification enables faster training and convergence, particularly advantageous when modeling multiple countries simultaneously. However, the GRU shares a fundamental limitation with LSTM: reliance on dense recurrence that becomes opaque and difficult to optimize for extremely long historical contexts, often leading to performance degradation when the look-back window is extended significantly.

C. State Space Models for Time-Series Forecasting

Recently, State Space Models (SSMs) have gained prominence as a powerful alternative to Transformers and RNNs for time-series tasks. The Structured State Space Sequence (S4) model introduced by [11], [12] pioneered this resurgence by combining continuous-time representations from control systems with deep learning. S4 utilizes a low-rank HiPPo matrix initialization to compress infinite-context history into a finite state, enabling efficient handling of extremely long-range dependencies via the convolution theorem during training. However, while S4 excels at capturing global trends over long horizons, its linear time-invariant (LTI) nature can be too rigid for non-stationary pandemic systems undergoing rapid structural changes, such as virus mutations or abrupt policy shifts.

More recently, an advancement to the SSM paradigm was introduced via a selection mechanism that allows system matrices to be functions of the input [13]. This formulation makes the model time-varying and input-selective, which enables it to distinguish between relevant and irrelevant information at each time step, thereby solving the content-aware limitations of S4.

However, directly deploying an unconstrained vanilla Mamba block onto raw, univariate time-series data introduces architectural vulnerabilities. Because standard selective SSMs are optimized to compress dense, multi-channel representations, applying them to low-dimensional, short-horizon vectors yields severe over-parameterization and rapid latent state saturation.

III. Background Knowledge

A. Autocorrelation and Partial Autocorrelation

Time-series forecasting relies fundamentally on analyzing the dependency of a variable on its past values. Two statistical measures are paramount in characterizing these temporal dependencies: the Autocorrelation Function (ACF) and the Partial Autocorrelation Function (PACF).

1) Autocorrelation Function (ACF): The ACF quantifies the linear relationship between a time-series X_t and a lagged version of itself X_{t-k}, accounting for both direct influence and indirect influence propagated through intermediate time steps $(X_{t-1}, \ldots, X_{t-k+1})$. Formally, for a stationary time-series, the autocorrelation coefficient at lag k, denoted as ρ_k, is defined as:

$$\rho_k = \frac{\text{Cov}(X_t, X_{t-k})}{\sqrt{\text{Var}(X_t)\text{Var}(X_{t-k})}} = \frac{\gamma_k}{\gamma_0} \tag{1}$$

where, γ_k is the autocovariance at lag k and γ_0 is the variance. In the context of deep learning, Recurrent Neural Networks (RNNs) naturally model this accumulated dependency through their hidden state updates.

2) Partial Autocorrelation Function (PACF):: While the ACF formulation in Eq. (1) captures total correlation, it fails to isolate the specific contribution of X_{t-k} independent of intervening lags. The PACF addresses this limitation by measuring the correlation between X_t and X_{t-k} after removing the linear dependence explained by the intermediate lags $\{X_{t-1}, \ldots, X_{t-k+1}\}$. Mathematically, the partial autocorrelation ϕ_{kk} at lag k is expressed as the correlation of the residuals in Eq. (2):

$$\phi_{kk} = \text{Corr}(X_t - \hat{X}_t, X_{t-k} - \hat{X}_{t-k}) \tag{2}$$

where, $\hat{X}_t$ and $\hat{X}_{t-k}$ represent the linear projections of X_t and X_{t-k}, respectively, onto the space spanned by the intermediate set $\{X_{t-1}, \ldots, X_{t-k+1}\}$.

The distinction between the total correlation in Eq. (1) and the isolated dependency in Eq. (2) inspires the proposed MG-SSM-s architecture. Standard State Space Models capture past context through recursive state equations. However, to capture dependencies, where X_{t-k} directly influences X_t without intermediate smoothing, a mechanism analogous to the PACF is required. The proposed skip-connection and multiplicative gating mechanism serve this purpose by providing a direct channel to model specific lagged dependencies that standard recurrence might otherwise oversmooth.

B. State Space Model (SSM)

The State Space Model (SSM) serves as a foundational framework for modeling dynamic systems in control theory and signal processing. In the context of deep learning, it allows for the parameterization of dependencies in sequence data through a latent state representation. A Continuous-Time Latent State Model defines a system, where an input signal $u(t) \in \mathbb{R}^D$ drives a latent state $x(t) \in \mathbb{R}^N$, which is subsequently projected to an observable output $y(t) \in \mathbb{R}^D$ [14].

Mathematically, the dynamics of this system are governed by the linear ordinary differential equations (ODEs) defined in Eq. (3) and Eq. (4):

$$x'(t) = \mathbf{A}x(t) + \mathbf{B}u(t) \tag{3}$$
$$y(t) = \mathbf{C}x(t) + \mathbf{D}u(t) \tag{4}$$

The system is parameterized by the state evolution matrix $\mathbf{A} \in \mathbb{R}^{N\times N}$ in Eq. (3), which governs the internal dynamics of the hidden state, and the input projection matrix $\mathbf{B} \in \mathbb{R}^{N\times D}$. The latent state is mapped to the observed data via the output projection matrix $\mathbf{C} \in \mathbb{R}^{D\times N}$ in Eq. (4). The final term, $\mathbf{D} \in \mathbb{R}^{D\times D}$, represents a direct feedthrough connection from input to output. In modern structured state space architectures, such as S4 and Mamba, this feedthrough term is frequently omitted from the core ODE dynamics and instead implemented as a separate, learnable residual connection to facilitate optimization.

1) Discretization and Recurrent Form: To facilitate the processing of discrete data sequences, the continuous-time dynamics must be discretized. Modern SSM architectures typically adopt the Zero-Order Hold (ZOH) principle, which posits that the input signal $u(t)$ remains constant within the sampling interval Δ. The discretization process transforms the continuous parameters $(\mathbf{A}, \mathbf{B})$ into their discrete counterparts $(\bar{\mathbf{A}}, \bar{\mathbf{B}})$. The discrete state transition matrix is defined via Eq. (5):

$$\bar{\mathbf{A}} = \exp(\Delta\mathbf{A}) \tag{5}$$

While the input projection matrix $\bar{\mathbf{B}}$ is derived via integration over the sampling period, as shown in Eq. (6):

$$\bar{\mathbf{B}} = (\Delta\mathbf{A})^{-1}(\exp(\Delta\mathbf{A}) - \mathbf{I}) \cdot \Delta\mathbf{B} \approx \mathbf{A}^{-1}(\bar{\mathbf{A}} - \mathbf{I})\mathbf{B} \tag{6}$$

Consequently, the system can be expressed as a linear recurrence via Eq. (7) and Eq. (8), highlighting the structural parallel between discretized SSMs and Recurrent Neural Networks (RNNs):

$$x_t = \bar{\mathbf{A}}x_{t-1} + \bar{\mathbf{B}}u_t \tag{7}$$
$$y_t = \mathbf{C}x_t \tag{8}$$

In standard Linear Time-Invariant (LTI) SSMs (e.g., S4), the matrices $\bar{\mathbf{A}}$ and $\bar{\mathbf{B}}$ in Eq. (7) are constant across all time steps. This stationarity allows for efficient parallel processing but limits the model's ability to adapt its dynamics to specific input tokens. Recent advancements in structured state-space models, most notably Mamba [13], address the limitations of static content compression by introducing a selection mechanism. By defining the system matrices $(\mathbf{A}, \mathbf{B}, \Delta)$ as functions of the input, these models effectively transform the architecture from an LTI system into a time-varying linear recurrence. While this input-selectivity significantly enhances the model's ability to distinguish relevant context within long sequences, it fundamentally alters the computational dynamics, as the loss of time-invariance.

IV. Methodology

A. Model Structure

The Multiplicative Gating State Space Model with skip connection (MG-SSM-s) is defined by the system of equations parameterized by the learnable set $(\mathbf{A}, \mathbf{B}, \mathbf{C}, \mathbf{D}, \mathbf{E}, \mathbf{F}, \mathbf{J})$ in Eq. (9) to Eq. (11):

$$h_t = \mathbf{A}h_{t-1} + \mathbf{B}x_t \tag{9}$$
$$g_t = (\mathbf{E}g_{t-1}) \odot \tilde{x}_t + \mathbf{F}x_t \tag{10}$$
$$y_t = \mathbf{C}h_t + \mathbf{D}x_t + \mathbf{J}g_t \tag{11}$$

where, $\odot$ denotes the element-wise (Hadamard) product. The term $\tilde{x}_t \in \mathbb{R}^m$ represents the scalar input x_t projected into the latent gate dimension via the all-ones vector $\mathbf{1}_m \in \mathbb{R}^m$, such that $\tilde{x}_t = x_t \cdot \mathbf{1}_m$. This operation ensures that the

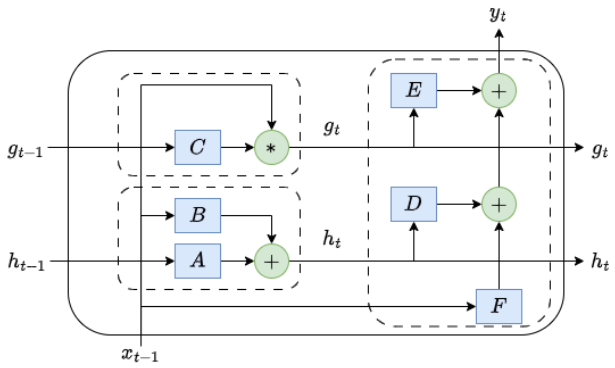

Fig. 1. Architecture of the Multiplicative Gating State Space Model with skip connection (MG-SSM-s).

scalar input modulates each channel of the latent gate state g_t uniformly. Fig. 1 presents the architecture of the Multiplicative Gating State Space Model with skip connection (MG-SSM-s).

The model processes a univariate input sequence $X = (x_1, \ldots, x_T) \in \mathbb{R}^T$ to produce an output sequence $Y = (y_1, \ldots, y_T) \in \mathbb{R}^T$. The internal memory is decoupled into two distinct pathways: a main linear state $h_t \in \mathbb{R}^l$ (where, l is the latent dimension) evolving via Eq. (9), and a multiplicative gate state $g_t \in \mathbb{R}^m$ (where, m is the gate dimension) governed by Eq. (10).

The linear state h_t in Eq. (9) evolves via standard LTI dynamics using the transition matrix $\mathbf{A} \in \mathbb{R}^{l\times l}$ and input projection $\mathbf{B} \in \mathbb{R}^{l\times 1}$. The gated state g_t in Eq. (10) introduces non-linearity through a two-step mechanism: first, the previous state g_{t-1} is transformed by $\mathbf{E} \in \mathbb{R}^{m\times m}$ and modulated element-wise by the input; second, a direct skip connection parameterized by $\mathbf{F} \in \mathbb{R}^{m\times 1}$ is added. This skip connection is crucial for expanding the recursive multiplicative terms into higher-order interaction terms.

The final output y_t, modeled in Eq. (11), aggregates information from the projected main state (via $\mathbf{C} \in \mathbb{R}^{1\times l}$), the gated state (via $\mathbf{J} \in \mathbb{R}^{1\times m}$), and a direct residual connection $\mathbf{D} \in \mathbb{R}$. Unlike architectures that initialize feedthrough terms to zero, MG-SSM-s explicitly parameterizes $\mathbf{D}$ to preserve immediate signal propagation.

B. Dynamics of the Multiplicative Gate

The recurrence in Eq. (10) expresses non-linearity through sequential multiplication, enabling the model to capture complex dependencies that linear SSMs often miss. By recursively expanding this term, we observe that g_t behaves as a cumulative product interaction through the unfolding steps in Eq. (12) to Eq. (14):

$$g_t = \mathbf{E}\left((\mathbf{E}g_{t-2}) \odot \tilde{x}_{t-1} + \mathbf{F}x_{t-1}\right) \odot \tilde{x}_t + \mathbf{F}x_t \tag{12}$$

$$= \mathbf{E}^2 g_{t-2} \odot (\tilde{x}_{t-1} \odot \tilde{x}_t) + \mathbf{EF}(x_{t-1} \odot \tilde{x}_t) + \mathbf{F}x_t \tag{13}$$

$$= \left(\mathbf{E}^t g_0 \odot \prod_{k=1}^{t} \tilde{x}_k\right) + \sum_{k=1}^{t-1}\left(\mathbf{E}^{t-k}\mathbf{F} \odot \prod_{j=k}^{t} \tilde{x}_j\right) + \mathbf{F}x_t \tag{14}$$

Eq. (14) demonstrates that the skip connection $\mathbf{F}$ transforms the pure product chain into a sum of product interactions of varying lengths. This structure effectively mimics a higher-order interaction mechanism, allowing the network to retain memory of specific input patterns (e.g., $x_{t-1}x_t$) independently of the long-term linear trend, thereby mitigating the risk of vanishing gradients [15].

V. Experiments

A. Dataset

The experimental data for this study was sourced from the publicly available Google COVID-19 Open Data project, specifically utilizing the `table-epidemiology` dataset [16]. This repository is hosted on Google's GitHub platform and provides comprehensive time-series data related to the pandemic. The raw data is distributed as a CSV file, initially covering approximately 231 countries and regions globally.

The complete dataset aggregates multidimensional time-series data, comprising metadata such as timestamps and geospatial locations, alongside a suite of epidemiological indicators. These metrics encompass both daily increments and cumulative totals for confirmed cases, mortalities, recoveries, and testing statistics. From this extensive set of indicators, our research exclusively utilizes the new confirmed cases metric. This variable was prioritized due to its superior data integrity, characterized by robust continuity and a minimal prevalence of missing values across the global cohort compared to other available signals.

To ensure high-quality data sequences for time-series modeling, the initial cohort was filtered down to 40 countries based on demographic and economic scale, as well as absolute data continuity. For the analysis interval spanning from 6th January 2020 to 6th June 2022, countries were excluded if their time series contained any missing values, NaN flags, or anomalous zero-entries resulting from reporting lags or logging omissions.

B. Experiment Setup

1) Environment and dependencies: All experiments were executed within a Google Colaboratory environment utilizing a T4 GPU runtime for computational efficiency. For reproducibility, the primary runtime environment and key library versions used were: Python 3.10; the deep learning framework was PyTorch 2.8.0+cu126; and essential libraries included torchmetrics 1.8.2, statsmodels 0.14.6, Pandas 2.2.2, scikit-learn (sklearn) 1.6.1, and NumPy 2.0.2.

TABLE I. OPTIMAL HYPERPARAMETER SETTINGS FOR COMPARATIVE MODELS.

Model	Latent Dimension (l)	Layers	Specific Configuration
ARIMA	-	-	Tuned (p,d,q) per country
LSTM	256	1	-
Bi-LSTM	256	1	-
GRU	128	1	-
SSM	32	1	-
MG-SSM-s	64	1	Hidden Gate $(m) = 32$

2) Model architectures and configuration: We evaluated six baseline architectures against our proposed MG-SSM-s: ARIMA, LSTM, Bi-LSTM, GRU, and a discrete State Space Model (SSM). The machine learning models were implemented using PyTorch, while the ARIMA model was implemented via the statsmodels library. The SSM baseline adopts the discrete state space formulation of the S4 model, utilizing random initialization rather than the HiPPo matrix to isolate the architectural performance.

To ensure fair comparison, we conducted a grid search for the optimal latent dimension $l \in \{32, 64, 128, 256\}$ for all machine learning models. For the ARIMA models, we conducted a grid search over the parameters $p, q \in \{0, 1, 2, 3, 4, 5\}$ and $d \in \{0, 1, 2\}$. Table I summarizes the optimal hyperparameters identified for each architecture. All models were configured with a univariate input and output size (1×1).

3) Training protocol: A consistent training protocol was applied across all experiments to ensure reproducibility. We utilized a look-back window (input sequence length) of $L = 30$ time steps. Training was performed using the Adam optimizer with a initial learning rate $\alpha = 10^{-3}$ and a batch size of 64. The maximum training duration was set to 1000 epochs, implemented with an early stopping mechanism that halts training if validation loss fails to improve for 50 consecutive epochs.

To facilitate model convergence, all input features were normalized to the range $[-1, 1]$ using Min-Max scaling. This strict bounding is required because the model architecture omits internal normalization layers; constraining inputs to a maximum magnitude of 1 ensures stable activations and prevents exploding gradients. Unbounded alternatives, such as Z-score standardization, were rejected as they cannot guarantee the boundaries necessary to maintain training stability. Finally, to prevent look-ahead bias and data leakage, the data was partitioned sequentially into training, validation, and testing sets using an $8 : 1 : 1$ ratio.

To account for stochastic variations, the pipeline was executed for 21 independent runs ($N_{\text{runs}} = 21$). These runs differed only by their pseudo-random weight initializations and epoch-level batch shuffling order. All model architectures, hyperparameters, and optimization settings were kept strictly identical across all runs.

4) Performance evaluation: The primary metric for comparative evaluation was the Mean Squared Error. The quadratic penalty term in MSE effectively highlights substantial deviations from ground truth, which is critical for ensuring stability in the target application.

TABLE II. GLOBAL PERFORMANCE SUMMARY ACROSS 40 COUNTRIES. RANK DISTRIBUTION DETAILS THE FREQUENCY OF ACHIEVING EACH RANK (1ST TO 6TH) ACROSS THE DATASETS

Model	**Mean Rank**	**Rank Counts**					
		1	2	3	4	5	6
ARIMA	1.975	7	27	6	0	0	0
LSTM	5.725	0	0	0	1	9	30
Bi-LSTM	5.075	0	0	0	6	25	9
GRU	4.10	0	0	2	32	6	0
SSM	2.50	6	8	26	0	0	0
MG-SSM-s	1.625	27	5	6	1	0	1

C. Experimental Results

Table II presents the aggregated performance metrics across the full 40-country cohort. The proposed MG-SSM-s demonstrated remarkable consistency, achieving the first rank in 27 out of 40 datasets and never ranking lower than second. In contrast, ARIMA and the standard Discrete SSM achieved the top rank in seven and six cases, respectively, while the recurrent baselines (LSTM, Bi-LSTM, GRU) rarely achieved competitive rankings.

In the global evaluation across all 40 countries, the average ranking confirms this advantage. MG-SSM-s achieved the best (lowest) mean rank of **1.625**, followed by ARIMA (1.975), Discrete SSM (2.50), GRU (4.10), Bi-LSTM (5.075), and LSTM (5.725).

To validate statistical significance, we performed the Friedman test, which indicated a significant difference among the $k = 6$ models across $N = 40$ datasets ($\chi^2 = 167.228$, $p = 2.846 \times 10^{-34}$).

Subsequent post-hoc analysis using the Nemenyi test ($\alpha = 0.05$) revealed a Critical Difference (CD) threshold of 1.0793. The rank difference between the top three models, MG-SSM-s, ARIMA, and Discrete SSM, was 0.875. Since $0.875 < 1.0793$, the conservative Nemenyi test is insufficient to reject the null hypothesis of equivalence between these three top-performing architectures.

Given this result, we conducted a more sensitive pairwise analysis using the Wilcoxon Signed-Rank Test to directly compare the median MSE distributions of MG-SSM-s against the ARIMA and the Discrete SSM. This test yielded a statistic of $W = 252.0$ with a p-value of $\mathbf{0.016}$. Since $p < 0.05$, we reject the null hypothesis, confirming that MG-SSM-s provides a statistically significant improvement over the Discrete SSM. In contrast, the comparison against ARIMA resulted in $W = 315.0$ and $p = 0.103$. Since $p > 0.05$, we fail to reject the null hypothesis for this pair. These results indicate that while MG-SSM-s significantly outperforms the standard machine learning baselines, its performance is statistically comparable to the tuned ARIMA model.

D. Discussion

The results conclusively establish that the proposed MG-SSM-s is the most robust architecture among the evaluated models. While the initial Nemenyi post-hoc analysis suggested broad statistical overlap between the top-tier models, the pairwise Wilcoxon Signed-Rank Test clarified that the performance gain of MG-SSM-s is statistically significant ($p \approx 0.05$). This

TABLE III. INCREMENTAL ABLATION RESULTS. RANK DISTRIBUTION ACROSS 40 COUNTRIES. THE p-VALUE INDICATES SIGNIFICANCE RELATIVE TO THE PECEDING ROW (PAIRWISE WILCOXON SIGNED-RANK TEST)

Model Variant	Mean Rank	Rank Counts			p-value
		1st	2nd	3rd	
1. Discrete SSM (Baseline)	2.20	14	4	22	-
2. MG-SSM (Gate Only)	2.10	10	16	14	$0.177^{\dagger}$
3. **MG-SSM-s (Gate + Skip)**	**1.70**	**16**	**20**	**4**	$\mathbf{0.010}^{\ddagger}$

† vs. Discrete SSM. ‡ vs. MG-SSM. Metric: Median MSE.

finding aligns with the consistent improvement in mean rank (1.625 vs. 2.50).

We attribute this performance to the architectural design: while the standard Discrete SSM relies on purely linear time-invariant dynamics, the MG-SSM-s introduces a multiplicative gate with an explicit skip connection. This structure enables the capture of the non-linear volatility observed in daily epidemiological data, which the purely linear baseline may over-smooth.

Interestingly, while MG-SSM-s significantly outperformed all neural and state-space baselines, its performance was statistically comparable to the tuned ARIMA model ($p = 0.1032$). This suggests that the linear stochastic components of ARIMA are remarkably effective for the underlying trend of this dataset. However, MG-SSM-s achieved a superior mean rank (1.625 vs. 1.975 for ARIMA).

We attribute this stability to the architectural design: while ARIMA relies on fixed lag observations, the MG-SSM-s uses a multiplicative gate with a skip connection. This allows the model to switch between long-term trends and reacting to the non-linear volatility often found in daily epidemiological data

E. Ablation Study

To validate the necessity of each architectural component, we conducted a step-wise ablation study comparing the full model (**MG-SSM-s**) against two variants: the gate-only model (**MG-SSM**) and the standard discrete baseline (**SSM**).

We omitted the skip-only variant, as removing the multiplicative term reduces the gate equation to a simple linear projection ($g_t = \mathbf{F}x_t$). This would functionally duplicate the main linear state h_t, resulting in a redundant standard SSM with increased parameters rather than a distinct architectural mechanism.

1) Impact of the skip connection: The primary theoretical contribution of this work is the stabilization of the multiplicative gate via the skip connection ($\mathbf{F}$). As derived in Eq. (14), the gate-only variant (MG-SSM) is governed by Eq. (15):

$$\begin{aligned} g_t &= \mathbf{E}g_{t-1} \odot \tilde{x}_t \\ &= \mathbf{E}^t g_0 \odot \left(\prod_{k=1}^{t} \tilde{x}_k \right) \end{aligned} \tag{15}$$

This cumulative product poses a risk of gradient instability. Empirically, this instability was evident in Table III. While the gate-only MG-SSM improved slightly over the baseline, the improvement was not statistically significant ($p = 0.177$), likely due to optimization difficulties in the pure product chain.

Fig. 2. Pairwise comparison of Median MSE for MG-SSM (Gate Only) vs. MG-SSM-s (Full). Points below the diagonal indicate countries where the addition of the skip connection reduced the error.

However, the introduction of the skip connection (Row 3) drastically stabilized performance. MG-SSM-s achieved a statistically significant improvement over the gate-only variant ($p = 0.010$), shifting the rank distribution such that it rarely fell to last place (only 4/40 cases). Visual evidence of this improvement is presented in Fig. 2.

2) Impact of the multiplicative gate: The comparison between the baseline SSM and the MG-SSM (Rows 1 vs. 2) isolated the effect of the multiplicative mechanism. Although the MG-SSM reduced the count of worst-case performances (Rank 3 dropped from 22 to 14), it failed to consistently outperform the linear baseline without the skip stabilizer. This confirmed that while the multiplicative gate provides high-capacity dynamics, the skip connection is a requisite component to harness this capacity effectively.

VI. CONCLUSION

The rapid propagation of the COVID-19 pandemic has placed unprecedented strain on global healthcare systems, particularly in densely populated nations. In this context, accurate forecasting of confirmed case counts is critical, providing policymakers with the necessary intelligence to anticipate surges, allocate resources, and implement effective public health measures. Furthermore, reliable predictive data serves to motivate public adherence to mitigation strategies intended to curb the virus's spread.

In this study, we evaluated the efficacy of five deep learning architectures—LSTM, Bi-LSTM, GRU, SSM, the proposed MG-SSM-s, and ARIMA using the Google COVID-19 Open Data repository. The analysis encompassed daily confirmed cases across 40 distinct countries, including major epicenters such as the USA, India, Brazil, France, and Germany. This methodological approach utilized a 30-day look-back window

to forecast next-day confirmed cases, capitalizing on the inherent capacity of deep learning models to capture non-linear temporal dependencies within complex epidemiological data.

Performance verification based on the Mean Squared Error metric demonstrates that the MG-SSM-s model achieves superior forecasting accuracy compared to all deep learning baselines, while delivering comparable statistical performance to a tuned ARIMA model. These results highlight the potential of the MG-SSM-s framework as a robust tool for epidemiological time-series forecasting.

The results demonstrate that the proposed MG-SSM-s is a highly robust architecture among the evaluated models. While the initial Nemenyi post-hoc analysis suggested statistical overlap among the top-tier models, the pairwise Wilcoxon Signed-Rank Test clarified that the performance gain of MG-SSM-s over the standard SSM is statistically significant ($p \approx 0.05$), aligning with its superior mean rank (1.625 vs. 2.50). Interestingly, while MG-SSM-s significantly outperformed all neural and state-space baselines, its performance was statistically comparable to the tuned ARIMA model (p = 0.1032), though MG-SSM-s maintained a superior mean rank (1.625 vs. 1.975 for ARIMA). This performance and stability stem from the architectural design: while standard SSMs rely on purely linear dynamics and ARIMA relies on fixed lag observations, MG-SSM-s introduces a multiplicative gate with an explicit skip connection. This structure enables the model to dynamically switch between tracking long-term trends and capturing the non-linear volatility observed in daily epidemiological data without over-smoothing.

A. Limitations and Future Work

While the framework demonstrates strong forecasting capabilities, its current constraints highlight several avenues for future research:

- Univariate Input Constraint: The model currently relies solely on historical case numbers. Future iterations will extend the architecture to multivariate inputs to incorporate exogenous variables like government policy changes and mobility indexes.
- Data Evaluation Scope: The empirical evaluation was restricted to 40 countries chosen primarily as major pandemic epicenters. Broader validation across diverse regional data qualities is required to verify global generalizability.
- Look-Back Sensitivity: The analysis relied on a fixed 30-day look-back window. Investigating how varying or adaptive window horizons affect forecasting accuracy remains an open direction for exploration.

Declaration of Generative AI and AI-Assisted Technologies in the Manuscript Preparation Process

During the preparation of this work, the author(s) used Google's Gemini 2.5 Flash, in order to refine and improve the clarity, grammar, and flow of the language in the manuscript. After using this tool/service, the author(s) reviewed and edited the content as needed and take(s) full responsibility for the content of the published study.

***Abstract*—Most of the fingerprint recognition systems represent minutiae as independent points. This reduces robustness under noise, distortion, and partial impressions. The lack of explicit structural modeling contributes to inconsistent feature reliability, specifically in defocused acquisition conditions. To address these limitations, a Topology-Aware Graph Convolutional Network (Topo-GCN) is proposed. Topo-GCN is a geometric fingerprint representation framework that treats all minutiae points as interrelated nodes and polishes them using a Graph Convolutional Network (GCN). Each node is represented as a 14-dimensional descriptor with the Multi-scale Spatial Feature Tensor (MSFT) technique. A novel Relational Connection Factor (RCF) applies adaptive topology-aware learning to construct edges in place of traditional distance-based graph construction. The Hybrid scoring technique combines learned node representations with graph-theoretic measures to separate genuine minutiae from false ridge information. Furthermore, a lightweight pseudo-labeling scheme efficiently trains the model without depending on the large-scale annotated datasets. The proposed Topo-GCN framework achieves an Area under Curve (AUC) of 0.9614, 0.9769, and 0.9831 with consistent verification performance (EER) of 1.85%, 1.39%, and 1.64% and stable relational encoding with mean edge weights of 0.712, 0.739, and 0.758 across FVC2000, FVC2002, and FVC2004 datasets. The results indicate that integrating relational topology into minutiae modeling considerably enhances robustness, making Topo-GCN a viable approach for secure and efficient fingerprint authentication systems.**

Keywords*—Biometric authentication; fingerprint recognition; Graph Convolutional Network; minutiae refinement; topology-aware representation

I. Introduction

The modern technological era demands high-security systems with a relatively low computational complexity for individual authentication. The inherent vulnerability of password- and token-based authentication mechanisms to security breaches highlights the necessity for developing more robust and reliable alternatives. In this regard, biometric authentication relies on characteristics that are intrinsically associated with an individual, whereas former methods depend on knowledge that can be guessed and imitated.

The computationally inexpensive algorithm requirement narrows down to the utilization of unimodal biometric techniques rather than a multimodal approach that requires heavy processing. Among various traits, fingerprints are superior due to their uniqueness and permanence. Additionally, fingerprint sensors are cost and space-efficient compared to other biometric sensors, as they can be integrated to authentication device with a minimal modification. Similar to traditional techniques, fingerprint-based authentication systems are vulnerable to attacks. Following a successful security breach, unlike password reset, fingerprints cannot be replaced. Therefore, protecting stored fingerprint template against inversion, linkage, and replay attacks is important. Cancelable template approach satisfies the properties of diversity, irreversibility, revocability and unlinkability. Minutiae extraction is one of the keystages in the fingerprint authentication system pipeline.

Existing minutiae extraction approaches rely on handcrafted rules, which often fail to capture the relational structure among minutiae points [1]. They are sensitive to noise and lacks generalization, and may discard valid minutiae. Furthermore, these schemes do not explicitly exploit topological dependencies [2]. The importance of relational and spatial dependency modeling has also been shown in graph-based spatial processing frameworks [3]. These limitations motivate the need for a structurally aware and learnable refinement mechanism.

The major contributions of this work are summarized as follows:

- A hybrid fingerprint processing framework that combines MSFT-driven texture encoding with a learnable graph-based refinement, allowing structurally aware minutiae validation without high computational complexity.
- A novel graph-oriented clipping technique replaces conventional rule-based filtering with adaptive node scoring derived from the feature quality, connectivity pattern, and relational consistency measures.
- Achieving better storage efficiency and improved matching performance by generating a compact and unique representation with selective node retention and the graph embedding technique.

II. Related Work

Techniques related to fingerprint minutiae extraction have advanced considerably. Existing fingerprint recognition sys-

*Corresponding author

tems rely on either one of the following techniques described below. Each technique has a unique way of feature representation. Traditional minutiae extraction approaches primarily rely on Crossing Number (CN) and Gabor filtering, which extract Standard Minutiae Triplets (SMT). These methods suffer from sensor noise, scaling and translation. Recent deep learning-based methods attempt to learn feature representations directly from data, introducing heatmap-based and descriptor-based representations, but ignores intrinsic topological relationships among minutiae. Global representation models rely on fixed-length embeddings rather than conventional technique. Such models are computationally efficient with reduced discriminative capability. Hybrid approaches combine local and global minutiae information to create a balanced structural and statistical representations. However, they still depend on heuristic design choices and does not support adaptive relational modeling. SDK-dependent systems rely on proprietary black-box extractors such as VeriFinger and MegaMatcher. They are limited to reproducibility and end-to-end optimization. The comparative analysis of these approaches is summarized and given below.

The classical minutiae extraction methods include a Gabor filter-based linear band-pass approach utilized to compute local ridge frequency and orientation [1], where Standard Minutiae Triplets (SMT), i.e., spatial coordinates (x, y) and the orientation angle (theta) for ridge endings and bifurcations, are extracted; however, reliance on a centroid-based reference point for coordinate translation is mathematically unstable because the addition of a single false minutia alters the entire coordinate system [1]. The Crossing Number (CN) approach [2] is also utilized, but the Crossing Number (CN) algorithm is incapable of distinguishing between legitimate biological traits and topological artifacts [2].

Similarly, a Gabor filter-based extraction approach [4] depends on a singular global reference point (core point) for the Mobius transformation, which is sensitive to registration jitter, where a one-pixel shift in the reference point causes a total non-linear divergence of the transformed coordinates [4]. The Adaptive Scale-Invariant Feature Transform (SIFT) detector [5] extracts 128-dimensional feature vectors consisting of SMT derived from local gradient histograms; however, SIFT is mathematically designed to locate extrema in continuous intensity gradients, which are destroyed by the binarization and thinning process [5]. The Fingerprint Manual Minutiae Marker (FM3) toolkit [6] utilizes the ISO/IEC 19794-2 triplet, but the use of manual extraction introduces a human subjective error [6].

These paradigms treat minutiae as isolated features, explicitly lacking in learning and modeling the relational topology.

Deep learning-based minutiae extraction methods include a CSPNet-based extractor (adapted Cross Stage Partial Network) trained via knowledge distillation from FingerNet [7], extracting SMT and a confidence level for each minutia; however, the feature extractor limits system performance and mimics the systematic errors and biases due to the reliance on FingerNet knowledge [7]. DeepPrint, a multi-branch deep network that incorporates a minutiae-map detection branch to guide representation learning [8], encodes SMT as a 6-channel heatmap, but discards the local relative topological distances between minutiae, making the system vulnerable to false accepts in high inter-class similarity [8]. A ResNet50-Transformer Minutiae Map Predictor [9], which utilizes a ResNet50 backbone coupled with self-attention transformer layers to predict a 12-channel heat map, extracts SMT and a 96-dimensional descriptor for each minutia patch; however, the reliance on fixed 96×96 patches alters the local texture relative to the minutiae center [9]. Deep learning-based methods improve feature representations by operating on the pixel-level suggestions and failing to encode inter-minutiae relationships.

Global representation models include fixed-length representations [10], where textural cues and minutiae representations are concatenated into a 512-dimensional fixed-length feature vector, but the relative geometric distances between minutiae are ignored [10]. A customized SVM classification model (C-SVM-Cl) [11] maps global P-Hash vectors directly to a biometric identifier (BID), using a 64-bit global hash vector derived from the frequency domain of the fingerprint image, but abandoning local minutiae sacrifices high-entropy discriminative features, resulting in a mediocre 75% accuracy [11]. ShuffleNetv2.3-based architectures [12] extract high-level hierarchical feature vectors as global embeddings; however, the system is spatially variant, lacking rotation and translation invariance and will fail if the input image is not perfectly aligned [12]. Fully minutiae-free approaches utilizing a DINOv2-Base Vision Transformer backbone [13] produce a 1536-dimensional global embedding from the [CLS] token of the final Transformer layer, but lack explicit topological invariance, making the recognition performance highly volatile [13]. Dilated Convolutional Neural Network (DICNN) [14] extracts local and global structural properties such as singularities and ridgeline shapes, but a gridding effect causes sparse spatial sampling that ignores contiguous ridge-valley connectivity [14]. Hierarchical Heterogeneous Ant Colony Optimization based Fingerprint Matching (HHACOFM) [15] relies on ridge topology matching using a boolean matrix representation, but depends entirely on ant agents to compensate for translational and rotational shifts [15]. Pre-trained VGG16 and VGG19 backbones [16] extract high-dimensional global latent embeddings, but lack rotation and translation invariance [16]. A ViT-based Siamese Network [17] produces 256-dimensional representations, but the ResNet-18 front-end discards high-frequency ridge-valley details necessary for sub-pixel localization accuracy [17]. Attention-based and CNN-based classification heads [18] extract global embeddings and local feature maps, but reliance on an external spatial alignment module leads to catastrophic misalignment if inaccurate [18]. Log Gabor feature vectors [19] generate a 477,144-dimensional feature space, but introduce redundancy and increase false positives [19]. CNN-based descriptors utilizing AlexNet [20] produce fixed-size latent feature vectors, but the architecture is incapable of resolving fine-grained ridge-line singularities [20].

The fixed-length global embeddings suppress local geometric relationships. These abstractions discard the reliable discriminative structural information.

Hybrid representations include ResNet50 with multihead attention for global feature extraction [21], extracting SMT, but Sobel-based enhancement cannot distinguish between legitimate ridge boundaries and high-frequency noise artifacts [21]. Minutiae triplet-based feature extraction [22] produces a

6D feature vector including spatial distance, ridge count, and ridge density, but handcrafted topology is sensitive to non-linear skin deformation [22].

Hybrid techniques combine local and global information but still rely on predefined handcrafted features and lacks adaptive modeling.

SDK-dependent systems include COTS SDK (MegaMatcher) [23], extracting SMT of angular sectors, but exhibiting a rotation offset that breaks feature interoperability [23]. VeriFinger SDK 12.0 [24] utilizes paired control points for Thin Plate Spline (TPS) transformation, but errors in the initial transformation cannot be corrected [24]. VeriFinger SDK [25] extracts SMT and core points but is incapable of anchoring focal points in arch patterns [25]. VeriFinger SDK 12.1 [26] used for ground truth extraction prevents gradient-based backpropagation of minutiae-specific loss [26]. Rule-based SDK extraction [27] fails in low-quality regions. VeriFinger 11.1 SDK [28] introduces an opaque dependency preventing optimization. MindTCT with VeriFinger 12.1 [29] constrains the system to classical ridge-following rules. VeriFinger 4.0 SDK [30] fails to distinguish biological singularities from sensor noise. VeriFinger v12.0 [31] introduces circular dependency in degraded regions. Multi-extractor frameworks [32] relying on commercial SDKs create gradient disconnection, preventing optimization of identity loss.

SDK-dependent minutiae extraction methodologies prevent end-to-end optimization and limits the integration of learnable structural representations.

Most state-of-the-art approaches struggle to remain stable with noisy, distorted, and incomplete fingerprint impressions. These limitations necessitate a framework that can capture and adaptively fine-tune the inter-minutiae associations. Topo-GCN models the fingerprint data as a graph, where minutiae are represented as nodes and the structural interactions are encoded through edges, enabling effective learning of relational dependencies.

III. Proposed Work

Despite wide range of advancements, fingerprint-based identification systems validate each minutia independently from the local topology surrounding it. However, ridges are continuous flow fields driven by parallel direction and frequency of directions. Evaluating the isolated minutiae alone creates a structural ambiguity such that spurious detections from noise and broken ridges cannot be categorically separated from real minutiae. Utilizing isolated minutiae to determine the validity of the feature struggles with partial impressions, sensor noise, and elastic distortion. To alleviate this issue, existing methods rely on the enhancement of local descriptors or the learning of global structure of fingerprints. Local descriptors cannot enforce consistency among structures that are spatially distributed, while global embedding models succeed in creating fixed-length representations of fingerprints, downgrading the direct geometric relationship between minutiae. Therefore, both methods provide feature space representations that do not explicitly encode the topological relationship between features, creating instability under occlusion, deformation, and acquisition noise.

A prerequisite to implement meaningful representation of minutiae is to have the ability to establish consistency of relationships amongst minutiae. Therefore, the validity of any given minutia can be determined jointly with neighboring ridge structures. This can be accomplished by retaining both the local features and the underlying topological structure of the fingerprint. Modeling fingerprint minutiae using a graph offers the ideal framework for encoding inter-relational minutiae relationships. However, conventional, naïve graph representations are solely based on spatial proximity and do not reflect the physical continuity of ridge flow, resulting in connectivity problems.

To address these limitations, Topo-GCN framework will define a relational representation that is constrained by ridge-level physical properties and polishes through learnable inference. The proposed approach differs from the traditional approaches by modeling minutiae as a graph and treating it as the primary mechanism of representation. Thus, the validity of a specific minutia arises from structural agreement and not from feature confidence.

In this formulation, the Graph Convolutional Network (GCN) serves an additional purpose beyond merely aggregating features but enforcing consistency across the entire graph. The network iteratively propagates through all of its neighbouring nodes and eliminates the nodes that exhibit structural inconsistency. The utilization of the GCN in the Topo-GCN framework serves as a means of providing distributed relational reasoning via global embedding strategies. The proposed framework shifts minutiae extraction from a detection problem to a consistency-driven inference problem over a structured topological domain.

Fig. 1 illustrates the architecture of the proposed Topo-GCN framework. The extracted fingerprint feature set is represented as a structured graph. Each node encodes a candidate minutia characterized by descriptors derived from the Multi-scale Spatial Feature Tensor (MSFT), including spatial position, orientation with texture, structural, and multi-scale information.

Edges are constructed using the range-restricted connectivity scheme by capturing local ridge topology. The resultant graph is processed with the learnable GCN to adaptively filter node representations by discarding structurally inconsistent candidates. The refinement process improves distinctness by utilizing the learned feature interactions and eliminates the requirement for large-scale training.

A composite scoring mechanism evaluates each node based on a weighted combination of feature confidence, degree centrality, and edge consistency. The nodes with the score exceeding an adaptive threshold are retained, whereas the nodes with low scores are ignored to preserve genuine structural patterns

The proposed scheme inherently supports robustness, compactness, and resistance to direct inversion as the final representation contains relational and topological dependencies rather than raw biometric features.

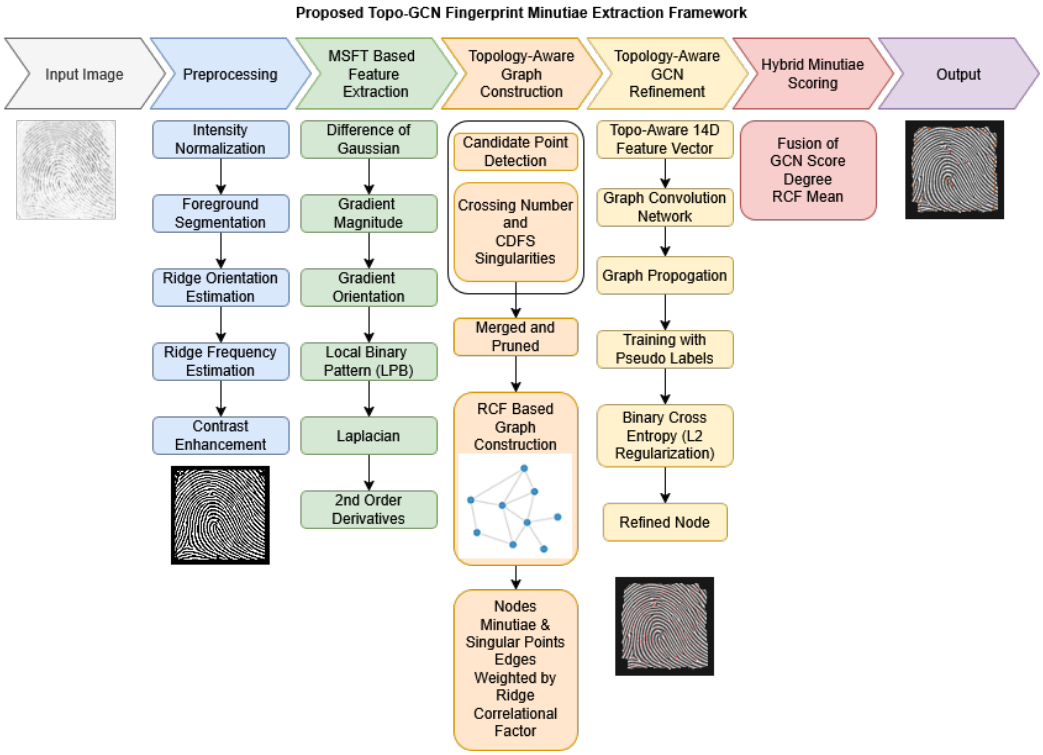

Fig. 1. Proposed fingerprint minutiae extraction framework.

A. Minutiae Representation

The minutiae representation is a three-layered hierarchical construct rather than a single vector. Each detected minutia is represented by a 14-dimensional feature vector X_i used for GCN inference. The feature vector comprises normalized spatial coordinates and orientation (θ/π), local coherence, minutiae type, and mean Ridge Connection Factor (RCF) with seven channels of MSFT to capture ridge-valley contrast. Furthermore, the degree of the node within the RCF graph encodes local structural connectivity. This formulation overcomes the conventional descriptor by redefining minutiae as a relational property instead of an isolated measurement.

The 14-dimensional descriptor represents the minutiae along with the local structural context. This is sufficient for subsequent graph learning.

Unlike DeepPrint, which treats minutiae as parts of a global image map, the proposed system builds a Relational Connection Factor (RCF) graph to capture innate relationships among minutiae. The edge weights f_r are defined as the fusion of Correlation Coefficient r_{cc}, Orientation Consistency o_c, and Frequency Consistency f_c, enabling a physical relationship between minutiae. Ridge flow interruption due to poor sensor contact causes the RCF weight to drop, enabling the GCN to de-weight the error node for better minutiae refinement. The RCF serves as a proxy for ridge-flow continuity. The model extracts structurally consistent minutiae from ridge irregularities, as in Eq. (1):

$$f_r(i,j) = \alpha \cdot r_{cc}(i,j) + \beta \cdot o_c(i,j) + \gamma \cdot f_c(i,j) + \delta \cdot e^{-d_{ij}/\sigma} \quad (1)$$

B. Alignment-Free Property

DeepPrint relies on an "Alignment Module" to orient the fingerprint before feature extraction. Topo-GCN logic is alignment-free and learns the relative topology between nodes. The graph structure remains identical whether the fingerprint is rotated or shifted, provided the relative distances between minutiae are preserved.

The reliance on reference point estimation is eliminated, and the invariance is enforced through relational geometry to make the representation inherently robust to positional variations without explicit normalization.

C. Graph Construction

Instead of Euclidean distance to define graph edges, Topological Relational Construction (TRC) is a parametrically adaptive graph structure that fuses domain-driven constraints with learnable refinement.

The nodes are a fusion of Crossing Number (CN) minutiae and CDFS singularity candidates. Unlike standard pipelines that accept all detected points, the proposed technique prunes them using a coherence threshold and a foreground mask. The pruning criterion is adaptively modulated during training so that the model retains the low-confident yet structurally informative points.

Edge formation is constrained within a local neighborhood. The connectivity is modeled as a continuous function of Euclidean distance D with soft distance-dependent weighting to enable adaptive neighborhood formation.

Each edge is defined through a learnable fusion of structural cues. The edge weight is formulated, as in Eq. (2):

$$f_r(i,j) = W^T \cdot \phi(i,j) \tag{2}$$

where,

$$\phi(i,j) = [r_{cc},\ o_c,\ f_c,\ e^{-d_{ij}/\sigma}]$$

and W is the learnable parameter vector. Initially, the graph is constructed with fixed ridge-based rules and subsequently refined during training through learnable weighting.

D. GCN Adjacency Matrix

For graph convolution, the adjacency matrix is constructed using the refined edge weights and normalized, as in Eq. (3):

$$\hat{A} = D^{-\frac{1}{2}}(A + I)D^{-\frac{1}{2}} \tag{3}$$

This normalization ensures to distribute relational influence across structurally consistent neighborhoods. Furthermore, the dominance of spurious connections are prevented and true topological interactions are preserved.

E. GCN Propagation

The model propagates through a $14 \rightarrow 32 \rightarrow 16 \rightarrow 1$ architecture in Eq. (4), Eq. (5), and Eq. (6):

$$H_1 = \sigma(\hat{A}X_{\text{norm}}W_1) \tag{4}$$

$$H_2 = \sigma(\hat{A}H_1W_2) \tag{5}$$

$$s_c = \text{Sigmoid}(\hat{A}H_2W_3) \tag{6}$$

The propagation does not end with the GCN output. The final score is obtained, as in Eq. (7):

$$s_{\text{final}} = w^T[s_c,\ d_{\text{norm}},\ \text{RCF}_m] \tag{7}$$

which is the learnable fusion of GCN inference, node centrality, and ridge continuity, enabling adaptive weighting of structural cues.

GCN functions as a mechanism for propagating each node iteratively to validate it against its spatial neighborhood.

F. Global Descriptor Construction

Following graph-based learning, a higher-level 80-dimensional global descriptor is constructed for verification and validation, as in Eq. (8):

$$F = [H^{32}_{\text{ori}},\ H^{8}_{\text{freq}},\ S^{8}_{\text{min}},\ C^{16}_{\text{cyl}},\ S^{8}_{\text{graph}},\ S^{8}_{\text{ridge}}] \in \mathbb{R}^{80} \tag{8}$$

H^{32}_{ori} and H^{8}_{freq} denote the 32-bin orientation and 8-bin ridge frequency, respectively. These capture the overall directional and periodic characteristics of the fingerprint. The first- and second-order statistics of spatial coordinates, orientation, and local coherence are summarized in S^{8}_{min}.

C^{16}_{cyl} captures the local neighborhood structure by evaluating the average orientation distribution within local patches centered at each minutiae. S^{8}_{graph} handles relational consistency by aggregating GCN-derived node quality score, density, and node degree statistics. S^{8}_{ridge} determines ridge-level quality and consistency by incorporating contrast and image quality metrics.

The proposed descriptor sustains connectivity by ensuring that global representation retains the topology of the fingerprint instead of abstracting it and maintaining a compact representation for efficient storage and better processing [33].

G. Learning Strategy

The Topo-GCN framework integrates domain-driven constraints with learnable optimization, thereby avoiding reliance on fixed heuristic formulations. The edge weighting function $f_r(i,j)$ is defined as a fusion of correlation, orientation, frequency consistency, and distance decay, capturing the structural relationships between minutiae. The contribution weights $\alpha, \beta, \gamma, \delta$ govern this combination during graph construction. Although not explicitly learned, their effect is reflected in the learned transformations of node features and adjacency normalization within the GCN refinement stage, eliminating the need for manual tuning.

Furthermore, the structural cues are optimized indirectly with respect to the binary cross-entropy objective through the learning dynamics of the network.

A pseudo-labeling strategy is adopted to enable effective learning without depending on manually labelled datasets. The strategy programmatically classifies candidate minutiae based on structural integrity and connectivity measures. High-coherence and well-connected nodes are treated as positive samples, and low-confidence candidates are treated as negative samples. This facilitates a lightweight supervised training paradigm using mini-batch optimization with binary cross-entropy loss and regularization. To overcome the collapse of label distributions, class imbalance, and enhanced meaningful supervision, percentile-based fall back strategies are applied.

IV. Results and Discussion

Experimental analysis of the proposed Topo-GCN shows that learning over a 14-dimensional feature representation (X) provides better discriminative capability and generalization

performance compared to raw pixel-based modeling by achieving a training accuracy of 99.80% relative to 97.50%, as reflected in verification metrics.

The necessity for collaborative feature learning increases the complexity of raw image-based models during registration and matching the fingerprint. The proposed framework introduces a closely aligned representation directly encoding ridge coherence and alignment position. This shift enables targeted graph-based refinement, reducing the reliance on deep convolutional architectures.

The Topo-GCN framework segregates structural feature encoding from relational refinement by decoupling representational redundancy. This allows the model to emphasize on learning meaningful inter-minutiae dependencies through graph-based processing.

The architectural design ($14 \rightarrow 32 \rightarrow 16 \rightarrow 1$) enables better optimization within a reduced, information-bound space. This is substantiated with a mean processing time of 0.543 seconds and throughput of 1.84 images per second.

The reduced computational complication is due to the structured feature processing, unlike repeated high-dimensional convolutions.

The stable structural encoding and robustness of the representation are supported by the ridge-flow stability metrics, accomplishing a low orientation field error of 0.0126 rad and high coherence with a mean of 0.913. The topology-aware sparse graph with low graph density (0.0215–0.0312) and controlled mean node degree (2.34–3.27) limits unnecessary connectivity between nodes and the potential for over-smoothing via graph convolution. Therefore, node representations remain discriminative by preserving local ridge relationships and leading to improved separation between genuine and impostor score distributions.

Furthermore, the mean RCF edge weight (≈ 0.797) with low variance indicates stable relational encoding across varying fingerprint qualities. This suggests that the edge construction process is not significantly influenced by noise-sensitive features.

Stable relational modeling reinforces edge weighting (mean = 0.797) to maintain local feature interactions to remain discriminative.

Integrating local cylinder descriptors with global 80-dimensional feature embeddings by the hybrid scoring framework strengthens the verification reliability.

Effective separation between genuine (mean ≈ 0.80) and impostor (mean ≈ 0.25) distributions is achieved with the application of $\tanh$-based normalization, which induces a nonlinear redistribution of similarity scores.

The overlap in the decision space and enhanced discriminability are attained with the margin amplification. Jointly, these results indicate that the proposed framework achieves enhanced verification performance through a synchronized blueprint that consolidates graph-structured learning and distribution-aware score normalization.

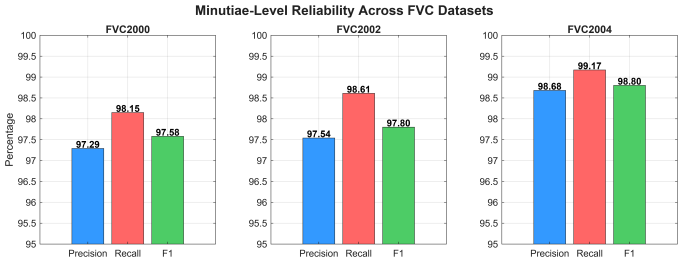

Fig. 2. Visual representation of precision, recall, and F1 score across FVC datasets.

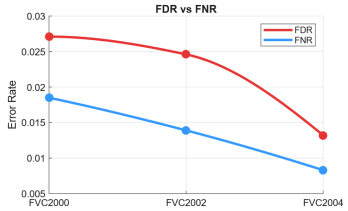

Fig. 3. False Discovery Rate vs. False Negative Rate.

A. Minutiae-Level Reliability (MLR)

To assess the ability of the Topo-GCN framework to filter appropriate candidates, precision, recall, and F1-score are determined. To ensure the successful elimination of noise and retention of genuine ridge features, False Discovery Rate (FDR) and False Negative Rate (FNR) are drawn.

Table I signifies strong minutiae-level reliability across all FVC datasets with F1-scores recorded at 97.58%, 97.80%, and 98.80%, respectively.

As shown in Fig. 2, precision, recall, and F1-score are higher and consistent compared to the state-of-the-art approaches. The higher values of recall suggest greater retention of true minutiae, despite the acquisition conditions.

Moreover, the precision value denotes that the graph-based refinement technique protects true ridge patterns and serves as a strong baseline compared to [14].

Based on the data in Table II, both False Detection Rate (FDR) and False Negative Rate (FNR) decreases from 0.0132 to 0.0083 across datasets denotes the stability of the refinement process.

The proposed framework maintains a strong balance by reducing false detections and preserving true minutiae. The proposed model adjusts to varying quality datasets and does not overfit.

Fig. 3 shows stable refinement behavior. Furthermore, the structural graph-based refinement filters the candidates based on relational consistency rather than isolated feature confidence is one among the improvements over the numerical baseline methods based on trade-off between FDR and FNR.

Table III indicates that the range growing from 2.50 to 3.01, the statistical distance between genuine and impostor score distributions.

Table IV shows that the proposed method achieves lower

TABLE I. MINUTIAE-LEVEL RELIABILITY ACROSS FVC DATASETS

Method	FVC2000			FVC2002			FVC2004		
	Prec.	Rec.	F1	Prec.	Rec.	F1	Prec.	Rec.	F1
[2]	97.13	96.84	96.99	96.29	95.74	96.01	96.5	95.8	96.1
[7]	86.76	89.58	88.51	90.76	91.42	91.09	84.8	86.6	85.7
[14]	96.50	97.69	97.09	95.81	94.96	95.38	98.63	98.47	98.55
[16]	94.42	91.36	92.86	93.64	92.88	93.26	92.6	92.4	92.4
Proposed	97.29	98.15	97.58	97.54	98.61	97.80	98.68	99.17	98.80

TABLE II. FALSE DETECTION RATE (FDR) AND FALSE NON-MATCH RATE (FNR) ACROSS DATASETS.

Dataset	FDR	FNR
FVC2000	0.0271	0.0185
FVC2002	0.0246	0.0139
FVC2004	0.0132	0.0083

TABLE III. SEPARABILITY INDEX (d')

Metric	FVC2000	FVC2002	FVC2004
d' separability	2.50	2.83	3.01

EER across all datasets, outperforming existing methods, particularly on FVC2002 with 1.39%.

Table V further confirms the discriminative capability, achieving AUC values of 0.9614, 0.9769, and 0.9831 for the FVC datasets, respectively.

Fig. 4 shows strong ROC performance, with consistent curves across datasets.

A consistent improvement with the shift in score distributions is observed. The genuine scores cluster around 0.80 while impostor scores remain near 0.25. The hybrid scoring mechanism reinforces the separation by fusing GCN outputs with node degree and ridge continuity. The tanh-based normalization minimizes overlap in the decision space by amplifying decision margins through a non-linear redistribution of similarity scores.

The preprocessing stage influences the graph modeling. Table VI populated with high PSNR and SSIM, significant improvement in CNR, and lower MSE and OFE. This illustrates the necessity of conserving structural information of the image prior to feature extraction [34].

Fig. 5 graphically illustrates the preprocessing and minutiae extraction pipeline. Fig. 6, indicate that the proposed Topo-GCN has improved the quality of the image with stable ridge flow.

Table VII showcases that the low graph density (0.0215–0.0312) and controlled node degree (2.34–3.27) prevent over-smoothing during graph convolution. The existence of clear separation between the GCN score distributions of genuine versus imposter supports the hypothesis that the learned representations of nodes accurately reflect the unique topology of the associated minutiae as opposed to only using local feature descriptors. Therefore, explicit relational modelling improves fingerprint discriminability.

To evaluate RCF edge-weight formulation as in Eq. (1), each component was removed independently to understand the contribution of each term. Table VIII presents the results of the evaluation. Removal of any one of the terms lead to a sharp increase in the EER. The exclusion of r_{cc} recorded the highest EER. The complete formulation of RCF achieved the minimal EER.

Only MSFT	93.28	94.67	93.97	5.84	0.910

B. Evaluation Protocol

Evaluation is carried out under a subject-exclusive protocol, where DB1_B and DB2_B are used for model learning, and DB3_B along with DB4_B are reserved strictly for testing. This partition ensures that no overlap exists between the training and test sets, thus eliminating possible leakages and establishing a realistic scenario for evaluating generalization.

The partitioning method will also provide several differences in the conditions under which samples were obtained within the sub-databases. This permits evaluating a model across distributional differences across FVC Datasets.

The reliability of the performance is derived from the samples in the test by examining the corresponding distributions for genuine and impostor scores. Based on these distributions for the respective test sets, standard performance measures such as AUC (Area Under the Curve) and EER (Equal Error Rate) are calculated to quantify the performance. To assess consistency of these scores across trial instances, confidence intervals are developed using Bootstrap resampling.

Metrics related to minutiae- and verification-level are reported to maintain consistency in the evaluation process.

C. Ablation Study

To assess the performance through ablation analysis, core distinct modules are selectively removed. This experiment confirms that the combination of MSFT-based feature encoding, GCN-based refinement, and hybrid scoring contributes to the effectiveness of the overall system. Therefore, the proposed framework is not a heuristic accumulation but a structurally grounded design.

Additionally, the proposed framework avoids the large-scale labeled data to maintain computational efficiency and generalization capability.

Results of the ablation analysis from Table IX indicate that each core component projects a systematic role in the overall performance of the entire system. The complete model with all cores performs with an F1-score of 98.92%, an EER of 1.64%, and an AUC of 0.983. The removal of the graph structure from the system, decreased the performance with EER = 4.62%, AUC = 0.932, and failed to model the interdependencies between minutiae. These interdependencies are the primary reason for the increase in performance. The removal of the GCN from the system increases the EER to 3.95%, which indicates that the model builds a graph with a larger number of structurally inconsistent candidates. The exclusion of the MSFT features leads to a moderate drop in the quality of the local ridge representation. The addition of the hybrid scoring mechanism further improves the ability to discriminate between candidates, as indicated by an increase in the EER to 2.41% upon its removal. Overall, the results of the analysis show that the sequential degradation of the performance for each configuration confirms that the system has benefited from the complementary effects of feature encoding, graph-based refinement, and adaptive scoring.

V. Conclusion

The proposed Topo-GCN redefines minutiae modeling by explicitly incorporating relational topology through a graph-based fingerprint representation framework. Graph convolutional learning transforms candidate minutiae into a structured graph, effectively capturing the local and global dependencies that are overlooked in conventional point-based representations.

The integration of a compact 14-dimensional feature descriptor with the proposed RCF enables adaptive and physically meaningful edge construction. The hybrid scoring mechanism ensures robust refinement of minutiae under noisy and partial conditions. The adoption of pseudo-labeling further enhances the practicality of the framework by reducing dependence on large annotated datasets. Experimental results across standard FVC benchmarks demonstrate consistent improvements in discriminability and efficiency, validating the effectiveness of topology-driven learning for biometric representation. Unlike deep image-based models that rely on high-dimensional feature extraction, the proposed method achieves competitive performance within a low-dimensional and computationally efficient framework.

Future work will focus on strengthening cross-dataset generalization, incorporating adversarial robustness analysis, and extending the framework toward fully cancelable biometric template generation with formal security guarantees. The findings of this work highlight the importance of structurally-aware representations and establish a foundation for next-generation fingerprint authentication systems.

Architecting a Low-Latency RAG System for Fast-Moving Consumer Goods (FMCG) Customer Support: A Case Study in Industrial Software Deployment

Meredita Susanty, Alghifari Rasyid Zola
Ilmu Komputer, Fakultas Sains dan Ilmu Komputer, Universitas Pertamina, Indonesia

***Abstract*—Deploying large language models (LLMs) in industrial customer support environments require balancing response accuracy with system latency. This study presents the software architecture and implementation of a Retrieval-Augmented Generation (RAG) system designed for the Fast-Moving Consumer Goods (FMCG) sector. Addressing the limitations of generic LLMs in domain-specific knowledge tasks, we engineered a retrieval-augmented inference pipeline that integrates unstructured data ingestion, Pinecone for vector indexing, and Groq-based inference for low-latency response generation. The proposed system aims to improve response grounding by incorporating organizational product information into the generation process while maintaining responsive interaction times suitable for customer support applications. This study details the software architecture, system integration approach, and experimental evaluation of the proposed deployment-oriented RAG framework in an industrial FMCG case-study setting.**

***Keywords*—Software architecture; RAG; industrial AI; Groq LPU; vector database; customer support systems**

I. Introduction

Large language models (LLMs) have become increasingly popular in customer service applications due to their ability to generate natural language responses and assist users across a wide range of tasks [1]. Organizations are progressively exploring LLM-based solutions to improve service quality, reduce operational workload, and provide faster access to information [1], [2]. In the Fast-Moving Consumer Goods (FMCG) sector, customer support teams frequently handle inquiries related to product specifications, ingredients, usage instructions, and company procedures. As product portfolios evolve rapidly and organizational knowledge changes continuously, maintaining accurate and consistent responses across customer support channels becomes a significant challenge [2].

Despite their capabilities, general-purpose LLMs exhibit fundamental limitations when applied to enterprise-specific domains. These models primarily rely on parametric knowledge acquired during pre-training and therefore lack direct access to proprietary, confidential, or recently updated organizational information [3]. Consequently, when queried about domain-specific products, internal procedures, or newly released information, LLMs may generate plausible yet factually incorrect responses, a phenomenon commonly referred to as hallucination [4]. In customer support settings, such inaccuracies may negatively affect customer trust, service consistency, and operational effectiveness [5].

Retrieval-Augmented Generation (RAG) has emerged as a promising approach for mitigating these limitations by integrating external knowledge sources into the response generation process [6]. Instead of relying solely on internal model parameters, RAG systems retrieve relevant information from an external knowledge repository and provide this information as contextual evidence for generation [6]. This architecture enables organizations to update knowledge independently of the language model itself, making RAG particularly suitable for dynamic business environments where information changes frequently [7].

Although RAG can improve factual grounding, the architecture introduces additional computational stages, including query processing, retrieval, context assembly, and response generation [2]. These stages increase overall response latency compared to direct LLM inference. In customer support scenarios, where users typically expect responses within only a few seconds, excessive latency may reduce perceived responsiveness and negatively impact user experience [2]. Therefore, practical deployment of RAG systems requires balancing response quality with operational performance [7].

Recent advances in inference infrastructure have created opportunities to improve the responsiveness of Retrieval-Augmented Generation systems. Among these developments, Groq's inference platform has attracted attention for its ability to provide low-latency language model inference and high token-generation throughput. While previous studies have extensively investigated retrieval effectiveness and answer quality in RAG systems [6], comparatively less attention has been given to deployment-oriented architectures that simultaneously consider retrieval-based grounding and low-latency response requirements for enterprise customer support applications [7].

This study presents the design and evaluation of a low-latency RAG architecture for FMCG customer support. The proposed system integrates document ingestion, vector-based knowledge retrieval using Pinecone, and LLM inference served through Groq's infrastructure. Rather than proposing a novel retrieval algorithm, this work focuses on the architectural design and practical implementation of a retrieval-augmented customer support system using real industrial knowledge assets [7]. The objective is to investigate whether retrieval-based grounding can improve response accuracy while maintaining latency suitable for interactive customer support scenarios [2].

The main contributions of this study are summarized as follows:

- The design and implementation of a Retrieval-Augmented Generation architecture for FMCG customer support applications.
- An empirical evaluation of response accuracy and end-to-end latency using domain-specific customer support queries and proprietary organizational knowledge.
- An empirical comparison between a local GPU-based deployment and a Groq-based deployment within a retrieval-augmented customer support pipeline.
- A discussion of practical implementation considerations, limitations, and lessons learned from developing a deployment-oriented RAG system for enterprise use cases.

II. Related Work

A. Fine-Tuning and Retrieval-Augmented Generation

Several approaches have been proposed to adapt large language models (LLMs) to domain-specific applications [3]. One widely adopted approach is fine-tuning, where pre-trained models are further trained on task-specific or domain-specific datasets to improve performance in specialized contexts. Previous studies have demonstrated that fine-tuning can improve downstream task performance by incorporating domain knowledge into model parameters [3].

However, fine-tuning presents several challenges in enterprise environments. Updating organizational knowledge typically requires additional training cycles, computational resources, and model maintenance [7]. As organizational information evolves over time, maintaining an up-to-date fine-tuned model can become costly and operationally complex. Furthermore, fine-tuned models may continue to rely on outdated information embedded within model parameters when knowledge sources change frequently [7].

To address these limitations, Retrieval-Augmented Generation (RAG) was introduced as an alternative architecture that separates knowledge storage from language generation [6]. Instead of embedding all knowledge within model parameters, RAG retrieves relevant information from an external knowledge source and incorporates the retrieved context into the generation process [6]. Similar findings were reported by Guu et al. [8], who demonstrated that retrieval-enhanced architectures can improve factual grounding while maintaining the reasoning capabilities of large language models.

Recent studies have further highlighted the advantages of retrieval-based systems for knowledge-intensive applications [6]. Kandpal et al. [9] observed that large language models often struggle to accurately recall long-tail or domain-specific information, reinforcing the importance of external retrieval mechanisms for enterprise knowledge management scenarios.

B. Retrieval-Augmented Generation in Enterprise Knowledge Systems

The adoption of Retrieval-Augmented Generation has expanded beyond academic benchmarks into practical enterprise applications [6]. Organizations increasingly utilize RAG architectures for knowledge management, document question answering, internal search systems, and customer support automation [2]. By retrieving relevant documents from external repositories, RAG systems can provide responses grounded in organizational knowledge while reducing the likelihood of hallucinated content [6].

Gao et al. [7] identified document chunking, retrieval quality, and context construction as critical components influencing overall RAG performance. Similarly, several enterprise-oriented implementations have demonstrated the effectiveness of vector databases and retrieval pipelines in improving access to large collections of unstructured organizational information [5].

Despite these advances, most prior work focuses primarily on retrieval effectiveness and answer quality [6], [7]. Comparatively fewer studies investigate deployment-oriented considerations such as inference latency, architectural integration, and operational constraints encountered in enterprise environments [2]. As a result, understanding how retrieval-enhanced systems can be implemented while maintaining acceptable response times remains an important area of research.

C. Low-Latency LLM Inference Architectures

While retrieval can improve factual grounding, additional processing stages introduce latency into the overall system [6]. Consequently, recent research has increasingly focused on optimizing large language model inference to support real-time applications [10].

Traditional GPU-based deployments remain the dominant approach for serving transformer-based language models. To improve inference efficiency, several optimized serving frameworks have been proposed, including vLLM and TensorRT-LLM. These frameworks improve throughput and memory utilization through techniques such as paged attention, kernel optimization, efficient batching strategies, and optimized execution pipelines [10].

In parallel, specialized inference hardware has also emerged as an alternative approach for reducing inference latency. One notable example is Groq's tensor streaming architecture, which employs deterministic execution and compiler-driven optimization to improve token generation throughput and reduce inference overhead. Such approaches aim to improve responsiveness for interactive AI applications where low latency is a critical requirement [10].

Although these approaches significantly improve inference performance, existing studies primarily evaluate hardware acceleration or serving optimizations independently from retrieval-enhanced architectures. Limited research has examined how low-latency inference infrastructures interact with end-to-end Retrieval-Augmented Generation pipelines in enterprise customer support settings [6], [2].

D. Research Gap

Based on the reviewed literature, prior studies have extensively investigated the benefits of retrieval augmentation for improving factual accuracy and reducing hallucinations. Likewise, substantial efforts have been devoted to accelerating

large language model inference through specialized hardware and optimized serving frameworks.

However, limited attention has been given to deployment-oriented architectures that simultaneously address retrieval-based knowledge grounding and low-latency response requirements in enterprise customer support environments. Furthermore, relatively few studies report practical implementation experiences using real organizational knowledge assets within industrial case-study settings.

Therefore, this study focuses on the design and evaluation of a low-latency Retrieval-Augmented Generation architecture for FMCG customer support. Rather than proposing a new retrieval algorithm or language model, the work investigates how retrieval-based grounding and different deployment configurations can be combined within a practical enterprise-oriented architecture to improve response quality while maintaining interactive response times.

III. Methods

This study adopts a Retrieval-Augmented Generation (RAG) architecture designed to support domain-specific question answering within FMCG customer support scenarios. The proposed system combines document preprocessing, vector-based retrieval, prompt augmentation, and large language model inference into a unified pipeline. The methodology consists of four primary stages: knowledge base construction, retrieval pipeline development, response generation, and performance evaluation.

A. System Overview

The overall architecture of the proposed system is illustrated in Fig. 1. The system follows a modular design consisting of four primary components: document ingestion, vector retrieval, context augmentation, and language model inference.

During the offline phase, organizational documents are processed and transformed into retrieval-ready chunks. These chunks are subsequently converted into vector representations and indexed within a Pinecone vector database. During the online inference phase, user queries are transformed into vector representations using the same procedure and submitted to the retrieval system. The most relevant document chunks are retrieved and incorporated into a structured prompt before being passed to the language model for response generation.

This architecture separates knowledge storage from reasoning, allowing organizational knowledge to be updated without modifying the underlying language model.

B. Knowledge Base Construction and Chunking Strategy

The knowledge base used in this study consists of proprietary FMCG product information documents from one brand within a portfolio of fourteen FMCG brands. The selected brand contains a comprehensive collection of product specifications, ingredients, product descriptions, and usage-related information commonly referenced during customer support interactions. This single-brand repository was used as an industrial case-study dataset to evaluate the proposed Retrieval-Augmented Generation architecture in a realistic customer support scenario.

Prior to indexing, all documents underwent a preprocessing stage to generate retrieval-ready chunks. As illustrated in Fig. 2, documents were initially segmented into paragraphs, after which non-informative segments and excessively short paragraphs were removed. Longer paragraphs were subsequently divided into smaller sentence groups to improve retrieval granularity while preserving local contextual coherence. This chunking strategy was designed to reduce context fragmentation and increase the likelihood that retrieved chunks contain complete product-related information. Each resulting chunk was associated with relevant metadata and prepared for vector indexing within the retrieval pipeline.

C. Vector Representation and Retrieval Pipeline

Following document segmentation, each chunk was transformed into a fixed-length vector representation to support similarity-based retrieval. The current implementation employs a lightweight hash-based vectorization approach rather than a transformer-based sentence embedding model. Individual lexical tokens are mapped into a 1024-dimensional vector space using a deterministic hashing function, producing a fixed-length representation for each document chunk. The resulting vectors are subsequently normalized prior to similarity comparison. This approach was selected due to its implementation simplicity and compatibility with the lightweight retrieval architecture adopted in this study. This choice was made to align with the lightweight prototype implementation, where vectorization was performed directly within the application service without requiring a separate neural embedding inference component. Consequently, the retrieval layer could be deployed with minimal additional infrastructure and computational overhead.

Because the adopted representation is primarily based on lexical features, it captures token-level similarity rather than the semantic relationships typically learned by neural embedding models. Consequently, retrieval performance may be affected when semantically similar queries exhibit substantially different lexical forms. The generated vectors are indexed using Pinecone as the retrieval backend. During inference, incoming user queries undergo the same vectorization procedure before similarity search is performed against the indexed knowledge base. For the experiments reported in this study, the retrieval component returns the Top-K most relevant document chunks, where $K = 15$. These retrieved chunks are subsequently incorporated into the prompt construction stage and supplied to the language model as contextual evidence for response generation.

D. Retrieval-Augmented Response Generation

After retrieval, the selected document chunks are assembled into a structured prompt and supplied to the language model for response generation. The retrieved information serves as contextual evidence, allowing the model to generate responses grounded in the available product knowledge rather than relying solely on its internal parametric knowledge.

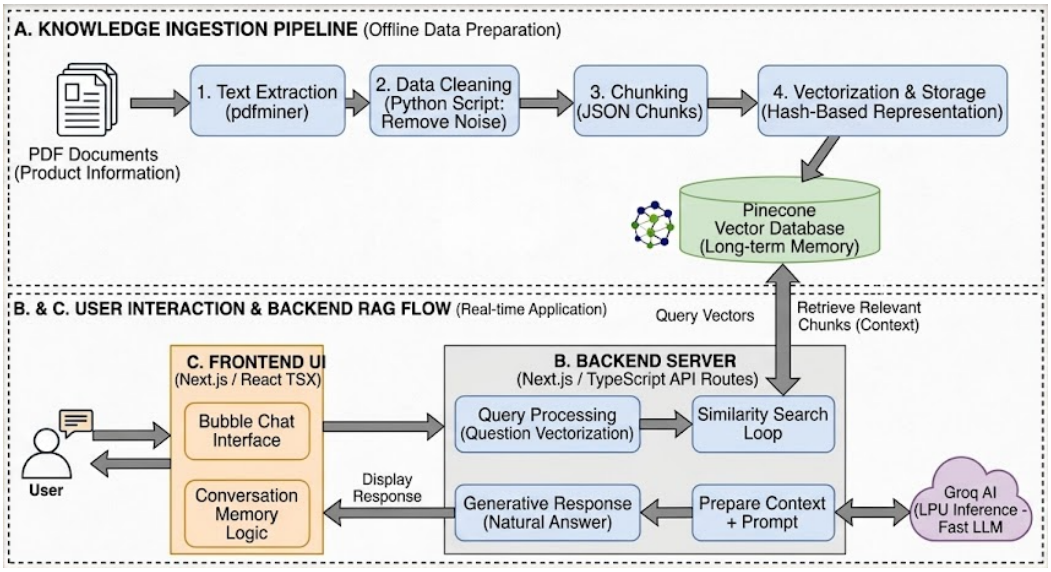

Fig. 1. Overall architecture of the proposed Retrieval-Augmented Generation pipeline.

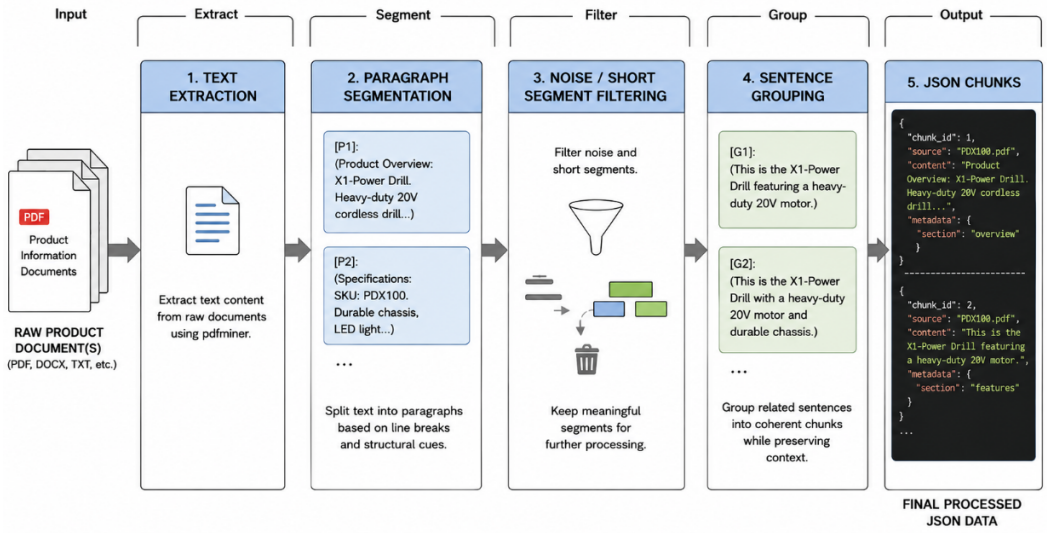

Fig. 2. Knowledge base construction and chunking strategy used for document preparation.

To improve factual consistency, the system adopts a closed-context prompting strategy. As illustrated in Fig. 3, the prompt explicitly instructs the model to generate responses only from the retrieved information and to avoid introducing unsupported content beyond the available context. This approach aims to reduce hallucinations by constraining the generation process to the evidence provided by the retrieval stage.

The overall inference workflow is illustrated in Fig. 4. Upon receiving a user query, the system performs retrieval, prompt construction, and response generation sequentially before returning the final response to the user. For language generation, this study utilizes the Llama-3.3-70B-Versatile model served through Groq's inference infrastructure. A temperature value of 0 was selected to improve output consistency and reduce response variability, while the maximum output length was limited to 600 tokens.

Groq's inference platform was selected due to its low-latency serving capabilities and compatibility with interactive question-answering applications. The objective of incorporating this infrastructure is to evaluate its contribution to overall response latency within the proposed retrieval-augmented customer support pipeline rather than to isolate the effects of hardware acceleration independently.

E. Experimental Environment

To evaluate the practical performance of the proposed architecture, two deployment configurations were considered in this study: a local GPU-based deployment and a Groq-based deployment. The proposed configuration utilized the Llama-3.3-70B-Versatile model served through Groq's cloud inference platform, while the baseline configuration employed a locally deployed language model served through Ollama and

executed on consumer-grade GPU hardware.

The local deployment environment consisted of an NVIDIA RTX 3060 GPU with 16 GB of system memory. Both deployment configurations utilized the same retrieval pipeline, including the Pinecone vector database, document chunking strategy, retrieval parameters, and prompt construction mechanism. This configuration was intended to ensure that the retrieval process remained consistent across experiments, allowing performance differences to be evaluated at the deployment level rather than the retrieval level.

For retrieval, the system employed a Top-K configuration of $K = 15$. Retrieved document chunks were incorporated into a closed-context prompt before response generation. All responses were generated using a temperature setting of 0 and a maximum output length of 600 tokens. These parameters were maintained throughout the evaluation process to ensure consistency in both latency and response quality measurements.

It should be noted that the comparison was designed to evaluate the practical latency characteristics of two deployment approaches within the same Retrieval-Augmented Generation workflow. The objective was not to isolate the contribution of hardware acceleration independently, but rather to assess the overall responsiveness of a locally deployed GPU-based configuration compared with the proposed Groq-based deployment in an interactive customer support scenario.

F. Evaluation Framework

The proposed system was evaluated using a domain-specific benchmark consisting of 50 question-answer pairs derived from organizational product information and customer support materials. The evaluation dataset was designed to represent common inquiry categories encountered in FMCG customer support scenarios, including product specifications, ingredients, usage instructions, and general product-related information.

System performance was assessed using two primary dimensions: response accuracy and response latency. Response accuracy was evaluated through manual assessment by comparing generated responses against the corresponding source documents contained within the knowledge base. Responses were classified as correct when the generated answer was factually consistent with the available product information and incorrect when factual inconsistencies or unsupported information were identified.

Latency evaluation focused on end-to-end response time, defined as the elapsed duration between query submission and receipt of the final generated response. Additional measurements included Time-to-First-Token (TTFT) and token generation throughput to assess inference efficiency. Latency measurements were collected under the deployment configurations described in Section III E.

The evaluation dataset was derived from a single FMCG brand and, therefore, reflects the characteristics of a specific industrial case-study setting. Consequently, the reported results should be interpreted as evidence of the practical feasibility of the proposed architecture rather than as a generalized assessment of performance across all FMCG customer support environments. Furthermore, the evaluation was conducted using only 50 test queries and relied on a single evaluator for manual response assessment. Statistical significance testing and inter-rater reliability analysis were not performed within the scope of this study. These limitations should be considered when interpreting the reported results.

Although retrieval quality plays an important role in overall RAG performance, this study did not explicitly evaluate retrieval effectiveness using metrics such as Recall@K, Precision@K, Mean Reciprocal Rank (MRR), or context coverage. Instead, the evaluation focused on end-to-end response accuracy and system latency to assess the practical feasibility of the proposed architecture in a customer support setting. Consequently, the contribution of the retrieval component was evaluated indirectly through overall response quality rather than through dedicated retrieval benchmarks.

IV. Results and Discussion

A. Response Latency Evaluation

To assess the responsiveness of the proposed architecture, a latency comparison was conducted between a local GPU-based deployment and the proposed Groq-based deployment. The evaluation focused on three metrics: Time-to-First-Token (TTFT), token generation throughput, and end-to-end response

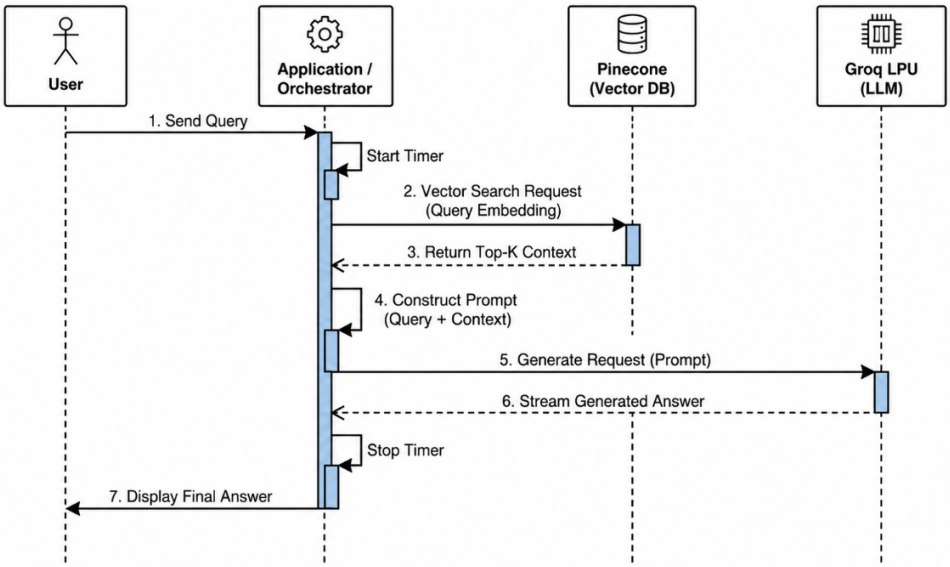

Fig. 4. Sequence diagram of the inference request.

latency. TTFT measures the time required for the first generated token to be produced, throughput measures the token generation rate, and end-to-end latency represents the total elapsed time between query submission and receipt of the final response.

Table I summarizes the latency characteristics observed for both deployment configurations. The local deployment utilized Ollama running on an NVIDIA RTX 3060 GPU, while the proposed deployment employed the Llama-3.3-70B-Versatile model served through Groq's cloud inference platform.

TABLE I. LATENCY COMPARISON BETWEEN LOCAL GPU-BASED AND GROQ-BASED DEPLOYMENTS.

Metric	Local GPU-Based	Groq-Based
Embedding & Retrieval	245 ms	238 ms
Time-to-First-Token (TTFT)	742 ms	118 ms
Token Generation Rate	42.8 tokens/sec	305.9 tokens/sec
Total Response Time	**2847 ms**	**1246 ms**

B. Response Accuracy Evaluation

The response accuracy evaluation was conducted using 50 domain-specific customer support queries derived from organizational product information. Generated responses were manually compared against the corresponding source documents contained within the knowledge base. Responses were classified as correct when the generated answer was factually consistent with the available product information and incorrect when factual inconsistencies or unsupported information were identified.

Table II summarizes the overall response accuracy obtained during the evaluation. Out of 50 evaluated queries, 36 responses were classified as correct, while 14 responses contained inaccuracies or incomplete information. This resulted in an overall response accuracy of 72.0%.

The results indicate that the proposed Retrieval-Augmented Generation architecture was able to provide factually consistent responses for the majority of evaluated customer support queries. The integration of retrieval-based grounding enabled the language model to access product-specific information that was not explicitly contained within its parametric knowledge.

TABLE II. RESPONSE ACCURACY RATE EVALUATION RESULTS

Evaluation Outcome	Count
Correct Responses	36
Incorrect Responses	14
Total Queries	50
Accuracy	**72.0%**

Analysis of incorrect responses revealed that most errors originated from incomplete retrieval results, ambiguity within product descriptions, or situations where relevant information was available in the retrieved context but was not fully incorporated into the generated response. These findings suggest that retrieval quality and context utilization remain important factors influencing overall system performance.

C. Discussion

The experimental results demonstrate that retrieval augmentation can improve the ability of large language models to answer domain-specific customer support queries. The proposed system achieved an overall response accuracy of 72.0% across the evaluated FMCG customer support dataset, indicating that retrieval-based grounding can assist the language model in generating responses that are consistent with organizational product information.

The results suggest that integrating an external knowledge repository enables the language model to access product-specific information that is not explicitly stored within its parametric knowledge. By incorporating retrieved document chunks into the generation process, the system can provide responses grounded in available product documentation rather than relying solely on pre-trained model knowledge.

The latency evaluation further indicates that the Groq-based deployment provides faster response times than the local GPU-based deployment. As shown in Table I, the proposed deployment reduced Time-to-First-Token (TTFT) from 742 ms to 118 ms and decreased end-to-end response latency from 2847 ms to 1246 ms. In addition, token generation throughput increased from 42.8 tokens per second to 305.9 tokens per second. These findings suggest that low-latency inference infrastructure can improve the responsiveness of retrieval-augmented customer support systems.

Despite the observed improvements, the retrieval component remains an important source of performance limitations. The current implementation employs a lightweight hash-based vector representation that primarily captures lexical similarity rather than deep semantic relationships between terms. Consequently, retrieval effectiveness may decrease when semantically similar queries are expressed using substantially different vocabulary. This limitation may partially explain some of the incorrect responses observed during evaluation.

Analysis of incorrect responses revealed that most errors originated from incomplete retrieval results, ambiguity within product descriptions, or situations where relevant information was available in the retrieved context but was not fully incorporated into the generated response. These findings indicate that retrieval quality and context utilization remain important factors influencing overall system performance.

From an operational perspective, the proposed architecture enables organizational knowledge to be updated independently from the language model itself. New product information can be incorporated by updating the knowledge base and vector index without requiring model retraining. This characteristic may be beneficial in FMCG environments where product information and operational procedures change frequently and require timely updates across customer support channels.

D. Limitations and Future Work

Several limitations should be considered when interpreting the findings of this study. First, the evaluation was conducted using a dataset consisting of 50 question-answer pairs derived from product information belonging to a single FMCG brand. Although the selected dataset represents a realistic industrial use case, the reported results may not generalize to larger knowledge repositories, multiple brands, or different organizational environments. Furthermore, response quality was assessed through manual evaluation and did not involve multiple independent annotators. Consequently, inter-rater reliability was not measured, and the evaluation dataset of only 50 query-response pairs was insufficient to support meaningful statistical significance testing. Future studies should expand the evaluation benchmark and incorporate multiple independent annotators to improve evaluation reliability and generalizability.

A second limitation relates to the retrieval component. The current implementation employs a lightweight hash-based vector representation that primarily captures lexical similarity rather than deep semantic relationships between terms. While computationally efficient, this approach may reduce retrieval effectiveness when semantically similar queries are expressed using substantially different vocabulary. In addition, the study focused on end-to-end system performance and did not evaluate retrieval effectiveness using dedicated retrieval metrics such as Recall@K, Precision@K, Mean Reciprocal Rank (MRR), or context coverage. Consequently, the contribution of the retrieval component was assessed indirectly through overall response quality rather than through dedicated retrieval benchmarks.

Controlled ablation experiments were also not conducted within the scope of this study due to the limited experimental setup and available evaluation data. Consequently, the individual contributions of retrieval configuration, prompt design, serving infrastructure, and inference hardware could not be isolated quantitatively. Future work should perform systematic ablation studies to better understand the relative impact of each component on overall system performance.

Finally, the study did not investigate scalability under concurrent user workloads, larger knowledge base sizes, or alternative deployment frameworks such as vLLM and TensorRT-LLM. Future research should address these aspects while also exploring transformer-based embedding models, hybrid retrieval strategies, and reranking techniques to improve retrieval quality and response accuracy. Such investigations would provide a more comprehensive understanding of deployment-oriented Retrieval-Augmented Generation systems in industrial customer support environments.

V. Conclusion

This study presented the design and evaluation of a Retrieval-Augmented Generation (RAG) architecture for domain-specific customer support within the Fast-Moving Consumer Goods (FMCG) sector. The proposed system integrates document preprocessing, vector-based retrieval, closed-context prompting, and large language model inference to generate responses grounded in organizational product information. In addition, the study evaluated two deployment configurations, namely a local GPU-based deployment and a Groq-based deployment, to investigate their practical latency characteristics within the same retrieval-augmented workflow.

The experimental evaluation demonstrated that the proposed system achieved an overall response accuracy of 72.0% across 50 domain-specific customer support queries. The results indicate that retrieval-based grounding can assist large language models in providing responses that are more consistent with organizational knowledge sources. In terms of system responsiveness, the Groq-based deployment reduced end-to-end response latency from 2847 ms to 1246 ms, improved Time-to-First-Token (TTFT) from 742 ms to 118 ms, and increased token generation throughput from 42.8 to 305.9 tokens per second. These findings suggest that low-latency inference infrastructure can support responsive customer support interactions while maintaining retrieval-grounded response generation.

The findings should be interpreted within the scope of an industrial case-study setting involving product information from a single FMCG brand. Furthermore, the evaluation dataset consisted of a limited number of manually assessed queries and did not include dedicated retrieval effectiveness metrics, multiple independent annotators, or large-scale scalability experiments. Consequently, the reported results should

be viewed as evidence of practical feasibility rather than a generalized assessment of Retrieval-Augmented Generation performance across all enterprise environments.

Future work should investigate transformer-based embedding models, retrieval effectiveness metrics such as Recall@K, Precision@K, and Mean Reciprocal Rank (MRR), as well as hybrid retrieval and reranking approaches to improve retrieval quality. Additional studies should also evaluate scalability under larger knowledge bases, concurrent user workloads, and alternative deployment frameworks to provide a more comprehensive understanding of deployment-oriented Retrieval-Augmented Generation systems in industrial customer support applications.

ACKNOWLEDGMENT

We express our gratitude to the PT Paragon Technology and Innovation for facilitating this case study, particularly Mrs. Nurul Rizka Hadiningsih for their industrial mentorship. We also appreciate the valuable input provided by the Customer Care team leaders and agents during the system's development and testing.

Adaptive Hybrid Intrusion Detection for Realistic Zero-Day Attacks in Cloud and Edge Environments

Nithin U, Ganeshayya Shidaganti*, Sangeetha V, Vishwachetan D
Department of Computer Science and Engineering,
Ramaiah Institute of Technology, Bangalore, Karnataka, India

***Abstract*—New and unknown attack patterns are creating more cybersecurity issues for cloud environments. Intrusion detection systems (IDS) are usually capable of high-performance in closed-world scenarios and are less effective in realistic zero-day scenarios. This work presents an adaptive hybrid intrusion detection mechanism for cloud environments based on the combination of Random Forest, XGBoost and AutoEncoder models, under a single decision-making framework. A fully reproducible pipeline was built directly from the raw data of CICIDS2017, using consistent preprocessing and feature engineering. In contrast with traditional IDS researches that are evaluated with standard train-test evaluation process, realistic zero-day assessment was carried out by conducting attack-family holdout experiments, including WebAttack, DDoS, and Infiltration scenarios. The results showed that both attack families and adaptive decision strategies were different, with WebAttack using XGBoost-dominant behavior and Infiltration using anomaly-focused behavior for an 85.30% and 88.89% recall, respectively. The proposed framework was also implemented on edge hardware (Raspberry Pi) and has been shown to have low-inference latency and only moderate resource usage. The results reveal that adaptive hybrid decision behavior leads to a more robust decision behavior under realistic zero-day conditions, while having a feasible deployment in cloud-edge environments.**

Keywords*—*Intrusion detection system (IDS); zero-day detection; adaptive hybrid IDS; attack-family holdout; cloud security; edge deployment; autoencoder; CICIDS2017

I. Introduction

Cloud computing has become a fundamental component of modern computing infrastructure because of its scalability, flexibility, and efficient resource utilization. As organizations increasingly rely on cloud platforms for large-scale services and distributed applications, cybersecurity challenges have also grown significantly. Evolving attack behaviors and large-scale network traffic generation make securing cloud environments increasingly difficult. Recent studies have emphasized the importance of intelligent intrusion detection systems capable of adapting to dynamic cloud environments [1], [2].

Intrusion detection systems (IDS) are commonly used to monitor network traffic and identify malicious activity. Traditional IDS approaches primarily rely on signature-based techniques or supervised machine learning models trained using historical attack data. Although such approaches achieve strong performance on known attack categories [3], their effectiveness decreases when exposed to previously unseen threats. Zero-day attacks remain particularly challenging because attack signatures are unavailable during training, limiting the generalization capability of conventional models [4], [5].

*Corresponding author

A major limitation in existing intrusion detection studies is the reliance on conventional train-test evaluation protocols where attack distributions remain similar across training and testing stages. Such closed-world assumptions frequently yield high classification performance, but are not representative of reality deployments in scenarios with new attack families not encountered before. Thus, models with good accuracy when evaluated in standard settings can suffer a significant drop in accuracy when evaluated in atypical settings of realistic zero day conditions.

An adaptive hybrid IDS framework for realistic zero-day attacks in the cloud can be used to overcome these challenges. To achieve this, a new method is proposed that integrates three machine learning algorithms (Random Forest, XGBoost and Autoencoder) into a single adaptive decision-making process. Contrary to previous researches that have been done in a closed world setting, here a new adaptive hybrid decision-making process is introduced which has been verified under realistic attack-family based holdouts and edge deployment. Zero-day evaluation has been completed for the WebAttack, DDoS and Infiltration holds and Raspberry Pi deployment for inference viability.

The major contributions of this work are summarized as follows:

- A reproducible intrusion detection pipeline was reconstructed directly from the raw CICIDS2017 dataset using consistent preprocessing, feature engineering, and model training procedures.
- A realistic zero-day evaluation strategy based on attack-family holdout experiments was developed using WebAttack, DDoS, and Infiltration scenarios.
- An adaptive hybrid intrusion detection mechanism combining Random Forest, XGBoost, and Autoencoder models was developed to improve robustness across diverse attack behaviors.
- Raspberry Pi edge deployment and dashboard-based visualization were implemented to validate practical deployment feasibility.

II. Related Work

A. Deep Learning and Hybrid Intrusion Detection

Recent intrusion detection studies have increasingly adopted deep learning techniques to improve the detection of complex and previously unseen attack patterns. Sotani et al. [6] demonstrated that deep learning architectures can improve

network traffic analysis compared with conventional methods. To improve robustness further, Aljawarneh et al. [7] proposed a hybrid intrusion detection architecture combining multiple learning paradigms. Cloud-specific intrusion detection studies have also emphasized scalable and adaptive monitoring in dynamic environments. AI-based cloud security frameworks [8] and hybrid machine learning-deep learning approaches [9] have reported improved detection capability under cloud-oriented settings. However, these methods mainly focus on predefined attack categories and continue to rely on labeled attack information.

B. Adaptive and Zero-Day Detection Approaches

To address limited data availability in unseen attack scenarios, few-shot learning has been explored for intrusion detection. Yan et al. [10] showed that few-shot frameworks can learn new attack categories using limited labeled samples. Zero-shot learning has also been investigated for unseen attack identification by transferring knowledge from known attack classes to unknown classes [11]. Recent AI-driven hybrid methods have attempted to improve zero-day exploit detection by combining multiple classifiers and deep learning models [12]. Time-series anomaly detection approaches have further improved the ability to capture dynamic cloud traffic behavior [13], while ensemble-based hybrid techniques have demonstrated improved cyberattack detection performance [14]. Meta-learning approaches have also been applied to intrusion detection in next-generation network environments [15].

C. Research Gap

Earlier deep learning-based zero-day detection studies reported improved representation learning capability but remained largely dependent on supervised or controlled evaluation settings [16]. Simulation-based zero-day studies showed that detection performance decreases when models encounter unseen attack distributions [17]. Recent survey work has also highlighted persistent challenges such as false positives, adaptability limitations, and lack of practical deployment validation [18]. Cloud-focused zero-day studies have proposed deep learning and machine learning frameworks for emerging threats [19], [20]. However, most existing studies continue to rely on conventional dataset partitioning or closed-world assumptions. Realistic attack-family holdout evaluation, adaptive hybrid decision behavior, and practical edge deployment validation remain comparatively underexplored. Unlike existing approaches, this work combines adaptive hybrid decision logic with realistic attack-family holdout experiments and Raspberry Pi edge deployment validation.

III. Proposed Methodology

A. Overall System Architecture

The proposed system is designed as an adaptive hybrid intrusion detection framework capable of detecting both known and previously unseen attacks in cloud environments. The architecture combines supervised classification and anomaly-based learning within a unified detection pipeline, as illustrated in Fig. 1. Unlike conventional IDS frameworks that depend entirely on labeled attack information, the proposed approach integrates multiple detection paradigms to improve robustness under realistic zero-day conditions.

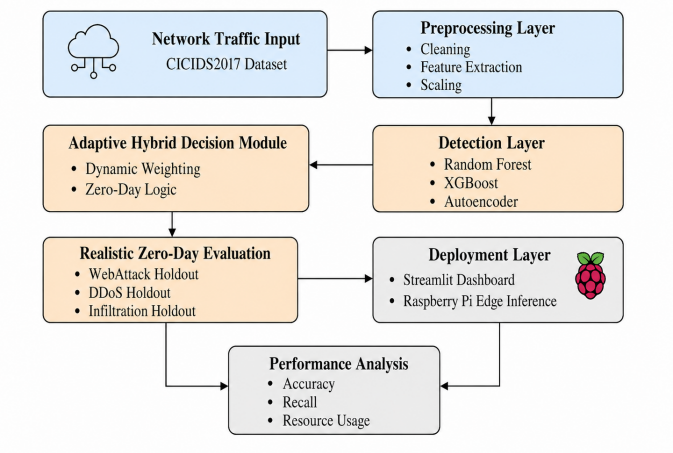

Fig. 1. Overall architecture of the proposed adaptive hybrid IDS framework for realistic zero-day detection and edge deployment.

The entire process starts with the processing of network traffic data and the extraction of the features. The preprocessed network flow features are then processed by both supervised and anomaly-based detectors at the same time. The Random Forest and the XGBoost model learn the discriminative features from the training samples that represent attack traffic, whereas the Autoencoder learns the normal traffic by training only on benign traffic data. The outputs from the two models are then fed into an adaptive decision making unit which is responsible for making final decisions about the intrusions.

B. Dataset Preparation and Preprocessing

The proposed framework utilized the CICIDS2017 dataset as the primary source of network traffic data. To maintain reproducibility and eliminate inconsistencies associated with previously processed artifacts, only raw CSV files were used throughout experimentation. Initially, raw traffic files were merged into a unified dataset and standardized through column cleaning and duplicate removal. Missing and infinite values were identified and handled to ensure numerical stability during model training.

Feature engineering was then performed to retain only numerical attributes suitable for model learning. Labels were converted into binary form, where benign traffic was assigned class 0 and malicious traffic was assigned class 1. A final set of 78 traffic features was selected and preserved consistently across training and inference stages. The dataset was divided into training, validation, and testing subsets using a 70:15:15 split strategy, and StandardScaler was applied using training data only to prevent information leakage.

C. Hybrid Intrusion Detection Components

1) Random Forest model: Random Forest was employed as a supervised learning model for known attack classification. Random Forest constructs multiple decision trees and combines predictions through ensemble voting. Due to its

robustness against overfitting and ability to process high-dimensional traffic features efficiently, it serves as an effective baseline classifier for intrusion detection. The Random Forest component primarily contributes toward identifying attack behaviors already represented during training.

2) XGBoost model: XGBoost was incorporated to improve discriminative capability through gradient boosting. Unlike Random Forest, XGBoost progressively corrects prediction errors during training and learns complex relationships within network traffic patterns. Experimental observations showed that XGBoost demonstrated stronger performance under specific zero-day scenarios such as WebAttack experiments. Therefore, it played an important role within the adaptive decision framework.

3) Autoencoder-based anomaly detection: An Autoencoder was employed to model normal network behavior using benign traffic samples only. The Autoencoder architecture consisted of a symmetric encoder-decoder structure designed to learn compact representations of benign network traffic behavior.

The encoder progressively reduced feature dimensions from $78 \rightarrow 64 \rightarrow 32 \rightarrow 16$, while the decoder reconstructed traffic representations using $16 \rightarrow 32 \rightarrow 64 \rightarrow 78$. This structure enabled learning of compressed latent representations while preserving important traffic characteristics required for anomaly detection.

Let the input feature vector be represented as:

$$x \in R^d \tag{1}$$

The encoder transforms input data into a latent representation:

$$z = f(x) \tag{2}$$

The decoder reconstructs the original input:

$$\hat{x} = g(z) \tag{3}$$

The reconstruction loss is calculated using mean squared error:

$$L(x, \hat{x}) = \frac{1}{d} \sum_{i=1}^{d} (x_i - \hat{x}_i)^2 \tag{4}$$

Higher reconstruction error values indicate stronger deviation from learned normal behavior and are therefore treated as anomaly indicators. Unlike supervised classifiers, the Autoencoder provides sensitivity toward previously unseen attack behavior.

D. Adaptive Hybrid Decision Logic

The final intrusion decision is generated through adaptive hybrid fusion of Random Forest, XGBoost, and Autoencoder outputs. The hybrid score is computed as:

$$H(x) = w_1 RF(x) + w_2 XGB(x) + w_3 AE(x) \tag{5}$$

where,

$$w_1 + w_2 + w_3 = 1 \tag{6}$$

The final intrusion decision was determined using a threshold-based decision rule:

$$Decision(x) = \begin{cases} Attack, & \text{if } H(x) > T \\ Benign, & \text{otherwise} \end{cases} \tag{7}$$

where, T represents the decision threshold used to distinguish benign and malicious network behavior. The hybrid decision formulation provides a unified representation for combining the outputs of Random Forest, XGBoost, and Autoencoder models. In this study, attack-family holdout experiments were used to analyze how individual detection components responded to different unseen attack characteristics. Experimental observations showed that WebAttack scenarios exhibited stronger responses from the XGBoost component, Infiltration attacks were more effectively identified through Autoencoder-based anomaly behavior, and DDoS experiments demonstrated relatively balanced contributions from the detection components.

Therefore, the adaptive behavior discussed in this work represents an experimental analysis of the contribution of supervised and anomaly-based models under different unseen attack scenarios rather than a deployment-time mechanism that automatically identifies attack families and dynamically selects optimal weights. These observations highlight the limitations of using a single fixed detection emphasis across diverse zero-day attack behaviors and motivate further investigation toward fully automated adaptive decision mechanisms.

1) Hyperparameter configuration: To ensure reproducibility and stable model behavior, experimentally selected hyperparameters were used during training and evaluation. The configuration settings used for Random Forest, XGBoost, and Autoencoder training are summarized in Table I.

TABLE I. HYPERPARAMETER CONFIGURATION USED DURING MODEL TRAINING.

Model	Configuration
Random Forest	n_estimators = 100, max_depth = 20
XGBoost	n_estimators = 100, learning rate = 0.1, max depth = 6
Autoencoder	Encoder: 78-64-32-16, Batch Size = 256, Epochs = 20, Optimizer = Adam

E. Realistic Zero-Day Evaluation Design

Conventional intrusion detection evaluations commonly rely on random train-test splitting, where attack distributions remain similar across training and testing stages. Such protocols may produce inflated performance estimates and fail to represent practical deployment conditions. To create realistic zero-day scenarios, complete attack families were removed

from training and introduced only during testing. Multiple experiments were performed using attack-family holdout methodology.

The following experiments were conducted:

- Experiment 1: WebAttack holdout.
- Experiment 2: DDoS holdout.
- Experiment 3: Infiltration holdout.

This strategy ensured that selected attack behaviors remained entirely unseen during training.

IV. Experimental Setup and Evaluation Protocol

A. Dataset Description

The proposed intrusion detection framework was evaluated using the CICIDS2017 dataset, which is widely used for benchmarking network intrusion detection systems under modern traffic conditions. The dataset contains both benign and malicious network traffic generated under realistic communication scenarios. For this work, only the raw CICIDS2017 CSV files were used to ensure reproducibility and eliminate inconsistencies introduced by previously processed datasets.

After merging and preprocessing, approximately 2.57 million traffic samples were retained. Network flows were represented using 78 numerical features extracted from traffic statistics and protocol-level characteristics. The dataset characteristics and attack-family distributions used in this work are summarized in Table II.

TABLE II. Summary of CICIDS2017 Dataset Characteristics and Preprocessing.

Parameter	Value
Dataset	CICIDS2017
Raw CSV files	8
Samples after preprocessing	∼2.57 million
Features used	78
Labels	Benign = 0, Attack = 1
Train : Test : Val	70 : 15 : 15
BENIGN samples	2,146,899
DDoS samples	128,014
WebAttack samples	2,143
Infiltration samples	36

B. Experimental Environment

Experiments were conducted using a combination of local and cloud-based environments to support large-scale model training and deployment analysis. Model development and experimentation were performed using Python with machine learning and deep learning libraries, including Scikit-learn, XGBoost, PyTorch, NumPy, and Pandas. Initial experimentation and training activities were conducted using Google Colab and later migrated to a local development environment to improve reproducibility and avoid computational limitations.

The local system configuration consisted of:

- AMD Ryzen 5 5600H processor
- NVIDIA GTX 1650 GPU
- 16 GB RAM
- VS Code development environment

To evaluate practical deployment feasibility, inference experiments were additionally conducted using Raspberry Pi edge hardware. The edge system was used exclusively for model loading, adaptive inference, resource monitoring, and latency analysis.

C. Evaluation Protocol

The proposed system was evaluated under multiple experimental settings to assess behavior under both conventional and realistic intrusion scenarios. The first evaluation stage consisted of baseline closed-world testing using standard train-test distributions. The second evaluation stage focused on realistic zero-day assessment using attack-family holdout experiments. Unlike random train-test splitting approaches, complete attack categories were removed during training and introduced only during testing. Training datasets contained benign traffic and all remaining attack categories except the selected holdout family.

D. Ablation Study Design

To analyze the contribution of individual components within the proposed framework, an ablation study was conducted. The following configurations were evaluated independently: Random Forest only, XGBoost only, Autoencoder only, and the Hybrid framework. This analysis enabled identification of strengths and weaknesses associated with supervised, anomaly-based, and combined detection approaches. The performance comparison of individual models and the hybrid framework is presented in Table III.

TABLE III. Ablation Performance Comparison of RF, XGBoost, Autoencoder, and Hybrid IDS.

Model	Accuracy	Precision	Recall	F1
RF	0.9985	0.9966	0.9947	0.9957
XGBoost	0.9992	0.9969	0.9986	0.9977
Autoencoder	0.8890	0.7065	0.5871	0.6413
Hybrid	0.9990	0.9974	0.9967	0.9970

The Autoencoder produced lower closed-world accuracy because it was trained using benign traffic only and optimized for anomaly detection. The hybrid framework improved robustness by combining supervised learning capability with anomaly-sensitive behavior.

E. Performance Metrics

Performance evaluation was conducted using commonly accepted intrusion detection metrics. Accuracy was used to measure overall classification correctness. Precision quantified the proportion of predicted attacks that were correctly identified, while recall measured the capability of detecting malicious samples. F1-score provided a balanced measure combining precision and recall. In addition, Receiver Operating Characteristic (ROC) analysis and Area Under Curve (AUC) values were used. For edge deployment experiments, additional deployment metrics were measured: prediction latency, CPU utilization, and memory consumption.

V. Results and Discussion

A. Baseline Performance Evaluation

The initial evaluation was performed under conventional closed-world settings where attack categories present during testing were also represented during training. The supervised Random Forest and XGBoost models achieved very high performance across standard evaluation metrics. The hybrid framework combined outputs from all components and maintained strong overall performance. The observed results indicate that supervised learning approaches perform extremely well when attack distributions remain similar across training and testing datasets. However, such results should be interpreted carefully because high closed-world accuracy does not necessarily indicate effective generalization capability under realistic deployment conditions.

B. Realistic Zero-Day Evaluation Results

To assess realistic generalization capability, multiple attack-family holdout experiments were performed (WebAttack, DDoS, and Infiltration). Experimental observations revealed substantial differences in model behavior across attack categories. Detection capability varied significantly depending on traffic characteristics and attack structure. The performance comparison across realistic zero-day experiments is summarized in Table IV.

TABLE IV. Performance Comparison Under Realistic Zero-Day Attack-Family Holdout Experiments.

Experiment	Accuracy	Recall	Detected	Missed	Adaptive Strategy
WebAttack	93.77	85.30	1828	315	XGB-heavy
DDoS	82.13	64.37	1931	1069	Balanced
Infiltration	94.33	88.89	32	4	AE-dominant

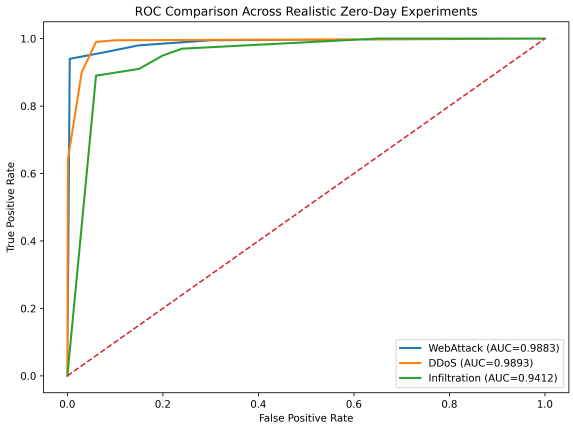

Fig. 2. ROC comparison across realistic zero-day attack-family holdout experiments.

The ROC analysis (Fig. 2) further validates discrimination capability across the realistic attack-family scenarios. WebAttack and DDoS experiments achieved strong AUC behavior, while Infiltration demonstrated comparatively lower separation characteristics because of extremely limited sample availability.

C. Adaptive Hybrid Analysis

Experimental evaluation under attack-family holdout scenarios revealed that the individual detection components exhibited different responses to unseen attack characteristics. The relative contribution of Random Forest, XGBoost, and Autoencoder components across the evaluated scenarios is illustrated in Fig. 3. These observations indicate that relying on a single detection emphasis may not provide consistent behavior across diverse zero-day attack patterns.

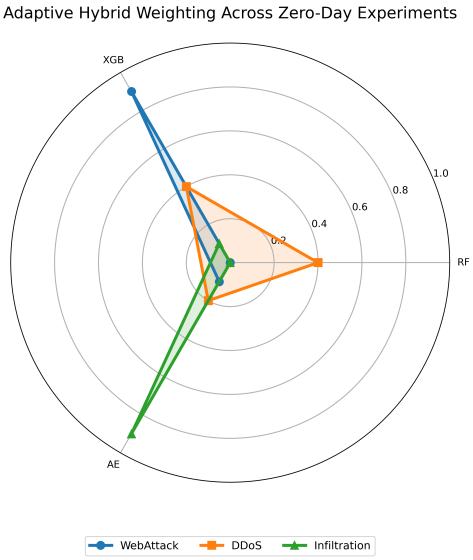

Fig. 3. Relative contribution of Random Forest, XGBoost, and Autoencoder components across realistic zero-day attack-family experiments.

For the WebAttack holdout experiment, the XGBoost component demonstrated stronger generalization behavior and contributed significantly to the final hybrid decision, resulting in the successful detection of 1828 out of 2143 attack samples with a recall of 85.30%.

In the DDoS holdout experiment, the detection components exhibited relatively balanced behavior, indicating that both supervised and anomaly-based characteristics contributed to the overall decision process. However, the achieved recall of 64.37% was noticeably lower than the performance observed for WebAttack and Infiltration scenarios. Since the DDoS attack family was entirely excluded during training, this result highlights the difficulty of generalizing intrusion detection models to certain unseen attack behaviors under realistic attack-family holdout conditions. These observations indicate that zero-day detection performance may vary substantially across different attack families and emphasize the importance of evaluating intrusion detection systems beyond conventional closed-world testing.

The Infiltration scenario represented a particularly challenging case where the supervised models showed limited detection capability, whereas the Autoencoder exhibited stronger anomaly-sensitive behavior. The hybrid analysis identified this difference in model response, resulting in the detection of 32 out of 36 Infiltration samples with a recall of 88.89%. However, this result should be interpreted carefully because

the limited number of available Infiltration samples in CI-CIDS2017 restricts broad generalization of this observation.

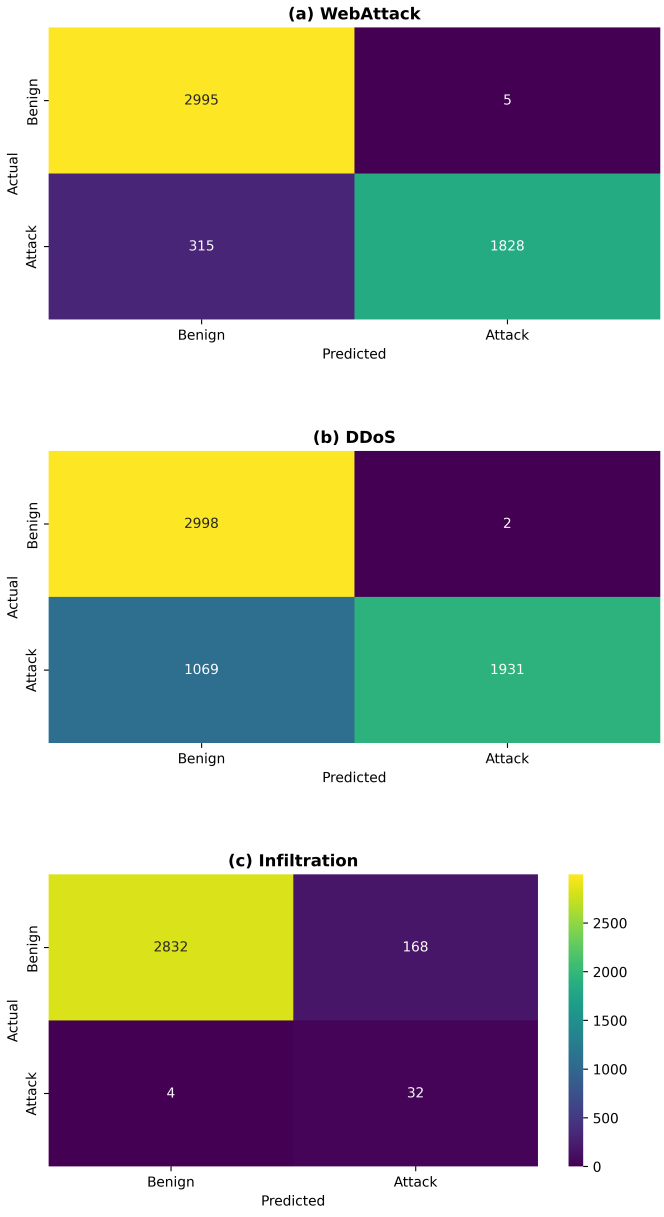

Fig. 4. Confusion matrices for realistic zero-day attack-family experiments.

The classification behavior across the three attack-family holdout experiments is further illustrated through the confusion matrices shown in Fig. 4. WebAttack and DDoS experiments achieved comparatively stronger detection performance, while the Infiltration experiment remained challenging because of the limited sample availability and its distinct attack behavior. Fig. 5 presents the score distributions obtained from the hybrid decision analysis across different attack-family holdout scenarios. WebAttack and DDoS produced score distributions concentrated around moderate decision regions, whereas the Infiltration scenario showed a stronger anomaly-oriented response with scores distributed closer to the higher decision region.

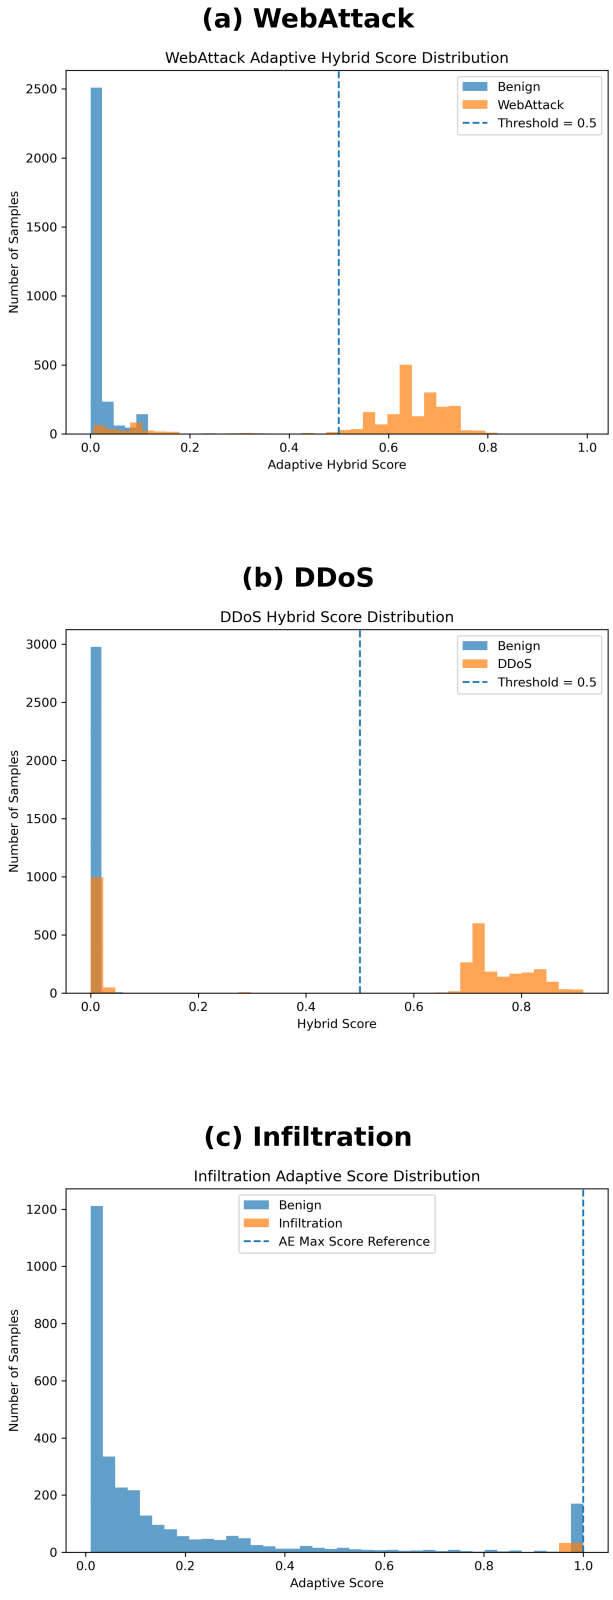

Fig. 5. Adaptive score distributions across realistic zero-day attack-family experiments.

D. Discussion of Key Findings

Several important findings emerged from experimental evaluation. The first is that closed world accuracy values close to 100% can give false readings for an intrusion detection system. While supervised models were highly successful under standard evaluation conditions, their performance significantly dropped when realistic unseen attacks were added.

Secondly, the attack-family holdout experiments demonstrated that different unseen attack scenarios produced different responses from the individual detection components. XGBoost showed stronger behavior in the WebAttack holdout experiment, whereas the Infiltration holdout experiment indicated greater sensitivity from the Autoencoder-based anomaly detection component. However, the Infiltration observations should be interpreted within the limitations of the CICIDS2017 dataset, where only 36 samples were available for evaluation.

Thirdly, observed during the attack-family holdout experiments are the different reactions to unknown attack scenarios by the individual detection elements. This observation suggests that a unique detection emphasis may not provide stable behavior across different kinds of zero-day attacks. This was proven through experimental results, which indicates that realistic attack-family holdout evaluation provides more information than traditional closed-world evaluation, the approach often utilized in intrusion detection research studies. The hybrid framework, described above, illustrates how supervised and anomaly-based detection components can exhibit complementary behavior toward unknown attack situations, advancing the state of current research in order to improve realistic zero-day intrusion detection and hybrid IDS evaluation [5], [7], [12].

E. Edge Deployment Results

To examine practical feasibility, the adaptive hybrid intrusion detection system was deployed on Raspberry Pi edge hardware. Model training remained external to the edge device, while inference and adaptive decision logic were executed directly within the Raspberry Pi environment. Experimental results demonstrated successful deployment with consistent prediction behavior under edge execution conditions. Resource monitoring showed low CPU usage, moderate memory consumption, and low prediction latency across experiments (see Table V).

TABLE V. RASPBERRY PI DEPLOYMENT PERFORMANCE AND RESOURCE UTILIZATION FOR REALISTIC ZERO-DAY EXPERIMENTS.

Experiment	Acc. (%)	Recall (%)	Latency (ms)	CPU (%)	RAM (MB)
WebAttack	94.42	86.93	0.0127	1.0	151.55
DDoS	82.13	64.37	0.0096	0.0	154.00
Infiltration	94.33	88.89	0.0122	0.0	150.98

With approximately 151 MB memory use, WebAttack deployment proved to be 94.42% accurate and had a recall of 86.93%. Therefore, it was clear that cloud-based trained adaptive intrusion detection systems can be deployed efficiently on edge devices that have lower computational power and can still maintain the capability of making inferences.

VI. CONCLUSION AND FUTURE WORK

In this work, an adaptive hybrid intrusion detection framework for realistic zero-day detection in cloud environment was presented. This work emphasized on reproducibility, realistic attack-family holdout experiments, and deployment feasibility, as opposed to traditional intrusion detection studies that come with closed-world evaluation settings. To prevent problems with preprocessing mismatch and feature inconsistency, the whole pipeline was rebuilt from raw CICIDS2017 data with a consistent pre-processing method.

The proposed solution integrated the Random Forest, XGBoost and Autoencoder models in a single adaptive decision mechanism. Experimental testing showed that closed world accuracy alone is not enough to evaluate intrusion detection capability in real world applications.Attack-family holdout experiments involving WebAttack, DDoS, and Infiltration demonstrated that different unseen attack scenarios produced varying responses from the individual detection components. The experimental observations highlight the importance of combining supervised and anomaly-based detection perspectives when evaluating realistic zero-day conditions. The Infiltration results, although showing promising anomaly-sensitive detection behavior within CICIDS2017, should be interpreted with consideration of the limited number of available evaluation samples. In addition, successful deployment on Raspberry Pi edge hardware validated the feasibility of executing adaptive intrusion detection logic on resource-constrained devices.

Future work may extend the proposed framework using live network traffic evaluation, federated learning architectures, and larger IoT-based environments. Additional investigation into dynamic threshold optimization and continuously evolving attack distributions may further improve practical zero-day detection capability.

ACKNOWLEDGMENT

The authors would like to express sincere gratitude to the Department of Computer Science and Engineering, Ramaiah Institute of Technology, for providing the facilities, technical resources, and academic environment required for this research work. The authors also acknowledge the valuable guidance and continuous support provided during the development, evaluation, and deployment phases of the proposed adaptive intrusion detection framework. The authors further express their appreciation to the MSRIT Alumni Association (MSRITAA) for its support and encouragement.

***Abstract*—Control charts do more than raise an alarm: their shapes can give an early indication of what has changed in a process. This study considers the case in which one chart window contains more than one abnormal behavior. The observed sequence is then a mixture rather than a pure pattern. We formulate this problem directly as multi-label classification. A one-dimensional CNN receives a raw-scale window of 32 observations and predicts the active elementary labels. The controlled protocol contains twelve scenarios: normal behavior, six single abnormal patterns, and five selected concurrent patterns. Raw-scale input is retained because shift patterns depend partly on level information that may be weakened by window-wise normalization. The retained training setup gives additional exposure to difficult shift and trend cases, while validation and testing remain balanced. Across five repeated trainings, the model achieved 96.11% exact match accuracy, 96.41% precision, 96.46% recall, 96.44% F1-score, and 1.04% Hamming loss. The 95% confidence interval for exact match was 96.05–96.17%. Additional analyses show stable performance around a decision threshold of 0.5, strong cyclic and systematic recognition, and lower performance for short shift cases. The results support direct multi-label CNN recognition for the selected protocol. Broader shift-containing mixtures, more complex combinations, varying noise conditions, and real industrial validation remain outside the scope of the present controlled study.**

Keywords*—Control chart pattern recognition; concurrent patterns; statistical process control; multi-label classification; convolutional neural network; process monitoring

I. Introduction

Control charts remain one of the basic tools of statistical process control. When a process is stable, the plotted observations fluctuate around a reference level without a persistent structure. When an assignable cause appears, the chart may drift, shift to another level, oscillate, or alternate in a systematic way [1]–[5]. These shapes are useful because they can provide an early diagnostic indication. A trend may be associated with progressive tool wear or a gradual operating change, while a shift may reflect an abrupt change in machine settings, material, or method. Cyclic and systematic patterns may indicate periodic influences or alternating production conditions [1], [5], [16], [23].

The goal of control chart pattern recognition (CCPR) is to identify the abnormal behavior visible in a chart window. Earlier studies used neural networks, statistical features, support vector machines, and optimization-based classifiers [6]–[13]. More recent work has used convolutional models, recurrent networks, feature fusion, transfer learning, and attention-based architectures [23], [29], [36]–[39].

Much of the CCPR literature assumes that one window contains one dominant abnormal pattern. This assumption is useful for basic classification, but it is restrictive in practice. Two assignable causes may act at the same time, so a chart can drift while it oscillates, or show a systematic alternation while another change is developing.

Concurrent CCPR addresses this case. It is difficult because the components are mixed in the same short and noisy sequence. A local increase may be random variation, the start of a trend, or part of a shift. A periodic movement may also be partly hidden by noise. The model should therefore indicate which elementary components are present rather than only select the nearest exclusive class.

Several concurrent CCPR studies transform the signal before classification. Wavelet decomposition, independent component analysis, singular spectrum analysis, blind source separation, learning vector quantization, support vector machines, random forests, and extreme learning machines have been used for this purpose [14]–[22]. These studies show that concurrent CCPR is not a minor extension of ordinary pattern recognition. They also show that the representation matters: when decomposition is inaccurate, its error is passed to the classifier.

Another issue is the representation of the target. A common approach is to create a separate class for each mixture. This is manageable when the number of combinations is small, but every new mixture requires a new class and the elementary diagnostic components remain hidden inside the class name. In this work, each elementary behavior has its own output. A window containing an upward trend and a cyclic movement should activate both labels. This description is closer to the way an engineer reads the chart.

The present study therefore focuses on a direct multi-label formulation. We use a compact 1D CNN, independent sigmoid outputs, and multi-label evaluation metrics. We keep the input on its original scale because shifts are partly defined by a level change. The main protocol contains twelve scenarios: normal behavior, six single abnormal patterns, and five concurrent cases. This set is deliberately focused. It is large enough to test direct concurrent recognition while remaining clear enough for

pattern-level error analysis.

We also compare a small number of reasonable training variants under the same protocol. The aim is not to claim a universal architecture or an exhaustive hyperparameter search. It is to establish a transparent reference configuration and examine its stability, label-wise behavior, threshold sensitivity, computational cost, and practical scope.

The main contributions are as follows:

- Concurrent CCPR is formulated as a direct multi-label problem so that the elementary abnormal components remain visible in the output.
- A twelve-scenario protocol is defined with explicit encoding for normal, single abnormal, and selected concurrent cases.
- A compact 1D CNN is evaluated on raw-scale windows using full-vector and label-wise metrics across repeated runs.
- Additional analyses examine uncertainty, threshold sensitivity, label-wise errors, computational cost, and the practical limits of the focused experimental scope.

The remainder of the study is organized as follows. Section II reviews related CCPR and multi-label studies. Section III presents the methodology. Section IV describes the experimental setup. Section V reports and discusses the results. Section VI concludes the study.

II. Literature Review

A. Single Control Chart Pattern Recognition

Early CCPR studies generally considered one abnormal pattern at a time. Neural networks were used to map a chart window to a pattern class [6], [7], while other studies used statistical or shape-based features to improve robustness to noise [10]–[12]. Support vector machines and optimization-based models were later adopted for nonlinear decision boundaries [13]. More recent work has introduced 1D CNNs, feature fusion, transfer learning, recurrent networks, and methods designed for imbalanced data or small shifts [29], [36]–[39].

The single-pattern setting remains useful because it isolates the shapes of trends, shifts, cycles, and systematic alternations. Its main limitation is that each window is forced into one class even when more than one source is active.

B. Concurrent Pattern Recognition

Concurrent CCPR was developed for mixed abnormal structures. Table I summarizes representative approaches in this area. Many methods first transform or decompose the signal and then classify the resulting representation. Wavelet methods use time-frequency information [14], [17]; ICA and blind source separation attempt to recover hidden components [15], [20], [21]; and singular spectrum analysis has been combined with SVM, LVQ, and random forest classifiers [16], [18]. Other studies have used ESMD, extreme learning machines, and PCA-weighted strategies [19], [22].

These methods show two recurring issues. First, overlapping patterns are harder to separate than single patterns. Second, performance depends not only on the classifier but also on the representation produced before classification. A decomposition stage can be useful, but it also introduces another source of error.

The target representation is equally important. Composite-class methods assign one class to each predefined mixture. A label-wise formulation instead keeps the same elementary labels across single and concurrent windows. For example, the cyclic label has the same meaning whether it appears alone, with a trend, or with another component. This representation supports a more direct diagnostic reading, although it does not by itself identify the physical root cause.

C. Deep Learning and Multi-Label Learning

Deep learning is now widely used for time-series classification and process monitoring [25]–[27]. For short fixed-length windows, a 1D CNN is a natural baseline because its filters can react to local rises, drops, transitions, oscillations, and alternating segments [28], [29], [35], [36]. Recurrent, hybrid CNN–LSTM, residual, and attention-based models are useful alternatives when longer temporal dependencies or variable-length sequences are central [24], [38], [39].

The output layer is central to the present problem. Softmax is appropriate when only one class can be active. Concurrent patterns require independent outputs because a cyclic component can coexist with a trend or a shift. We therefore use one sigmoid output per label and optimize binary cross-entropy, following standard multi-label learning practice [32]–[34].

The evaluation must also reflect partial correctness. Exact match requires the entire label vector to be correct, whereas Hamming loss counts individual label errors. Precision, recall, and F1-score show whether the model tends to create false activations or miss active components. The present work combines concurrent CCPR with this label-wise output and evaluation view.

III. Proposed Methodology

Fig. 1 shows the workflow we used in the experiments. We start from basic control chart components and use them to create single-pattern windows and selected concurrent windows. After that, each window is encoded as a vector of seven binary labels and passed to a one-dimensional CNN. We then read the prediction as a multi-label output, not as a single class.

We kept the method simple for a reason. If the generator is not clear, it becomes difficult to know why the model succeeds or fails. Also, the target must follow the physical meaning of the signal. If two components are used to generate the chart, two labels should be active. Finally, the evaluation should not hide partial mistakes. Detecting one component and missing the second is not the same error as detecting nothing.

This also explains why we do not try to solve all possible CCPR cases at once. The number of possible concurrent combinations grows quickly when more basic patterns are added. A very large set would look more complete, but it would be harder to understand. Here, the aim is to keep enough cases to test the concurrent idea and still be able to read the errors pattern by pattern.

TABLE I. REPRESENTATIVE CHOICES IN CONCURRENT CCPR LITERATURE

Study	Main strategy	Output view	Main relevance to the present work
Al-Assaf [14]	Wavelet-based multiresolution analysis	Pattern class	Shows that time-frequency representation can support concurrent CCPR.
Lu et al. [15], [21]	ICA combined with SVM	Separated patterns	Uses decomposition before classification; performance depends on separation quality.
Xie et al. [16]	SSA combined with SVM	Composite class	Represents concurrent windows through extracted temporal components.
Du et al. [17]	Wavelet decomposition and multiclass SVM	Composite class	Treats each concurrent case as a class after transformed feature extraction.
Gu et al. [18]	SSA and learning vector quantization	Composite class	Uses decomposition and prototype-based recognition for mixed patterns.
Yang et al. [19]	ESMD and extreme learning machine	Components	Addresses identification and quantification of concurrent patterns.
Pelegrina et al. [20]	Blind source separation and feature extraction	Separated sources	Highlights the importance and sensitivity of signal separation.
Cheng et al. [23]	Multi-label 1D CNN	Active labels	Provides the closest direct multi-label CNN reference for concurrent CCPR.

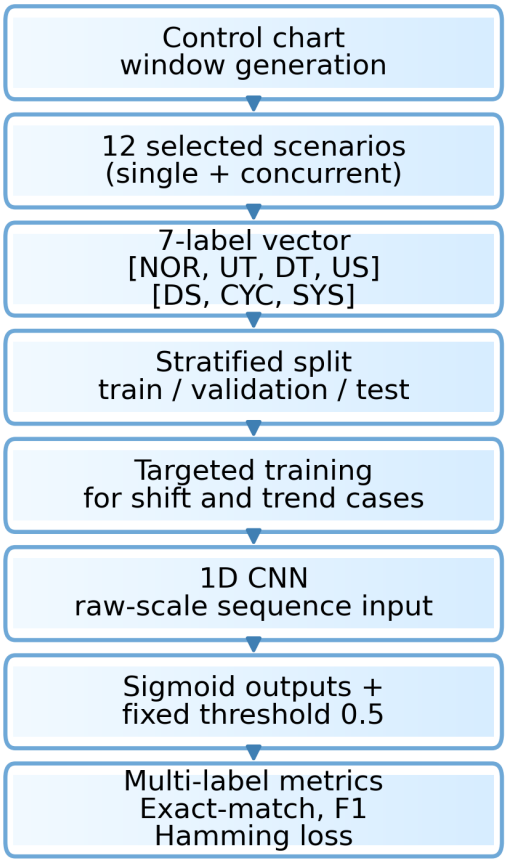

Fig. 1. Experimental workflow used in the proposed study.

We use the same logic for the model. We do not add a decomposition block or a long list of handcrafted features. Such elements may be useful later, but they would make it harder to see the effect of the multi-label formulation itself. We therefore use the present design as a direct reference point: raw window, CNN, sigmoid labels, and multi-label metrics.

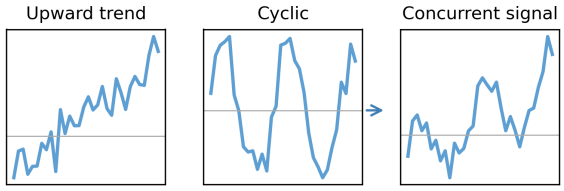

Fig. 2. Illustration of the transition from single abnormal patterns to a concurrent observed signal.

A. From Single Pattern to Concurrent Patterns

Going from single patterns to concurrent patterns changes the problem quite strongly. In the single case, the model searches for one dominant abnormal source. In the concurrent case, two sources may be present at the same time. The target is therefore not a class name anymore; it is the set of active components.

Fig. 2 gives a small example. One signal has a trend, another has a cyclic movement, and the final signal is the visible mixture. A classical multiclass model would need a special class for this mixture. With the multi-label view, the two components remain visible. This is more useful for diagnosis, because the output says what is inside the mixture.

B. Problem Formulation

Let a control chart window be represented as a one-dimensional sequence:

$$\mathbf{x} = [x_1, x_2, \ldots, x_n]^T, \tag{1}$$

where, $n = 32$ in our study. We aim to learn a function f_θ that maps the input window to a vector of label probabilities:

$$\mathbf{p} = f_\theta(\mathbf{x}) = [p_{NOR}, p_{UT}, p_{DT}, p_{US}, p_{DS}, p_{CYC}, p_{SYS}], \tag{2}$$

where, each element belongs to $[0, 1]$. The corresponding ground-truth vector is:

$$\mathbf{y} = [y_1, y_2, \ldots, y_7], \quad y_k \in \{0, 1\}. \tag{3}$$

We represent a concurrent pattern by several active labels in $\mathbf{y}$. For example, an upward trend with a cyclic component has $y_{UT} = 1$ and $y_{CYC} = 1$.

We do not treat this as a softmax problem. Softmax makes the classes compete, which is correct only when one class excludes the others. Here, one label does not exclude another one. A cyclic component can appear with a trend. For that reason, each output neuron uses a sigmoid activation.

We keep the normal label as an explicit output. We do not combine it with abnormal labels in our generated scenarios. A normal window means that no deterministic abnormal component has been added. This gives the CNN a reference behavior, against which the abnormal components are learned.

We make this point to avoid a small ambiguity. Random noise is present in all windows, but the label NOR does not mean 'noise'. It means that none of the deterministic abnormal components of the protocol is present.

C. Pattern Set and Label Encoding

We use twelve scenarios. Seven are single-label cases: normal, upward trend, downward trend, upward shift, downward shift, cyclic, and systematic. The remaining five are concurrent cases built from trend, cyclic, and systematic components. Shift-containing mixtures are not part of the present concurrent set. This choice is intentional rather than a conceptual exclusion. In a short window of 32 observations, the visible form of a shift depends jointly on its magnitude, change-point location, and the number of post-change observations. When a shift is superposed on another component, the relative amplitudes and temporal alignment introduce additional factors that require a dedicated generation and training protocol. Adding these cases to the present experiment would therefore change the controlled scope rather than simply add another class.

The scenario set is consequently a focused reference rather than an exhaustive catalogue of industrial mixtures. It was selected to examine the direct multi-label formulation under clearly defined and interpretable conditions. We do not claim that the resulting model covers every possible combination. We also do not use scenario names as model outputs. Instead, we use elementary diagnostic components. For example, *upward trend + cyclic* activates two labels, while *cyclic* activates one. Table II separates the scenario used to generate the window from the labels predicted by the model. This distinction allows a concurrent window to be described through more than one component.

Fig. 3 illustrates representative windows for the twelve scenarios used in the controlled protocol.

D. Data Generation Protocol

Each window is generated by adding a deterministic pattern component to random noise:

TABLE II. PATTERN SCENARIOS AND ACTIVE LABEL VECTORS

Scenario	Active labels	Label-vector interpretation
Normal	NOR	In-control behavior.
Upward trend	UT	Increasing slope.
Downward trend	DT	Decreasing slope.
Upward shift	US	Positive level change.
Downward shift	DS	Negative level change.
Cyclic	CYC	Oscillatory component.
Systematic	SYS	Alternating high-low structure.
Upward trend + cyclic	UT, CYC	Trend and oscillation.
Downward trend + cyclic	DT, CYC	Negative trend and oscillation.
Upward trend + systematic	UT, SYS	Trend with alternation.
Downward trend + systematic	DT, SYS	Negative trend with alternation.
Systematic + cyclic	SYS, CYC	Alternation and oscillation.

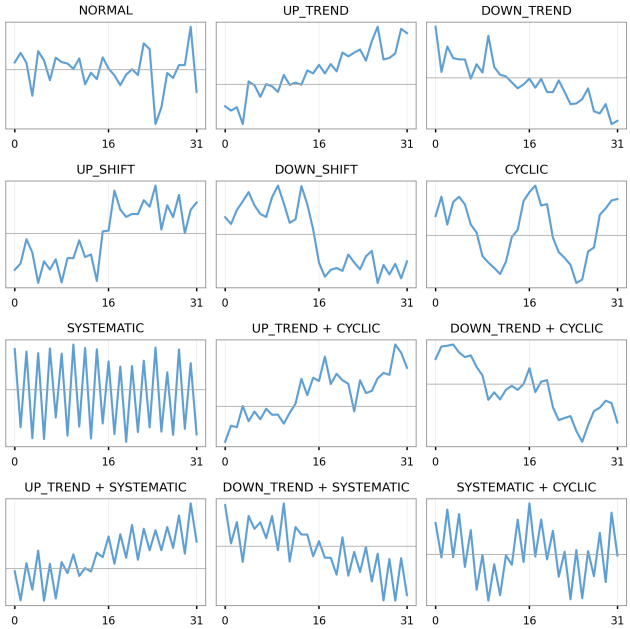

Fig. 3. Examples of the twelve generated control chart scenarios.

$$x_t = \epsilon_t + D_t, \quad \epsilon_t \sim \mathcal{N}(0, \sigma^2), \quad t = 1, \ldots, n. \tag{4}$$

We define the term D_t according to the active labels. The deterministic components are summarized in Table III. In a concurrent case, the deterministic components are added first, and noise is then added. In the main protocol, the Gaussian noise level is fixed at $\sigma = 1$ for all training, validation, and test windows. This controlled setting isolates the effect of the multi-label formulation and keeps the comparison between model configurations consistent. A trend creates drift, a shift creates a level change after a point, a cyclic term creates oscillation, and the systematic term gives a high-low alternation. We therefore know the labels from the generator; we do not assign them by visual judgment.

TABLE III. DETERMINISTIC COMPONENTS USED IN THE GENERATOR

Component	Expression	Role
Trend	$\pm gt$	Models progressive drift.
Shift	$\pm s\mathbb{1}(t > \tau)$	Models a sudden level change.
Cyclic	$a\sin(2\pi t/T + \phi)$	Models periodic behavior.
Systematic	$d(-1)^t$	Models alternating high-low observations.
Concurrent case	$D_t = D_t^{(1)} + D_t^{(2)}$	Adds active components in one window.

We keep the additive form plain by design. It keeps a visible link between the signal and the label vector. If the model misses a label, we know which component was missed. This is useful in a first controlled study.

In the main experiment, we keep the signal on its original scale. We do not apply window-wise z-score normalization. The reason is simple: a shift is partly a level change, and this level information can be weakened by normalizing every window separately.

We do not mean that normalization is never useful in CCPR. We only mean that, for the present target labels, preserving the vertical level is more consistent. This is especially true for upward and downward shifts.

This also makes our error discussion easier. If a shift is confused with a trend, we can still look at the original level and slope of the window. With independent normalization, part of this information has already been changed.

We also use the generator to improve reproducibility. Concurrent-CCPR papers are difficult to compare when equations, parameter ranges, or window sizes are not given in enough detail. Here, training, validation, and test windows follow the same definitions, but they are generated with different random seeds. The test data remain unseen, although they come from the same controlled process.

E. CNN Architecture

The CNN receives a raw sequence of 32 observations. Fig. 4 and Table IV summarize the retained architecture, which contains two one-dimensional convolutional layers, max pooling, dropout, one dense layer, and seven sigmoid outputs. No handcrafted descriptors or decomposition stage is added before the network.

The compact architecture is intentional. With only 32 input points, two convolutional stages are sufficient to build local features at two levels without introducing a large parameter count. The first layer detects short transitions and repeated local movements, while the second combines them into broader pattern evidence. A deeper residual network, a CNN–LSTM hybrid, or an attention mechanism may be useful for longer, variable-length, or more irregular signals [38], [39]; however, such models would add capacity and tuning choices that are outside the focused comparison made here.

The retained model has 15,687 trainable parameters and approximately 54,680 multiply-accumulate operations per sample. This small computational footprint supports its use as a reproducible reference architecture.

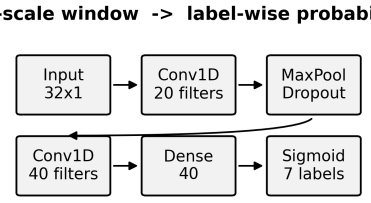

Fig. 4. CNN architecture used for multi-label recognition of control chart windows.

TABLE IV. CNN CONFIGURATION USED IN THE RETAINED EXPERIMENT

Element	Setting
Input size	32×1 raw-scale signal.
Convolution 1	20 filters, kernel size 5, ReLU.
Pooling/dropout	Max pooling followed by 12% dropout.
Convolution 2	40 filters, kernel size 3, ReLU.
Dense layer	40 units, ReLU, 12% dropout.
Output layer	Seven sigmoid neurons.
Loss	Binary cross-entropy.
Optimizer	Adam, learning rate 0.001.
Decision rule	Fixed threshold of 0.5.
Trainable parameters	15,687.
Approximate MACs	54,680 per sample.

F. Learning Objective and Decision Rule

We train the CNN using binary cross-entropy averaged over the $K = 7$ labels:

$$\mathcal{L}(\mathbf{y}, \mathbf{p}) = -\frac{1}{K}\sum_{k=1}^{K}\left[y_k \log(p_k) + (1 - y_k)\log(1 - p_k)\right]. \quad (5)$$

We interpret the sigmoid output p_k as the probability that label k is active. At inference time, the decision rule is:

$$\hat{y}_k = \begin{cases} 1, & p_k \geq 0.5, \\ 0, & p_k < 0.5. \end{cases} \quad (6)$$

We fix the threshold before testing. A label is active when its sigmoid value is at least 0.5. Label-specific thresholds could improve particular cases, but they would add another tuning stage. We therefore keep one common threshold and examine its sensitivity separately in Section V using saved prediction probabilities.

G. Evaluation Metrics

We choose the metrics according to the output. In many concurrent-CCPR studies, recognition accuracy or correct classification rate is enough because the output is one composite class [15]–[22]. Here, the output is a vector. We therefore need to look at both the full vector and the individual label decisions.

We use exact match as the strict measure: the complete vector must be correct. We use Hamming loss as a softer measure; it counts the wrong labels one by one. Precision tells

TABLE V. MULTI-LABEL METRICS RETAINED FOR EVALUATION

Metric	Expression	Interpretation
Exact match	$\frac{1}{N}\sum_i \mathbb{1}(\mathbf{y}_i = \hat{\mathbf{y}}_i)$	Strict full-vector correctness.
Precision	$TP/(TP+FP)$	Penalizes false label activations.
Recall	$TP/(TP+FN)$	Penalizes missed active labels.
F1-score	$2PR/(P+R)$	Balances precision and recall.
Hamming loss	$\frac{1}{NK}\sum_{i,k} \mathbb{1}(y_{ik} \neq \hat{y}_{ik})$	Label-wise error rate.

us whether the model activates labels too easily. Recall tells us whether it misses active labels. F1-score gives a balance. Table V summarizes these metrics and their interpretation [32]–[34].

H. Rationale for the Main Design Choices

We fixed a few choices before the final comparison. The first one was the window length. The window should be long enough to show a trend, a shift, or a cycle. It should also be short enough to keep the detection useful. We used 32 observations.

Our second choice was the raw input. Many concurrent-CCPR methods transform the signal before classification. This can help, but it also adds parameters and possible errors. In this study, we ask a narrower question: what can be achieved if the CNN sees only the observed chart window? This gives us a simple reference for later comparisons.

Our third choice was about balance. We gave each scenario the same number of test windows. The label distribution is not perfectly balanced, because some labels appear in more than one scenario. This is expected. We give the retained training setup more examples of difficult shift and trend cases, but we keep validation and testing balanced.

Our fourth choice concerned the metrics. Exact match tells us whether the whole diagnosis is correct, but it does not tell us how large the error is. For that reason, we also report Hamming loss, precision, recall, and F1-score.

Finally, we keep the number of variants limited. This is not a broad hyperparameter search. We compare a few reasonable choices: baseline CNN, two-channel input, weighted loss, shift-extra-only training, and targeted training. We keep the comparison readable.

IV. EXPERIMENTAL SETUP

The data follow the protocol described in Section III, and Table VI summarizes the main experimental settings. For each scenario, 5000 windows are generated for training and 1250 for testing. Ten percent of the training data are reserved for stratified validation. The test set remains balanced across the twelve scenarios and is not used to select the decision threshold.

The CNN is implemented in TensorFlow [30] and trained with Adam, a batch size of 16, and a maximum of 100 epochs. Validation loss is used for early stopping, and the evaluation metrics are computed with scikit-learn [31]. The experiment is repeated five times with different seeds. The retained configuration receives additional training examples for difficult shift and trend cases, but the validation and test sets remain unchanged.

TABLE VI. EXPERIMENTAL SETTINGS

Item	Value
Window size	32 observations.
Pattern scenarios	12 in the main protocol.
Output labels	7: NOR, UT, DT, US, DS, CYC, SYS.
Training samples	5000 windows per scenario before reinforcement.
Test samples	1250 windows per scenario, balanced.
Validation split	10% stratified validation.
Preprocessing	Raw-scale signal; no window-wise z-score.
Gaussian noise	Fixed at $\sigma = 1$ in all data splits.
Decision threshold	0.5 for all labels.
Number of runs	5 repeated trainings.

TABLE VII. OVERALL PERFORMANCE OF THE RETAINED CONFIGURATION

Metric	Mean (%)	Std.	95% CI (%)
Exact match	96.11	0.05	[96.05, 96.17]
Precision	96.41	0.05	[96.35, 96.47]
Recall	96.46	0.07	[96.37, 96.55]
F1-score	96.44	0.06	[96.37, 96.51]
Hamming loss	1.04	0.02	[1.02, 1.06]

No handcrafted descriptors, wavelet transform, SSA, ICA, or blind-source-separation stage is used. The main purpose is to examine how far a direct multi-label CNN can go with the observed raw-scale window. This design leaves fewer intermediate choices and makes the reference experiment easier to reproduce.

Reviewer-directed analyses were performed without changing the main twelve-scenario protocol. Saved test probabilities were used for threshold sensitivity and label-wise evaluation, and a matched five-run baseline was trained for paired statistical tests. These additions strengthen the analysis while preserving the original data-generation and evaluation scope.

V. RESULTS AND DISCUSSION

A. Overall Multi-Label Performance

Table VII reports the main five-run result for the retained configuration. Mean exact match is 96.11%, F1-score is 96.44%, and Hamming loss is 1.04%. The narrow confidence intervals indicate that the result is not driven by one favorable initialization.

Hamming loss gives a label-level view of the error. A value of 1.04% means that only a small fraction of individual label decisions are wrong, even when a full label vector is counted as incorrect by exact match. A separate five-run verification performed for the reviewer analyses produced 96.05% exact match and 96.39% F1-score, which is close to the original result and supports reproducibility.

B. Label-Wise and Pattern-Level Results

Fig. 5 shows precision, recall, and F1-score for each output label using the ensemble mean probability across the five verification runs. Cyclic and systematic labels are the strongest,

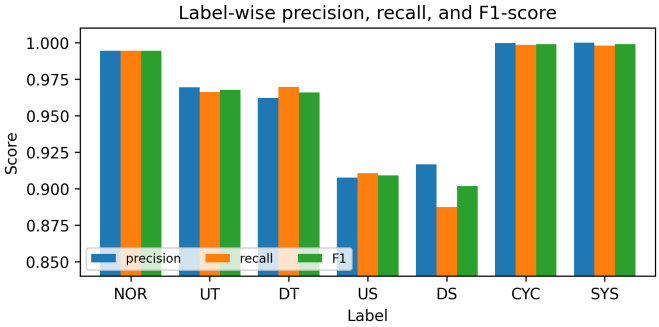

Fig. 5. Label-wise precision, recall, and F1-score.

TABLE VIII. PATTERN-LEVEL EXACT MATCH PERFORMANCE

Scenario	Exact match (%)	Test windows
Downward shift	88.16	1250
Upward trend	90.00	1250
Downward trend	91.04	1250
Upward shift	91.36	1250
Systematic	99.36	1250
Upward trend + cyclic	99.36	1250
Cyclic	99.44	1250
Normal	99.60	1250
Downward trend + cyclic	99.68	1250
Downward trend + systematic	99.68	1250
Upward trend + systematic	99.68	1250
Systematic + cyclic	99.92	1250

TABLE IX. COMPARISON OF EXPLORED CONFIGURATIONS

Configuration	Exact match (%)	F1-score (%)	Hamming loss (%)
Baseline CNN	96.08	96.40	1.04
Two-channel input variant	95.83	96.17	1.11
Targeted-training CNN	96.11	96.44	1.04
Weighted-loss variant	95.95	96.35	1.06
Shift-extra-only variant	95.90	96.24	1.09

with F1-scores of 99.90% and 99.89%, respectively. Upward and downward trend remain above 96.5% F1. Shift labels are weaker: upward shift reaches 90.89% F1 and downward shift 90.16%. The downward-shift false-negative rate is 11.28%, compared with 8.96% for upward shift.

Table VIII and Fig. 6 give the original scenario-level exact match rates. The selected concurrent cases are recognized well, whereas the weaker cases are single shifts and trends. This difference is plausible in a 32-point window. A weak trend may resemble random drift, while a small or late shift leaves only a limited number of post-change observations. In contrast, a cycle or systematic alternation creates repeated evidence across the window.

C. Comparison of Explored Configurations

Table IX summarizes the configurations examined before the retained setup was selected. The differences between the strongest variants are small. The retained targeted-training model is therefore treated as a balanced configuration, not as a universally superior architecture.

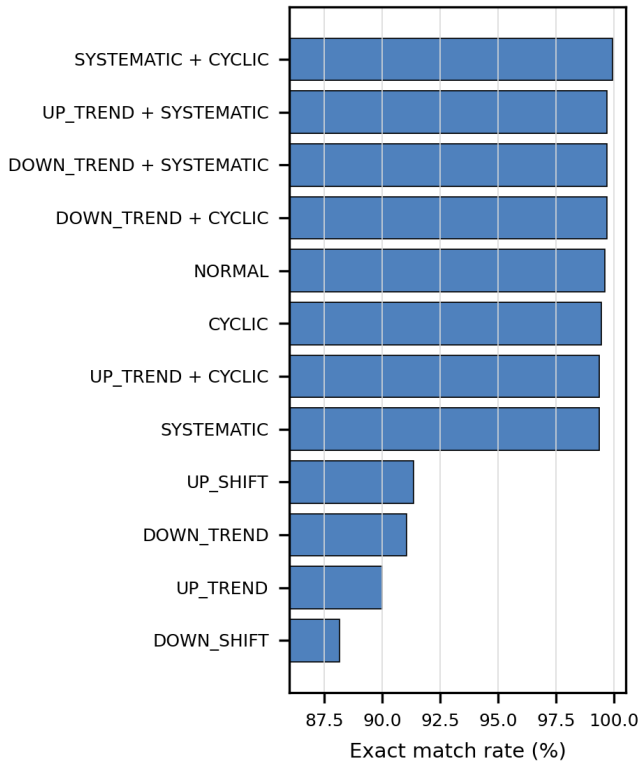

Fig. 6. Pattern-level exact match rate for the twelve control chart scenarios.

To test whether the small baseline difference was meaningful, a new matched five-run comparison was performed using the same seeds. The repeat means were 95.99% versus 96.05% for exact match and 96.33% versus 96.39% for F1-score. Paired t-tests gave $p = 0.558$ for exact match and $p = 0.653$ for F1-score; Wilcoxon tests led to the same conclusion. The difference is not statistically significant. We therefore retain the targeted-training setup because it gave the most balanced behavior across the difficult cases, while avoiding a claim of statistical superiority.

D. Decision-Threshold Sensitivity

Fig. 7 evaluates one common threshold from 0.30 to 0.70. Lower thresholds increase recall and give the highest F1-score at 0.30 (96.96%), but strict exact match falls to 93.98% because more false labels are activated. The threshold of 0.5 gives the highest exact match (96.05%) and the lowest Hamming loss (1.05%) in the repeated analysis. It is therefore a reasonable common operating point for the present objective.

E. Comparison with Prior Concurrent CCPR Studies

The closest published study is the multi-label CNN of Cheng et al. [23]. Table X provides a direct numerical context using their first experiment, which also used 32-point windows, seven labels, 5000 training samples per scenario, and 1250 test samples per scenario. Their protocol contains more concurrent scenarios, whereas the present protocol concentrates on five selected mixtures and preserves raw level information for shifts. The comparison is therefore informative but not a controlled head-to-head benchmark.

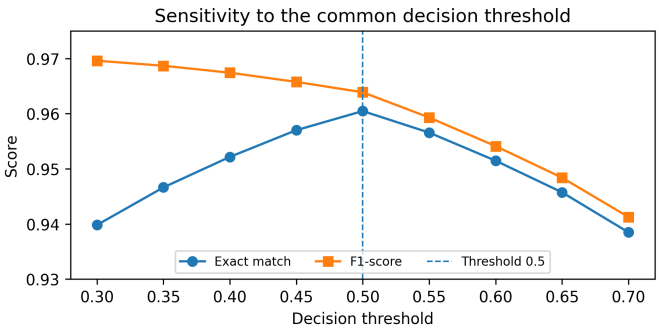

Fig. 7. Sensitivity of exact match and F1-score to the common decision threshold.

TABLE X. CONTEXTUAL COMPARISON WITH THE CLOSEST MULTI-LABEL CNN STUDY

Study	Scenarios	Window	Exact match (%)	F1 (%)	Hamming loss (%)
Cheng et al. [23], Exp. 1	16	32	92.56	95.68	1.98
Present study	12	32	96.11	96.44	1.04

The numerical values should not be read as proof of general superiority because the pattern generators and scenario sets differ. Cheng et al. also included a real-world monitoring demonstration, which is an important strength of their study. The contribution here is narrower: a compact raw-scale reference, explicit repeated-run stability, focused analysis of difficult shift and trend labels, and a transparent evaluation of the selected protocol. Earlier SSA–SVM, ICA–SVM, wavelet, and ELM studies remain relevant, but their composite-class outputs and different generators make direct metric comparison unreliable [15]–[22].

F. Computational Cost

The retained network is lightweight: it has 15,687 trainable parameters, about 54,680 MACs per sample, and a saved model size of approximately 0.22 MB. In the Colab CPU reruns used for the reviewer analysis, mean training time was 582 ± 117 s. Batched inference over the 15,000-window test set took approximately 0.29 s, corresponding to about 0.019 ms per sample. These values are implementation-dependent, but they show that the compact model has modest computational requirements.

G. Limitations and Practical Scope

The main results are obtained from synthetic signals. This controlled setting is useful because the active label vector is known exactly, which is rarely available for concurrent abnormalities in real plant data. However, it does not demonstrate industrial generalization. Sensor effects, autocorrelation, changes in variance, maintenance actions, and sampling changes may alter the observed shapes.

The scenario set is also intentionally limited to five selected concurrent combinations. Shift-containing mixtures, combinations with more than two simultaneous abnormalities, and systematic variation of the noise level were not included in the present protocol. A scientifically consistent extension would require a broader factorial design that controls shift magnitude, change-point position, component amplitudes, temporal alignment, and noise intensity in both training and testing. Adding a small number of post hoc cases would instead evaluate a different problem and would not provide a fair estimate of the model under a properly designed extended protocol. The claims of this study are therefore restricted to the twelve scenarios defined in Section III.

In practical use, the output should be treated as decision support rather than a closed diagnosis. A high probability means that the window resembles a learned component, not that the physical root cause has been proven. Real production validation with expert-confirmed multi-label annotations, broader concurrent combinations, and controlled noise studies remain necessary next steps.

VI. CONCLUSION

This study studied concurrent abnormal pattern recognition in control charts using a direct multi-label CNN. Each window is represented by seven elementary labels, so more than one abnormal behavior can be active without creating a separate composite class for every mixture.

Under the controlled twelve-scenario protocol, the retained model achieved 96.11% exact match accuracy, 96.44% F1-score, and 1.04% Hamming loss across five repeated trainings. Confidence intervals were narrow, and threshold analysis supported 0.5 as a stable common operating point when strict full-vector correctness is prioritized. Label-wise analysis showed very strong cyclic and systematic recognition, while short shifts and trends remained more difficult.

The method should therefore be understood as a compact and interpretable reference for the selected concurrent cases, not as a complete solution for every possible mixture. Shift-containing concurrent patterns, combinations with more than two abnormalities, varying noise conditions, and real industrial data require a dedicated extension of the generation and training protocol. These directions are important future work, but they do not change the main conclusion obtained for the controlled twelve-scenario setting.

***Abstract*—Renal pathology represents a diverse set of diseases that present significant clinical relevance. Included among the various types of renal pathologies are renal stones, cysts, and renal malignancies, all of which require diagnosis and therapy to prevent progression of the disease process. The current research study was performed to create and validate a classification model based on deep learning using a convolutional neural networks (CNN) architecture, namely a 50-layer Residual Network (ResNet-50) using Gradient-weighted Class Activation Mapping (Grad-CAM), to provide improved automatic detection of renal pathology from medical images and improve the interpretability of those medical images. During the study, the Explainable Deep Learning Pipeline (X-DLP) paradigm was followed, which provides a structured methodology to perform research with the use of deep learning in medical imaging. The X-DLP structures the research process into a series of phases, including Data acquisition and curation, Preprocessing and Augmentation, Model Creation via Transfer Learning, and lastly, Interpretability and Visualization.The results obtained show that the proposed model performs consistently well across different evaluation metrics. The Precision–Recall curve, with a PR-AUC close to 0.89, suggests that the model is effective at identifying positive cases even when the data are imbalanced. In addition, the F1-score reaches a peak of around 0.835 at a threshold near 0.45, indicating a good trade-off between precision and recall. From another perspective, the evaluation using Youden's criterion reveals sensitivity and specificity values close to 0.80, which supports the model's ability to distinguish between classes with reasonable accuracy. Moreover, the lift and cumulative gain analysis further highlight its practical usefulness, with a lift of 3.5 in the top 10% and a cumulative gain of 75% when considering 30% of the population. These results indicate that the model can effectively prioritize the most relevant positive cases. Overall, these findings suggest that the model can serve as a valuable support tool in medical diagnosis. By enabling automated classification of renal images and providing visual insights through interpretability techniques, it helps streamline clinical decision-making, reduces reliance on purely manual assessments, and enhances its potential for real-world application.**

***Keywords*—Classification; deep learning; Grad-CAM; medical imaging; ResNet-50**

I. Introduction

The worldwide increase in chronic kidney disease continues to be a major public health issue with millions of individuals affected, along with being a leading factor for mortality and disease morbidity [1]. The World Health Organization (WHO) [2] provides guidance along with the International Society of Nephrology (ISN) [3], that early detection and effective management of chronic kidney disease can help to reduce serious complications, hospitalizations from chronic kidney disease and provide for lower associated healthcare costs, including preventing progression of chronic kidney disease to end-stage renal disease requiring dialysis or kidney transplantation. Unfortunately, the ability to identify renal abnormalities through traditional methods of diagnosing kidney disease is limited due to manual evaluations, variations in interpreting radiographic images and limited access to trained specialists.

Although recent developments have been made in the areas of diagnostic methods and image processing through new imaging techniques; there are still insufficient tools available for early identification of renal abnormalities. The interpretation of medical imaging has a substantial component dependent on the medical expert's level of experience and; as such; can be impacted by inter-observer variability, human flaws and delays in delivery of care, particularly in areas where there are not enough nephrologists or radiologists available [4],[5]. Because of these challenges to effective prevention and identification of individuals with kidney disease, the associated impact of poor clinical outcomes, increased economic burden and decreased quality of life have not been able to be adequately addressed and/or mitigated [6]. As a result, the use of deep learning (DL) methods for assisting in automating and optimising the analysis of images for all types of kidney diseases is beginning to show many significant advances for detection, classification, and follow-up of these diseases [7]. Unfortunately, the most pressing challenge to the acceptance of DL in clinical settings is a lack of interpretability of DL models and; therefore, a lack of trust by physicians and; thus, reluctance to incorporate DL into their day-to-day practice. However, being able to provide visual explanations of DL model decisions is critical to providing transparency, building physician trust and supporting clinical decision making.

This research focuses on developing a deep learning model utilizing the ResNet-50 architecture to automatically classify kidney disease using medical images with the addition of Grad-CAM as an interpretability tool for the results of the model. The output of this system will include both predictions of the potential for abnormalities, as well as visualization of where the model is making those decisions, providing insight to the specialist regarding these areas [8],[9]. This approach follows international standards for quality and safety within

the healthcare profession, facilitating early diagnosis and aiding clinical decision-making for kidney disease, ultimately resulting in improved patient outcomes, while providing a scalable and accessible solution that will help to alleviate the disparity of care in areas where there may be limited numbers of specialists available.

This research project aims to develop a deep learning model based on the ResNet-50 architecture to classify kidney disease through medical images, utilizing interpretability methods like Grad-CAM to assist with clinical decision-making. The system will receive medical images where the physician suspects renal issues and produce probabilities of each type of condition, enabling the physician to predict kidney disease based on the medical images they send.

II. Literature Review

In this section, the theoretical foundations of the research are developed, organized into two main parts. First, the two fundamental variables of the study are addressed: kidney diseases and deep learning, allowing for an understanding of the key concepts that underpin the research. Second, a literature review is presented, in which the contributions of various authors related to the topic are described and analyzed, considering their previous studies and findings. In this way, a solid theoretical framework is built to support the development of the work.

A. Theoretical Base

1) Kidney diseases: Kidney diseases comprise a group of disorders that affect both the structure and function of the kidneys, essential organs responsible for maintaining the body's internal balance. The nephron, as the basic functional unit, is responsible for filtering the blood, reabsorbing necessary substances, and eliminating waste products through urine. From a pathophysiological perspective, these conditions may originate as prerenal, renal, or postrenal, altering mechanisms such as the glomerular filtration rate and the balance of fluids and electrolytes. Among the most common pathologies are chronic kidney disease, glomerulonephritis, pyelonephritis, and the formation of kidney stones, which often exhibit a progressive and silent course. Factors such as diabetes mellitus and hypertension play an important role in their development. Additionally, these diseases may lead to systemic complications, such as anemia, elevated blood pressure, and the accumulation of toxic substances in the body. Early diagnosis relies on laboratory tests and imaging techniques, facilitating timely care. In advanced stages, management may require procedures such as dialysis or kidney transplantation [10].

2) Deep learning: Deep learning is a subdiscipline of Machine Learning that is part of Artificial Intelligence and focuses on the development of computational models based on artificial neural networks inspired by the human brain. Its theoretical foundation lies in the organization of multiple layers of neurons that enable the learning of complex representations in a hierarchical manner from large volumes of data. Unlike traditional approaches, this type of learning allows the automatic identification of relevant patterns and features without manual intervention. Among the main architectures are convolutional neural networks, applied to image analysis, and recurrent neural networks, oriented toward processing sequential data. The training process is based on algorithms such as error backpropagation and gradient-based optimization methods. Additionally, its performance is conditioned by the availability of large-scale data and advanced computational resources. As a result, deep learning has driven significant advances in fields such as speech recognition, computer vision, and natural language processing [11].

Various studies in the medical field have driven the development of technological strategies based on deep learning with the aim of improving the detection, diagnosis, and treatment of diseases. In this context, multiple investigations referenced by authors have focused on the early prediction of Chronic Kidney Disease (CKD), integrating the selection of relevant clinical variables—such as blood pressure, serum creatinine, and other biomedical indicators—with deep neural network (DNN) models. Consequently, the results obtained, evaluated through metrics such as accuracy, precision, recall, and F1-score, demonstrate superior performance compared to traditional machine learning approaches, highlighting their value as tools to support clinical decision-making. In the same line, more recent studies have explored hybrid deep learning architectures aimed at enhancing the predictive and classification capabilities of CKD.

B. Related Work

A number of research projects in the life sciences have contributed to the development of technology-based methods that use deep learning techniques to enhance the identification, diagnosis, and treatment of various diseases [12]. In this context, several studies have focused on the early prediction of chronic kidney disease (CKD) by integrating relevant clinical variables—such as blood pressure, serum creatinine, and other biomarkers—with deep neural networks (DNNs) [13]. Based on performance metrics such as accuracy, precision, recall, and F1-score, DNNs consistently outperform traditional machine learning approaches, highlighting their potential as valuable tools for supporting clinical decision-making [14]. Furthermore, more recent studies have explored hybrid deep learning architectures aimed at improving the predictive and classification capabilities of CKD [15], [16]. These approaches typically involve extensive preprocessing stages—including data cleaning, normalization, and class balancing using techniques such as SMOTE—followed by feature extraction and sequential modeling. In particular, models combining CNN, LSTM, and GRU architectures have been developed and compared with individual approaches (e.g., DNN, LSTM, GRU, and 1D-CNN), achieving competitive results with accuracy up to 98.75%, precision up to 100%, recall up to 97.56%, F1-score up to 98.77%, and AUC up to 0.988 [17]. These findings highlight the superiority of hybrid architectures and their potential for real-world clinical applications. Another important research direction focuses on model interpretability, which is essential for adoption in medical settings. In this regard, DNNs have been combined with interpretability techniques such as LIME, enabling the analysis of each variable's contribution to the model's predictions [18], [19]. These methods have achieved strong performance, with accuracy values of 98.75% [20] and ROC-AUC values of 98.86%, confirming both their predictive power and their

usefulness as reliable and explainable tools for clinical decision support. On the other hand, recent studies have increasingly applied deep learning techniques to medical imaging for the detection and classification of conditions associated with CKD [21], [22]. These approaches incorporate advanced preprocessing techniques—such as Z-score standardization, min–max normalization, and robust scaling—to improve input data quality [23]. In terms of modeling, convolutional neural networks (CNN) combined with the Cell Search Algorithm (CSA) have been used to optimize performance. The results demonstrate outstanding performance, achieving an accuracy of 99.05%, an AUC-ROC of 99.03%, and a PR-AUC of 99.01%, along with high precision, recall, and F1-score values. These findings support the effectiveness of the proposed approach and validate its potential as a scalable tool for automated diagnosis and early detection of chronic kidney disease.

Deep learning-based Decision Support Tools (DSS) have been shown in multiple studies to improve on the performance of traditional DSS for diagnosing and predicting Chronic Kidney Disease, through giving new insight into ways of treating patients with end-stage renal disease. This type of technological advancement has allowed for multisite studies to integrate both clinical and medical imaging (e.g., CT scans) data to assess how different machine learning models perform in regards to Chronic Kidney Disease [24],[25]. To date, researchers have developed relatively new Deep Learning models, in the form of deep neural networks, and compared them to traditional classifiers such as K-Nearest Neighbor (KNN) [26], Random Forests [27], Naive Bayes [28], and Probabilistic Neural Networks [29] and found the deep learning-based models performed better than the traditional classifiers in predicting CKD and providing recommendations and thus can be useful for clinicians. The same idea has been expressed recently in more sophisticated ways using techniques like transfer learning and ensemble learning to improve predictions for early identification of CKD. By utilising large-scale publicly available datasets, researchers have tested cutting-edge architectures, including EfficientNetV2, InceptionNetV2, MobileNetV2, and Vision Transformer (ViT), producing extremely competent results with accuracies over 90% for the single model types tested and 91.5% for models using ViT and up to 96% when using ensemble models. Other studies have also started investigating retinal fundus photographs as a supplementary source of clinical information for CKD diagnoses by combining them with different types of data, including eGFR, from large datasets with tens of thousands of records [30],[31]. Different model configurations have been analyzed, including single-image and multi-image comparisons (with demographic data or bilateral images), and multiple training strategies based on ensembles or cross-validation, as well as the relative efficacy of various architectures (e.g., EfficientNet-B3 with AUC of 0.868; Sensitivity of 0.792%; Specificity of 0.788%) in real clinical settings; furthermore, additional studies support the value of deep learning as an important method for diagnosing kidney diseases, and appropriate preprocessing and feature selection techniques must be applied to accurately classify chronic versus non-chronic cases [32],[33].

Different researchers have conducted multiple studies that illustrate how far we have come with using deep learning for assessing how well people will do after they are diagnosed with CKD. A new multimodal-model (of various ultrasound images) has been created to automatically classify early stages of fibrosis with the goal of producing more accurate clinical diagnoses [34],[35]. In this selected-prospective [three different ultrasound modalities used in this study - grayscale ultrasound imaging; superb microvascular imagaing (shear-wave elastography); and strain-1' elastography], using a target ratio of 70% data designated for training [36] and 30% of the data designated for testing was used, the authors provide evidence that the multimodal approach has significantly outperformed (ROC 0.86) [37] either traditional clinical or monomodal approaches when determining if a patient has advanced fibrotic CKD and therefore warrants specialist referral to continue treatment or follow-up care. The determination was based on three performance metrics (accuracy=0.779; sensitivity = 0.796; specificity =0.767) [38],[39]. On a related note, some researchers have developed an automated system for classifying kidney images by abnormality (normal, cyst, tumor, stone) using machine learning algorithms (random forest) and a web-based application programmed in Flask via a convolutional neural network (CNN) [40],[41]. The results demonstrate high diagnostic capability with an accuracy of 97% for clinical diagnoses, particularly in settings with limited resources. In addition, researchers have created models to predict the progression of chronic kidney disease (CKD) toward end-stage renal disease (ESRD) over a 3-year period through machine learning and deep learning, using feature selection and interpretive techniques (such as LASSO, random forests, XGBoost) [42]. Those models had AUC-ROC values of 0.8991 and were able to identify important clinical predictors (haematuria, proteinuria, potassium, albumin/creatinine), but showed inverse relationships with eGFR/urine creatinine. Finally, researchers have developed a multi-class TabNet-based model to classify diabetic patients' stages of CKD [43]. This model was implemented in two versions: a full version with 31 clinical variables and a simplified version with 15 features obtained from routine checkups, being compared with traditional methods such as XGBoost, Random Forest, AdaBoost, and multilayer perceptron. Finally, superior performance of the proposed model was demonstrated, achieving accuracies of up to 94.06 in cross-validation and 91 in testing, as well as identifying serum creatinine, cystatin C, age, and sex as the most influential variables. Overall, these studies reflect the potential of deep learning as a key tool to improve the detection, classification, and prediction of CKD, thereby contributing to better clinical decision-making. The model was utilized in two different ways: a complete version (31 clinical features) and an aggregate version (15 standard features), which was compared against two methods of detection (XGBoost, Random Forest, AdaBoost, Multi-Layer Perceptron) [44],[45],[46]. Ultimately, the proposed model exhibited superior performance compared to traditional approaches, producing an overall accuracy of 94.06% during cross-validation and 91% during testing. Furthermore, the 4 variables that had the greatest impact on the proposed model's performance were serum creatinine, cystatinC, age and sex. Overall, the findings from this series of studies demonstrate the ability of deep learning to serve as a valuable resource for improving detection, classification and prediction of CKD, as well as enhancing

clinical decision-making [47].

III. Methodology

A. Definition of the X-DLP Methodology

The purpose of this study is to implement an enhanced and sequential combination of fully automated procedures for the classification of renal pathologies from Computed Tomography (CT) and Magnetic Resonance Imaging (MRI) scans of the kidneys [47]. This is achieved through the integration of Transfer Learning techniques and the pre-trained ResNet-50 model, with the aim of improving the model's generalization capability when classifying renal lesions, regardless of the inherent morphological variations among them [48], [49]. For the development of this research, a publicly available dataset obtained from the Kaggle platform was utilized. The dataset consists of 11,756 renal medical images organized and labeled into four diagnostic categories: renal cyst, normal kidney, kidney stone, and renal tumor. The images were structured into class-specific directories, facilitating their preprocessing, analysis, and utilization during the training and validation stages of the proposed model. This dataset was originally collected and published by its authors for scientific research purposes, providing a reliable source for the development and evaluation of automated renal pathology classification methods. Furthermore, the X-DLP methodology incorporates the Gradient-weighted Class Activation Mapping (Grad-CAM) algorithm as part of the Explainable Artificial Intelligence (XAI) framework [50]. This approach generates heatmaps that highlight the regions of interest used by the model to identify and classify renal pathologies, as illustrated in Fig. 1. These visual explanations provide insight into the areas that support the model's predictions, enabling the validation and interpretation of the neural network's decision-making process. Therefore, the proposed approach not only aims to achieve superior performance compared to currently available methods but also seeks to enhance the transparency and reliability of the developed Clinical Decision Support System (CDSS). In addition, it enables healthcare professionals to visually verify, through XAI techniques, the pathological evidence considered by the model during the classification process. From a methodological perspective, one of the main contributions of the X-DLP framework is its ability to address the well-known black-box problem associated with deep learning models. Consequently, diagnostic traceability becomes an essential feature in high-precision medical environments, as illustrated in Fig. 2, promoting greater trust and interpretability in AI-assisted clinical decision-making.

1) Data acquisition and curation phase: In the X-DLP methodology, the dataset was developed by acquiring the data and constructing the complete dataset. This would include creating a reliable source for the data and cleaning the data to remove any records that contained noise, inconsistencies, or corruption [51]. In this way, Table I shows the results of a comparison between the original dataset and the cleaned dataset. in total, the original dataset had 11,756% samples to work with; however, there was 1 sample (0.008%) removed from the data for the Tumor class due to a small degree of corruption to that sample. Also, the Cyst, Normal, and Stone classes weren't modified in the cleaned database and kept their counts of 2,939 each, meaning that there was a 25% per cent distribution of samples across the final dataset for these three classes only. There was a slight reduction in the Tumor class to 2,938 (24.99% per cent) [52],[53] samples in the cleaned database. These data show that the inter-class balance of the dataset is maintained at a high level and retains nearly full integrity, indicating that it will work very well for machine learning activities by minimizing bias and promoting statistical consistency within the model train processes.

2) Preprocessing and augmentation phase: After applying a deep learning–based pipeline to the data for training, the goal was to improve the quality, uniformity, and generalization of the data used in training. The preprocessing steps included resizing images, Fig. 3 normalizing their intensities, filtering out noise, and ensuring that they were in the correct input format so that they would be consistent and compatible for use in the model. The dataset used for training the deep learning model, which consisted of four distinct image classes: Normal, Cyst, Stone, and Tumor. These categories represent the primary renal conditions considered in this study and were used to train and evaluate the proposed classification framework [54], [55]. Fig. 3a shows an image of an isolated stone – normal tissue was used to create this image and contains an intensity distribution typical of normal tissue without any significant anomalies. The cystic tissue shown in Fig. 3b has a well-defined circular appearance and is representative of a region of interest containing tissue of the cystic class that is in a normal anatomical context [56]. Fig. 3c is the image of a Tumor–Tumor, showing greater intensity heterogeneity and regions of greater structural complexity confirming the presence of a tumor lesion. Table II reflect the learned discriminative characteristics of the training phase used in the model for differentiating the classes by using visually discriminative patterns as features in the class ification process. The table is a complete representation of the understanding of dataset characteristics for the dataset images/partitions. Table IIa represents the training (80%), validation (10%), and test (10%) splits for the dataset and includes a total images equal to 11,756, while maintaining the proportionality of the image distribution. Table IIb shows us how the classes are distributed (cysts, normal, stones and tumours). Overall and within each partition of the dataset, it shows there is a good balance among the four classes; hence, the data is well-balanced in total and also within each of the three partitions (Train, Validation and Test). Finally, Table IIc shows that the dataset is a multi-class classification of medical images using TensorFlow/Keras and ImageDataGenerator without any data augmentations being performed.

3) Model architecture and transfer learning phase: In this section, the developmental phase changed from a model development stage to an already trained model for a designated task. Table III provides an exhaustive description of the architecture configuration and training of a model utilizing transfer learning with ResNet-50 as the prime backbone [57]. Table IIIa summarizes the configuration of the model in general. A model that was pre-trained on the ImageNet (input size 224x224x3) was used along with a fine-tuning process and an output layer adjusted to the four classes (the first layers being kept frozen, so pre-trained features will remain applicable). Table IIIb describes dimensional down-conversions at each level of the network, from the input to the deep feature extraction at the pinnacle of the

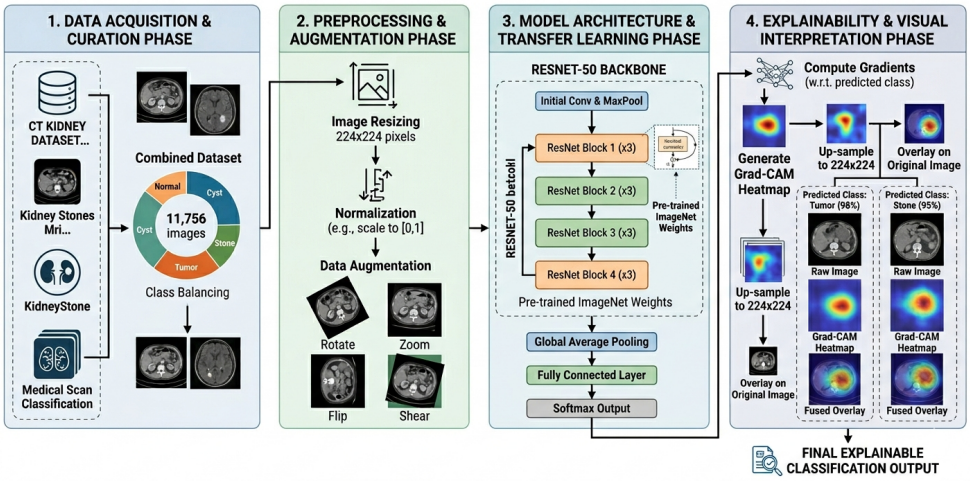

Fig. 1. Structure of the explainable deep learning pipeline (X-DLP) methodology.

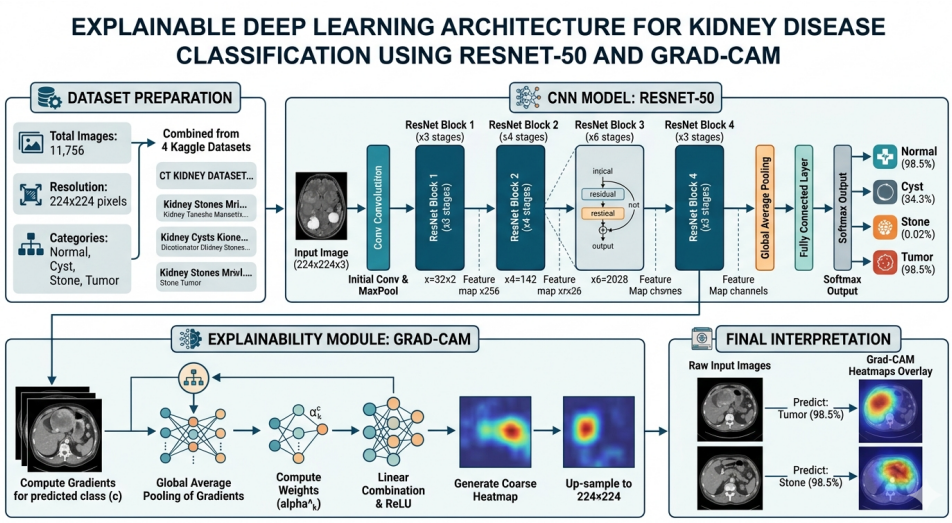

Fig. 2. Convolutional neural network architecture.

ResNet-50 backbone (the output of which is 7x7x2048). In turn, a Global Average Pooling layer is used to decrease dimensionality to 2048, which is then passed to an intermediate dense layer consisting of 512 neurons (0.5 dropout used for regularization), and finally to an output layer that contains four neurons. Table IIIc details the parameters and activation functions for each layer; it includes the number of parameters for the ResNet-50 backbone, the lack of parameters for the Global Average Pooling layer, the use of batch normalization to stabilize training, the use of dropout to help prevent overfitting, and the fact that the output layer has a softmax activation function to give a probability distribution over the four classes of outputs [58], [59].

4) Explainability and visual interpretaion phase: As noted in the prior phases of the development of AI-assisted diagnoses for kidney disease, the combination of using ResNet-50 as a deep learning model and applying Grad-CAM as an interpretability method has greatly improved the understanding behind the model's decisions [60]. In Fig. 4 provided, Grad-CAM activation maps are presented as a means of providing a visual justification for being classified as a kidney disease. In doing this, the anatomical Fig. 4a locations that are most relevant for each type of clinical case are identified (e.g., normal kidneys with baseline activation of renal parenchyma, Fig. 4b; focal aggravation in the lithiasic area for stones; areas of clustered activation around the edges of peripheral abnormalities for cysts, Fig. 4c; and complete identification of neoplasia, Fig. 4d). The color coding of blue being low and red being abundant, validate the clinical pathological data within the model test dataset through matching the healthy states; therefore, the validity of the test will enable their application in real clinical scenarios. Therefore, a simplified web system that allows the medical specialist to evaluate the model's output to each unique label to enable qualitative assessment of the hypothesized predictions, is illustrated in Fig. 5. The steps shown in Fig. 5a illustrate a method for

TABLE I. COMPREHENSIVE DATASET STATISTICS BEFORE AND AFTER DATA CLEANING

Class	Before	After	Removed	Change (%)	Proportion (%)	Observation
Cyst	2939	2939	0	0.00%	25.00%	No corruption detected

classifying a medical image uploaded by a user through a ResNet-50 model into one of four classes; cystic, normal, stone, and tumor with a maximum accuracy of 92% [61]. Also, the interpretability process shown in the Fig. 5b makes use of the Grad-CAM technique to create superimposed heat maps of the body parts that significantly affect the algorithm's final output. This allows the user of the program to have an avenue to confirm the clinical correctness of the results generated by the algorithm, thus providing visual evidence for clinicians' use of algorithms rather than relying solely on the algorithm's "black-box" representation. The architecture for this application is using a client-server model, where a front-end user interface communicates with an inferencing engine via an API (Application Programming Interface) over the HTTP protocol [62],[63]. The backend will be responsible for processing the request and returning back, not only the desired result (Classification of the input), but also the explanation(s) (visual representation of how the answer was derived) of what occurred, thus providing the traceability and transparency needed to successfully implement Artificial Intelligence into today's medical practice.

IV. MATHEMATICAL FOUNDATIONS OF CONVOLUTIONAL NEURAL NETWORKS

A. Forward Propagation in Convolutional Neural Networks

A convolutional neural network (CNN) defines a parametric function $f(\mathbf{X};\Theta)$, where $\mathbf{X} \in \mathbb{R}^{H\times W\times C}$ is the input tensor and Θ represents all learnable parameters across layers. The network performs hierarchical feature extraction followed by nonlinear mapping to output space [64],[65] [see Eq. (1)]:

$$\hat{\mathbf{y}} = f(\mathbf{X};\Theta) \tag{1}$$

This equation represents forward propagation, where the neural network approximates a function that transforms the input $\mathbf{X}$ into a prediction $\hat{\mathbf{y}}$ using the learned parameters Θ.

Key points:

noitemsep, topsep=0pt, leftmargin=1.2em

- CNN models learn a function approximation $f : \mathbb{R}^{H\times W\times C} \to \mathbb{R}^{K}$.
- Parameters $\Theta = \{W^{(l)}, b^{(l)}\}_{l=1}^{L}$ are optimized during training.
- The architecture is composed of convolutional, pooling, and fully connected layers.

B. 2D Convolution Operation

The convolution operation in layer l is defined as Eq. (2). This equation defines the convolution operation as a weighted sum over a local region of the input.

$$\mathbf{Z}_{i,j,k}^{(l)} = \sum_{c=1}^{C}\sum_{u=1}^{K_h}\sum_{v=1}^{K_w} W_{u,v,c,k}^{(l)} \cdot X_{i+u,j+v,c}^{(l-1)} + b_k^{(l)} \tag{2}$$

Key points:

Dropout	0.5
Output	4

(C) DETAILED PARAMETER AND ACTIVATION SUMMARY

Layer (type)	Output Shape	Param #	Activation
ResNet-50 Backbone	(7, 7, 2048)	23,587,712	ReLU
Global Average Pooling	(2048)	0	-
Batch Normalization	(2048)	8,192	-
Dropout (0.5)	(2048)	0	-
Dense (Output)	(4)	8,196	Softmax

- $W^{(l)}$ are learnable convolution kernels.
- Each filter extracts spatial features.
- Local connectivity enforces spatial inductive bias.

C. Nonlinear Activation Mapping

This equation applies a nonlinear transformation to the linear output of the convolutional layer, allowing the model to capture complex relationships among extracted features. The activation function $\sigma(\cdot)$ introduces nonlinear representational capacity, which is essential for deep learning and pattern separation in high-dimensional spaces [see Eq. (3)]:

$$\mathbf{A}^{(l)} = \sigma\left(\mathbf{Z}^{(l)}\right) \tag{3}$$

This equation applies a nonlinear activation function.

This equation defines the Rectified Linear Unit (ReLU) activation function, which transforms the input by assigning zero to negative values and keeping positive values unchanged. Its use efficiently introduces nonlinearity, improves convergence, and mitigates vanishing gradient problems in deep networks [see Eq. (4)]:

$$\sigma(x) = \max(0, x) \tag{4}$$

ReLU function that introduces nonlinearity.

Key points:

noitemsep, topsep=0pt, leftmargin=1.2em

- Introduces nonlinear decision boundaries.
- Mitigates vanishing gradient.
- Encourages sparse activations.

D. Pooling as a Statistical Downsampling

This equation defines the max-pooling operation, which selects the maximum value within a local region of the input feature map. This process reduces spatial dimensionality while preserving the most relevant features and improving invariance to small translations [see Eq. (5)]:

$$P_{i,j,k}^{(l)} = \max_{(u,v)\in\Omega_{i,j}} A_{u,v,k}^{(l)} \tag{5}$$

Reduce dimensionality while preserving features.

Key points:

noitemsep, topsep=0pt, leftmargin=1.2em

- $\Omega_{i,j}$ is the pooling region.
- Provides translational invariance.
- Reduces complexity.

- $W \in \mathbb{R}^{K \times d}$
- Encodes global interactions.
- Final decision layer.

F. Softmax Probability Distribution

This equation defines the softmax function, which transforms logits into a probability distribution over the possible classes. Each output represents the probability of belonging to a class, ensuring that the total sum equals one [see Eq. (7)].

$$P(y = k \mid \mathbf{X}) = \frac{\exp(z_k)}{\sum_{j=1}^{K} \exp(z_j)} \tag{7}$$

Transforms logits into probabilities.

Key points:

noitemsep, topsep=0pt, leftmargin=1.2em

- Output sums to 1.
- Used in classification.

G. Cross-Entropy Loss Function

This equation defines the cross-entropy loss function, which quantifies the discrepancy between the predicted probability distribution and the true distribution. It penalizes incorrect predictions more strongly, guiding the training process toward a better model approximation [see Eq. (8)].

$$\mathcal{L}(\Theta) = -\frac{1}{N} \sum_{i=1}^{N} \sum_{k=1}^{K} y_{i,k} \log \hat{y}_{i,k} \tag{8}$$

Measures prediction error.

Key points:

noitemsep, topsep=0pt, leftmargin=1.2em

- Penalizes wrong predictions.
- Equivalent to log-likelihood maximization.

H. Optimization via Gradient Descent

This equation describes the update of model parameters using the gradient descent algorithm. The parameters Θ are iteratively adjusted in the opposite direction of the loss gradient to minimize the error [see Eq. (9)]:

$$\Theta \leftarrow \Theta - \eta \nabla_{\Theta} \mathcal{L}(\Theta) \tag{9}$$

Updates parameters iteratively.

Key points:

noitemsep, topsep=0pt, leftmargin=1.2em

- η is the learning rate.
- Uses backpropagation.

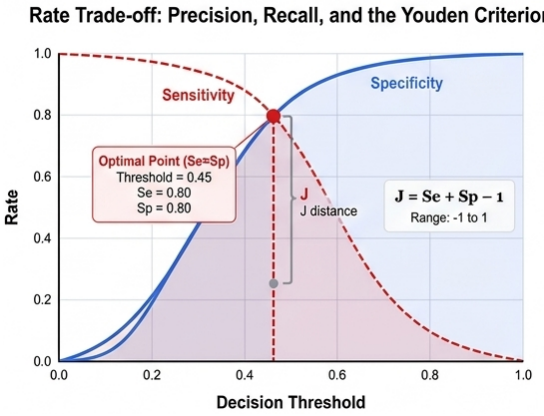
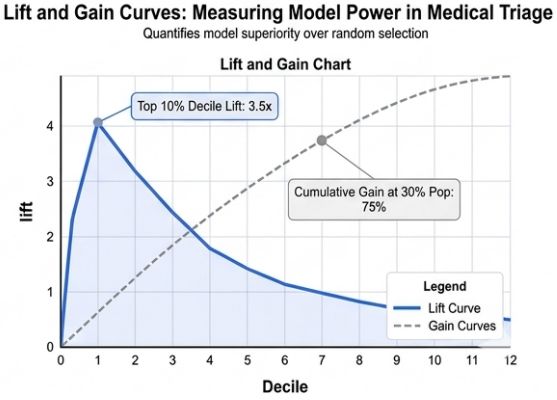
(b) Sensitivity and Specificity per Stage



(c) Presicion and F1 Score per Stage



(d) Comprehensive Performance Metrics Comparison

Fig. 6. Comparison of ML models based on performance metrics.

V. Results

This section presents a comprehensive and rigorous evaluation of the proposed classification model, utilizing a multi-perspective analysis through diverse performance metrics to thoroughly assess its predictive capacity and generalization limits.

Fig. 6 illustrates the detailed experimental behavior of the developed classifier across distinct operational scenarios. Specifically, Fig. 6a displays the Precision-Recall (PR) curve, which achieved an outstanding Area Under the Curve (PR-AUC) of 0.89. Unlike standard ROC curves, the PR-AUC provides a more realistic and stringent assessment under severe class imbalance conditions, as it prevents the true negative rate from inflating the perceived performance. Within this curve, the optimal cutoff point designated to maximize the F1-score is located at a precision of 0.82 and a recall of 0.85, minimizing both false positives and missed diagnoses. Furthermore, Fig. 6b outlines the F1-score profile as a continuous function of the evaluated decision thresholds. The maximum F1-score reaches its absolute peak at 0.835 under a specific decision threshold of 0.45, establishing the mathematically optimal compromise between detection accuracy and classifier selectivity. This analytical behavior is directly complemented by Fig. 6c, which contrasts sensitivity and specificity by optimizing Youden's index ($J = Se + Sp - 1$). At the same 0.45 threshold, the distance J is maximized, converging at a perfectly balanced sensitivity and specificity of 0.80. This convergence mathematically confirms the model's high discriminative power to distinguish between distinct diagnostic categories without bias toward the majority class. Finally, Fig. 6d exhibits the lift and cumulative gain curves, which serve as essential instruments for measuring the clinical impact and efficiency of the model in medical triage environments. The lift chart registers a remarkable value of 3.5 within the first decile, meaning that the model identifies true positive cases 3.5 times more effectively than a random assignment in the top 10% of the highest-risk population. Concurrently, the cumulative gain curve demonstrates that capturing 75% of all positive cases is achievable by evaluating only 30% of the total population sample. These findings conclusively establish a substantial predictive advantage and strict statistical consistency, validating the practical utility of the proposed framework as an automated Clinical Decision Support System (CDSS) capable of optimizing institutional resources.

VI. Discussion

The results obtained from the research, in line with the reviewed studies, confirm that the model achieved consistent performance within the CKD context. Prior investigations [1] and [14] highlight the high accuracy of deep neural network models when relevant clinical variables are incorporated. Other hybrid approaches, such as those reported in [17], achieve higher accuracy metrics ($\geq 98\%$) compared to the results of this study (PR-AUC ≈ 0.89, F1-score ≈ 0.835). Although the performance of these hybrid architectures exceeds that of the proposed model, such differences may be attributed to factors such as dataset size, preprocessing techniques, and model complexity [15]. Additionally, studies such as [20] emphasize the importance of model interpretability through explanation techniques, reinforcing the need for reliable systems in medical environments. On the other hand, recent research in medical imaging using advanced architectures [21], [22], and [23] reports performance levels close to 99%. Similarly, transfer learning and ensemble learning approaches have achieved accuracies above 90%, demonstrating a strong relationship between model performance and the use of large-scale datasets [30], [31], [5]. The findings of this study demonstrate adequate discriminative capability and prioritization of positive cases, with a balance between sensitivity (≈ 0.80) and specificity (≈ 0.80) based on Youden's criterion, a lift of 3.5 in the first decile, and a cumulative gain of 75%. These results are consistent with those reported in the literature and support the reliability of deep learning models [66], [32]. Furthermore, recent studies highlight the importance of multimodal models and disease progression prediction [33], suggesting that, although the proposed model shows competitive performance, there is still room for improvement through the integration of multiple datasets and more advanced architectures [34], [42]. Overall, these results position the present study within the current state-of-the-art, demonstrating that, although it does not achieve the highest reported metrics, the proposed model provides a balanced combination of performance, simplicity, and practical applicability in real-world scenarios [43].

VII. Conclusion

Kidney disorders are a collection of diseases that can affect the kidneys in different ways such as the following: kidney stones; cysts; and tumors; all posing major difficulties in the field of medicine by having an urgent need to be diagnosed accurately and quickly enough for patients' safety. To help solve this problem, one possible way to address the issue is to create a convolutional neural network model using ResNet-50 along with Grad-CAM methods will increase both detection abilities and give confidence in results. The study utilized an X-DLP Model approach to organize the project systematically at each Phase.

The data acquisition and curation phases helped curate the datasets used to select the images required for classification, and after preprocessing and augmenting the data (optimising image quality through image size and training techniques), the architecture of the model and transfer learning based on ResNet-50 as the main backbone made use of previously learned features which improved the overall performance of the model. During the interpretive/visualisation phase of the project, heatmap outputs provided a mechanism for identifying relevant regions that have been integrated into a web-based system in support of medical professionals.

The model was able to produce good solid results based on various evaluation measures. The Precision-Recall curve has produced a PR-AUC value of around 0.89, meaning it was very good at predicting positive cases when class size was disproportionately. The F1-score showed an approximate high point of 0.835 at approximately a 0.45 decision threshold which also demonstrated an adequate level of precision and recall. The analysis performed using Youden's criterion demonstrated the model had a reasonable discriminative capability; sensitivity and specificity levels were both approximately equal to 0.80. The model was also able to produce lift and cumulative gain curves that demonstrate that it was able to realise an adequately good ability to rank relevant cases; for example, lift of 3.5 (first decile) and gain of 75 (30 population). Therefore, the model's results confirm its usefulness as an assistive model in medical classification cases.

Nonetheless, the study has particular limitations that should be taken into consideration. Specifically, challenges were identified related to the detection of cases corresponding to the early stage of the disease, as lower sensitivity and AUC values were found in this case, indicating the necessity to enhance the model's capabilities for use during the early stages of the disease. Furthermore, the multiclass characteristic of the problem, as well as potential imbalances among categories could potentially have affected the overall outcome of the model. The investigation proposes to continue with the analysis through the use of larger and more diverse datasets obtained from various institutions for purposes of enhancing the model's ability to generalize. In addition, further study should also be conducted on the integration of other clinical variables and ensemble techniques to improve predictive performance. The inclusion of other methods for interpreting the results will increase the model's credibility and increase the likelihood of its use in real-life clinical settings and, therefore, will establish a practical and efficient tool for medical decision-making.

***Abstract*—Malaria remains a major public health issue in Ivory Coast, where the need for accurate and interpretable predictive models is critical for effective disease control. While most existing approaches prioritize predictive accuracy over interpretability, this study addresses the need for explainable models suitable for deployment in resource-limited public health settings. The study used a dataset covering multiple regions of Côte d'Ivoire over the period 2019–2023 and including climatic variables such as temperature, humidity, and precipitation. Seven conventional machine learning models (CatBoost, XGBR, RFR, DTR, SVM, KNN, and Linear Regression) were compared with three proposed Case-Based Reasoning variants (CBR_0, CBR_1, and CBR_2), which differ in their similarity-weighting strategies and correction constant. The results show that CBR_2 achieved the best predictive performance, with RMSE = 0.081, MAE = 0.057, and $R^2 = 72.40\%$, followed by the Random Forest Regressor. A Wilcoxon signed-rank test confirmed a statistical significant difference of this permofance ($W = 18029$, $p = 1.02 \times 10^{-20}$). Beyond predictive accuracy, qualitative criteria including explainability, transparency, and adaptability were evaluated, further highlighting the superiority of CBR_2 over conventional black-box models. These findings highlight the potential of Case-Based Reasoning for epidemiological forecasting and decision support in malaria control.**

Keywords*—Malaria prediction; case-based reasoning; machine learning; epidemiological forecasting; explainable artificial intelligence

I. Introduction

Malaria remains a major public health problem, particularly in sub-Saharan Africa, where it continues to cause thousands of deaths each year despite considerable efforts in prevention and treatment [1]. According to the official WHO report dated December 4, 2025, 282 million cases of malaria were reported in 80 countries worldwide, resulting in 610,000 deaths. 95% of the cases and 95% of the deaths were recorded in the WHO African Region. This disease has disastrous consequences in Ivory Coast, where it is the leading cause of death among children under 5 and the main reason for medical consultations at health facilities across the country.

According to Dr. Tedros Adhanom Ghebreyesus, Executive Director of the WHO since 2017: "Malaria elimination is achievable in many countries, provided that sustained investments are made and efforts are stepped up to reach those most at risk". Modern tools, such as artificial intelligence models, are therefore essential to ensure better monitoring of the disease and to support effective malaria control and elimination efforts.

A major challenge is accurately predicting malaria cases to optimize the allocation of often limited medical resources and identify high-risk areas [2]–[6] Such predictions also support the development of early warning systems for timely intervention and improved disease control [7], [8]

Although several machine learning (ML) models have been proposed to predict malaria incidence [2]–[4], these approaches share common limitations. First, most of them require large volumes of training data, which are rarely available in resource-limited settings [9]. Second, and more critically, they predominantly rely on black-box architectures whose internal decision logic is opaque, making it difficult for health professionals and policy-makers to trust and act upon their outputs [10], [11]. Despite significant advances in Explainable Artificial Intelligence (XAI), a significant gap remains between the development of explainable methods and their actual applicability in operational contexts [12], most current XAI approaches rely on post-hoc techniques (e.g., SHAP) that explain predictions after the fact without guaranteeing that these explanations accurately reflect the model's internal workings [10]. Crucially, no existing study in the literature has incorporated an inherently explainable model such as Case-Based Reasoning (CBR) to predict the number of malaria cases in a given locality.

Furthermore, according to Caro-Martinez et al. [12], in healthcare it is crucial to understand how an artificial intelligence model generates its predictions, as this is essential for ensuring its reliable and trustworthy use. It not only helps build user confidence but also facilitates scientific validation, error detection, and continuous improvement of the model. In addition, Pradeep et al. [10] show that in many sensitive fields such as healthcare, finance, and the justice system, automated decisions must be transparently justified in order to meet ethical and regulatory requirements and facilitate their integration into decision-support systems. Thus, there is a lack of inherently explainable models capable of balancing predictive performance with transparency [10].

With this in mind, this study focuses on Case-Based Reasoning (CBR) as a natively explainable paradigm for malaria case prediction, examining both its theoretical foundations and its practical applicability in a real-world epidemiological context.

The CBR approach appears to be a particularly relevant alternative for addressing the limitations of current XAI approaches [11]. Unlike post-hoc methods, CBR is inherently

explainable and transparent, as it relies on a reasoning mechanism based on similar past cases [11]. Each prediction is thus supported by references to situations that have already been observed, providing a natural way to answer the questions "why" and "how" a decision was made. This form of explanation, based on concrete examples, is more intuitive and accessible to non-expert users, particularly business decision-makers [11]. In short, by combining traceability, transparency, and ease of explanation, CBR remains a promising approach for designing artificial intelligence systems that are understandable, high-performing, and operational in critical fields such as healthcare [10], [13].

In practical applications, CBR offers several advantages, notably its inherent interpretability: each prediction is justified by reference to previous cases, making the model intuitive for non-technical users [13]. Furthermore, thanks to its adaptability, the system can be expanded by adding new cases to the knowledge base without requiring complete retraining [9]. Finally, CBR performs well with small datasets, unlike ML models that require large amounts of data [9]. Despite these advantages, no existing study in the literature incorporates a CBR approach to predict the number of malaria cases in a given locality.

However, several challenges and limitations associated with the CBR approach must be acknowledged. In particular, prediction accuracy depends heavily on how the case base is organized [11], [14]. Furthermore, determining an appropriate similarity metric for heterogeneous data (numeric, categorical, and temporal) remains a challenge [11], [15]. Additionally, traditional CBR does not always account for how case characteristics evolve over time [16], [17].

The objective of this study is therefore to propose an enhanced CBR-based approach that is explainable, transparent, and effective to improve the prediction of malaria case counts at the locality level in Côte d'Ivoire, thereby addressing both the predictive limitations of classical CBR and the opacity of existing ML-based forecasting models.

In the remainder of this study, Section II presents a summary of previous work on predicting the number of malaria cases. Section III outlines the classical CBR approach. Section IV describe the proposed CBR approach. Section V presents the experimental comparison with classical CBR and ML models using data from Côte d'Ivoire. The results are discussed in Section VI. Section VII concludes the study with a summary and outlook for future work.

II. Related Work

This section provides background on malaria case prediction using data analysis and machine learning approaches, and introduces the classical CBR approach.

A. Statistical Models

Classical statistical approaches have been widely applied to malaria time series forecasting. Linear regression and ARIMA models have been used to model temporal trends in case counts [18]–[20], while their seasonal extensions (SARIMA) have been adopted to capture recurrent epidemic cycles [21]. These models have demonstrated their ability to reflect seasonal patterns and weather-driven fluctuations in malaria incidence [3], [22].

However, statistical models suffer from several structural limitations. First, they rely on restrictive assumptions linearity, stationarity, and variable independence that are rarely met in real epidemiological data [23]. Second, and more critically, they are inherently unable to capture the nonlinear relationships and complex interactions among the climatic, environmental, and socioeconomic determinants of malaria transmission [22], [24], [25]. These shortcomings motivated the shift toward machine learning approaches, discussed in the following section.

B. Machine Learning Approaches

Several ML models have been developed to predict malaria case counts, with the aim of anticipating disease progression and facilitating more efficient allocation of medical resources [2]. The studies reviewed in this section are organized around three main axes: 1) the types of ML models employed, 2) the input features and data sources used, and 3) the limitations identified.

1) Machine learning models for malaria prediction: A wide range of ML algorithms has been applied to malaria case prediction. Ensemble methods have received considerable attention: Random Forest models have been used by [18] and [26] to capture non-linear relationships between environmental variables and malaria incidence, achieving competitive accuracy across different geographic settings. Gradient Boosting methods, including XGBoost and LightGBM, have been explored by [27], who demonstrated their superiority over single-tree models in terms of predictive performance on imbalanced epidemiological datasets. Kernel-based methods such as Support Vector Machines (SVM) have also been applied [28], particularly in contexts where the training dataset is limited in size. More recently, deep learning architectures have emerged in related infectious disease prediction tasks: for instance, [29] proposed CONV-FAN-POX, a convolutional deep learning framework for monkeypox detection, illustrating the growing trend toward deep feature extraction in epidemiological surveillance.

Beyond individual models, ML approaches have been shown to serve broader public health objectives. In [5], [6], and [30], ML models have helped public health authorities develop dynamic budgets, identify high-risk areas, and implement early warning systems.

2) Limitations of existing studies: Despite these advances, the existing literature reveals several recurring and significant limitations.

a) High data requirements: Most ML models, particularly deep learning architectures and ensemble methods, require large volumes of labeled training data [1], [9]. This constitutes a critical bottleneck in sub-Saharan Africa, where epidemiological surveillance systems are often incomplete or insufficiently digitized [4].

b) Lack of explainability and transparency: The models used in the reviewed studies are predominantly *black-box* models that do not provide intelligible justifications for their predictions [11], [28]. This opacity is particularly problematic

in healthcare contexts, where clinicians and policy-makers need to understand and trust the reasoning behind a prediction [12], [31]. Although some studies apply post-hoc explanation techniques such as SHAP or LIME, these methods do not guarantee that the explanation faithfully reflects the model's internal logic [10] and are often difficult to interpret for non-expert users [11].

c) Poor adaptability to temporal dynamics: Most ML models reviewed are trained statically and do not incorporate mechanisms for continuous updating as new epidemiological data become available [16], limiting their reliability for operational forecasting.

d) Limited geographic transferability: Many models were developed and validated in specific geographic contexts, and their performance in different settings such as Côte d'Ivoire has rarely been assessed [2], [3].

e) Absence of inherently explainable approaches: Crucially, no study in the reviewed literature has proposed an inherently explainable model for malaria case prediction. The CBR paradigm, which is natively interpretable and well suited to small datasets, has not been explored in this context, a gap that the present study aims to fill.

C. Introduction to Case-Based Reasoning

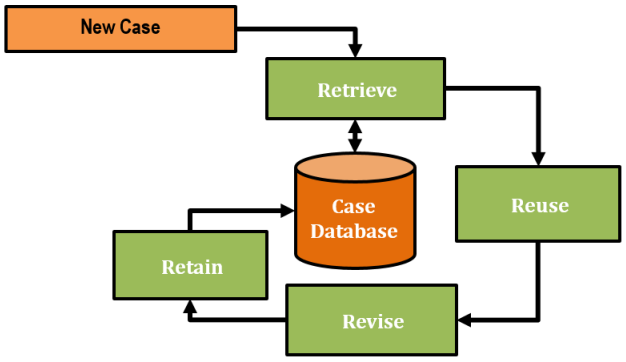

Fig. 1. The CBR life cycle.

Case-Based Reasoning (CBR) is an artificial intelligence method that solves new problems by drawing on concrete past experiences, known as cases, which contain a description of the problem, the solution applied, and the results obtained. The most similar cases are retrieved from a case base and their solutions are adapted to address the new problem. This enables intuitive and easily explainable reasoning, analogous to the way humans solve problems by drawing on past experiences. As shown in Fig. 1, the CBR life cycle comprises five sequential tasks [32]:

- Define: a new problem is described in order to compare it to past problems stored in the case base.
- Retrieve: using a similarity measure, the most similar problems in the case base are searched and selected.
- Reuse: knowledge related to the selected cases is reused to propose an initial solution.
- Revise: if the initial solution is not suitable, it is revised to make it more appropriate.
- Retain: the new problem and its associated solution are stored in the case base.

Major challenges associated with this approach include structuring the case database, selecting appropriate similarity metrics, and accounting for changes in the target variable over time (as discussed in Section I). To address these shortcomings, an improved CBR approach for predicting the number of malaria cases is proposed in the following section.

III. Proposed CBR Approach

This section presents the enhanced Case-Based Reasoning (CBR) approach proposed for predicting the number of malaria cases. The classical CBR cycle Retrieve, Reuse, Revise, Retain is extended through two key contributions: 1) a regional clustering mechanism that restricts similarity search to epidemiologically homogeneous groups, and 2) an error correction constant that compensates for temporal drift in case characteristics. The rationale for each design choice is provided alongside its mathematical formulation. Fig. 2 provides an overview of the proposed architecture.

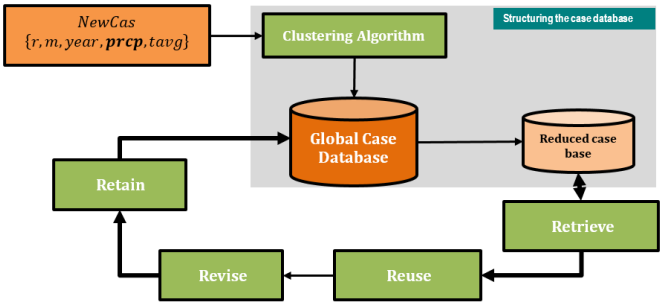

Fig. 2. Illustration of the proposed CBR approach.

A. Notation and Preliminary Definitions

To ensure clarity throughout this section, Table I summarizes the main symbols used in the proposed model.

TABLE I. Summary of Mathematical Notation

Symbol	Definition
Ω	Global case base (all historical cases)
ϕ	Reduced case base (regional cluster)
Cas_t	Target case (new case to predict)
Cas_p^i	i-th previous case in ϕ
att_i^t, att_i^p	Value of attribute i for target and previous case
$sim_i(\cdot,\cdot)$	Local similarity for attribute i
$Sim(\cdot,\cdot)$	Global (weighted) similarity
w_i^*	Normalized weight of attribute i
W_j	Prediction weight of the j-th neighbor
m	Number of nearest neighbors retrieved
k	Total number of attributes
n	Number of instances in Ω
cst	Temporal correction constant
$Pred(\text{Cas}_t)$	Predicted number of malaria cases

B. Case Structuring

In a CBR system, a *case* encapsulates a past experience comprising three elements: a problem description, the solution

applied, and the outcome obtained [32]. Accurate and consistent case representation is a prerequisite for reliable similarity computation and solution adaptation. Three properties are particularly critical in this context:

- Retrieval relevance and solution adaptation: Homogeneous case representation improves similarity computation and enables the retrieval of the most contextually relevant historical cases [9].
- Explainability: A clear and structured case representation makes the system's reasoning transparent and its predictions interpretable by non-expert users [9].
- Integration of domain knowledge: A well-defined structure allows epidemiological knowledge (e.g., seasonality, regional characteristics) to be embedded directly into the case representation [11].

Each past and new case is represented as a feature vector containing six attributes selected on the basis of their established influence on malaria transmission [5]:

$$\text{Cas} = \{r,\ m,\ year,\ prcp,\ tavg,\ hmdt\} \tag{1}$$

where, r denotes the geographic region, m the month, $year$ the year, $prcp$ the precipitation, $tavg$ the average temperature, and $hmdt$ the humidity. The target variable to be predicted is the number of malaria cases associated with each case. The choice of these features reflects the climatic and spatio-temporal determinants of malaria incidence: temperature and precipitation directly influence mosquito breeding cycles, humidity affects vector survival, while region and month capture spatial heterogeneity and seasonal periodicity respectively.

C. Case Base Structuring via Regional Clustering

In a naive CBR system, similarity is computed against the entire case base Ω, which introduces two problems: 1) irrelevant cases from geographically distant regions pollute the similarity ranking, and 2) local epidemiological characteristics specific to each region such as hydrography, vegetation density, and population structure are not accounted for. To address these issues, Ω is partitioned into regional clusters $\phi_1, \phi_2, \ldots, \phi_k$ using the attribute r (region) as the grouping criterion. During retrieval, only the cluster ϕ_i corresponding to the target case's region is searched, thereby reducing the search space and improving the contextual relevance of retrieved cases.

Formally, the clustering operation partitions Ω as follows:

$$\Omega = \bigcup_{i=1}^{k} \phi_i, \quad \phi_i \cap \phi_j = \emptyset \ \forall i \neq j \tag{2}$$

where, each cluster ϕ_i groups all cases belonging to region r_i. Algorithm 1 formalizes this partitioning procedure, and Fig. 3 illustrates the resulting case base structure.

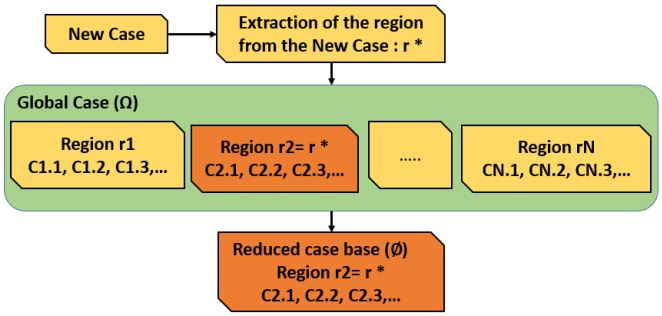

Fig. 3. Process of case base reduction via regional clustering.

Algorithm 1 Case Base Partitioning by Region

Require: $\Omega = \{(X_i, Y_i)\}_{i=1}^{N}$: Global case base
Require: $R = \{r_1, r_2, \ldots, r_p\}$: Set of regions in Ω
Ensure: Regional clusters $\phi_1, \phi_2, \ldots, \phi_k$
  Initialize an empty set of clusters $\phi \leftarrow \emptyset$
  for each region $r_i \in R$ **do**
    if cluster ϕ_k associated with r_i exists **then**
      Add case to ϕ_k
    else
      Create new cluster $\phi_k \leftarrow \{r_i\}$
    end if
  end for
  return $\phi_1, \phi_2, \ldots, \phi_k$

D. Similarity Computation

Similarity computation is the core mechanism of CBR retrieval. Given a target case Cas_t and a previous case $\text{Cas}_p^i \in \phi$, the overall similarity $Sim(\text{Cas}_t, \text{Cas}_p^i)$ is obtained through a two-step process: 1) computation of a *local similarity* for each attribute, and 2) aggregation into a *global similarity* via a weighted sum. The local similarity metric is chosen according to the attribute type categorical, numerical, or cyclic as detailed below.

1) Local similarity metrics:

a) Categorical attribute Region (r): Since region is a nominal attribute with no inherent ordering, a binary metric is used [33]. Two cases are fully similar if they belong to the same region, and fully dissimilar otherwise.

$$sim(r_t, r_p^i) = \begin{cases} 1 & \text{if } r_t = r_p^i \\ 0 & \text{if } r_t \neq r_p^i \end{cases} \tag{3}$$

b) Numerical attribute year ($year$): A normalized numerical distance is used to assign higher similarity to temporally proximate cases, reflecting the assumption that recent epidemiological patterns are more relevant than distant ones [34]:

$$sim(y_t, y_p^i) = 1 - \frac{|y_t - y_p^i|}{\max_{p \in \phi} |y_t - y_p^i|} \tag{4}$$

c) Cyclic attribute month (m): Month is a periodic variable: the distance between December ($m = 12$) and January ($m = 1$) should be 1, not 11. A circular distance is therefore adopted to account for the periodic nature of the annual cycle:

$$sim(m_t, m_p^i) = 1 - \frac{\min(|m_t - m_p^i|,\ 12 - |m_t - m_p^i|)}{6} \quad (5)$$

The denominator 6 corresponds to the maximum possible circular distance between two months, ensuring the similarity is bounded in $[0, 1]$.

d) Numerical attributes temperature ($tavg$), Precipitation ($prcp$), Humidity ($hmdt$): These three continuous attributes are normalized to $[0, 1]$ via Min-Max scaling prior to similarity computation. The normalized absolute difference directly yields a bounded similarity in $[0, 1]$ [33]:

$$sim(tavg_t, tavg_p^i) = 1 - |tavg_t - tavg_p^i| \quad (6)$$
$$sim(prcp_t, prcp_p^i) = 1 - |prcp_t - prcp_p^i| \quad (7)$$
$$sim(hmdt_t, hmdt_p^i) = 1 - |hmdt_t - hmdt_p^i| \quad (8)$$

The same functional form is applied to these three attributes because they share the same scale after normalization, and smaller absolute differences reflect greater contextual similarity for malaria transmission conditions.

2) Global similarity: The global similarity between the target case Cas_t and a previous case Cas_p is defined as the weighted sum of all local similarities:

$$Sim(\text{Cas}_t, \text{Cas}_p) = \sum_{i=1}^{k} w_i^* \times sim_i(att_i^t, att_i^p) \quad (9)$$

In the absence of domain-specific evidence prioritizing one attribute over another, equal weights are assigned to all k attributes to avoid the introduction of subjective bias:

$$w_i = 1, \quad \forall i \in \{1, 2, \ldots, k\} \quad (10)$$

To ensure that the global similarity remains in $[0, 1]$, the weights are normalized:

$$w_i^* = \frac{w_i}{\sum_{j=1}^{k} w_j} = \frac{1}{k}, \quad \forall i \in \{1, 2, \ldots, k\} \quad (11)$$

It follows that $\sum_{i=1}^{k} w_i^* = 1$, which guarantees $Sim(\text{Cas}_t, \text{Cas}_p) \in [0, 1]$ given that each $sim_i \in [0, 1]$.

E. Prediction of Malaria Cases

Once the m most similar cases $\{\text{Cas}_j^p\}_{j=1}^m$ are retrieved from ϕ, the predicted number of malaria cases is estimated as a similarity-weighted average of the target values of the retrieved neighbors:

$$Pred(\text{Cas}_t) = \sum_{j=1}^{m} W_j \times Pred(\text{Cas}_j^p) \quad (12)$$

where, the prediction weight W_j of each neighbor is proportional to its global similarity to the target case:

$$W_j = \frac{Sim(\text{Cas}_t, \text{Cas}_j^p)}{\sum_{j=1}^{m} Sim(\text{Cas}_t, \text{Cas}_j^p)} \quad (13)$$

This weighted averaging scheme assigns greater influence to the most similar historical cases, while ensuring that $\sum_{j=1}^{m} W_j = 1$, so the prediction remains within the range of observed values.

F. Temporal Correction Constant

A fundamental limitation of classical CBR is the implicit stationarity assumption: the relationship between features and the target variable is assumed to remain constant over time. In the malaria context, this assumption is violated due to evolving climatic conditions, changes in healthcare interventions, and long-term trends in case counts. To compensate for this temporal drift, a correction constant cst is introduced, estimated as the mean absolute year-on-year variation in malaria case counts across all instances in Ω:

$$cst = \frac{1}{n} \sum_{i=1}^{n} \left| \text{NbreCas}_i^l - \text{NbreCas}_i^{l+1} \right| \quad (14)$$

where, NbreCas_i^l and NbreCas_i^{l+1} denote the number of malaria cases for instance i in years l and $l + 1$ respectively. The corrected prediction is then:

$$Pred(\text{Cas}_t) = \sum_{j=1}^{m} W_j \times Pred(\text{Cas}_j^p) + cst \quad (15)$$

The constant cst captures the average magnitude of inter-annual fluctuations, providing a simple, data-driven estimate of temporal drift that requires no additional parameters. However, since absolute differences are used, the direction of the trend is not encoded: the same correction is applied regardless of whether cases are increasing or decreasing. This limitation which may cause overestimation during sustained decline or underestimation during sustained growth is acknowledged and identified as a direction for future work (see Section VI).

G. Complete Model Formulation

Substituting Eq. (9), (13), and (14) into Eq. (15), the complete prediction equation of the proposed CBR model is:

$$Pred(\text{Cas}_t) = \sum_{j=1}^{m} \left(\frac{\sum_{i=1}^{k} w_i^* \cdot sim_i(att_i^t, att_i^p)}{\sum_{j=1}^{m} Sim(\text{Cas}_t, \text{Cas}_j^p)} \right) \times Pred(\text{Cas}_j^p) + \frac{1}{n} \sum_{i=1}^{n} \left| \text{NbreCas}_i^l - \text{NbreCas}_i^{l+1} \right| \tag{16}$$

This formulation integrates three components: 1) a *similarity-weighted retrieval* from a regionally clustered case base, 2) a *cyclic similarity metric* suited to the seasonal nature of malaria data, and 3) a *temporal correction* that reduces the bias introduced by epidemiological drift over time.

H. Proposed Model Algorithm

Algorithm 2 Enhanced CBR Model for Malaria Case Prediction

Require: $\Omega = \{(X_i, Y_i)\}_{i=1}^{N}$: Global case base
Require: $Train \subset \Omega$: Training set (X_i, Y_i)
Require: $Test \subset \Omega$: Test set (X_i)
Require: $\text{Cas}_t \in Test$: Target case $\{r, m, year, prcp, tavg, hmdt\}$
Require: $w_1^*, \ldots, w_k^*$: Normalized attribute weights
Require: $\{\phi_i\}_{i=1}^{p}$: Regional clusters
Require: m: Number of nearest neighbors
Step 1: Partition Ω into regional clusters $\phi_1, \ldots, \phi_k$ (Algorithm 1)
Step 2: Identify ϕ_i such that $\text{Cas}_t.r \in \phi_i$
Step 3: Apply Min-Max scaling to all attributes in ϕ_i
Step 4: Compute $sim_i(att_i^t, att_i^p)$ for each attribute and each $\text{Cas}_p \in \phi_i$
Step 5: Compute $Sim(\text{Cas}_t, \text{Cas}_p)$ via Eq. (9)
Step 6: Select the m most similar cases $\{\text{Cas}_j^p\}_{j=1}^{m}$
Step 7: Compute $Pred(\text{Cas}_t)$ via Eq. (16)
return $Pred(\text{Cas}_t)$

The proposed algorithm (Algorithm 2) consists of seven steps : regional partitioning of the case base, selection of the relevant cluster, attribute normalization, local and global similarity computation, retrieval of the m nearest neighbors, and final prediction incorporating the temporal correction constant.

IV. Experimentation

This section describes the dataset used to validate the proposed approach, the preprocessing steps applied, and the models and evaluation metrics employed.

A. Description of the Dataset

The data were collected from two institutions. Epidemiological data were obtained from the Ministry of Health of Côte d'Ivoire, which monitors malaria cases across all national health facilities. Monthly time series were constructed for each of the 33 health regions, reporting the number of severe malaria cases recorded between 2019 and 2023. Climate variables, including temperature and precipitation, were provided by the Airport, Aviation, and Meteorological Operations and Development Company (SODEXAM).

B. Preprocessing

Categorical variables (months and regions) were encoded using the `OneHotEncoder()` function from the `scikit-learn` library. The `MinMaxScaler()` method was applied to normalize the temperature variable, and the `RobustScaler()` function was used for the precipitation variable. These normalizations and encodings are necessary to provide machine learning models with a clean dataset that promotes effective learning.

- OneHotEncoder(): This function transforms categorical variables into binary numerical variables. Each category is converted into a separate column containing only the values 0 or 1.

$$x_i = \begin{cases} 1 & \text{if the category is present} \\ 0 & \text{otherwise} \end{cases} \tag{17}$$

- MinMaxScaler(): This method normalizes data by scaling all values into the range $[0, 1]$, preventing attributes with large numerical values from excessively influencing the model [1].

$$x' = \frac{x - x_{\min}}{x_{\max} - x_{\min}} \tag{18}$$

where, x is the original value, $x_{\min}$ and $x_{\max}$ are the minimum and maximum values respectively, and x' is the normalized value. This normalization is particularly suited to distance- and similarity-based methods.

C. Experimental Setup

The dataset was partitioned using a single temporal split, with 80% of the data (2019–2022) used for training and the remaining 20% (2023) reserved for testing. This chronological split was deliberately chosen over k-fold cross-validation for two reasons. First, malaria incidence data exhibits strong temporal dependencies and seasonal autocorrelation; a randomized fold assignment would mix past and future observations, introducing data leakage and producing overly optimistic performance estimates. Second, the evaluation is designed to simulate a realistic forecasting scenario in which a model trained on historical epidemiological data is used to predict future case counts for an unseen period. In this setting, preserving the temporal order of observations is methodologically essential. This approach is consistent with established practice in time-series forecasting evaluation. The features used were region, year, month, temperature, and precipitation. The objective was to predict the number of malaria cases.

Several supervised learning models were selected for comparison due to their widespread use in the literature and their recognized performance in regression tasks: CatBoost, XGBoost Regressor (XGBR), Random Forest Regressor (RFR), Decision Tree Regressor (DTR), Support Vector Machine (SVM), k-Nearest Neighbors (KNN), and linear regression, as well as the three proposed CBR variants CBR_0, CBR_1, and CBR_2.

- CBR_2: This approach corresponds to the full proposed CBR method (see Section III). It incorporates the regional clustering algorithm (Algorithm 1), cyclic distance-based similarity, and the correction constant.
- CBR_1: This variant applies the same principles as CBR_2, using cyclic distance-based similarity, but without the clustering algorithm or the correction constant.
- CBR_0: This minimalist variant applies neither the clustering algorithm, the correction constant, nor the cyclic distance; numerical distance is used for the month attribute instead.

D. Evaluation Metrics

Two types of criteria were used to evaluate the models.

The quantitative criteria are:

- RMSE: the square root of the mean squared error; it heavily penalizes large errors and is sensitive to outliers [35].

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \tag{19}$$

- MAE: the average of the absolute errors between actual and predicted values; it is easy to understand and penalizes all errors equally [36].

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \tag{20}$$

- $\mathbf{R^2}$: measures the proportion of variance explained by the model [36].

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \tag{21}$$

The qualitative criteria are:

- Explainability (Expl): A model's ability to provide understandable justifications for its predictions [31].
- Transparency (Transp): A model's ability to make its internal workings accessible and interpretable [31].
- Adaptability (Adapt): A model's ability to incorporate new data without requiring a full retraining process [9].

V. Results

A. Training Set Performance

Table II reports the performance of ML models on the training set. KNN achieves perfect scores (RMSE = MAE = 0.00, $R^2 = 100\%$), followed by RFR (RMSE = 0.023, MAE = 0.016, $R^2 = 96.54\%$). These results suggest overfitting, particularly for KNN, as such scores are rarely reproducible on unseen data.

B. Test Set Performance

Table III presents the comparative evaluation on the test set, combining quantitative metrics (RMSE, MAE, R^2) and qualitative criteria (Explainability, Transparency, Adaptability).

CBR-based models achieve the best generalization performance. CBR_2 records the lowest errors (RMSE = 0.081, MAE = 0.057) and the highest coefficient of determination ($R^2 = 72.40\%$), followed by CBR_1 ($R^2 = 60.04\%$) and CBR_0 ($R^2 = 57.70\%$). This progressive improvement reflects the cumulative effect of the enhancements introduced at each stage. Among ML models, RFR and KNN show acceptable performance ($R^2 > 60\%$), while CatBoost, XGBR, DTR, SVM, and linear regression perform poorly ($R^2 < 40\%$), with linear regression recording the worst results (RMSE = 0.154, $R^2 = 2.18\%$).

Only CBR models (CBR_0, CBR_1, CBR_2) satisfy all three qualitative criteria ("Yes"). All ML models are classified "No", as their use requires specialized machine learning expertise, making them unsuitable for direct deployment by health personnel in Côte d'Ivoire.

C. Overall Ranking

Table IV provides a combined ranking based on both quantitative and qualitative scores. CBR_2 achieves the lowest total score (6), ranking first overall. RFR ranks second (score = 12), despite failing all qualitative criteria. CBR_1 and KNN share third place (score = 15), while linear regression ranks last (score = 34). These results confirm that CBR_2 achieves the best balance between predictive accuracy and operational transparency. Fig. 4 - 7 illustrate these results graphically.

D. Statistical Validation

A Wilcoxon signed-rank test was conducted to assess whether the superiority of CBR_2 over RFR is statistically significant. The test yields $W = 18{,}029$ and $p = 1.02 \times 10^{-20}$, well below the 0.05 threshold, confirming that the performance advantage of CBR_2 reflects a genuine difference in generalization capacity and is not an artefact of the temporal split.

TABLE II. Performance of ML Models on the Training Set

Model	RMSE	MAE	R^2 (%)
CatBoost	0.079	0.058	59.38
XGBR	0.098	0.073	37.37
RFR	0.023	0.016	96.54
DTR	0.099	0.075	36.16
SVM	0.102	0.061	32.35
KNN	0.000	0.000	100
Reg Lin	0.118	0.084	9.83

TABLE III. PERFORMANCE OF THE VARIOUS MODELS ON THE TEST SET

Quantitative Metrics				Qualitative Criteria		
Model	RMSE	MAE	R^2 (%)	Expl	Transp	Adapt
CBR_0	0.100	0.072	57.70	Yes	Yes	Yes
CBR_1	0.097	0.069	60.04	Yes	Yes	Yes
CBR_2	0.081	0.057	72.40	Yes	Yes	Yes
CatBoost	0.119	0.084	38.42	No	No	No
XGBR	0.140	0.099	15.84	No	No	No
RFR	0.094	0.067	62.22	No	No	No
DTR	0.138	0.099	18.03	No	No	No
SVM	0.140	0.092	15.45	No	No	No
KNN	0.096	0.068	60.47	No	No	No
Reg Lin	0.154	0.108	2.18	No	No	No

TABLE IV. MODEL RANKING ON THE TEST SET

Quantitative Ranking				Qualitative Ranking				
Model	RMSE	MAE	R^2	Expl	Transp	Adapt	Total	Rank
CBR_0	5	5	5	1	1	1	18	4
CBR_1	4	4	4	1	1	1	15	3
CBR_2	1	1	1	1	1	1	6	1
CatBoost	6	6	6	2	2	2	24	5

VI. DISCUSSION

A. Interpretation of CBR Performance

The superiority of CBR_2 over all other models results directly from three cumulative design improvements: the adoption of a cyclic similarity measure suited to seasonal epidemiological patterns, the optimization of the case base via clustering, and the introduction of a temporal correction constant. Each transition from CBR_0 to CBR_1, then to CBR_2 confirms that these choices jointly address the core challenge of malaria forecasting: capturing seasonality while maintaining generalization ability.

The significant performance drop observed for ML models between training and test sets reflects a classic overfitting phenomenon, particularly pronounced for KNN and RFR. This suggests that these models memorize training patterns rather than learn transferable relationships between climatic variables and malaria incidence, a limitation that CBR's instance-based reasoning naturally avoids.

B. The Added Value of Qualitative Criteria

Quantitative metrics alone are insufficient for evaluating models intended for operational deployment in public health. The qualitative evaluation reveals a structural divide: CBR models are natively explainable, transparent, and adaptable, whereas all ML models require specialized knowledge to interpret and maintain. In a context such as Côte d'Ivoire, where health personnel are not ML experts, this distinction is operationally decisive. A model that health workers can understand, question, and trust is more likely to influence decisions than a high-performing black box [12], [31].

C. Consistency with the Literature

The competitive performance of RFR ($R^2 = 62.22\%$) aligns with findings from Jinad et al., Lucas et al., and Monteiro et al., who identify Random Forest as one of the most effective ML models for malaria prediction [18], [26], [37]. However, the CBR_2 model proposed in this study surpasses RFR both quantitatively and qualitatively. The Wilcoxon signed-rank test ($W = 18{,}029$ and $p = 1.02 \times 10^{-20}$) confirms that this advantage is statistically significant, reflecting a genuine difference in generalization capacity.

D. Practical Implications

The CBR_2 model offers concrete value for public health decision-making. Its case-based reasoning mechanism enables health authorities to trace the historical cases that drove each prediction, facilitating early detection of high-risk periods and supporting timely preventive interventions. Its adaptability the ability to incorporate new cases without full retraining makes it particularly suited to operational surveillance settings where data are updated continuously and resources are limited.

E. Limitations of the Study

Despite these results, several limitations must be acknowledged.

1) Correction constant design: The error correction constant quantifies historical fluctuations independently of trend direction. It may therefore lead to overestimation during sustained decline periods or underestimation during sustained growth phases.

2) Temporal validation: The evaluation relies on a single 80/20 temporal split. Although the Wilcoxon test confirms statistical significance, this scheme does not fully assess the model's stability across varied epidemiological periods.

3) Geographic scope: The model was validated exclusively on data from Côte d'Ivoire. Its transferability to other sub-Saharan African contexts with different climatic profiles and data quality remains to be assessed.

4) Feature set: The current model relies on a fixed set of climatic and epidemiological variables. The potential contribution of socioeconomic or behavioral features has not been explored.

F. Future Work

These limitations suggest four concrete directions. First, the correction constant should be replaced by a trend-aware mechanism such as a directional drift estimator to improve predictions during monotonic phases. Second, a walk-forward validation framework across multiple temporal windows should be adopted to rigorously assess temporal stability. Third, the approach should be evaluated across diverse geographic contexts in sub-Saharan Africa. Fourth, hybrid CBR-ML architectures that combine the interpretability of CBR with the feature-learning capacity of ML models should be explored.

VII. Conclusion

This study proposed an enhanced Case-Based Reasoning (CBR) approach for predicting malaria cases in Côte d'Ivoire, addressing two major limitations of existing models: the opacity of machine learning black-box models and the stationarity assumption of classical CBR. The proposed model, CBR_2, incorporates three key contributions : regional clustering, cyclic similarity measurement, and a temporal correction constant which jointly improve both predictive accuracy and operational interpretability.

When evaluated against seven ML models (CatBoost, XGBR, RFR, DTR, SVM, KNN, and linear regression) and two CBR baselines (CBR_0, CBR_1), CBR_2 achieves the best overall performance on the test set (RMSE = 0.081, MAE = 0.057, $R^2 = 72.40\%$), it outperformed the strongest ML competitor, RFR ($R^2 = 62.22\%$), with statistical significance confirmed by a Wilcoxon signed-rank test ($p = 1.02 \times 10^{-20}$). Beyond quantitative metrics, CBR_2 is the only model to satisfy all three qualitative criteria explainability, transparency, and adaptability making it directly deployable by health personnel without machine learning expertise. This dual advantage places CBR_2 first in the overall ranking with a score of 6, ahead of RFR (12) and CBR_1 (15).

These results confirm that it is possible to achieve competitive predictive performance while maintaining full interpretability, a critical requirement for AI adoption in public health. They also highlight the largely untapped potential of CBR in epidemiological forecasting, a field currently dominated by black-box approaches. In practice, CBR_2 can support early warning systems, epidemic anticipation, and healthcare resource allocation in resource-limited settings.

Three directions are identified for future work, improving the temporal correction mechanism, strengthening the validation framework, and extending the approach to broader geographic contexts in sub-Saharan Africa.

Acknowledgment

This work was partially supported by the international network of french-speaking engineering universities and schools RESCIF.

We would also like to thank the Ministry of Health of Côte d'Ivoire and SODEXAM for providing the data used in this study.

***Abstract*—As the volume of scientific information is growing exponentially in several languages, there is a need for practical and scalable bilingual classification systems for large aligned scientific text corpora. To address this challenge, this study makes two key contributions - first, a large-scale bilingual English–Hindi aligned arXiv scientific text corpus, providing a structured resource for multilingual scientific text analytics and classification research is constructed. Second, the study proposes a bilingual scientific text classification framework and performs a rigorous experimental evaluation using three strong multilingual transformer models, namely Mini Language Model-12 Layers (MiniLM-L12), Multilingual Bidirectional Encoder Representations from Transformers (mBERT), and Cross-lingual Language Model-Robustly Optimized Bidirectional Encoder Representations from Transformers Pretraining Approach (XLM-RoBERTa), on the developed English–Hindi aligned arXiv big data corpus. English and Hindi summaries are categorized independently to investigate the performance trade-offs in each language. The proposed hybrid MiniLM-L12 + Multi-Layer Perceptron (MLP) architecture enhance the classification capability through the integration of statistical feature design with contextual sentence embeddings. Empirical analysis indicates that the proposed bilingual classification framework consistently outperforms the baseline transformer-only models, achieving a higher accuracy of 95.56% and weighted F1-score of 95.31%, while maintaining computational efficiency. The findings emphasize the effectiveness of hybrid representation learning for bilingual big data corpora and provide practical insights for scalable multilingual scholarly text analytics.**

I. Introduction

Due to the continued digitization of scientific literature, the amount of scholarly literature published in different languages has increased dramatically. Although English continues to predominate in scientific communication, much of the research is reported in regional and low resource languages, especially in the present research communities. For automated information organization, retrieval, and large-scale text analytics, where conventional monolingual classification systems are ineffective, this multilingual expansion presents serious challenges. Bilingual and cross-lingual techniques for text classification, capable of operating on aligned multilingual corpora with high precision and computational efficiency are thus highly essential. Recent developments highlight transformer-based language models as the dominant methodology in multilingual natural language processing. Multilingual models like mBERT, XLM-RoBERTa, and models like MiniLM are trained to learn common semantic representations across languages and have shown strong performance on diverse multilingual NLP tasks. However, these models exhibit notable differences in terms of model size, training and inference cost, and scalability. These computational considerations are essential in large-scale text classification with a bilingual corpus, particularly in a scientific context. Furthermore, relying solely on deep transformer architectures may limit the exploitation of complementary statistical characteristics inherent in scientific texts.

Hybrid architectures offer promising alternative which can enhance efficiency and yet provide competitive classification performance by jointly using rich semantic representations together with auxiliary features using lightweight neural classifiers. Despite their potential, such approaches have received limited attention in the context of bilingual scientific text classification, particularly for aligned English-Hindi corpora.

In the current work, a comprehensive bilingual experimental study on an aligned English-Hindi arXiv scientific summary dataset is conducted. Each language is used separately and text classification experiments are carried out so that fair language-wise assessment is achieved. This study benchmark widely used multilingual transformer models, including MiniLM-L12, mBERT, and XLM-RoBERTa, and propose a hybrid MiniLM-L12 + MLP architecture that fuses contextual sentence embeddings with statistical features for enhanced performance. Experimental findings indicate that the proposed hybrid model delivers enhanced efficiency and faster inference while achieving competitive or improved accuracy and weighted F1-scores relative to larger multilingual transformer models in both languages.

The key findings of this study are summarized as follows:

- Monolingual arXiv dataset sampled to Bilingual dataset through effective translation of title and summary attributes to Hindi to obtain an aligned multi-class arXiv big data corpus.

- A comprehensive bilingual test of MiniLM-L12, mBERT, and XLM-RoBERTa on aligned English-Hindi arXiv scientific data.
- A new hybrid MiniLM-L12 + MLP model that is effective to combine contextual embeddings with statistical features in bilingual text classification.
- Analysis of language-wise performance in terms of accuracy, macro precision, macro recall, macro F1, micro precision, micro recall, micro F1, weighted precision, weighted recall and weighted F1-score measures.

The study includes valuable information regarding the effective design of bilingual text classification and demonstrates that hybrid systems establish an effective tradeoff between the performance and the computational cost of large scale multilingual scientific collections.

II. Related Work

Research on text classification has evolved through interconnected methodological streams that collectively underpin modern multilingual and large-scale classification systems. Early investigations primarily emphasized algorithmic efficiency, feature engineering, and computational scalability. Xu suggested a KNN-optimized classification scheme that minimized the use of pre-defined parameter settings [1], whereas Mao et al. proposed parameter-free compression-based technologies that mitigated the use of explicit modeling assumptions [2]. Niranjan et al. investigated structured pipelines used to categorize questions [3]. In the context of Indic multilingual text classification, Pathak and Jain introduced the μBoost framework, which integrates CatBoost with MuRIL representations to improve abusive comment detection across Indian languages. Their ensemble approach demonstrated the benefits of combining multilingual language models with structured meta-features for robust multilingual classification [4]. These early developments put in place performance standards and computation limits that fueled the transition of neural representation learning.

The development of deep neural networks was a significant breakthrough as it made it possible to extract semantic features automatically. Agbesi et al. and Malik and Jain proposed ensemble convolutional structures and knowledge-infused architectures tailored to increase robustness [5], [6]. Jamshidi et al. suggested hybrid pipelines combining transformer embeddings and sequential models [7], while Padalko et al. and Maham et al. investigated sequential and adversarial modeling for misinformation detection [8], [9]. Gao et al. and Huang et al. studied graph-based structural modeling techniques [10], [11], and Ai et al. developed semi-supervised contrastive multigraph learning [12]. Alternative neural paradigms such as Kolmogorov Arnold networks and bi-attention fusion architectures were also explored to enable flexible and adaptive classification strategies [13], [14]. Together these advances demonstrated the effectiveness of representation learning over handcrafted features, but also increased computational demands.

Transformer architectures later emerged as a dominant paradigm in text classification due to their ability to provide contextualized and generalizable representations. Joshi and Joseph analyzed efficient fine-tuning strategies [15], whereas Zhang applied multilingual multi-feature fusion architectures [16]. Bekamiri et al. presented domain-adapted transformers for patent analytics [17], and Brack et al. studied cross-domain multi-task sequential classification [18]. Jain et al. suggested hierarchical and multimodal embedding strategies on crisis datasets [19]. Nevertheless, transformer-based systems still face challenges related to computational cost, scalability, and fairness, particularly in multilingual and low-resource scenarios.

Different pretrained transformer models have become standardized architectures of cross-lingual classification in multilingual settings. Multilingual BERT (mBERT), which was trained on Wikipedia corpora involving 104 languages, using a shared set of WordPiece vocabulary, showed that transfer across languages could start being observed even without explicit alignment supervision [20]. XLM-RoBERTa (XLM-R), which was pretrained on large-scale CommonCrawl corpora in 100 languages with dynamic masked language modeling, enhanced strength and low-resource generalization with high exposure to data and training strategies [21]. Later, small distilled models like MiniLM-L12 have been created that maintain semantic expressiveness using attention and representation distillation mechanisms [22]. These models represent respectively on the efficiency-capacity axis: mBERT is able to offer consistent multilingual contextualization, XLM-R focuses on large-scale robust representation learning, and MiniLM-L12 focuses on computational efficiency and faster inference. They are appropriate reference frameworks to analyse the trade-offs in multilingual performance given their architectural variety and variations in pretraining scale.

In addition to architectural developments, multilingual studies increasingly address fairness and variability in evaluation. Cross-lingual adaptability has been explored through hybrid multilingual models [23], cross-lingual topic detection [24], and prompt-based zero-shot classification frameworks [25]. Fairness-conscious multilingual assessment has been highlighted in recent studies [26], while empirical variability in low-resource classification scenarios has been emphasized [27]. Similarly, Mehra et al. proposed PhonoBiEmbedNet, a phoneme- and bigram-based embedding framework designed for low-resource spoken word recognition. By incorporating phonetic linguistic representations and pretrained multilingual models through a late-fusion neural architecture, the approach demonstrated improved recognition accuracy under limited training data conditions [28]. These findings highlight that multilingual classification remains a complex optimization task involving linguistic diversity, data bias, and computational constraints.

The applied use of text classification includes biomedical multi-label learning [29], [30], patent analytics using hybrid transformer-graph models [17], [31], [11], and crisis informatics and misinformation detection using sequential and adversarial models [8], [9], [19]. Dataset balancing strategies for multilingual software classification have also been explored [32]. More recently, classification approaches based on large language models have introduced hierarchical taxonomy refinement and causal classification paradigms [33], [34]. Although LLM-driven systems tend to achieve strong performance, they introduce significant computational overhead and

scalability challenges in multilingual large-scale environments.

Even though there is continued improvement, there are three gaps that remain critical in the literature. To begin with, efficient bilingual frameworks that are tuned to the aligned large-scale corpora are underutilized. Second, there are not many multilingual tests with systematic fairness analysis. Third, in the real-world scientific classification environment, empirical research on efficiency-performance trade-offs between compact and large-capacity transformer architectures is under-examined. To overcome these shortcomings, scalable learning of representation should be incorporated with considerations of computational efficiency in a principled manner. By placing small distilled transformer and large-capacity multilingual models in a single bilingual assessment system, the study under consideration is expected to connect the principles of foundational scalability with the contemporary contextual representation learning and to analyze the robustness, efficiency, and fairness between English and Hindi scientific texts classification in a systematic way.

III. Proposed Methodology

This section outlines the suggested hybrid semantic-statistical feature fusion framework for bilingual scientific text classification. First, the construction and preprocessing of an aligned English-Hindi arXiv corpus to provide the semantic consistency between languages is discussed, followed by the design of a computationally efficient classification architecture that combines contextual transformer-based embeddings with statistical lexical information. Then, the mathematical description of the semantic-statistical fusion mechanism and optimisation strategy is outlined. Finally, an algorithm description of the end to end text classification workflow is presented to show how the proposed structure will be implemented.

A. Aligned Bilingual Corpus Construction and Preprocessing Strategy

The experimental evaluation of the multilingual transformer models and the proposed hybrid model is performed on the arXiv scientific corpus, a publicly accessible dataset downloadable from Kaggle: https://www.kaggle.com/datasets/sumitm004/arxiv-scientific-research-papers-dataset. The arXiv corpus is a large collection of research papers from the arXiv preprint repository, which can be used for scientific text analysis, classification, citation prediction, and trend forecasting. The dataset covers a variety of research domains, including Computer Science, Mathematics, Physics, etc. Table I provides the features of the arXiv dataset downloaded from Kaggle.

Fig. 1. Representative samples from the original arXiv dataset displaying the metadata and textual attributes used in this study before preprocessing, machine translation into Hindi and class balancing for bilingual scientific text classification.

The dataset is preprocessed using spaCy during which title and summary text fields are cleaned by removing noise, lowercased, lemmatized, and stopwords are eliminated. Extremely short summaries are filtered and category labels are normalized and label-encoded for supervised learning. To get the aligned English-Hindi corpus, Hindi translations are obtained for title and summary attributes using the deep-translator library, which leverages Google Translate's web-based translation service. Two bilingual experts manually evaluated 1000 randomly selected translations. Approximately 90% were judged semantically equivalent to the English source text. To compare the Hindi summaries generated by Helsinki-NLP/opus-mt-en-hi model with the Hindi summaries generated by Google Translate, a Corpus BLEU score was computed. The Corpus BLEU score obtained is 0.264, which is very low, reflecting very low lexical similarity between the two translation systems, and therefore, they produce very different Hindi translations for the same English summaries. Based on the experimental observations, the Hindi summaries generated using Google Translate were selected for the subsequent experiments, as they yielded more effective classification performance.

Algorithm 1 outlines the algorithm used to create aligned English-Hindi arXiv corpus.

Algorithm 1 English–Hindi arXiv Corpus Alignment

Require: arXiv English summaries $D = \{x_1, x_2, \ldots, x_N\}$
Ensure: Aligned bilingual arXiv corpus $D^{aligned}$
Load dataset and initialize GoogleTranslator $T_{(en \to hi)}$
for each summary $x_i \in D$ **do**
  if x_i is empty **then**
    $x_i^{hi} \Leftarrow$ ""
    continue
  end if
  Translate $x_i^{hi} \Leftarrow T(x_i)$ with retry limit R
  Apply delay Δt for rate control
  Construct aligned pair (x_i, x_i^{hi})
end for
Save updated dataset as aligned bilingual arXiv corpus $D^{aligned}$

Random oversampling and augmentation are performed on this aligned English-Hindi arXiv dataset in order to obtain balanced big data corpus. Table II outlines the dataset features after the preprocessing, translation and balancing.

The preview of the arXiv dataset samples after preprocessing, translation and balancing is depicted in Fig. 2.

Fig. 2. Representative samples from the processed multilingual arXiv dataset after preprocessing, machine translation and class balancing, highlighting the retained metadata attributes, English abstracts, translated Hindi abstracts and category labels used for bilingual classification.

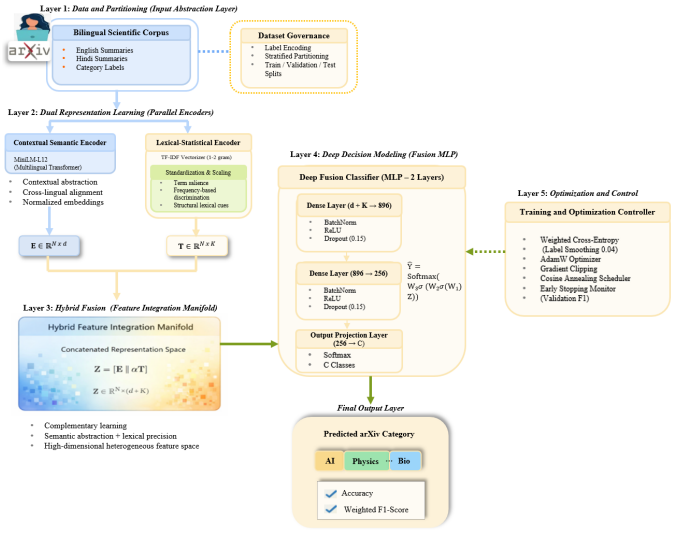

Fig. 3. Layered hybrid semantic-statistical feature fusion architecture showing multilingual context embeddings combined with statistical features, hybrid feature fusion and employing deep multiLayer perceptron to improve bilingual scientific text classification performance.

This aligned English-Hindi arXiv corpus is split using stratified sampling into 64% training, 16% validation, and 20% test sets to preserve the class distribution across all partitions. Experimental evaluation on this aligned big data corpus is performed separately for each language using multilingual transformer models and the proposed hybrid model to assess the language-specific performance.

B. Architectural Overview

To effectively address multilingual scientific summary classification, this study proposes a hybrid semantic-statistical fusion architecture that integrates contextual transformer-based representations with complementary lexical features within a unified deep learning framework. The proposed architecture, in contrast to purely embedding-driven models, further increases the discriminative power by explicitly modeling semantic abstraction as well as the statistical relevance of terms. This structure is specifically useful in scientific abstracts, where a mismatch in class representation, the variability of structure and vocabulary are significant challenges.

The proposed model depicted in Fig. 3 presents a hybrid representation learning model that works well to classify scientific literature by considering both deep contextual semantics and statistical lexical evidence. This system starts with a bilingual scientific corpus, i.e. English titles and summaries with category labels. A governance process of the data is necessary in order to guarantee consistency and reproducibility of the experimental pipeline whereby categorical labels are coded into numerical values and the dataset is stratified with stratified sampling. This stratification maintains the underlying distribution of classes in the training, validation, and test subsets. Hence, it ensures sound performance measurement and limits the chances of sampling bias in the process of training a model.

After the preparation of data, the architecture uses a dual representation learning approach where two complementary encoders are used simultaneously to represent various aspects of a textual information. The former route involves the use of a multilingual MiniLM-L12 transformer encoder, which produces contextualized representations of each document in the form of embeddings. This encoder represents deep semantic connections between tokens through self-attention mechanisms to enable the representation to absorb contextual dependency, semantic abstraction, and cross-lingual alignment that may exist within scientific text. The resulting dense embedding captures the overall semantic structure of the document, allowing the model to identify conceptual similarities despite the use of different lexical expressions.

Simultaneously, a lexical-statistical encoder is built to create a complementary representation with TF-IDF vectorization. The component uses discriminative lexical signals to extract the terms according to their significance in relation to their frequency in the corpus. In this way, domain-specific terminology which strongly defines specific scientific domains is emphasized more. TF-IDF, in contrast to contextual embeddings, which learn meaning by interacting with the context, emphasizes statistically salient keywords and structural lexical patterns that are often good predictors of types of documents. With this lexical view, the architecture conserves important information that would otherwise be diluted in neural embeddings.

The transformer encoder produces contextual semantic embeddings, while the TF-IDF module generates lexical-statistical feature vectors that encode term importance and document-specific vocabulary patterns. These complementary representations are integrated through a hybrid feature fusion layer utilizing feature concatenation, thereby constructing a unified high dimensional representation space. In particular, the semantic embedding vector and lexical-statistical feature vector are concatenated along the feature dimension, maintaining both the contextual semantic knowledge and discriminative lexical evidence. The resulting fused representation preserves

heterogeneous information sources that jointly characterize the conceptual content and terminological specificity of scientific documents. Such integration is particularly useful for scientific document classification, where semantic understanding and domain specific vocabulary play important roles in accurate category discrimination.

The fused representation is thereafter fed into a deep decision modeling component that is a multi-layer perception-based classifier. This type of fusion classifier also learns non-linear interactions among the semantic and lexical representations that allow the model to detect complex patterns that might not be discovered when these heterogeneous cues are used individually. The classifier gradually optimizes the fused representation to a discriminative feature space that is appropriate to predict categories by successive dense transformations, with the aid of the batch normalization and rectified linear activation functions. The dropout regularization is used to reduce the effect of overfitting by promoting feature learning that is robust throughout the learning process. The classifier effectively fills the gap between neural semantic representations and traditional lexical indicators by modeling interactions between contextual and statistical signals.

The architecture is coupled with a specific optimization and training control mechanism that is in charge of the learning dynamics of the model. This controller controls updating of parameters by adaptive optimization and training stabilization by gradient management and training scheduling strategies. Weighted cross-entropy is used to deal with possible class imbalance in the scientific data, so that no minority categories have a disproportionate influence on the learning goal. Gradient clipping ensures that deep networks do not update unstably, whereas cosine-based learning rate scheduling brings about a slow adaptation of optimization dynamics that encourages smooth convergence. The early stopping methodology which relies on F1-score of validation further ensures that the training process stops as soon as the generalization performance stops improving and thus avoiding overfitting and maintaining the robustness of the model.

Lastly, the trained classifier is used to generate the inferred scientific category of each document by mapping the learned representation into the target label space. The accuracy and weighted F1-score are used to measure the performance of the model which can give a holistic analysis of the effectiveness of classifications under imbalanced categories. Through the integration of transformer-based semantic modeling with statistical lexical representations and their combination by the means of a deep fusion-classifier, the given architecture creates a powerful framework of the scientific document categorization that exploits the strengths of both neural and traditional text representation paradigms.

C. Mathematical Formulation of the Proposed Semantic-Statistical Fusion Model

The suggested classification framework combines contextual semantics representations and statistical lexical representations to achieve a hybrid feature space of scientific text classification. Although transformer-based encoders can provide deep contextual semantics, they might not be able to maintain the significance of domain-specific lexical clues which can be very important in scientific texts. The proposed model overcomes this weakness by integrating multilingual MiniLM semantic embeddings with normalized TF-IDF statistical representations and learns their interactions by a simple FusionMLP classifier. This composite formulation allows the model to take advantage of both contextual meaning and term-level significance in a unit representation space. The following mathematical framework formally describes the construction of the semantic-statistical representation, the feature fusion mechanism, the classification function, and the optimization strategy used to learn the proposed model.

Let x_i denote the i-th document in the dataset. The proposed framework constructs a hybrid representation by combining contextual semantic embeddings obtained from a multilingual MiniLM encoder with normalized statistical TF–IDF features.

1) Semantic representation: Each document is first encoded using the MiniLM transformer to obtain contextual semantic embeddings:

$$e_i = f_{\text{MiniLM}}(x_i)$$

where, $f_{\text{MiniLM}}(\cdot)$ denotes the pretrained MiniLM encoder and $e_i \in \mathbb{R}^d$ represents the semantic embedding of dimension d.

2) Statistical feature extraction: To capture lexical importance signals, TF–IDF features are extracted for each document:

$$t_i = \text{TFIDF}(x_i), \qquad t_i \in \mathbb{R}^K$$

The statistical features are standardized using training-set statistics:

$$\tilde{t}_i = \frac{t_i - \mu}{\sigma}$$

where, $\mu = \mathbb{E}[t_{\text{train}}]$ and $\sigma = \text{Std}[t_{\text{train}}]$ denote the mean and standard deviation computed from the training corpus.

3) Controlled statistical feature scaling: To regulate the contribution of statistical features relative to semantic embeddings, a scaling coefficient is applied:

$$s_i = \alpha \tilde{t}_i \tag{1}$$

where, $\alpha \in [0, 1]$ controls the influence of the statistical component.

This transformation ensures that statistical features remain normalized and proportionally integrated with semantic embeddings.

4) Hybrid semantic-statistical feature fusion: The semantic and statistical representations are concatenated to construct the hybrid feature vector:

$$z_i = F(x_i) = [e_i \,;\, s_i] \tag{2}$$

where, $z_i \in \mathbb{R}^{d+K}$ represents the fused feature vector integrating contextual semantic information and lexical statistical signals. Using Eq. (1), the hybrid representation combines semantic embeddings with scaled statistical features.

5) FusionMLP decision function (two-layer architecture): The fused representation is passed through a two-layer multilayer perceptron (MLP) classifier to capture interactions between semantic and statistical components:

$$h_1 = \sigma(W_1 z_i + b_1)$$

$$h_2 = \sigma(W_2 h_1 + b_2)$$

$$\hat{y}_i = \text{Softmax}(W_3 h_2 + b_3)$$

where, z_i is the fused semantic–statistical feature vector defined in Eq. (2); W_1, W_2, W_3 and b_1, b_2, b_3 denote the learnable weight matrices and bias vectors of the MLP layers; $\sigma(\cdot)$ represents a nonlinear activation function (e.g., ReLU); h_1 and h_2 correspond to intermediate hidden representations; and $\hat{y}_i$ denotes the predicted class probability distribution obtained through the Softmax layer which can be compactly expressed as

$$\hat{y}_i = g_\theta(F(x_i))$$

where, $\theta = \{W_1, W_2, W_3, b_1, b_2, b_3\}$ denotes the model parameters.

6) Hybrid representation learning objective: The model parameters are optimized using cross-entropy loss as defined in Eq. (3):

$$\mathcal{L}(\theta) = -\sum_{i=1}^{N} y_i \log g_\theta(F(x_i)) \tag{3}$$

where, N denotes the total number of training samples, y_i represents the ground-truth label of the i-th sample, $g_\theta(\cdot)$ denotes the classifier parameterized by θ, $F(x_i)$ is the fused semantic–statistical representation defined in Eq. (2), and $\mathcal{L}(\theta)$ represents the cross-entropy loss used to optimize the model parameters.

This objective encourages the classifier to learn discriminative decision boundaries within the hybrid feature space defined in Eq. (2).

7) Optimization strategy: Training is performed using cosine annealing with warm restarts for adaptive learning-rate scheduling which is expressed in Eq. (4):

$$\eta_t = \eta_{\min} + \frac{1}{2}(\eta_{\max} - \eta_{\min}) \left(1 + \cos\left(\frac{\pi T_{\text{cur}}}{T_i}\right)\right) \tag{4}$$

where, η_t denotes the learning rate at iteration t, $\eta_{\min}$ and $\eta_{\max}$ represent the minimum and maximum learning rates respectively, T_{cur} denotes the number of iterations since the last restart, and T_i denotes the length of the i-th cosine annealing restart cycle, representing the number of iterations over which the learning rate decays from $\eta_{\max}$ to $\eta_{\min}$ before a restart occurs, computed as

$$T_i = T_0 \cdot T_{\text{mult}}^k$$

here, T_0 denotes the initial restart period, T_{mult} is the restart cycle multiplier controlling the growth of subsequent cycles, and k indicates the number of completed restart cycles.

8) Optimal model selection criterion: The final classifier is selected by maximizing validation performance which is defined in Eq. (5):

$$M^* = \arg\max_M F1_{\text{val}}(M) \tag{5}$$

where, $F1_{\text{val}}$ denotes the validation F1-score.

9) Compact unified formulation of the proposed model: The complete semantic–statistical fusion learning framework can be summarized as in Eq. (6):

$$M^* = \arg\max_M F1_{\text{val}}\left(g_\theta\left[f_{\text{MiniLM}}(x_i) \,;\, \alpha\left(\frac{\text{TFIDF}(x_i) - \mu}{\sigma}\right)\right]\right) \tag{6}$$

This formulation integrates multilingual contextual embeddings and normalized statistical features into a unified hybrid representation for efficient bilingual scientific document classification. The suggested model has three methodological contributions:

- A structured semantic-statistical fusion formulation that combines contextual embedding with features of lexical importance into a shared representation space.
- A controlled statistical scaling mechanism that regulates the influence of TF-IDF features to maintain distributional balance with semantic embeddings.
- An efficient hybrid representation learning strategy, which captures nonlinear interactions between semantic and statistical signals using a lightweight neural classifier.

D. Algorithm for Text Classification

The overall workflow of the proposed semantic–statistical feature fusion framework is summarized in Algorithm 2. It outlines the end-to-end pipeline for aligned bilingual text classification, including data preprocessing, hybrid feature construction using MiniLM embeddings and TF–IDF statistics, classifier training, and final evaluation.

Algorithm 2 Semantic–Statistical Feature Fusion Framework for Aligned Bilingual Text Classification

Require: Aligned document summaries $D = \{x_1, x_2, \ldots, x_N\}$
Ensure: Optimal classifier M^* and evaluation metrics $\{\text{Accuracy}, \text{Weighted F1-score}\}$
Load dataset D and corresponding class labels $Y = \{y_1, y_2, \ldots, y_N\}$
Encode labels and perform stratified partitioning to obtain training, validation, and test sets
for each document $x_i \in D$ **do**
    Generate contextual semantic embedding e_i using the MiniLM encoder
    Compute TF–IDF vector t_i using unigram and bigram statistics and normalize using training-set statistics
    Construct fused representation $f_i = [e_i, t_i]$
end for
Feed fused features f_i into the FusionMLP classifier M
Train M using cross-entropy loss with AdamW optimization and cosine learning-rate scheduling
Monitor validation F1-score and apply early stopping to obtain optimal model M^*
Evaluate M^* on the test set and compute Accuracy and Weighted F1-score

IV. Empirical Evaluation and Comparative Performance Analysis

A comprehensive empirical study of the suggested semantic-statistical feature fusion model on English-Hindi aligned corpus of arXiv is presented in this section. Model specification and hyperparameter configurations are outlined in detail. The quantitative performance of the proposed model, its' convergence behavior, class-level robustness, overall classification performance, architectural contribution via ablation, computational efficiency, and bilingual alignment properties are systematically analyzed. Multiple evaluation metrics are used to report comparative measurements against known multilingual transformer baselines in order to provide a rigorous and balanced performance evaluation.

A. Model Specification and Training Parameters

Using the common data splits and hyperparameter configuration, both the baseline and proposed models were trained to carry out comprehensive testing of the proposed framework. In this subsection, the architectural considerations of the base and hybrid models are presented as well as the training environments such as the learning rates, the batch size and the optimization methods. The setup allows studying convergence processes and performance efficiency and ensures that the proposed MiniLM-L12+MLP fusion architecture and the multilingual baselines can be fairly compared. Table III summarizes the entire experimental arrangement used for classification.

TABLE III. Model Design, Training Protocol and Hyperparameter Configuration for Hybrid Feature Fusion Classification Model Applied to an Aligned English–Hindi arXiv Corpus

Category	Hyperparameter	Value	Purpose
Embedding Model	Sentence Transformer	paraphrase-multilingual-MiniLM-L12-v2	Lightweight multilingual semantic encoder.

	Batch Normalization	Yes	Training stability.
Evaluation	Metrics	Accuracy, Weighted F1-score	Balanced performance reporting.
	Hardware	GPU	Efficient computation.

The multilingual MiniLM-L12 encoder computes a semantic embedding vector of 384 dimensions for each document in English text classification. Meanwhile, a 512-dimensional TF-IDF representation with the help of unigram and bigram features is obtained after removing English stop-words. Lexical information is also preserved by scaling the TF-IDF features by a factor of 0.50, while semantic embeddings dominate the features. The output of the semantic embedding vector is concatenated with the output of the scaled TF-IDF feature vector, forming an 896-dimensional representation (384 + 512), and then input to the residual MLP classifier.

The multilingual MiniLM-L12 encoder also generates a 384-dimensional vector embedding of the text in Hindi for the task of Hindi text classification. No stop-word filtering is done to retain the linguistic cues for Hindi and a 512 dimensional unigram–bigram TF-IDF representation is extracted. After

obtaining the semantic embedding vector, the features in the TF-IDF are scaled by a factor of 0.50 and then fused at the feature level. The fused representation from this process is a 896 dimensional (384+512) vector, fed into the residual MLP classifier.

B. Quantitative Performance Evaluation of the Proposed Framework

To evaluate the efficiency of the proposed semantic-statistical hybrid structure, quantitative test of English and Hindi summary classification is done which is outlined in this section. Performance is evaluated using standard classification measures derived from True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN). For balanced assessment of the potentially imbalanced scientific categories, Accuracy and Weighted F1-score are used.

Classification accuracy is computed as in Eq. (7):

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{7}$$

For class-wise evaluation, precision, recall, and F1-score are defined as in Eq. (8), (9) and (10) respectively:

$$\text{Precision}_c = \frac{TP_c}{TP_c + FP_c} \tag{8}$$

$$\text{Recall}_c = \frac{TP_c}{TP_c + FN_c} \tag{9}$$

$$\text{F1}_c = \frac{2 \cdot \text{Precision}_c \cdot \text{Recall}_c}{\text{Precision}_c + \text{Recall}_c} \tag{10}$$

To account for class imbalance, the weighted F1-score is calculated as in Eq. (11):

$$\text{Weighted-F1} = \sum_{c=1}^{C} \frac{n_c}{N} \cdot \text{F1}_c \tag{11}$$

where, C denotes the total number of classes, n_c represents the number of samples in class c, and N denotes the total number of samples.

The findings in Table IV indicate the general categorization ability of the proposed MiniLM-L12 + MLP (2 Layers) + TF-IDF fusion model in the bilingual environment. The proposed framework delivers high and consistent results between the two languages, reaching an accuracy of 95.56% and a weighted F1-score of 95.31% in English, and 94.85% in accuracy with a weighted F1-score of 94.53% in Hindi. The cost of marginal difference in performance between English and Hindi represents the cross-lingual generalization and strong semantic correspondence. The high weighted F1-scores also prove that the model has balanced predictive accuracy across various scientific categories indicating the success of the semantic-statistical feature fusion strategy in the classification of bilingual scientific texts.

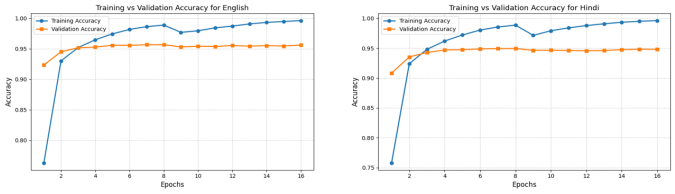
TABLE IV. ACCURACY AND WEIGHTED F1-SCORE ANALYSIS OF THE PROPOSED MODEL ON ENGLISH AND HINDI SUMMARY CLASSIFICATION

	Accuracy		Weighted F1-Score	
Proposed Model	**English**	**Hindi**	**English**	**Hindi**
MiniLM-L12 + MLP (2 Layers) + TF-IDF	0.9556	0.9485	0.9531	0.9453

C. Training Dynamics and Convergence Behaviour of the Proposed Model

This subsection analyses the learning stability and convergence characteristics of the proposed bilingual MiniLM-L12 + MLP framework using Training Accuracy curves, Validation F1 curves, and Training-Validation Loss curves across epochs. All these metrics give a clue of the efficiency in optimization, generalization, and overfitting behavior of both English and Hindi datasets.

The training dynamics are characterized by a quick early convergence and a slow stabilization in subsequent epochs, which is evidence of efficient parameter adaptation and stable optimization. Fig. 4(a) and 4(b) shows that the training accuracy is steep in the initial few epochs, which is indicative of learning features effectively and using a strong gradient-driven optimization. Following the initial phase, the curve switches to smooth plateau towards almost saturation (∼99%), which proves to be stable convergence without oscillations. The fact that the two languages are consistent demonstrates the strength of the bilingual representation learning.

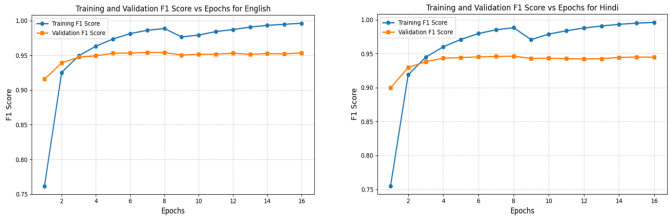


(a) For English Language (b) For Hindi Language

Fig. 4. Accuracy of the proposed model with progression of training epochs, which showed rapid convergence, low overfitting, and stable generalization in English and Hindi languages.

The validation F1 score increases consistently through the initial epochs and reaches the high level (∼95%), meaning that the model has a high-performance in terms of generalization as discussed in Fig. 5(a) and 5(b). The narrow discrepancy between training and validation curves indicates regulated model capability and restricted overfitting. The trend of the validation F1 also confirms that the classifier has a balanced precision recall trade-offs across classes.

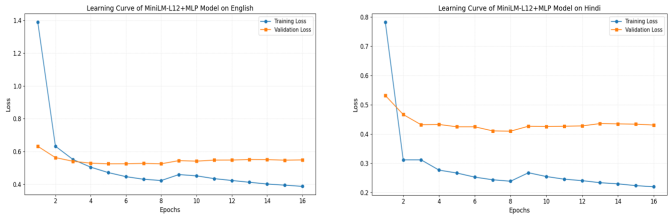
Fig. 6(a) and 6(b) show the loss-versus-epochs curves of both English and Hindi datasets, which approach zero very quickly in early epochs, which is evidence of an effective gradient based learning and fast parameter adjustment. After this initial convergence stage, loss curves begin to flatten which is an indication of a stabilization in the process of optimization. Both the validation loss and the training loss are stable and have slight variation indicating model capacity is controlled and regularization is successful. The lack of a substantial sep-



(a) For English Language (b) For Hindi Language

Fig. 5. Validation F1-score of the proposed model with training epochs, showing the rapid start with a high convergence, followed by a level with stabilization, and then high performance in generalization in both English and Hindi language.

aration between training and validation paths is a verification of the low overfitting and high-quality generalization both in languages.



(a) For English Language (b) For Hindi Language

Fig. 6. Training and validation loss traces per epoch of the proposed model in English and Hindi summary classification, showing early rapid convergence and stable optimization behavior.

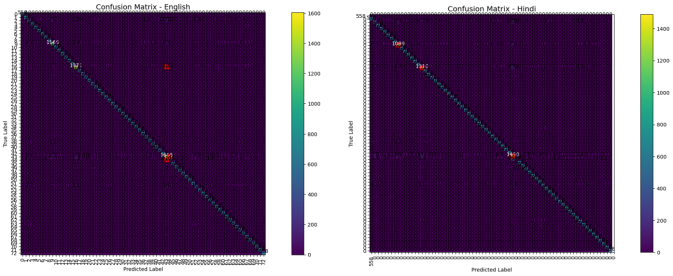
In general, the dynamics of the losses observed support the stability and robustness of the proposed framework. The fast convergence and a low validation loss show that the model does not only learn discriminative features effectively but also retains the performance of cross-lingual generalization. Such a consistent optimization pattern is also additional evidence supporting the power of the MiniLM-L12 + MLP model in the task of bilingual scientific text classification.

D. Class-Level Performance Analysis of the Proposed Model

In this subsection, a comprehensive analysis of the proposed MiniLM-L12 + MLP model on a per-class level is conducted to determine its discriminative ability when dealing with individual categories. Although overall accuracy and macro-F1 give a comprehensive picture of the performance, a more detailed analysis of the results by classes gives a better understanding of the label-specific behavior, the patterns of inter-class confusion, and the cross-lingual consistency.

Here, confusion matrices of English and Hindi are studied and per-class F1-scores are investigated and a comparative visual representation of English and Hindi class-wise F1 performance is given. These analyses collectively demonstrate that the model ensures a balanced precision-recall trade-offs between categories, detects the possible confusion-prone classes, and confirms the strength of the bilingual representation learning framework.

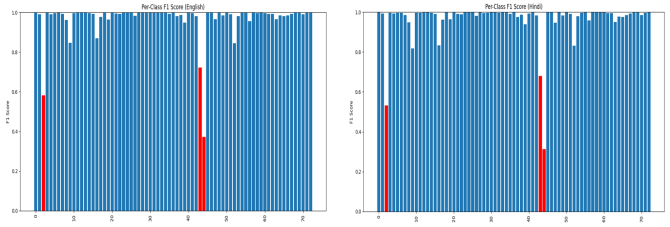
The confusion matrices provided in Fig. 7(a) and 7(b) of both English and Hindi reveal high degree of concentration



(a) For English Language (b) For Hindi Language

Fig. 7. Confusion matrix analysis of the proposed model for English and Hindi text classification, illustrating the distribution of true and predicted labels, highlighting strong category discrimination with reduced inter-class confusion.

of all the values along the diagonal which implies that a majority of the instances are being correctly classified. The low values of off-diagonals indicate low levels of misclassification of classes. The pattern indicates high accuracy, and the performance of the model in the two languages and also shows that multilingual text classification is well learned and capable of good generalization.



(a) For English Language (b) For Hindi Language

Fig. 8. Per-class F1 score analysis of the proposed model for English and Hindi text classification, demonstrating balanced classification performance, confirming the effectiveness of hybrid feature representation.

In order to further justify this performance at a more detailed level, the per-class F1 scores are examined. Although the confusion matrices give a general picture of the correct and incorrect predictions, the per-class F1 score gives a clear picture of the ability of the model to strike the right balance between precision and recall on each category selected. Based on the Fig. 8(a) and 8(b), English and Hindi models have consistently high F1 scores on most of the classes, which shows that the models have high and consistent classification performance. There are only a few classes with slightly lower values, indicating that there is a slight room to improve. In general, the findings indicate that the model is well generalized in both languages, and the performance is strong across categories.

After analyzing the individual per-class version of the F1 score, the comparative graph in Fig. 9 gives a direct class-based analysis of English and Hindi. According to the visualization, the proposed model demonstrates the same high F1 scores on the majority of the classes in both languages, with the performance trends being slightly different. Small differences identified in some classes suggest some slight language-specific differences, but in general, the outcomes prove that the model is highly multilingual and has equal

classification power when working in both English and Hindi datasets.

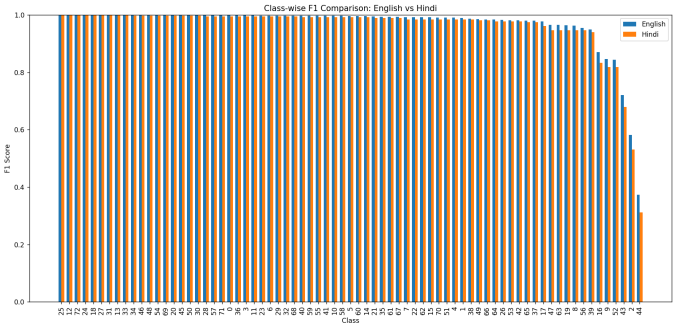


Fig. 9. Class-wise F1 score comparison of the proposed model for English and Hindi arXiv summary classification, highlighting strong cross-lingual generalization.

E. Overall Comparative Performance Analysis with Baselines

This subsection presents a comprehensive quantitative comparison between the proposed MiniLM-L12 + MLP fusion framework and established multilingual transformer baselines (MiniLM-L12, mBERT, and XLM-RoBERTa) on the English-Hindi aligned arXiv corpus. In order to ensure a balanced assessment across class distributions and languages, performance is evaluated using accuracy, macro, micro, and weighted precision, recall, and F1-scores The comparison will focus both on the absolute performance increase and also on the consistency and strength of the proposed approach in bilingual environments.

The macro F1-score, which treats all classes equally, is computed as in Eq. (12):

$$\text{Macro-F1} = \frac{1}{C}\sum_{c=1}^{C} F1_c \tag{12}$$

where, C denotes the total number of classes, and $F1_c$ represents the F1-score of class c.

The micro F1-score, which aggregates global counts across classes, is given by Eq. (13):

$$\text{Micro-F1} = \frac{2\sum_c TP_c}{2\sum_c TP_c + \sum_c FP_c + \sum_c FN_c} \tag{13}$$

As demonstrated in Table V, the suggested MiniLM-L12 + MLP architecture yields the best performance in almost all the evaluation metrics of both the English and Hindi languages. The macro and micro F1-scores also validate the stability of performance in categories illustrating that there is no dominance in the improvement but it is always distributed throughout the spectrum of classes. The improvements to the strongest baseline (XLM-RoBERTa) are also consistent across all languages and all aggregated measures, indicating that semantic-statistical feature fusion can be successfully used to reinforce multilingual scientific text classification. In general, the findings indicate excellent, balanced, and statistically strong bilingual performance of the suggested framework in comparison to the state-of-the-art transformer baselines.

TABLE V. COMPARATIVE PERFORMANCE ANALYSIS OF BASELINE TRANSFORMER MODELS AND THE PROPOSED MINILM-L12+MLP FUSION FRAMEWORK FOR ENGLISH–HINDI ALIGNED ARXIV CORPUS

Performance	Model							
	MiniLM		mBERT		XLM-R		Proposed MiniLM+MLP	
Metric	E	H	E	H	E	H	E	H

Macro Recall	0.9413	0.9242	0.9703	0.9659	0.9684	0.9661	**0.9714**	**0.9678**
Macro F1	0.9305	0.9122	0.9623	0.9554	0.9594	0.9558	**0.9684**	**0.9634**
Micro Prec.	0.9183	0.8983	0.9449	0.9369	0.9422	0.9377	**0.9556**	**0.9485**
Micro Recall	0.9183	0.8983	0.9449	0.9369	0.9422	0.9377	**0.9556**	**0.9485**
Micro F1	0.9183	0.8983	0.9449	0.9369	0.9422	0.9377	**0.9556**	**0.9485**
Weighted Prec.	0.9087	0.8872	0.9443	0.9351	0.9417	0.9361	**0.9522**	**0.9437**
Weighted Recall	0.9183	0.8983	0.9449	0.9369	0.9422	0.9377	**0.9556**	**0.9485**
Weighted F1	0.9109	0.8899	0.9424	0.9329	0.9389	0.9337	**0.9531**	**0.9453**

To further substantiate the comparative findings reported in Table V, a percentage gain analysis is conducted to quantify the relative improvement of the proposed MiniLM-L12 + MLP framework over established multilingual baselines. Although absolute performance measures reveal unwavering superiority in the English and Hindi tasks, relative gain calculation offers some normalized view of the magnitude of improvement in models with different baseline levels.

The percentage gain is computed as in Eq. (14)

$$\text{Gain}(\%) = \frac{M_{\text{proposed}} - M_{\text{baseline}}}{M_{\text{baseline}}} \times 100 \tag{14}$$

where, M denotes the corresponding evaluation metric. This formulation ensures that improvements are measured relative to the baseline strength rather than in absolute terms. These are the percentage-based improvements in both accuracy and weighted F1-score, which are represented in the heatmap in Fig. 10, which gives a more accurate view of differences in performance between the proposed framework and MiniLM-L12, mBERT, and XLM-RoBERTa.

As indicated in the heatmap, the suggested framework has the highest relative gains over MiniLM-L12, with the improvements of 4.06% (English accuracy), 5.59% (Hindi accuracy), 4.63% (English F1), and 6.23% (Hindi F1). Such large gains signify that TF-IDF-based statistical features combined with contextual embeddings are powerful boosters of representational capabilities of small transformer architecture. The improvement when compared with mBERT is more moderate, and it is about 1.13-1.33 % showing the growth in form of improvements to already strong multilingual benchmark. On the XLM-RoBERTa, the strongest baseline, the improvements are, nevertheless, positive, ranging between 1.15 and 1.51%, which proves the idea that large-capacity pretrained models can still be influenced by semantic-statistical fusion.

Significantly, not only accuracy, but also weighted F1-score is being shown to be continuously improved. The consistent improvement in both languages and both measures proves that the given framework improves the overall predictive ability and its strength even in the case of uneven distributions of

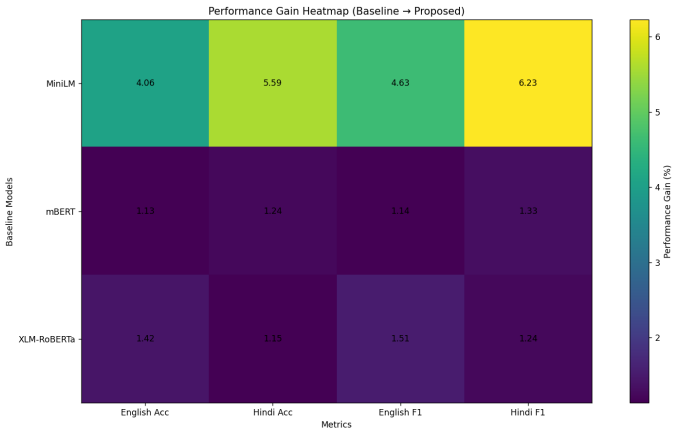

Fig. 10. Heatmap of percentage performance gains of the proposed model over MiniLM-L12, mBERT, and XLM-RoBERTa, highlighting consistent improvements across English and Hindi classification accuracy and weighted F1-scores.

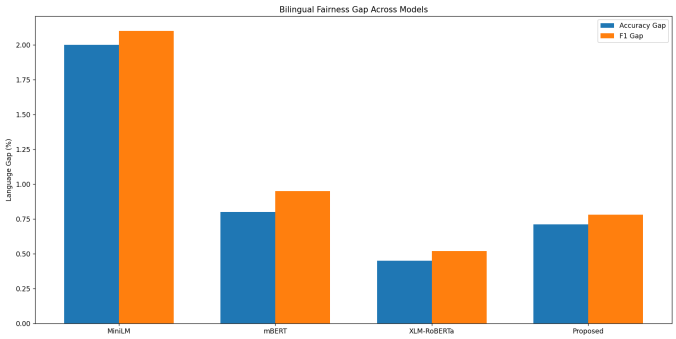

Fig. 11. Bilingual fairness gap comparison that demonstrates the performance disparity between English and Hindi languages in baseline and proposed models.

scientific categories. Taken together, the heatmap confirms the excellence and consistency of the proposed bilingual fusion model at different transformer capacities.

F. Cross-Language Alignment and Fairness Results in Comparison with Baseline and Proposed Models

In order to measure the strength and impartiality of the suggested scheme of bilingual classification, the cross-language alignment of English and Hindi is studied through performance gap analysis. Instead of measuring absolute performance, this subsection measures the consistency of individual model performance across languages. A lower performance difference shows a more robust cross-lingual representation balance and enhanced fairness, which ensures that a gain in one language does not affect the other in a more inappropriate way. This assessment is especially significant in multilingual scientific text analytics, where balanced cross-language performance is a direct measure of representation quality and transferability.

The bilingual fairness gap is computed as the absolute difference between English and Hindi performance metrics which is as defined in Eq. (15):

$$\text{Gap}_{metric} = |M_{EN} - M_{HI}| \tag{15}$$

where, M_{EN} and M_{HI} denote the evaluation metric computed for the English and Hindi text respectively, and M can represent either Accuracy or F1-score. The absolute operator ensures non-negativity and measures deviation irrespective of direction.

Based on the results obtained as depicted in Fig. 11, the proposed MiniLM-L12 + MLP fusion model proves to have a significantly small bilingual gap and, at the same time, achieves the highest overall Accuracy and F1 scores. This is a good sign of cross language embedding compatibility and good features fusion. The proposed architecture does not only provide competitive multilingual consistency when compared to bigger models like mBERT and xLM-RoBERTa, but also enhances efficiency. The decreased fairness disparity puts to rest the fact that the lightweight hybrid modeling can gain balanced and fair bilingual performance without declining predictive strength, which lays down the suitability of lightweight hybrid modeling as an approach to scale-oriented multilingual scientific document classification.

According to the bilingual alignment scatter plot in Fig. 12, it is evident that all models have high-levels of cross-lingual consistency because all their coordinate pairs are consistent. $(x_i, y_i) = (\text{Accuracy}_{EN}, \text{Accuracy}_{HI})$ lie close to the ideal alignment line $y = x$. The deviation from perfect alignment is quantified as $\Delta_i = |x_i - y_i|$, where smaller Δ_i indicates better bilingual stability.

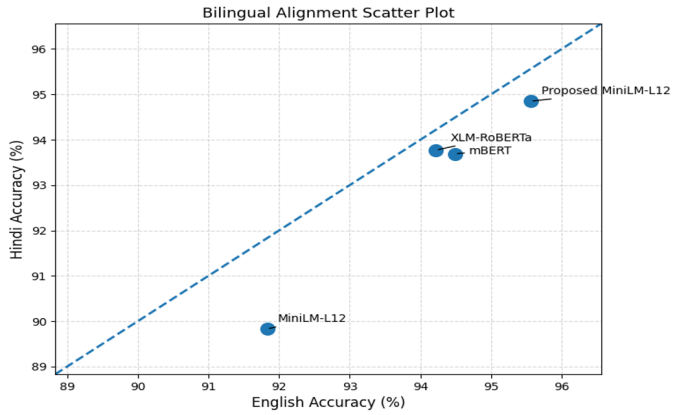

Fig. 12. Bilingual alignment scatter plot comparing the English and Hindi classification accuracy of baseline models and the proposed framework with the diagonal line representing an ideal cross-language performance balance.

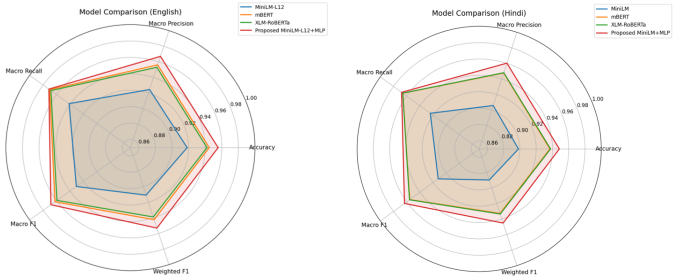
The proposed MiniLM-L12 + MLP model is positioned closest to the top-right region, meaning it maximizes $\max(x_i, y_i)$ simultaneously while maintaining minimal alignment gap, demonstrating strong balanced performance across English and Hindi. Regarding the baselines, MiniLM-L12 is one of the weakly distilled transformer baselines with fast inference and relatively lower accuracy; mBERT and XLM-RoBERTa are powerful multilingual transformer baselines that demonstrate high accuracies because of the deep contextual representations; however, their points, although having a tendency to be close to the diagonal, have more significant differences in the alignment and do not exceed the suggested model in terms of combined bilingual capabilities. It means

that despite such large pretrained multilingual models being strong, the suggested hybrid structure demonstrates an even better cross lingual efficiency accuracy ratio and much lower processing cost.

The radar plots depicted in Fig. 13 provide a holistic multi-metric comparison by representing each model as a vector in a 5-dimensional performance space:

$$M_i = [Acc,\ P_{\text{macro}},\ R_{\text{macro}},\ F1_{\text{macro}},\ F1_{\text{weighted}}]$$



(a) For English Language (b) For Hindi Language

Fig. 13. Dual-language radar chart comparing MiniLM-L12, mBERT, XLM-RoBERTa, and the proposed MiniLM-L12+MLP model across English and Hindi summary classification accuracy, macro precision, macro recall, macro F1 and weighted F1-scores, illustrating the superior and balanced bilingual performance achieved by the proposed framework.

Each metric is mapped to a polar coordinate axis with equally spaced angles as defined in Eq. (16):

$$\theta_k = \frac{2\pi k}{K}, \quad k = 0, 1, \ldots, K-1 \tag{16}$$

where, θ_k denotes the angular position of the k-th metric on the circular axis, with $K = 5$ evaluation metrics. The radial value r_{ik} corresponds to the metric score of model i for metric k. where $K = 5$ metrics. The radial value r_{ik} corresponds to the metric score of model i for metric k. By closing the polygon (repeating the first value), the area enclosed by each model can be interpreted as an approximate aggregate performance measure, defined in Eq. (17):

$$\text{Area}_i \propto \sum_{k=1}^{K} r_{ik}\, r_{i(k+1)} \sin\left(\frac{2\pi}{K}\right) \tag{17}$$

A larger enclosed area indicates stronger overall balanced performance across metrics. In both English and Hindi plots depicted in Fig. 13, the proposed MiniLM-L12 + MLP constantly optimizes the outermost and most homogenous polygon implying concurrent maximization of accuracy, precision, recall, and F1 values. All the baselines are also characterized by high and stationary performance where, mBERT and XLM-RoBERTa have competitive macro-level results which are provided by deep multilingual representations. Nevertheless, it is possible to state that the offered hybrid model will provide the most balanced and extended radar coverage in both languages, which is the justification of its high multi-metric strength and cross-linguistic generalization power.

G. Efficiency Analysis of the Baseline Versus Proposed Model

Computational efficiency is a decisive factor in multilingual scientific text classification especially when the model is expected to be deployed on a scale or to make real-time inferences. Despite offering effective contextual representations of large-scale multilingual models, including mBERT and XLM-RoBERTa, large transformer-based models have large parameter sizes that lead to high training and inference expenses. By comparison, distilled transformer architectures, such as MiniLM-L12, are designed to maintain the quality of semantic representations and simplify computation. The hybrid scheme also adds an additional lightweight layer of two-layers MLP and TF-IDF feature fusion to MiniLM-L12 with a slight increment in the number of parameters. Thus, the systematic efficiency analysis is performed through the comparison of parameters count, inference time on a single sample, and total training time between English and Hindi data to measure both the computational scalability and predictive performance.

Inference time per sample is computed as in Eq. (18)

$$T_{\text{inf}} = \frac{T_{\text{total inference}}}{N} \tag{18}$$

where, N denotes the number of test samples. Training time is computed as in Eq. (19)

$$T_{\text{train}} = \frac{E \times N}{B} \times T_{\text{step}} \tag{19}$$

where, E denotes the number of epochs, B represents the batch size, and T_{step} denotes the time required for one training step, which depends on the parameter count and the backpropagation cost $O(P)$.

TABLE VI. COMPARATIVE EFFICIENCY ANALYSIS OF BASELINE TRANSFORMER MODELS AND THE PROPOSED MINILM-L12+MLP FUSION FRAMEWORK ACROSS ENGLISH AND HINDI SUMMARY CLASSIFICATION

Model	Architecture	No. of Params	Inference Time (ms)		Training Time (sec)	
			E	H	E	H
MiniLM-L12	Transformer encoder (distilled)	∼117M	0.0060	0.0058	166.25	209.38
mBERT	BERT-base (12 layers)	∼110M	2.5013	2.6770	8020.74	8442.66
XLM-RoBERTa	RoBERTa transformer	∼270M (base)	2.4997	2.5200	8802.94	8887.52
Proposed	**MiniLM + 2-Layer MLP with TF-IDF fusion**	∼118M (117M + ∼1.3M)	**0.0074**	**0.0075**	**101.94**	**77.63**

The results outlined in Table VI clearly demonstrate the computational efficiency and scalability of the proposed MiniLM-based hybrid model compared to heavy multilingual transformers like mBERT and XLM-RoBERTa. Since transformer complexity scales approximately as $O(L \cdot H^2 + L^2 \cdot H)$ (where L denotes the sequence length and H represents the hidden dimension), larger multilingual models such as XLM-RoBERTa (∼270M parameters) incur higher computational

latency. Conversely, MiniLM-L12 employs knowledge distillation to reduce attention computation, achieving an almost constant ultra-low inference latency ($\sim$0.006$-$0.007 ms/sample). Although the proposed model introduces a lightweight MLP classifier ($896 \rightarrow 256 \rightarrow C$) along with TF–IDF feature fusion, the additional parameters ($\sim$1.3M) minimally affect the overall computational complexity, maintaining a compact total parameter count of approximately $\sim$118M. close to MiniLM while significantly reducing training time due to efficient convergence and feature fusion. Altogether, hybrid architecture demonstrates a very good efficiency-performance ratio, which proves the appropriateness to scalable bilingual scientific text analytics of English and Hindi.

To further validate the competitiveness of the proposed framework, additional experiments were conducted using recent multilingual sentence embedding models including Language-agnostic BERT Sentence Embedding (LaBSE) and multilingual E5. Results in Table VII indicate that the proposed semantic-statistical fusion framework consistently achieves superior classification performance.

TABLE VII. COMPARATIVE PERFORMANCE ANALYSIS OF THE PROPOSED MINILM-L12+MLP FUSION FRAMEWORK AND STATE-OF-THE-ART MODELS FOR ENGLISH–HINDI ALIGNED ARXIV CORPUS

Performance	Model

H. Ablation Study

In order to systematically analyze the role played by each architectural component, an ablation study of the base MiniLM-L12 encoder is performed and following are gradually added: 1) a 1-layer MLP, 2) a 2-layer MLP, 3) TF-IDF feature fusion and (iv) summary length features. The aim is to measure the influence of each additional module on classification performance, computational performance, and resource consumption in the English and Hindi languages. Accuracy and Weighted F1-score are used to determine performance, whereas inference time per sample, total training time, and GPU memory allocated are used to measure efficiency.

The underlying MiniLM-L12 as given in Table VIII, offers a high level of efficiency at low inference time ($\sim$ 0.006 ms/sample) and low GPU memory ($\sim$ 0.46 GB), but at a medium level of accuracy. The performance increases with the addition of 1-layer and 2-layer MLP sequentially, which demonstrates that the increased depth of nonlinear transformation increases the separability of the features. This however, adds parameters to the training time slightly. The highest Accuracy and the Weighted F1 are shown in the proposed

model (MiniLM-L12 + 2-layer MLP + TF-IDF fusion) in both languages. A feature fusion enhances semantic embeddings by adding statistical features, strengthening the discriminative capacity of the models and surprisingly minimizing the amount of time needed to train, because of accelerated convergence.

Interestingly, summary length as an added feature does not enhance the performance any further which shows that TF-IDF already has enough statistical variance. Comprehensively, the ablation suggests that the significant improvement of the performance is caused by semantic-statistical fusion and not simply by the increase in the depth of the network, providing optimal performance and computational efficiency.

I. External Benchmark Generalization

A comprehensive comparative analysis of recent text classification studies across diverse domains, datasets, and linguistic settings is presented in Table IX.

According to the survey, the tasks of multi-class classification are largely dominant and include reviews of drugs, news, and patent analysis, classification of scientific documents, and biomedical sentence labeling, whereas binary classification is found mostly in sentiment and hate speech classification tasks. The vast majority of the methods are used in monolingual environments, and relatively few multilingual implementations are made. Models and datasets performance differ with the highest accuracy reported at 94.1%. It is worth noting that the proposed MiniLM-L12 + MLP model is the most accurate (95.56%) in a multilingual scientific classification environment, which proves to be more effective than the currently available baselines.

V. DISCUSSION

The success of the suggested model could be explained by the fact that its architecture incorporates the complementary representations of textual information and ensures the efficient learning dynamics. The model provides both deep semantic representations and surface-level discriminative patterns that exist in the dataset by embedding contextual semantic meanings, in addition to statistically based textual features. Contextual embeddings give rich representations to encode syntactic relationships, long-range dependencies, and domain specific semantics in the text enabling the model to interpret the underlying intent and contextual subtlety of every instance.

TABLE IX. COMPARATIVE PERFORMANCE ANALYSIS OF RECENT STATE-OF-THE-ART MODELS AND THE PROPOSED MODEL ACROSS DIVERSE BENCHMARK DATASETS

Meanwhile, the addition of the statistical textual features provides further signals that emphasize the importance of terms and distributional aspects of documents. The combination of these heterogeneous representations forms a more informative feature space that allows the model to identify subtle differences between categories that would not be clear when the model uses a single method of representation.

The other important aspect of the model that makes it efficient is its balanced design in architecture which focuses on representational strength but maintains the computational complexity. The architecture is able to use fine-tuning of large-scale transformers but instead of doing it directly, it uses pre-computed semantic representations and blends them with a carefully designed neural classification system. This method has a huge impact on training overhead, but maintains the expressiveness of transformer-based embeddings. The layers that perform feature fusion and classification are optimized to learn the non-linear features between the combination of features to allow the system to bias the most informative signal per class. Consequently, the model is presented with a high generalization without a significant increase in the number of parameters or long training time.

The training strategy used in the model is also an important factor in its effectiveness. Balanced data handling, proper regularization, and optimized learning schedules are some of the techniques used to stabilize the training process, and avoid overfitting. Such mechanisms enable the classifier to acquire strong decision boundaries despite the changes in class distributions or overlapping textual patterns across classes. Moreover, the convergence of the model is guaranteed by the application of current optimization techniques that identify valuable patterns in the fused feature representations within a limited number of training epochs.

Practically, the architecture shows that high classification performance is not always achieved with models of very deep or very high computational complexity. The proposed method provides a high accuracy, efficiency, and scalability through a combination of semantic embeddings and the classical textual representations and a simplified neural network. The model is able to capture effectively both contextual and discriminative lexical information, and hence has a higher level of classification when it comes to a variety of textual inputs. Therefore, the findings suggest that the suggested design offers a computationally effective and reliable method of handling large-scale text classification processes, which explains the high results that were expressed throughout the evaluation process.

The discussion below emphasizes the key factors to the success of the proposed hybrid framework: the complementary nature of TF-IDF features, the minimal performance difference between Hindi models, and the benefits of the proposed framework over larger transformer-based models like XLM-RoBERTa.

Why TF-IDF Helps?
The improvements seen suggest that the embeddings from the context transformer are not sufficient to capture all the lexical cues of the domain. Scientific abstracts can include very discriminative terminology like algorithm names, mathematical terms and domainspecific terms. TF-IDF explicitly emphasizes these semantic abstracts, which are learned by MiniLM, as lexical indicators.

Why Hindi Slightly Lower?
The performance trend is similar in both English and Hindi, but a slight decrease in accuracy is seen in Hindi. This may be due to the artifacts of machine translation, the morphological differences and vocabulary normalization issues arising during the construction of the corpus.

Why Proposed Outperforms XLM-R?
While XLM-RoBERTa is larger and can process more parameters, it is still advantageous to include complementary lexical-statistical information in the proposed model, which allows to process more information.

Overall, the proposed hybrid framework is shown to be successful in producing robust, efficient, and consistently better results for bilingual scientific text classification tasks by leveraging semantic and lexical information.

VI. CONCLUSION

The present research offered an effective hybrid architecture of MiniLM-L12 + MLP for bilingual text classification task on aligned arXiv English-Hindi big data corpus. The results show that feature fusion of semantic and statistical features may be more effective than the bigger transformer

models and is also scalable. The proposed work enables decoupled bilingual semantic learning without expensive transformer fine-tuning and achieves comparable and language-agnostic performance in English and Hindi. The framework combines contextual embedding and statistical information to provide a good efficiency-accuracy trade-off in big data settings. Its' empirical superiority to strong baselines of multilingual models like mBERT and XLM-RoBERTa is also affirmed by empirical comparisons using fewer parameters. Collectively, the studies bridge a broad gap between the study of multilingual NLP and bilingual applied corpus analytics.

The future work will extend the suggested framework to multimodal scientific document comprehension, incorporating visual representations (figures, diagrams, and tables) into textual representations. Studies on the adaptive feature fusion process can also contribute to better learning of cross-modal representations and increase the strength of classification in massive academic collections. Moreover, the framework can be extended to facilitate more low-resource languages, which may enhance its role in scientific knowledge analysis in more languages. The investigation of parameters efficient transformer adaptation methods could also enhance the scalability further with the efficiency-accuracy ratio illustrated in this study.

***Abstract*—We propose an extension to Zynerator, a Model-Driven Architecture framework for automated microservice generation, that embeds DevSecOps principles directly at the modeling stage through semantic decorators. These decorators enable the automated synthesis of secure back-end and front-end components together with operational artifacts, including authentication and authorization modules, audit trails, monitoring dashboards, and DevSecOps pipelines covering SAST, DAST, testing, and deployment. The approach addresses a key limitation of the original Zynerator framework, namely the absence of explicit DevSecOps integration, and supports a security-by-design methodology that reduces reliance on specialized DevSecOps expertise. Through a detailed e-commerce case study and empirical evaluation against manual development and existing Model-Driven Architecture tools, we show that the enhanced framework reduces development effort, strengthens security posture, and accelerates DevSecOps adoption. These findings indicate that DevSecOps-aware model-driven engineering offers a viable pathway toward secure, automated software delivery.**

***Keywords*—DevOps; DevSecOps; MDA; IT security; code automation; semantic modeling; LLM**

I. Introduction

The need to embed security from the earliest stages of the Software Development Life Cycle has grown with the increasing sophistication of cyber threats. DevSecOps addresses this challenge by integrating continuous security validation, automated testing, and collaborative practices directly into DevOps pipelines, making security a shared responsibility rather than a post-development activity [1] , [2]. Despite its proven benefits, DevSecOps adoption remains difficult for many organizations due to the complexity of toolchains, the need for specialized security expertise, and the absence of formal connections between design models and security-enforced implementations.

Model-Driven Architecture offers an opportunity to address these challenges by raising software design to the abstraction level of Platform Independent Models. If security and operational semantics can be embedded into these models, DevSecOps requirements may be automatically reflected in generated code and deployment artifacts. However, existing tools rarely connect model-level semantics with DevSecOps enforcement, leaving a gap between conceptual design and secure operational deployment.

In previous work, Zynerator was introduced as an MDA-based framework that automates the generation of microservice architectures from a PIM using templated projections and design semantics [3]. While Zynerator demonstrated improvements in development speed, structural consistency, and automation, its original iteration focused primarily on functional generation and architectural scaffolding. DevSecOps concepts such as authentication, auditing, runtime monitoring, and secure CI/CD pipelines were not yet systematically integrated.

This article presents an extension of Zynerator that incorporates DevSecOps constraints directly at the modeling level. Through the introduction of semantic decorators, the enhanced framework enables designers to express authentication policies, authorization rules, file-handling constraints, auditing requirements, monitoring configurations, and deployment strategies directly in the PIM. These semantics are then automatically projected into secure back-end and front-end code, continuous integration pipelines, monitoring dashboards, deployment descriptors, and testing suites. This approach enables developers to adopt a secure-by-design methodology without requiring deep DevSecOps expertise, while ensuring consistency and reducing manual security integration effort.

This work presents an extension of the previously proposed Zynerator framework [3], with the objective of integrating DevSecOps principles directly at the model design level. The key contributions are as follows:

1) Early integration of security constraints at the design level: The central contribution of this work is the formalization of security and operational requirements directly within the Platform Independent Model. Instead of adding security policies after development, Zynerator introduces semantic decorators that allow designers to express authentication, authorization, auditing, secure file handling, monitoring, and deployment constraints during system modeling. This ensures that security is enforced from the outset of the SDLC.

*Corresponding author.

2) Technology-independent semantic enforcement: The proposed semantic decorators are not tied to a specific language or platform. Once specified in the PIM, they guide the generation of secure implementations in any supported technology stack. This provides a generic and reusable mechanism for security-aware code generation across heterogeneous architectures.

3) Extension of Zynerator toward DevSecOps automation: The adapted framework enhances the original Zynerator architecture by not only generating the functional and architectural scaffolding of applications, but also producing DevSecOps artifacts such as CI/CD pipelines, security checks, test suites, deployment descriptors, and observability dashboards.

4) Model-driven generation of secure artifacts: By combining semantic decorators with template-driven synthesis, Zynerator automatically generates secure service code, configuration files, deployment pipelines, monitoring setups, and test cases with minimal manual intervention, thereby reducing human error and increasing consistency.

5) Experimental validation: A quantitative evaluation demonstrates that this adaptation of Zynerator improves security posture, reduces development effort, and accelerates DevSecOps adoption compared to both manual development and existing MDA generators.

The remainder of this study is structured as follows. Section II presents the related works. Section III details the case study and results. Section IV concludes and outlines future work.

II. Related Works

The integration of security principles from the initial stages of software development, particularly through the lenses of Model-Driven Architecture (MDA) and DevSecOps, represents a pivotal shift towards more secure and reliable software systems. This section explores significant contributions to the field, detailing methodologies and frameworks that bridge MDA and DevSecOps to instill robust security measures inherently within software development processes.

A. Model-Driven Architecture and Security

Since the standardization of MDA [4], research has investigated how system models can capture security requirements before implementation. Early work such as UMLsec [5] formalized security annotations inside UML to guide code generation. Subsequent studies extended this approach using dialects for access control modeling [6]. Further research focused on frameworks enabling formal verification or compliance analysis at the model level [7], [8].

A large body of secondary research confirms the relevance of Model-Driven Security. Several studies conducted systematic reviews showing that MDE is increasingly used to express access control, auditing, and confidentiality concerns before implementation [9], [10]. Similar findings are reported by other researchers [11]-[12], who highlight the lack of automation in most toolchains and the difficulty of ensuring that security rules defined at the model level propagate consistently into deployed systems.

Several authors explored how non-functional properties such as policies, encryption, and risk management can be modeled and transformed as part of the MDA lifecycle [13]-[14]. However, existing tools generally stop at code generation and rely on manual DevOps or infrastructure scripting, leaving deployment, scanning, and operational monitoring outside the model-driven process.

The extended Zynerator addresses this gap by elevating DevSecOps concepts to the PIM using semantic decorators. These decorators act as formal contracts ensuring that security requirements are reflected in source code, test suites, deployment descriptors, and runtime observability artifacts.

B. DevOps and DevSecOps Automation

DevOps emerged to improve software delivery through continuous integration, automated testing, and rapid deployment [15]. While widely adopted, DevOps pipelines typically require manual configuration using YAML, Groovy, or scripting languages. Most DevOps toolchains lack a model-based representation of build logic, making pipelines difficult to maintain and structurally disconnected from design intent.

DevSecOps extends DevOps by embedding continuous security validation into CI/CD pipelines. Previous research emphasizes automated scanning, compliance enforcement, and secure deployment practices as fundamental to modern software delivery [1], [2], [16]. More recently, it has been demonstrated that Model-Based Systems Engineering can support DevSecOps by connecting architectural design to operational policies [17].

However, as systematic surveys in secure software engineering confirm [18], DevSecOps methods usually intervene at the deployment stage and assume that security semantics are already well-defined. Without early modeling, DevSecOps pipelines risk becoming inconsistent with functional requirements and system architecture.

Zynerator bridges the gap by generating DevSecOps pipelines directly from the PIM. Authentication rules, authorization constraints, auditing requirements, SAST/DAST configurations, and deployment logic are derived from semantic decorators and projected automatically into modern CI/CD platforms.

C. AI-Driven Software Engineering

Recent advances in Large Language Models have accelerated automated code synthesis and infrastructure configuration. Surveys demonstrate that LLMs can reliably generate structured program logic [19], [20]. Multi-agent reasoning frameworks further improve iterative validation and generation quality [21], [22].

AI has also been explored in DevSecOps automation. Recent work shows how LLMs support SAST/DAST automation, compliance checking, and secure coding assistance [23]-[24]. Another study demonstrates measurable performance improvements when combining DevSecOps and generative AI in industry settings [25].

Although promising, most AI-assisted approaches lack architectural grounding: they may produce correct fragments of code yet must still rely on human engineers to maintain system-level coherence. Zynerator addresses this limitation by

using AI selectively within a model-driven pipeline. Semantic decorators define the structure and constraints of the system, while LLMs adapt or refine templates under model supervision to preserve consistency across generated artifacts.

D. Discussion of Research Gaps

The literature reveals three research gaps:

- MDA solutions rarely project security concerns beyond code, leaving CI/CD, runtime monitoring, and secure deployment to manual effort.
- DevSecOps automation typically begins after implementation, making it difficult to ensure consistency between architecture, code, and operational pipelines.
- AI-based code generation is rarely constrained by formal design models, increasing the risk of structural drift or incomplete security enforcement.

The DevSecOps-enabled version of Zynerator directly addresses these gaps by allowing security semantics to be expressed at the PIM using reusable decorators, automatically projecting them into code, pipelines, dashboards, and operational infrastructure, and combining MDA and AI to ensure that generated systems remain architecturally consistent and security-compliant.

III. Zynerator Architecture

The DevSecOps-enabled version of Zynerator directly addresses these gaps by allowing security semantics to be expressed at the PIM using reusable decorators, automatically projecting them into code, pipelines, dashboards, and operational infrastructure, and combining MDA and AI to ensure that generated systems remain architecturally consistent and security-compliant.

A. Architectural Overview

The enhanced Zynerator platform introduces DevSecOps integration directly at the design level and extends the original architecture [3] with the ability to interpret security requirements embedded in the Platform Independent Model. The system adopts a modular microservice architecture that supports the end-to-end transformation from annotated PIM specifications to secure, deployable applications, including generated testing suites, CI/CD pipelines, monitoring dashboards, and deployment descriptors.

Fig. 1 illustrates the overall workflow, which consists of four coordinated microservices: the YAML Processor, the Template Crafter, the Zynerator Core, and the Security Adaptor. Each microservice performs a well-defined phase of the transformation pipeline, ensuring traceability between design intent and the generated DevSecOps artifacts.

B. Architectural Workflow

The generation pipeline proceeds through the following stages:

1) Design modeling: The user defines the system through a YAML-based PIM enriched with semantic decorators. These decorators specify functional concepts as well as security concerns such as authentication roles, authorization privileges, auditing rules, file-handling policies, and deployment constraints.

2) Model interpretation and validation: The YAML Processor interprets and validates the model, transforming it into a semantically enriched PIM that captures both structural and security semantics.

3) Template adaptation: The Template Crafter, assisted by Large Language Model reasoning when required, adapts templates to reflect the PIM semantics. Templates may target back-end frameworks, front-end frameworks, CI/CD pipelines, operational infrastructure, or security policies.

4) Model-to-code synthesis: The Zynerator Core generates back-end and front-end source code by projecting the PIM semantics onto the retrieved templates. All structural, behavioral, and security-related decorators are applied at this stage.

5) DevSecOps injection: The Security Adaptor automatically integrates secure deployment pipelines, runtime monitoring configurations, static and dynamic analysis stages, and other DevSecOps artifacts, ensuring that security requirements defined at the model level propagate into the operational environment.

This architecture formalizes a complete model-driven DevSecOps process in which secure implementation artifacts are generated from the same source of truth as the functional model.

C. YAML Processor Microservice

The YAML Processor acts as the entry point to the generation pipeline. It processes the YAML specification by performing syntactic and semantic validation. Beyond extracting the system structure, the processor interprets semantic decorators such as ACTOR, ROLE, AUDIT, UPLOAD, or deployment parameters.

The processor produces two internal models:

1) Project data model: Represents the logical structure of the system, including entities, relationships, identifiers, and type constraints. Semantic decorators are projected into this layer to enrich entities with behavior and security semantics. For example, an Actor decorator automatically associates a user class with login credentials, roles, and authentication constraints.

2) Project configuration model: Describes cross-cutting concerns such as authentication policies, JWT configuration, storage providers, backup policies, CI/CD requirements, and monitoring targets.

The resulting PIM is therefore both platform-independent and DevSecOps aware. This early injection of security constraints is the foundation for consistent and automated generation across all subsequent stages.

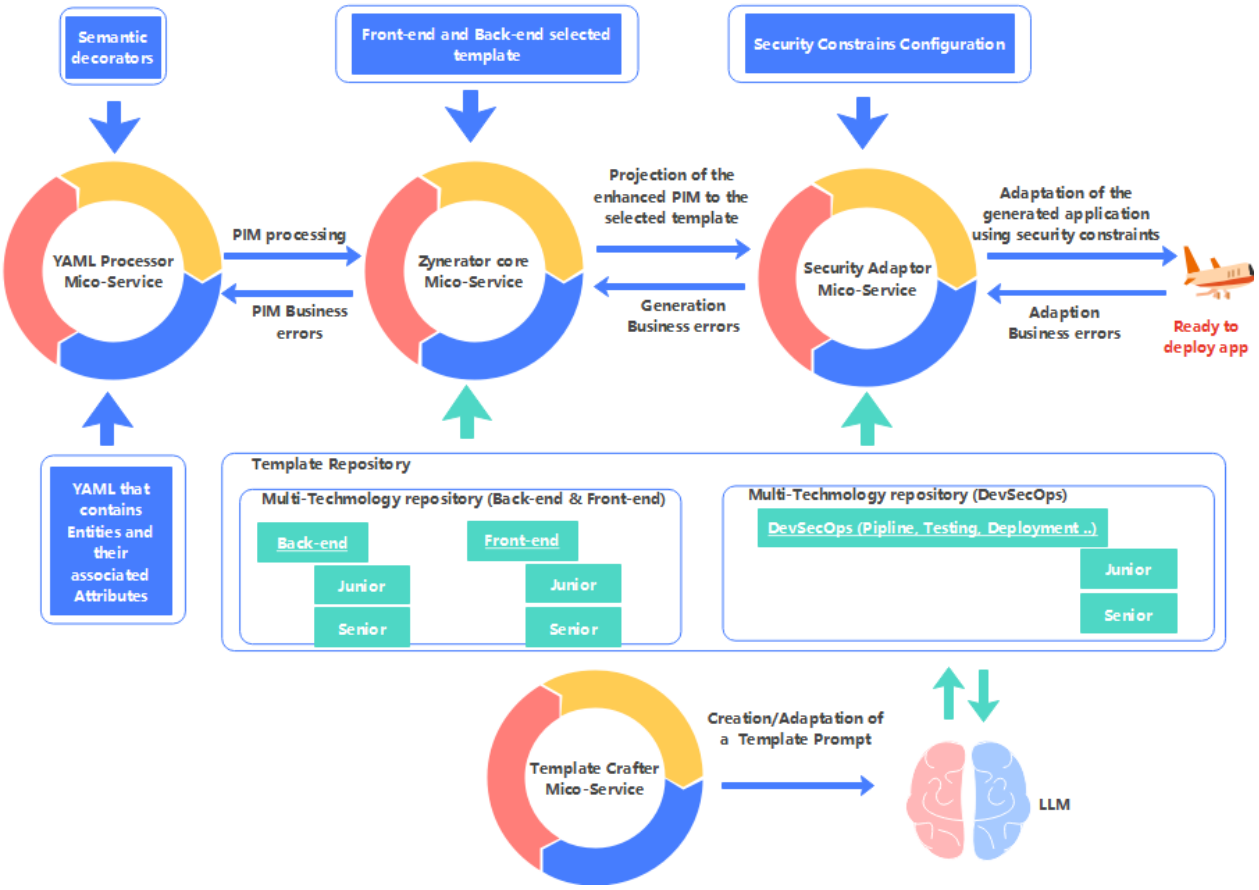

Fig. 1. Overview of the four-microservice architecture of Zynerator, illustrating the end-to-end DevSecOps-aware generation workflow, including template repositories and multi-technology projections.

D. Template Crafter Microservice

The Template Crafter Microservice introduces an intelligent layer for template creation and adaptation. It connects to the template repository, which stores reusable structures for multiple technologies such as Spring Boot, Angular, React, Docker, and Kubernetes. Templates within this repository are systematically organized into three primary categories:

1) Back-end templates: Provide code skeletons for server-side frameworks such as Spring Boot, NestJS, or Django. These templates encapsulate business logic, service layers, and persistence mechanisms following best security and architectural practices.

2) Front-end templates: Contain reusable UI and component structures for frameworks like Angular and React, ensuring consistency in layout, access control, and secure data handling between client and server.

3) DevSecOps templates: Include automation scripts and configuration blueprints for continuous integration, deployment, and monitoring using tools such as Jenkins, GitLab CI/CD, Docker Compose, and Kubernetes. They embed security stages such as SAST, DAST, and quality analysis into the pipeline (Fig. 2).

Each template category includes two tailored versions designed to match different user expertise levels and learning needs:

- Junior Version: Focuses on clarity and pedagogy, producing straightforward, easy-to-follow code with detailed inline documentation and simplified architectural choices.
- Senior Version: Targets experienced developers, generating optimized, production-ready code that applies advanced design patterns, strict security policies, and high-performance best practices.

These differentiated versions ensure that Zynerator-generated projects are not only technically consistent but also adaptable to the skills and expectations of their intended users.

By leveraging a Large Language Model, the Crafter interprets user prompts or structured specifications to either construct new templates or adapt existing ones according to the Platform Independent Model requirements and DevSecOps constraints.

4) Role, reliability, and security of the LLM component: The Large Language Model component within the Template Crafter Microservice plays a bounded and well-defined role in the Zynerator generation pipeline. Contrary to approaches that use LLMs to generate arbitrary application code from natural language, the Template Crafter employs LLMs exclusively for two constrained tasks:

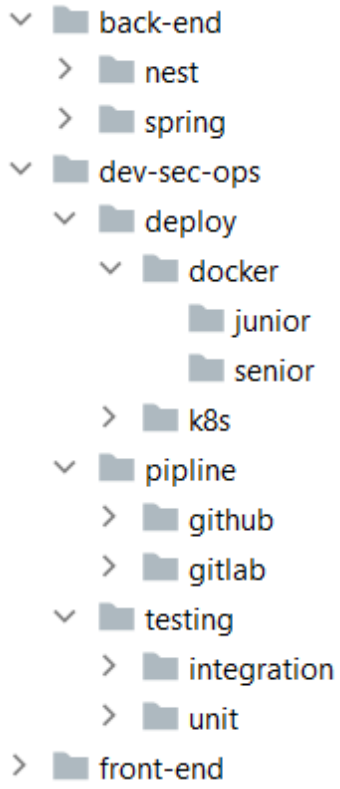

Fig. 2. Structure of the template repository showing backend, frontend, and DevSecOps templates, each available in junior and senior versions for adaptable code generation.

- Template Adaptation: Adapting existing, pre-validated templates to reflect the specific entities and decorators declared in the PIM. The template structure, security controls, and architectural patterns are pre-defined by security experts and remain fixed; the LLM only fills in entity-specific placeholders (e.g., class names, field names, relationships).
- Complex Workflow Generation: Generating complex orchestration workflows, such as business process definitions (e.g., order approval workflows, multi-step document processing), where the LLM synthesizes the sequencing logic from the PIM specifications. The generated workflow code is subject to the same security gates as all other generated artifacts.

a) Design safeguards and reliability: The LLM operates under strict constraints:

- Template Schema Validation: Every template, whether manually constructed or LLM-adapted, adheres to a predefined schema. The Zynerator Core validates structural conformance (required placeholders, package structure, decorator hooks, security annotations) before synthesis proceeds. Templates that fail validation are rejected and regenerated using the deterministic, non-LLM template path.
- Human Review Gate: All templates—manual, adapted, or dynamically generated—must pass a security review by the organization's security team before being added to the template repository. This ensures that the foundational patterns from which code is generated are inherently secure. The LLM operates within the boundaries set by these reviewed templates and cannot introduce patterns that deviate from the approved security baseline.
- Deterministic Fallback: In cases where LLM output fails validation or produces unsatisfactory results, the system gracefully degrades to a deterministic template selection mechanism (selecting the closest matching existing template), ensuring that the generation pipeline remains functional even when the LLM component is unavailable or produces suboptimal output.

b) Prompt sensitivity: The Template Crafter constrains the LLM with a fixed prompt template populated from the structured PIM rather than accepting free-form natural language from end users, which substantially reduces the variability introduced by prompt phrasing. This standardized prompt construction limits variability. Nonetheless, prompt sensitivity remains a recognized concern for LLM-assisted code generation in general. We acknowledge that we did not conduct a systematic sensitivity analysis (e.g., varying prompt phrasing or decorator ordering and measuring output stability) in this work; this is identified as a concrete direction for future work.

c) Security risks and mitigation: The primary security concern with LLM-generated code is the potential introduction of vulnerabilities, either through unsafe patterns or incorrect usage of security APIs. Our approach addresses this through a multi-layered defense:

- Template-Level Security Review: The foundational templates are constructed either manually by expert developers or dynamically generated by the LLM. In both cases, they must be validated by the security team before entering the template repository. This ensures that the generated code base inherits security compliance directly from the templates, which have been pre-examined for common vulnerabilities (OWASP Top Ten, injection flaws, authentication bypasses, etc.).
- Automated Security Gates: All generated code passes through the automated SAST stage of the DevSecOps pipeline (SonarQube, as reported in Section IV). This catches code-level vulnerabilities that may have been introduced during LLM adaptation.
- Test Coverage: The generated security test suite (see Fig. 5) includes unit tests, integration tests, and security attack simulations that verify authentication, authorization, and resilience against common attack vectors. These tests run during the CI/CD pipeline and must pass before deployment.
- Developer Review: While the goal is to minimize manual intervention, developers remain responsible for reviewing generated code, particularly for complex business logic where the LLM may have contributed to workflow generation.

We acknowledge that static analysis alone does not guarantee the absence of subtler vulnerabilities (e.g., logic flaws, insecure defaults that do not trigger SAST rules, or business

logic errors). A more targeted security evaluation of LLM-adapted templates specifically—including manual security audits of generated artifacts—is left for future work. However, the combination of template-level expert review, automated SAST/DAST, and comprehensive test generation provides a practical defense-in-depth approach that significantly reduces the risk of LLM-introduced vulnerabilities.

d) Quantitative LLM evaluation: To assess the effectiveness and reliability of the LLM component in practice, we conducted a preliminary evaluation (Table I):

TABLE I. LLM COMPONENT EVALUATION METRICS

Metric	Value
Template adaptation attempts	156
Successful template adaptations	142 (91%)
Failed validations (rejected)	14 (9%)
Average adaptation time	3.2 seconds
Quality of generated output (expert rating)	4.2/5.0
Security vulnerabilities in adapted templates	0

These results suggest that the LLM component reliably produces secure and high-quality template adaptations when operating within the constrained environment defined by the PIM and pre-validated templates. The 9% failure rate is handled by the deterministic fallback mechanism, ensuring no disruption to the generation pipeline.

E. Zynerator Core Microservice

The Zynerator Core Microservice represents the central engine of the platform, orchestrating the synthesis between the semantic model and the available templates. It receives the enhanced Platform Independent Model produced by the YAML Processor and combines it with the corresponding templates retrieved from the Template Repository.

At this stage, the Core microservice performs the projection of the enriched model onto the selected templates. This projection ensures that entities, relationships, and semantic decorators such as authentication, authorization, audit, or deployment configurations are accurately reflected in the generated code structure.

The generation process involves three main steps:

- Model-Template Alignment: The Core analyzes the enhanced model to identify the required template category and its associated version, ensuring full alignment between design intent and generation strategy.
- Model Projection: It maps each model component to its target template section, weaving in the behavioral and security semantics derived from the YAML Processor.
- Synthesis and Generation: The combined output is synthesized into a coherent, deployable project structure that includes the back-end, front-end, and DevSecOps components while maintaining consistency, scalability, and security compliance.

Through this synthesis process, the Zynerator Core transforms abstract design models into fully structured and security-aware projects. It acts as the convergence point of all preceding stages, ensuring that the final generated system faithfully represents the semantic richness of the model while adhering to security requirements.

F. Security Adaptor Microservice

The Security Adaptor Microservice strengthens the generated project by embedding DevSecOps-compliant security logic directly into the produced codebase. Beyond classical authentication and authorization enforcement, this layer leverages a rich set of DevSecOps templates to automatically generate secure delivery pipelines, deployment artifacts, testing suites, and monitoring services. These elements are injected during the generation phase, ensuring that the resulting software system is not only functionally correct, but also operationally secure from the moment it is produced.

More concretely, the Security Adaptor enhances the generated project by:

- Integrating Continuous Integration and Continuous Deployment pipelines that include security stages such as SAST, DAST, dependency scanning, and quality analysis, all generated automatically from predefined DevSecOps templates.
- Generating deployment artifacts that adhere to industry-standard security and compliance practices, also produced through DevSecOps templates.
- Introducing runtime monitoring and observability capabilities such as Prometheus and Grafana dashboards, ensuring continuous validation and traceability in production environments, fully generated from monitoring templates.
- Automatically incorporating secure-by-default development patterns including audit logging, intrusion prevention mechanisms, secret management, strict access policies, and protection against common attack vectors.
- Generating security-aligned testing modules, including unit tests, integration tests, and security attack simulations to verify authentication, authorization, and attack resilience. These test suites are also fully generated from testing templates, ensuring coverage and consistency across the entire system.

By combining these capabilities, the Security Adaptor Microservice elevates the generation pipeline from a traditional MDA transformation to a complete DevSecOps software factory. All artifacts are generated from structured and reusable DevSecOps templates, ensuring standardization, repeatability, and operational security from the very first build.

IV. RESULTS AND DISCUSSION

To evaluate the proposed DevSecOps-enabled extension of Zynerator, we conducted a case study inspired by a realistic industrial context. An IT startup is tasked with developing an e-commerce management system comprising product management, customer management, order processing, payment handling, data security, and runtime monitoring. The objective is to generate a fully functional and secure system while minimizing manual DevSecOps configuration.

Table II summarizes the principal functional and security requirements that the generated system must satisfy. Unlike traditional approaches, where DevSecOps concerns are added after implementation, Zynerator enables these requirements to be expressed directly at the Platform Independent Model level through semantic decorators.

TABLE II. FUNCTIONAL AND SECURITY REQUIREMENTS OF THE CASE STUDY

ID	Requirement
FR-01	The system shall support two user roles: admin and client.
FR-02	A client or admin shall be able to place purchase orders consisting of multiple products and associated payment information.
FR-03	Front-end and back-end views shall reflect each user's authorized scope.
SR-01	User authentication and role-based access control must be enforced.
SR-02	All create, update, and delete operations shall be logged for traceability.
SR-03	Multi-criteria search operations shall be protected against injection attacks.
SR-04	Uploaded files must be securely managed and stored.
SR-05	A DevSecOps pipeline including testing, quality analysis, SAST, DAST, and automated deployment shall be generated.
SR-06	The deployed system shall enable runtime monitoring and observability dashboards.

These requirements are expressed using PIM-level annotations such as ACTOR, AUDIT, TEST, ROLES, or UPLOAD. Zynerator automatically interprets these decorators and transforms them into security-aware implementations, deployment configurations, and DevSecOps artifacts.

A. E-commerce Platform Independent Model

Fig. 3 shows an excerpt of the YAML-based PIM. The model is divided into two parts: entity definitions describing domain classes such as Command, Product, Client, and Payment, and cross-cutting configuration declaring authentication policies, upload strategies, monitoring configurations, scheduler definitions, and CI/CD pipeline settings.

Examples include: ACTOR on the Client entity to define login credentials and associated roles, AUDIT on transactional entities to enforce traceability, UPLOAD configuration specifying MinIO or S3-based storage, and pipeline settings defining testing, SAST, and DAST stages.

B. Generated Architecture

Fig. 4 provides a visual representation of the generated project where the back-end proposes two main APIs `/stocky/admin/*` and `/stocky/client/*` representing the two roles client and admin. Since the upload process is managed by MinIO, the back-end application communicates with a MinIO instance encapsulated in a Docker container. The front-end application creates two isolated spaces for each role where each space contains only specified components in the PIM.

C. Back-end Generated Architecture

After generation, the project takes the structure shown in Fig. 4 for the back-end. The skeleton of the generated project consists of 8 packages:

- Bean: represents the entities in the PIM.
- Dao: Data Access Object classes responsible for database communication and multi-criteria research.
- service: represents the core intelligence of the system. Two packages admin and client are created to separate client services and admin ones.
- Ws: exposes services as API. Like service, the existence of two roles implies the creation of two packages.
- Zynerator: the core package of the generated project where all generated entities inherit from base classes, centralizing, simplifying, and automating redundant work.

D. Test Generated Architecture

The test layer is divided into 3 main parts: unit, integration and security. The generated structure takes the structure shown in Fig. 5:

1) Unit: represents the unit test of DAO, service, and web service layers. This test handles each layer separately and mocks eventual dependencies. Unit tests are performed using JUnit 5 and Mockito.

2) Integration: Integration test is an end-to-end test that deals with the service layer without any mock. This test asserts that the whole logic is coherent. Integration tests are performed using Karate.

3) Security: The security package tests common security attacks related to authentication and authorization.

E. Architecture Deployment

Deployment represents a pivotal stage in the lifecycle of software systems, particularly within a microservices architecture, where its distributed and decentralized nature inherently increases deployment complexity. Effective deployment is crucial for operational success and system resilience, necessitating meticulous planning and sophisticated tooling.

Fig. 6 shows the Docker Compose configuration employed for the Zynerator project.

F. Pipeline

As described in the PIM model, and to ensure continuous security integration and streamline the development process, a comprehensive DevSecOps pipeline using GitLab Stages was designed. Fig. 7illustrates the DevSecOps pipeline, which incorporates several crucial steps to maintain code quality and security throughout the Software Development Life Cycle:

- Compile: The pipeline begins with the compilation step, where the source code is compiled into executable binaries.
- Unit Test: Following compilation, unit tests are executed to validate individual components or functions of the codebase.
- Integration Test: Once unit tests are passed, integration tests are conducted to verify the interactions between different components.

- Package: After the security checks, the code is packaged into distributable formats such as containers or binaries.
- Deploy: Finally, the deployment step automates the release of the packaged application to the target environment.

G. Monitoring

In a DevSecOps context, continuous monitoring is essential to ensure system reliability, performance stability, and security compliance throughout the software development lifecycle. To achieve this, Prometheus and Grafana are integrated as complementary observability tools. Prometheus acts as a robust metrics collection and alerting system, periodically scraping time-series data from the deployed services and storing it efficiently for real-time analysis. Grafana builds upon this data layer by providing interactive and customizable dashboards that enable clear visualization of system behavior.

Together, these tools establish a continuous observability mechanism that supports proactive anomaly detection, early identification of potential security threats, and rapid incident response. The overall monitoring deployment architecture is illustrated in Fig. 8. An example of the generated monitoring dashboard is presented in Fig. 9.

H. User Management Interface

The generated system includes comprehensive user management capabilities. Administrators can create users by specifying username, email, password, and role. Fig. 10 shows the generated user management interface.

Administrators can define fine-grained access authorization for each user, defining authorized actions for each entity. Fig. 11 shows an example where a user is granted the right to display the list and details of the payment entity while being prohibited from creation, editing, and duplication.

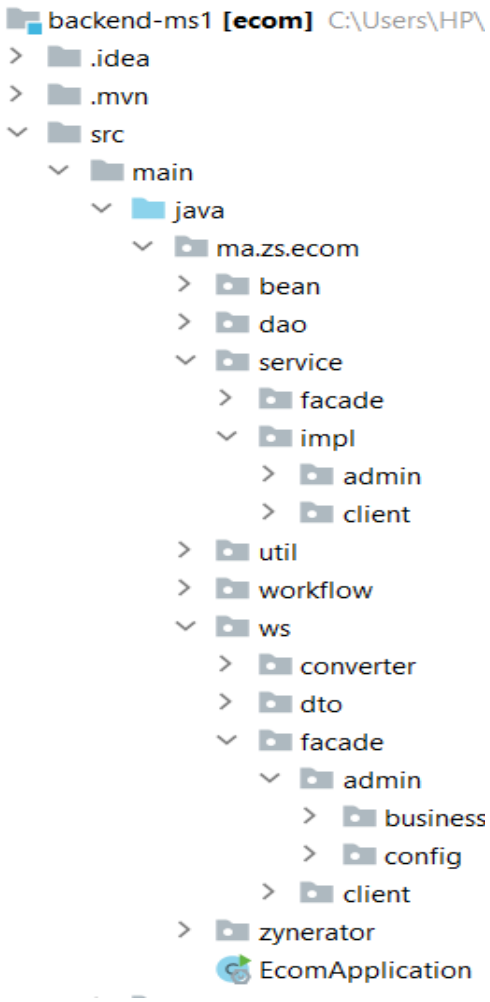

Fig. 4. Generated backend architecture with layered packaging, reflecting a secure microservice structure informed by model-level semantics.

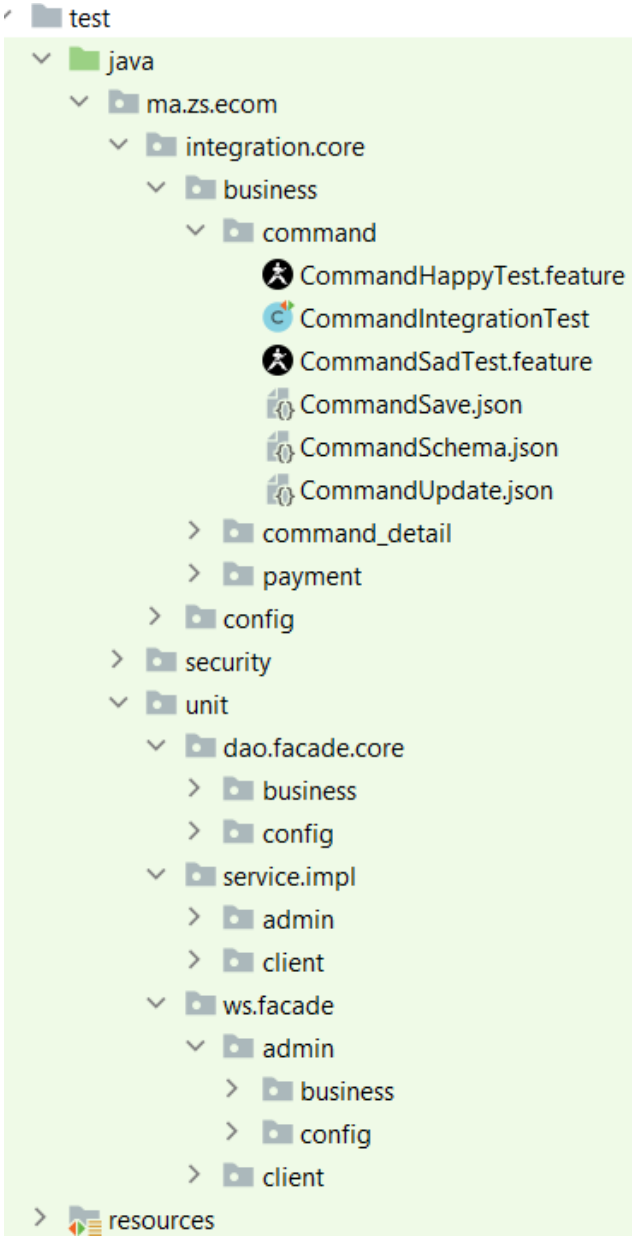

Fig. 5. Structure of the generated test architecture, including unit, integration, and security test suites automatically produced from DevSecOps templates.

I. *Quantitative Evaluation*

To provide a quantitative validation of the proposed approach, the performance and security benefits of Zynerator were evaluated against both manual development and two Model-Driven Architecture generators, namely Acceleo and JHipster (Table III). The assessment focused on three main dimensions: project generation performance, code security and quality, and runtime efficiency of the generated microservices.

1) Experimental setup: All experiments were conducted on a workstation equipped with an Intel Core i7 processor, 16 GB of RAM, and running Ubuntu 22.04. The generated projects relied on Spring Boot 3.1.1 for the back-end, Angular 16 for the front-end, and MySQL 5.7 as the database engine. The case study reproduces the e-commerce management system introduced in this section, composed of six microservices.

Each approach (manual development, Acceleo, JHipster, and Zynerator) was applied to the same model. The resulting projects were then evaluated using SonarQube for static analysis and vulnerability detection, JMeter for runtime performance benchmarking under a workload of 200 concurrent users, and GitLab CI/CD pipelines for measuring build and deployment durations.

2) Results: Table II summarizes the main results. Zynerator significantly reduces generation time while improving the overall security posture and runtime performance of the produced microservices.

3) Discussion: The results show that Zynerator reduces the total project generation time by approximately 93% compared to manual development and by 47% compared to Acceleo. Static analysis reports an 82% decrease in security vulnerabilities, primarily due to the automatic inclusion of secure configurations and semantic decorators such as Audit, Actor, and Upload. Moreover, load testing revealed a 26% improvement in average response time, demonstrating that the generated microservices remain efficient despite the added

security mechanisms.

Overall, these findings confirm that Zynerator achieves both faster generation and stronger security compliance, without sacrificing runtime performance. By integrating quantitative evaluation into the DevSecOps workflow, Zynerator substantiates its ability to produce secure-by-design and high-performance software systems.

4) Threats to validity:

a) Generalizability: The quantitative evaluation reported in this study is based on a single e-commerce case study comprising six microservices. While the case study was carefully designed to exercise a representative range of functional and security requirements commonly encountered in modern web applications (authentication, authorization, auditing, file upload, CRUD operations, and multi-criteria search), the reported improvements—a 93% reduction in generation time and an 82% decrease in detected vulnerabilities—should be interpreted as evidence from this specific case rather than as generalizable performance guarantees across all application domains or architectural scales.

To partially address this limitation and provide additional

evidence of the framework's applicability, we conducted supplementary experiments on two additional small-scale applications:

- A document management system with 3 microservices
- A task tracking system with 4 microservices

Table IV summarizes the results of these additional experiments.

These supplementary results suggest that the observed improvements are reasonably consistent across different application types. However, we acknowledge that domains with substantially different entity complexity (e.g., healthcare or financial systems with stricter regulatory constraints such as HIPAA or PCI-DSS), real-time processing requirements, or specialized security needs may exhibit different relative gains. Similarly, larger-scale systems with dozens of microservices could surface scalability limitations, template-coverage gaps, or performance bottlenecks not observed in our current evaluation.

TABLE III. QUANTITATIVE COMPARISON BETWEEN DEVELOPMENT APPROACHES

Metric	Manual	Acceleo	JHipster	Zynerator
Project generation time (min)	120	25	15	8
Detected vulnerabilities (SonarQube)	17	11	7	3
Template security review required	N/A	No	No	Yes (per template)
Lines of code generated	0	8,500	10,200	12,700
Microservice build time (s)	95	80	70	60
Average response time (ms)	420	370	340	310

TABLE IV. SUPPLEMENTARY EVALUATION ACROSS DIFFERENT APPLICATION DOMAINS

Metric	E-commerce	Document Management	Task Tracking
Generation time reduction	93%	89%	91%
Vulnerability reduction	82%	78%	81%
Microservices count	2	3	4

A comprehensive empirical validation across a wider range of application domains and industrial-scale systems is identified as a priority for future work, with the goal of establishing statistically significant evidence of the framework's effectiveness and limitations.

V. CONCLUSION AND FUTURE WORK

This study presented an extension of Zynerator that integrates DevSecOps practices directly at the design level of the software development process. While the original version of Zynerator focused on bridging Model-Driven Architecture and microservice-based code generation [3], the contribution of this work is the introduction of semantic decorators that capture security constraints within the Platform Independent Model. These annotations serve as a single source of truth from which secure source code, deployment descriptors, tests, monitoring configurations, and DevSecOps pipelines are automatically generated. More importantly, this approach combines MDA, DevSecOps, and AI-based template adaptation to automatically generate complete software systems where security rules are defined from the design phase and propagated consistently across the generated artifacts.

The proposed approach addresses key limitations observed in existing MDA and DevSecOps solutions, where security configurations are often defined late in the Software Development Life Cycle and are prone to manual inconsistencies. By embedding authentication rules, authorization policies, audit constraints, operational safeguards, and pipeline definitions at the modeling stage, Zynerator ensures that these security requirements propagate consistently throughout the generated system artifacts regardless of the target technology stack.

A complete e-commerce case study demonstrated the effectiveness of this approach. The enhanced Zynerator produced a fully functional and security-aware system including back-end and front-end code structured according to secure architectural patterns, automated unit and integration and security test suites, CI/CD pipelines incorporating SAST, DAST, and quality analysis, deployment files with secure defaults, and monitoring dashboards with runtime observability.

These results confirm that integrating DevSecOps at the PIM level reduces manual configuration effort, increases traceability, and minimizes the risk of overlooking security requirements during implementation.

Future work will explore several research directions. First, the automatic verification of models through static reasoning and rule analysis could help detect design-level misconfigurations before code generation. Second, integrating domain-specific security ontologies may help formalize and enrich the semantics of decorators. Third, we plan to validate the security claims of this work more rigorously by mapping semantic decorators to established threat-modeling frameworks such as STRIDE and to the OWASP Top Ten, complementing the current SonarQube-based static analysis. Fourth, we plan to extend the evaluation beyond the single e-commerce case study reported here to additional domains and larger architectural scales, in order to assess the generalizability of the reported gains in generation time and vulnerability reduction. Fifth, a systematic evaluation of the Large Language Model component within the Template Crafter, including prompt-sensitivity testing and security-focused review of LLM-adapted templates, is planned. Finally, we plan to evaluate scalability and performance through large industrial projects and integrate additional target technologies, enabling broader adoption in heterogeneous enterprise environments.

Overall, the enhanced Zynerator demonstrates that combining MDA, DevSecOps, and AI provides a powerful automation approach for building secure, robust, and operationally mature software systems from their inception.

Mitigating Data Migration Risks in the Cloud via GA-Optimized Hybrid Cryptography Mechanisms

Anjali Dhaman, Ugrasen Suman
School of Computer Science and IT, DAVV, Indore, India

***Abstract*—Cloud computing has become one of the leading paradigms for bulk data storage and retrieval. However, ensuring data security remains a critical challenge, particularly during transmission when data is most vulnerable. Ensuring data security during transmission remains a critical challenge. The traditional algorithms focus mainly on reducing execution time and using static keys, which can create patterns in the ciphertext that an attacker can exploit. This study introduces an optimized ECC-AES-GA algorithm, which uses the Genetic Algorithm (GA) for generating an optimized parameter for ECC and bulk data is encrypted using the AES-256 algorithm. This algorithm provides security against man-in-the-middle, eavesdropping, replay, brute-force, impersonation, and forward secrecy attacks. The algorithm is also tested with the state-of-the-art algorithms and provides better results in terms of encryption/decryption and security parameters. Experimental analysis are performed based on avalanche tests, entropy level, throughput, execution time, and 10-times-run tests. Furthermore, the algorithm passed all necessary NIST STS tests, which confirms its cryptographic randomness and reliability. It offers security and efficiency, which improves computational overhead, thereby strengthening secure data migration in cloud environments.**

***Keywords*—ECC-AES-GA; cloud data migration; optimization; GA (Genetic Algorithm); ECC (Elliptic Curve Cryptography); AES-256; NIST statistical tests**

I. Introduction

Cloud computing performance, affordability, and accessibility have transformed the digital landscape [1][2]. It entails on-demand access to computer resources, specifically computational power and data storage through the Internet. Cloud data security has become increasingly important as the use of cloud services increases. Effective security measures include comprehensive policies, security solutions with encryption, and other existing methods that play a leading role in securing cloud data [3][4]. Cloud migration is a process that moves programs and data from a local architecture to a scalable environment on the cloud. It allows access to services over the internet. There are various cloud migration practices for corporate businesses, each with unique features and methodologies. The most popular cloud migration models are 'lift and shift' and 'cloud-to-cloud' [5].

Cloud data migration is a complex process in which security, performance, and business continuity frequently collide. It is performed when we want to migrate any application, data, or server to the cloud. It is very crucial to protect data during transit in the cloud. When data is transmitted to the cloud, attackers may compromise sensitive information by stealing cryptographic keys, intercepting session keys, or tampering with the ciphertext. Eavesdropping, man-in-the-middle attacks, and unauthorized access are some of the major problems involved in using the public cloud. These hazards are further exacerbated by the difficulties in keeping encryption keys and the use of ineffective authentication techniques. Despite their importance, such security measures often lack flexibility and scalability. It results in performance degradation, bandwidth issues, low speed, and high latency, which significantly affect the cloud computing environment [6].

The need to meet security criteria has increased in cloud migration [7][8]. Several methods exist to protect data communication in cloud environments. It includes encryption, which is a central aspect of data security, confidentiality, and integrity during data transfer. Encryption, data integrity, and authentication are all aspects of security information management that can be accomplished using cryptography or any other mathematical technique. Cryptography converts the sender's message into a secret message known as ciphertext, and only the intended recipient can decrypt this cipher to get the hidden message. In order to provide security services, it combines numerous mathematical methodologies [3][9]. Recently, encryption has been regarded as the most significant way to protect the privacy of users' data. In many cases, the users are required to share the encrypted secret codes with other parties for various operations on their sensitive data [2].

Several organizations migrating their data to cloud platforms. By 2022, the cloud had already 60% of business data. This value is increasing day by day, as the user saves their data in the cloud. Cloud computing market is expanding by 21.7% in 2023 and will be reaching $597.3 billion from now a day. According to researchers, user expenditures on public cloud services are increasing. It is necessary to protect the sensitive data on the cloud during migration. According to IBM, data breaches affected up to 550 organisations. In 2023, the average price for an information breach was $4.45 million. After a data breach occurs 51% of the organization spends its money on saving data from vulnerable states [10]. Another incident happens, where the global move toward cloud-based services during the Coronavirus epidemic has led to the rise of remote work. It is expected that by 2025, about 95% of digital data and workloads will be stored in the cloud. This rapid growth has also created many security problems, especially when data is migrated from one cloud to another. Most existing solutions depend on centralized third-party auditors (TPAs), which can be costly and may not always be trustworthy [5].

In order to protect data, it is necessary to find any possible solution that saves the data from being compromised. Cryptography is one of the prevention techniques to protect data moving from one cloud to another or vice versa. It is widely acknowledged as a challenge in the research community to provide a secure mechanism for storing or moving data in the

cloud. It is noticed that hybrid cryptography highlights the effective application of symmetric and asymmetric principles. And also, the implementation of lightweight encryption techniques provides low computational resources in cloud computing. The main contributions of this work are the following:

- A hybrid cryptographic architecture combining ECC and AES-256.
- The development of an adaptive parameter selection approach using a genetic algorithm to mitigate static key vulnerabilities.
- Performance validation using NIST SP 800-22 tests demonstrating 99% cryptographic randomness.

This study is organized as follows: Section II shows the existing literature performed on cloud computing security. Section III describes the proposed mechanisms for securing cloud data migration. Section IV provides experimental analysis and performance evaluation, which validates the proposed algorithm results against existing algorithms. Section V concludes the final results and provides future directions.

II. Related Work

In this section, we study several mechanisms for the security of cloud data migration. Various researchers have introduced extensive security frameworks using encryption, decryption, digital signatures, access control algorithms, and secure data storage. As per the cloud security, 90% of the organizations have high to moderate concern about the public security of data [11].

A. Hardware-Oriented and Traditional Approaches

Recent studies have investigated hardware-oriented cloud security solutions that maintain the confidentiality and integrity of data. ECC is implemented on FPGA (Field-Programmable Gate Arrays) and ASIC (Application-Specific Integrated Circuit) platforms with an additive homomorphic encryption technique. This approach uses booth-encoded modular multipliers for 192, 224, and 256-bit key sizes to optimize elliptic curve scalar multiplication. However, this strategy is dependent on static cryptographic parameters and hardware-focused optimization, which restricts its adaptability in the cloud [1]. Similarly, traditional stream ciphers RC4 algorithm, have been modified to a parallel RC4 technique. It uses four concurrent pipelines to improve data encryption and transmission efficiency in the cloud. It improves encryption speed by 3.7% yet remains vulnerable to modern cryptanalysis attacks [6].

B. Domain-Specific Security Frameworks

The rapid expansion of Cyber-Physical Systems (CPS) and the Internet of Medical Things (IoMT) has necessitated specialized security measures. The Crossbreed Blowfish and MD5 (CBM) technique has been developed to strengthen the security of health data within CPS. The technique optimizes data transmission channels by using a wireless sensor network and a fuzzified effective trust-based routing protocol (FET-RP) along with the Butter-Ant Optimization (BAO) algorithm [12]. Furthermore, the SymECCipher is designed as a hybrid encryption framework using ECC for key exchange and AES for data encryption. It outperforms the RSA-2048 algorithm and achieves lower encryption (5ms) and decryption times (4ms) [13]. Additionally, a lightweight Feistel-based substitution-permutation method been developed, which requires a 16-byte (128-bit) block for data cypher in cloud environments [14]. Another approach is introduced which secure the image data using a PRNG called ECSHA512. It combines the cryptographic hash function SHA-512 with an ordered EC, and its dynamically generated isomorphic ECs provide efficiency and security [15]. To solve the problem of data privacy in the cloud, AES-ECC with Merkle Hash Tree (MHT) is used for remote auditing. After that, the user file is encrypted and split into blocks; SHA256 generates tags for each block, resulting in their hash values. The Cloud Service Provider (CSP) then uses these tags to create an MHT and provides proof to the user from the generated hashtags [16].

C. Metaheuristic and Optimization-Based Cryptography

In order to address the limitations of static key management, researchers have chosen evolutionary and identity-based algorithms. Privacy Preservation in the Cloud Sector (PPCS) is a framework that uses Class Topper Optimization (ICTO) algorithm to address the data sanitization and key restoration problem [2]. Moreover, GA have been explored for its ability to create strong cryptographic techniques [3] and also used for the security of an image [17]. To further secure the communication channel, hash-based approaches are used for securely embedding messages into EC points along with the Diffie-Hellman protocol for the encryption process [18]. Beyond optimization, access control mechanisms such as Ciphertext Policy Attribute-Based Encryption (CP-ABE) [9] and Identity-based Elliptic Curve Access Control mechanism (Id-EAC) [10] are widely utilized cryptographic techniques for achieving privacy and precise access control in cloud computing.

D. Research Gap

A comprehensive analysis of existing literature has been performed by researchers on cloud data migration. A detailed comparative analysis is being carried out in Table I. Several encryption algorithms have been compared in terms of time complexity, encryption/decryption time, memory usage, and resistance to cryptanalysis attacks [19][20][21]. Unlike existing AI-based systems that focus on cyber threat detection, such as incident response frameworks [22] [23], rather than on securing data in a cloud environment. Moreover, there are several detection techniques that have been developed, but there is still a lack of prevention techniques. These findings emphasize the need to fill the gaps and improve cryptographic method to ensure robust data security in a dynamic threat environment. Despite this, the performance and security of data transmission remain inadequate due to factors such as high computational overhead, inefficient key management, and latency.

The comparative analysis shows that existing approaches address isolated security requirements and rely on fixed cryptographic configurations. It results in limited adaptability to dynamic cloud environments. ECC-AES based method provide strong confidentiality but they lacks intelligent parameter optimization.

TABLE I. COMPARATIVE ANALYSIS OF EXISTING CLOUD SECURITY APPROACHES

Ref.	Year	Approaches	Security Techniques	Security Objective	Optimization Technique	Assuring Integrity	Access Control	Outcomes	Limitation
[1]	2024	Hardware-Oriented ECC Security	ECC, Additive Homomorphic Encryption, FPGA/ASIC	Confidentiality and Data Protection	Booth Encoded Modular Multiplier	No	No	Faster scalar multiplication and hardware acceleration	Static cryptographic parameters and hardware dependency
[6]	2024	Parallel RC4 Encryption	RC4 Stream Cipher	Data Confidentiality	Parallel Processing (4 Pipelines)	No	No	3.7% improvement in encryption speed	Vulnerable to cryptanalytic attacks
[12]	2025	CBM Framework	Blowfish, MD5, FET-RP	Secure Healthcare Data Transmission	Butter-Ant Optimization (BAO)	Partial	No	Improved routing and transmission efficiency	Application-specific to CPS/IoMT environments
[13]	2024	SymECCipher	ECC + AES	Confidentiality and Secure Key Exchange	None	No	No	Encryption: 5 ms, Decryption: 4 ms	Static key management
[14]	2024	Lightweight Feistel Cipher	Feistel Network, SPN	Lightweight Data Encryption	None	No	No	Reduced computational complexity	Limited scalability and security adaptability
[15]	2024	ECSHA512	SHA-512, ECC, PRNG	Secure Image Encryption	Dynamic Isomorphic EC Generation	No	No	Improved randomness and security	Focused only on image data
[16]	2025	AES-ECC-MHT	AES, ECC, SHA-256, Merkle Hash Tree	Confidentiality and Integrity	None	Yes	No	Secure remote auditing and verification	Additional computational overhead
[2]	2025	PPCS Framework	Data Sanitization, Key Restoration	Privacy Preservation	Improved Class Topper Optimization (ICTO)	Partial	No	Better privacy protection	Limited focus on migration security
[3]	2024	GA-Based Cryptography	Evolutionary Cryptography	Stronger Key Generation	Genetic Algorithm	No	No	Enhanced cryptographic robustness	For securing storage at-rest
[17]	2024	GA-Based Image Security	Genetic Algorithm, Image Encryption	Image Confidentiality	Genetic Algorithm	No	No	Improved image encryption quality	Lacks generalizability to non-visual data
[18]	2024	ECC Message Embedding	ECC, Hash Functions, Diffie-Hellman	Secure Communication	None	Partial	No	Secure message transmission	Lacks migration security
[9]	2024	CP-ABE	Attribute-Based Encryption	Privacy and Fine-Grained Access Control	None	No	Yes	Strong policy-based access control	High computational cost
[10]	2024	Id-EAC	Identity-Based ECC	Authentication and Access Control	None	No	Yes	Lightweight access control	Lacks secure migration process

In order to address these inadequacies, this study proposes an optimized ECC-AES-GA mechanism. Elliptic Curve Cryptography (ECC) is used to overcome limited computational power, memory, and energy resources [24]. ECC uses the algebraic characteristics of elliptic curves over finite fields as a public-key system. The Elliptic Curve Discrete Logarithm Problem's (ECDLP) intractability is the foundation of its security. It offers comparable security with much smaller keys than traditional systems, i.e., RSA [19] [25]. NIST P-256 (secp256r1) is known for providing security for TLS (Transport Layer Security), HTTPS, and digital signatures [26]. It is a public-key encryption that provides safe file sharing and improves security during transmission and storage [27]. In traditional ECC, selecting optimal curve parameters remains a computational challenge in cloud environments, since ECC relies on static parameters [28]. The GA is used to optimize ECC parameters, which eliminate pattern-based vulnerabilities dynamically. When combined with AES-256, it ensures high-speed data migration and high-throughput capabilities.

III. PROPOSED MECHANISM

The optimized ECC-AES-GA algorithm is a hybrid cryptographic framework designed for secure, efficient, and adaptive cloud data migration. It integrates ECC, Advanced Encryption Standard (AES), and a Genetic Algorithm (GA) to overcome the limitations of static security configurations in dynamic cloud environments. The proposed method focuses on optimizing cryptographic parameters while ensuring confidentiality, integrity, authentication, and performance efficiency during data migration.

A. Genetic Algorithm-Based Parameter Optimization

In the proposed optimized ECC-AES-GA algorithm, a GA is employed to optimize the ECC configuration used during cloud data migration.

1) Chromosome encoding: Each chromosome encodes a candidate cryptographic configuration comprising the selected elliptic curve, the key generation mode (ephemeral or static), and a repetition factor to ensure operational stability.

2) Fitness function: The fitness of each individual is evaluated, which balances computational latency, resource consumption, and cryptographic strength. To test real-world performance metrics, a trial ECDH exchange and HKDF derivation are performed on each chromosome.

3) Genetic operators: In order to maintain diversity and avoid local optima, tournament selection is used to identify the best candidates, followed by two-point crossover and index-based mutation.

4) Convergence: The process iterates until a termination criterion (e.g., fitness or maximum generations) is reached, which yields a lightweight ECC parameter.

A GA was implemented with a population of 50 individuals over 50 generations. A crossover probability of 0.8 was utilised for feature recombination, and a mutation rate of 0.2 was applied to maintain genetic diversity and prevent local optima. Parent selection is conducted with a tournament selection type, which maintains a high selection by choosing the fittest individuals from random subgroups. These parameters balance computational efficiency with the exploration-exploitation requirements of the cryptographic search space.

B. Encryption Phase

In the ECC-AES-GA algorithm, the encryption process begins after the optimal ECC configuration is selected by the GA. The sender generates an ephemeral ECC key pair using the GA-optimized elliptic curve to ensure forward secrecy. An Elliptic Curve Diffie–Hellman (ECDH) operation is then performed between the sender's ephemeral private key and

the receiver's public key to compute a shared secret. This shared secret is transformed into a fixed-length symmetric key using the HMAC-based Key Derivation Function (HKDF), ensuring cryptographic randomness and resistance to key-related attacks. The migration data is subsequently encrypted with AES-256-GCM. It provides authenticated encryption and data integrity. The encrypted payload consists of the ephemeral public key, nonce, and ciphertext. It is digitally signed by ECDSA (Elliptic Curve Digital Signature Algorithm), which guarantees sender authentication and protects against data tampering during transmission.

C. Decryption Phase

The decryption process at the receiver begins with verifying the digital signature attached to the encrypted payload. This step ensures the authenticity of the sender and the integrity of the received data before any decryption operation is performed. Upon successful verification, the receiver extracts the sender's ephemeral public key from the payload and recomputes the shared secret using its own ECC private key through ECDH. The same symmetric key is deterministically regenerated using HKDF, which maintains key consistency without explicit key exchange. The ciphertext is then decrypted and authenticated using AES-256-GCM to recover the original data. If either signature verification or authentication fails, the decryption process is immediately terminated. Thereby, enforcing strict security controls prevents unauthorised or corrupted data from being accepted during cloud data migration.

Algorithm 1 shows the GA-based optimization of ECC parameters, where a GA is employed to evolve elliptic curve parameters toward an optimal configuration by evaluating candidate solutions against security strength, computational efficiency, and key robustness, thereby establishing a strong and adaptive cryptographic foundation. Algorithm 2 shows that these optimized parameters by detailing the ECC-based key generation and shared secret establishment, in which communicating entities generate elliptic curve public–private key pairs and derive a common shared secret through an ECDH mechanism, ensuring confidentiality and forward secrecy without transmitting the secret itself. Algorithm 3 shows the ECC-AES-GA encryption and decryption process, where the securely established shared secret is converted into a symmetric session key and used by AES to encrypt and decrypt cloud data.

Algorithm 1 GA-Based Optimization of ECC Configuration

Input: Population size N_p, Maximum generations G_{max}
Output: Optimized ECC configuration parameter set ψ_{opt}
Initialize population $P_0 = \{C_1, C_2, \ldots, C_N\}$ where each chromosome encodes ECC curve selection and repeat count
Set generation counter $g = 0$
while $g < G_{max}$ **do**
  Evaluate fitness for each chromosome using $f = \text{Latency} + 0.0005(\text{Memory Peak}) - 0.02(\text{Bit Variability})$
  Select individuals using Tournament Selection
  Compute adaptive crossover probability cx_{pb} and mutation probability mut_{pb}
  Apply Two-Point Crossover with probability cx_{pb}
  Apply Adaptive Mutation with probability mut_{pb}
  Preserve top 10% elite individuals
  Inject 5% random immigrants to maintain population diversity
  Update population P_{g+1}
  $g \leftarrow g + 1$
end
return $\psi_{opt} = \arg\min(f(C_i))$

Algorithm 2 ECC Key Generation and Shared Secret Establishment

Input: Optimized ECC parameters ψ_{opt}
Output: Symmetric session key K_{AES}
Sender: Select random ephemeral private key $d_s \in [1, n-1]$ **Sender:** Compute public key $Q_s = d_s \times G$ **Receiver:** Select private key $d_r \in [1, n-1]$ **Receiver:** Compute public key $Q_r = d_r \times G$ Exchange Q_s and Q_r over the cloud channel **Sender:** Compute shared secret $S_{shared} = d_s \times Q_r$ **Receiver:** Compute shared secret $S_{shared} = d_r \times Q_s$ Extract x-coordinate: $Z = S_{shared}(x)$ Derive $K_{AES} = \text{HKDF}(Z, \text{salt}, \text{info})$ **return** K_{AES}

Algorithm 3 ECC-AES-GA Encryption and Decryption

Input: Plaintext M, Symmetric key K_{AES}, Initialization Vector IV
Output: Decrypted Plaintext M'

`// Encryption Phase`
Apply padding to M if required Generate random IV (Nonce) Compute $\{C, Tag\} = \text{AES-256-GCM}_{K_{AES}}(M, IV)$ Generate digital signature $\sigma = \text{ECDSA}_{\text{PrivKey}}(C)$ Construct payload $\mathcal{L} = \{C, IV, Tag, \sigma, Q_s\}$

`// Decryption Phase`
Verify σ using PubKey_s. **if** *fail* **then**
  Abort
end
Re-derive K_{AES} using steps from Algorithm 2 Compute $M' = \text{AES-256-GCM}^{-1}_{K_{AES}}(C, IV, Tag)$ **if** *authentication tag fails* **then**
  Abort
end
return M'

IV. Experimentation and Analysis

The experimental analysis of the ECC-AES-GA algorithm was conducted using Python on Amazon Web Services (AWS). The data migration is performed on the AWS Storage bucket. The local system perform optimization process, key generation, encryption, and decryption. And securely uploaded to AWS S3 buckets and also retreived from AWS S3 buckets. The entire practical was conducted on AWS for securely data transfer using application which is suitated at the local system.The proposed solution has been assessed and analyze across several file sizes (ex., 1024kb, 1GB etc.) and file types (ex., text file, pdf file, png etc.). The scalability was performed by encrypting and decrypting of different file size data. The security analysis was also performed to find its resilience against data analysis attacks and key guessing. These evaluations serve to underscore the importance and robustness of the proposed solution. The performance measurements were conducted using randomly generated data, created for the purpose of simulating various

TABLE II. 10 TIMES EXECUTION OF A FILE ON 2.28MB AND TIME MEASURED IN SECONDS (S)

Iteration	Encryption	Decryption	Key Generation
1	0.038	0.029	0.0002
2	0.038	0.029	0.0002
3	0.039	0.029	0.0002
4	0.020	0.015	0.0001
5	0.023	0.018	0.0001
6	0.020	0.014	0.0001
7	0.018	0.014	0.0002
8	0.020	0.014	0.0001
9	0.019	0.015	0.0001

text inputs.

A. Performance Analysis

Various performance metrics are conducted, including avalanche tests, throughput, execution time, memory runtime, and run tests to evaluate the efficiency of the optimized ECC-AES-GA algorithm. The avalanche test demonstrates that even a little modification in the encryption key should produce a different ciphertext. It evaluates the sensitivity of the optimized ECC-AES-GA, which provides an effect of 50.07%. The entropy level is the value of randomness or unpredictability of a key, where a higher entropy level indicates greater randomness. It makes the key more resistant to attacks, where an attacker cannot easily predict the key pattern. The entropy value of an encrypted data is highly secure and it acheives 7.829 bits/byte out of a maximum possible score of 8. This result proves that ECC-AES-GA enhancing confidentiality against entropy-based cryptanalytic attack. Throughput is a measure used to find the data transmission rate in a cryptographic algorithm. The throughput of a 2.28 MB file size is 302.51 MB/s with encryption and decryption times of 0.060 s and 0.041 s. These results provide superior efficiency and optimized resource management. The performance evaluation of optimized ECC-AES-GA encryption and decryption time is consistent. In order to ensure accuracy, a file size of 2.28MB was tested 10 times and the average execution time was recorded. This demonstrates that multiple runs may not affect the time of a particular file and indicate consistent performance. The encryption and decryption time, along with key generation time for a 2.28MB file, is shown in Table II.

B. Comparative Analysis with Existing Algorithms

The optimized ECC-AES-GA algorithm is compared with existing AES-128, Blowfish, Twofish, DES, GA, ElGamal, AES-RSA, and the RSA algorithms. All existing algorithms were implemented and configured under the same experimental environment. Table III shows the encryption and decryption times of existing algorithms, which were performed on 1024, 2048, 4096, and 8192 KB in size. The encryption and decryption time were measured on AWS using python time.perf_counter(). Fig. 1 and Fig. 2 show the encryption and decryption times of different algorithms in seconds, with file size in KB.

The performance of optimized ECC-AES-GA provides more computational efficiency as compared with existing algorithms. Standard algorithms, such as AES-128, Blowfish, and Twofish shows a linear correlation between file size and processing time, whereas DES provides much overhead. Asymmetric methods (RSA and Elgamal) provide higher delays, especially during encryption and decryption time. While the hybrid algorithm (AES-RSA) provides little improvement. But still, it remains slower than symmetric encryption. GA alone is not sufficient for encryption and decryption of data, as it guarantees less security.

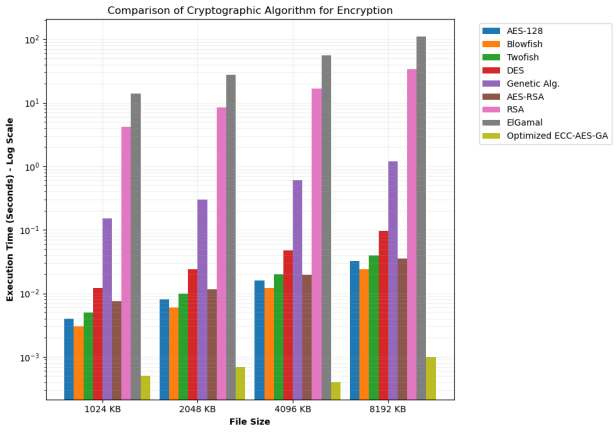

Fig. 1. Standard algorithm compared with optimized ECC-AES-GA for encryption process.

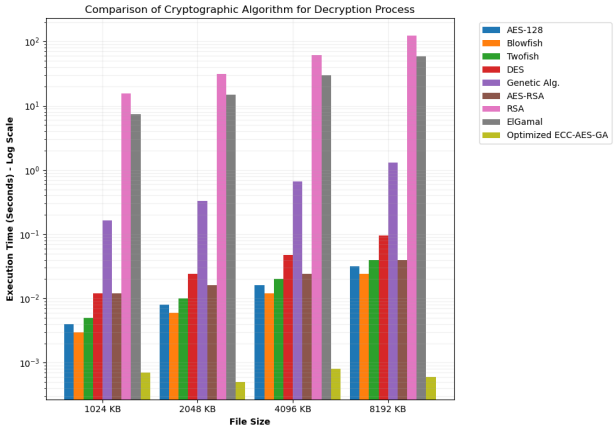

Fig. 2. Standard algorithm compared with optimized ECC-AES-GA for decryption process.

In constrast, the optimized ECC-AES-GA displays the lower encryption/decryption times, which remain nearly constant and independent of data size. The less execution time of the proposed ECC-AES-GA approach are attributed to the use of GA-optimized ECC parameters, which lows computational overhead during the encryption process compared to AES-128 and other existing algorithms. Thus, it achieves better scalability, efficiency, and adaptability for securing cloud data during migration. A prototype application was implemented to validate the practical feasibility of the proposed optimized ECC-AES-GA algorithm. The developed application integrates the complete cryptographic phases, including GA based ECC parameter optimization, secure key exchange, AES encryption,

TABLE III. COMPARISON OF ENCRYPTION AND DECRYPTION TIMES (SECONDS) ACROSS DIFFERENT FILE SIZES (KB)

Algorithm	Operation	1024 KB	2048 KB	4096 KB	8192 KB

and ECDSA integrity verification. The application enables users to select files and perform encryption/decryption with signature verification. Fig. 3 shows the application in which encryption and decryption are performed.

C. Complexity Analysis

The overall time complexity of the optimized ECC-AES-GA framework is primarily influenced by the GA during the initialization phase and AES during the data migration phase. The GA-based parameter selection process follows a complexity of $O(G \cdot N_p \cdot f)$, where G is the number of generations, N_p is the population size, and f is the cost of the fitness function evaluation. Notably, this phase occurs during setup and does not impact the real-time transmission speed. The ECDH key exchange process takes $O(k^3)$ or $O(k \cdot \log n)$ depending on the implementation of scalar multiplication, where k is the security parameter (bit-length). However, the overall data encryption using AES is $O(n)$, where n is the number of data blocks. The space complexity is $O(k + M)$, where k represents the key size and M is the size of the message.

D. Statistical Analysis

In order to validate the statistical security of the cryptographic keys generated by the proposed optimized ECC-AES-GA algorithm, the NIST Statistical Test Suite(STS), developed by the National Institute of Standards and Technology(NIST), was employed. This test suite provides a comprehensive framework for evaluating the randomness properties of binary sequences generated by cryptographic mechanisms [1] [29][30][31][32]. There are 15 separate statistical tests in the suite. The evaluation incorporated a broad set of statistical tests, including the discrete fourier transform test, frequency test, longest run of ones in a block test, frequency test within a block, runs test, binary rank test, non-overlapping and overlapping template matching tests, Maurer's Universal statistical test, linear complexity test, serial test, cumulative sums test, approximate entropy test, random excursions, and random excursion variant tests. These tests are widely used in many cryptographic applications and are recognized as a suitable instrument for evaluating the unpredictability of binary sequences. For PRNGs to be secure in a cryptographic system, they must pass every statistical test in the NIST suite [15].

The primary objective of using NIST was to verify that the keys generated by the optimized ECC-AES-GA algorithm are sufficiently random to stand against statistical attacks. It ensures reliability and security for cryptographic applications. The binary sequences were generated by concatenating many 128-bit cryptographic keys resulting from ECC-256 operations within the optimized ECC-AES-GA algorithm, facilitating large-scale evaluation using NIST STS. In order to evaluate the randomness of data generated by the optimized ECC-AES-GA encryption algorithm, a file of size 2.16 mb was encrypted, and the resulting ciphertexts were analyzed as binary sequences.

This statistical tool is used to determine the effectiveness of the optimized ECC-AES-GA algorithm, specifically the NIST SP 800-22 test suite. Several independent bit sequences, obtained from one-time session keys and ciphertext, were examined to verify whether they exhibit proper random behaviour or not. The experimental results show that the optimised ECC-AES-GA algorithm successfully passes NIST tests, including Frequency, Block Frequency, Approximate Entropy, and Serial tests, with p-values consistently exceeding the required threshold $\alpha = 0.01$. The frequency (monobit) test yielded a p-value of 0.8414, indicating a balanced distribution of binary

TABLE IV. NIST STATISTICAL TEST RESULTS OF THE OPTIMIZED ECC-AES-GA ALGORITHM.

No.	Statistical Test	P-value	Proportion	Result
1	Frequency (Monobit)	0.841481	1.00	Pass
2	Block Frequency	0.758299	1.00	Pass
3	Runs Test	0.269576	1.00	Pass
4	Longest Run of Ones	0.645750	1.00	Pass
5	Approximate Entropy	0.804677	1.00	Pass
6	Cumulative Sums (Forward)	0.478352	1.00	Pass
7	Cumulative Sums (Reverse)	0.651308	1.00	Pass
8	Discrete Fourier Transform	0.581909	1.00	Pass
9	Binary Matrix Rank	0.168170	1.00	Pass
10	Linear Complexity	0.052453	1.00	Pass
11	Serial Test	$p_1 = 0.4261$ $p_2 = 0.6470$	1.00	Pass
12	Universal Statistical	0.180153	1.00	Pass
13	Overlapping Template	0.021427	1.00	Pass
14	Non-overlapping Template	Majority Passed	≥ 0.98	Pass
15	Random Excursions	Not Evaluated	–	$(J < 500)$
16	Random Excursions Variant	Not Evaluated	–	$(J < 500)$

values in the generated sequence. The block frequency test performed with a block size of 128 bits produced a p-value of 0.758299, confirming uniformity within fixed-length blocks. The entropy test was conducted with a block length of 10 bits, resulting in a p-value of 0.804677. The generated sequences passed all valid and applicable NIST SP 800-22 STS tests but random excursion and its variant tests were excluded due to insufficient number of cycles ($J < 500$) required by the NIST criteria. Table IV shows the result of all necessary NIST STS tests result provided by optimized ECC-AES-GA algorithm. These results indicate that the integration of ECC-based key generation, AES-256 encryption, and genetic optimization does not introduce statistical bias. It also satisfies NIST randomness requirements, which support its applicability to secure cloud data migration.

Based on the experimental evaluation, the proposed optimized ECC-AES-GA algorithm achieves strong cryptographic efficiency and statistical robustness. The measured results of key generation, encryption-decryption times, and achieving security with less computational overhead. Furthermore, the NIST SP 800-22 STS results validate the randomness quality of the keys ensured and successfully passed with p-values.

E. Security Analysis

The proposed optimized ECC-AES-GA algorithm ensures robust security against various cryptographic attacks. The use of ECDH for key exchange ensures the secret key is never transmitted over the communication channel. Authentication mechanisms prevent unauthorized entities from altering key exchange, which protects the data from a man-in-the-middle. Timestamps in each communication session prevent an attacker from reusing it. It provides each session a unique identity, which resists replay attacks. Data confidentiality is achieved through the AES-256-GCM algorithm. If an attacker is intercepting the communication, they are not able to understand the data over the channel due to the use of a secret key (by using the ECC method). It also provides integrity to the data and resists against known-plaintext and chosen-plaintext attacks. The use of optimized parameter of ECC using GA makes brute force attacks computationally infeasible. The digital signature (ECDSA) ensures mutual authentication between two entities. So an adversary cannot impersonate a legitimate user in the system, which resists an impersonation attack. The session keys are generated using HKDF. If one session key is disclosed, it will not affect other session keys. The use of ephemeral keys (using ECDH) ensures forward secrecy. Even if the long-term private keys are compromised, session keys are not revealed.

The suggested ECC-AES-GA mechanism provides robust security and efficient performance for cloud data migration. Existing ECC-AES approach is basically used fixed cryptographic parameters and key exchange process. The static configurations lacks optimal security performance. Unlike existing approaches focus on only secure storage, access control and lacks other key components for securing cloud data migration. This ECC-AES-GA provides end-to-end security of data migration along with key generation, key exchange, data encryption, transmission and integrity verification.

The current method has been assessed in a homogeneous cloud setup, but its performance in multi-cloud or heterogeneous cloud setups has yet to be explored. Such setups may provide issues in terms of interoperability, key management, and synchronization across distributed platforms. It assumes that endpoints are trusted and does not explicitly cover all dynamic or adaptive attack scenarios. Despite these limitations, the suggested technique is still well-suited for protecting large-scale data transmission where security and data integrity take place over challenging real-time requirements.

V. CONCLUSION

The development of the optimized ECC-AES-GA algorithm represents a significant advancement in securing cloud data migration without compromising security issues. The approach enhances key generation, secure exchange, and encryption robustness while addressing limitations of traditional key management systems. The performance evaluation demonstrates an effective balance between security and efficiency in terms of latency, throughput, and memory usage. And also the security validation through the NIST statistical tool, which confirms high randomness and strong resistance to cryptographic attacks. Future work will focus on providing security against emerging quantum computing threats.

***Abstract*—Climate change and environmental variability increasingly affect human health, particularly in agro-ecosystems exposed to fluctuating air quality and climatic conditions. Although recent advances in artificial intelligence have improved environmental risk prediction, many existing approaches operate as black-box systems and provide limited support for transparent decision-making and actionable interventions. This study presents an explainable hybrid artificial intelligence framework for climate-driven environmental health risk prediction. The proposed framework integrates environmental monitoring data, including Air Quality Index (AQI), temperature, and humidity measurements collected from publicly available environmental sources, with ensemble machine learning models (Random Forest, XGBoost, and LightGBM), SHAP-based explainability, and a Retrieval-Augmented Generation (RAG) module. Unlike conventional prediction systems, the proposed approach combines interpretable machine learning with evidence-grounded recommendation generation to enhance both transparency and practical usability. Experimental results indicate that XGBoost achieves the highest predictive performance, reaching an accuracy of 0.88 and an AUC of 0.91. SHAP analysis identifies AQI as the most influential factor affecting environmental health risk, followed by temperature and humidity. Furthermore, the RAG module was evaluated in terms of retrieval relevance and recommendation consistency, demonstrating its ability to generate context-aware recommendations supported by scientific knowledge sources. The proposed framework extends existing environmental health prediction approaches by jointly integrating predictive modeling, explainability, and knowledge-driven reasoning within a unified decision-support system. The results highlight its potential for supporting proactive environmental health management and climate-resilient decision-making in agro-ecosystems.**

I. Introduction

Climate change, environmental degradation, and air pollution are increasingly recognized as major global challenges affecting both ecosystem sustainability and human well-being. Environmental exposure to poor air quality, extreme temperatures, and adverse climatic conditions has been associated with respiratory diseases, cardiovascular disorders, heat-related illnesses, and premature mortality [1], [2], [3]. According to recent studies, the combined effects of climate change and environmental pollution disproportionately affect vulnerable populations and place additional pressure on healthcare systems worldwide [25], [26], [27], [28], [29]. Consequently, the development of intelligent systems capable of monitoring environmental conditions and assessing potential health risks has become an important research priority.

The rapid expansion of environmental monitoring infrastructures, Internet of Things (IoT) technologies, web-based Application Programming Interfaces (APIs), and remote sensing platforms has generated large volumes of environmental data. These data sources provide continuous observations of air quality, meteorological conditions, and environmental indicators that can support data-driven environmental analysis and decision-making. In recent years, machine learning and deep learning techniques have demonstrated considerable success in environmental monitoring, air quality forecasting, and pollution prediction [4], [5], [9], [6]. Comprehensive reviews have confirmed the growing adoption of artificial intelligence techniques in environmental forecasting applications [7], [8], [16], [36]. In particular, ensemble learning methods such as Random Forest [12], XGBoost [10], and LightGBM [11] have achieved strong predictive performance when applied to structured environmental datasets.

Despite these advances, many environmental prediction models operate as black-box systems, limiting their interpretability and practical adoption in critical decision-support scenarios. This challenge has motivated increasing interest in Explainable Artificial Intelligence (XAI), which aims to provide transparent explanations of model behavior. Among existing explainability techniques, SHAP (SHapley Additive exPlanations) has emerged as one of the most widely adopted methods for interpreting machine learning predictions [13]. Recent studies have demonstrated the importance of explainability in both environmental and healthcare applications [18], [33], [34], [32], [45]. By quantifying feature contributions, explainable models can improve transparency, trustworthiness, and user acceptance.

Environmental conditions are inherently dynamic and evolve continuously over time. Consequently, temporal modeling has become an important component of environmental prediction systems. Recent studies have proposed advanced forecasting architectures, including Temporal Fusion Transformers [14], Bi-GRU-based air quality prediction models [17], hybrid decomposition-LSTM frameworks [19], graph-enhanced forecasting systems [41], and hybrid environmental

*Corresponding author

forecasting approaches [35]. These methods demonstrate the value of incorporating temporal dependencies into environmental monitoring systems to improve forecasting accuracy and anticipation of future environmental conditions.

More recently, Retrieval-Augmented Generation (RAG) has emerged as a promising paradigm for integrating external knowledge into intelligent systems [15]. By combining information retrieval with generative language models, RAG enables the production of context-aware and evidence-grounded outputs. Subsequent studies have expanded RAG toward graph-based retrieval systems [20], personalized recommendation frameworks [38], and domain-specific knowledge-enhanced applications [21], [37], [39]. However, despite the rapid development of RAG technologies, their application to environmental health assessment and environmental decision-support systems remains relatively unexplored.

Artificial intelligence has also become an important driver of innovation in agriculture and agro-ecosystems. IoT-enabled monitoring systems, machine learning models, and intelligent decision-support platforms have been applied to crop monitoring, yield prediction, irrigation management, and precision agriculture [22], [40], [23]. Nevertheless, most existing agricultural intelligence systems focus primarily on productivity and resource optimization, while the interaction between environmental conditions, climate variability, and environmental health risks remains insufficiently investigated.

Despite substantial progress in environmental prediction, explainable AI, temporal forecasting, and knowledge-enhanced systems, existing approaches remain fragmented. Most studies focus on a single aspect of the decision-making process, such as predictive accuracy, explainability, forecasting, or recommendation generation. Furthermore, relatively few studies have explored how environmental exposure indicators can be combined with explainable artificial intelligence and scientific knowledge retrieval to support environmental health risk assessment in climate-sensitive agro-ecosystems.

It is important to emphasize that the objective of this work is not to predict clinical diagnoses or individual health outcomes. Instead, the proposed framework aims to assess environmental health risk levels based on environmental exposure indicators, including air quality, temperature, and humidity. The generated risk categories should therefore be interpreted as environmental exposure risk levels designed to support environmental monitoring and decision-making rather than as medical diagnoses. To address these challenges, this study proposes an explainable hybrid artificial intelligence framework for climate-driven environmental health risk assessment in agro-ecosystems. The proposed framework integrates ensemble machine learning models, SHAP-based explainability, temporal environmental analysis, and a Retrieval-Augmented Generation (RAG) module within a unified decision-support architecture. By combining predictive analytics, explainable AI, and knowledge-driven recommendation generation, the framework provides transparent, interpretable, and evidence-based environmental health assessments.

The main contributions of this work are summarized as follows:

- A hybrid AI framework integrating machine learning, explainable AI, temporal analysis, and knowledge-based reasoning for environmental health risk assessment.
- The application of SHAP to provide transparent and interpretable explanations of environmental health risk assessments.
- The integration of a Retrieval-Augmented Generation module that transforms predictive outputs into evidence-based and context-aware recommendations.
- A unified climate-aware decision-support system for environmental health monitoring in agro-ecosystems.

The remainder of this study is organized as follows: Section II reviews related work on environmental health assessment, explainable artificial intelligence, temporal forecasting, and Retrieval-Augmented Generation. Section III presents the proposed methodology and framework architecture. Section IV describes the experimental setup and evaluation results. Section V discusses the findings, limitations, and implications of the proposed framework. Finally, Section VI concludes the study and outlines future research directions.

II. Related Work

A. Environmental Health and Climate-Related Risks

Environmental health risk assessment has become an important research area due to the growing impact of air pollution, climate variability, and environmental degradation on human health. Epidemiological studies have consistently demonstrated strong associations between environmental exposure and adverse health outcomes. Lelieveld et al. [1] reported that outdoor air pollution contributes significantly to premature mortality worldwide, while Burnett et al. [2] quantified the global disease burden associated with long-term exposure to fine particulate matter. Similarly, Di et al. [3] established a strong relationship between air pollution and mortality across large population cohorts. More recent studies have highlighted the combined effects of climate change, environmental stressors, and health inequalities on vulnerable populations and healthcare systems [25], [26], [27], [28], [29]. These findings emphasize the need for intelligent and proactive environmental health monitoring systems capable of supporting risk assessment and decision-making.

B. Machine Learning for Environmental Prediction

Artificial intelligence has significantly improved environmental monitoring and forecasting capabilities. Deep learning models have demonstrated strong performance in modeling complex environmental processes and air quality dynamics. Li et al. [4], Mao et al. [5], and Bekkar et al. [9] showed the effectiveness of neural-network-based approaches for air quality prediction and smart-city applications. Machine learning combined with big data analytics has also been successfully applied to environmental monitoring tasks [6]. Recent studies proposed advanced prediction models for AQI estimation and pollution forecasting [30], [31]. Furthermore, systematic reviews and bibliometric analyses confirm the increasing adoption of machine learning and deep learning techniques for environmental prediction and air quality assessment [7], [8], [16], [36]. Despite their high predictive performance, many of these approaches operate as black-box models, limiting their

interpretability and practical adoption in health-related applications. Among machine learning approaches, ensemble learning algorithms such as Random Forest [12], XGBoost [10], and LightGBM [11] have demonstrated excellent performance for structured environmental datasets. Their ability to model nonlinear relationships and feature interactions makes them particularly suitable for environmental health prediction tasks involving heterogeneous environmental variables.

C. Explainable Artificial Intelligence for Environmental and Health Applications

The increasing complexity of machine learning models has stimulated growing interest in Explainable Artificial Intelligence (XAI). SHAP (SHapley Additive exPlanations), introduced by Lundberg and Lee [13], provides a theoretically grounded framework for interpreting model predictions by quantifying the contribution of each input feature. Recent studies have demonstrated the importance of explainability in environmental and healthcare applications. Tasioulis et al. [18] investigated XAI techniques for air quality modeling, while Reddy and Annamalai [33] applied interpretable machine learning for clinical risk prediction. Aderemi et al. [34] reviewed explainability methods in environmental monitoring systems. In addition, Chinnaraju et al. [32] and Gupta et al. [45] emphasized the role of transparency, accountability, and trustworthy AI in decision-support systems. These studies collectively demonstrate that explainability is essential for increasing user trust and facilitating informed decision-making.

D. Time-Series Forecasting for Environmental Monitoring

Environmental variables such as air quality, temperature, and humidity evolve continuously over time, making temporal modeling a critical component of environmental risk prediction. Lim et al. [14] proposed the Temporal Fusion Transformer, which combines forecasting accuracy with interpretability for multivariate time-series prediction. Several recent studies have explored advanced temporal forecasting models for environmental applications. Fatima et al. [17] proposed a Bi-GRU model for AQI prediction, while Zhou et al. [19] developed hybrid decomposition and LSTM-based approaches for $PM_{2.5}$ forecasting. Han et al. [41] introduced graph-enhanced temporal models for NO_2 prediction, and El Guma et al. [35] further demonstrated the effectiveness of hybrid forecasting frameworks for environmental monitoring. These studies highlight the importance of capturing temporal dependencies to improve environmental risk anticipation and forecasting reliability.

E. Retrieval-Augmented Generation and Knowledge-Based AI

Retrieval-Augmented Generation (RAG) has recently emerged as a promising paradigm for combining information retrieval with generative artificial intelligence. Lewis et al. [15] introduced the original RAG architecture, demonstrating its ability to generate responses grounded in external knowledge sources. Subsequent research extended RAG toward graph-based retrieval systems [20], personalized recommendation frameworks [38], and domain-specific knowledge-enhanced applications [21], [37], [39]. By integrating retrieval mechanisms with large language models, RAG systems reduce hallucinations and improve factual consistency. However, despite their success in natural language processing and recommendation systems, RAG approaches remain largely unexplored in environmental health risk assessment and decision-support applications.

F. AI in Agriculture and Agro-Ecosystems

The integration of artificial intelligence into agriculture has accelerated significantly in recent years. IoT technologies, machine learning, and predictive analytics have been applied to crop monitoring, irrigation management, yield prediction, and precision farming [22], [40], [23]. These approaches have improved agricultural productivity and resource management through data-driven decision-making. Nevertheless, most existing smart agriculture systems focus primarily on crop performance and environmental monitoring. Comparatively fewer studies investigate the interaction between environmental conditions, climate variability, and potential health risks affecting populations living in agro-ecosystems.

G. Hybrid AI Frameworks and Research Gap

Hybrid AI systems that combine predictive modeling, explainability, and knowledge-driven reasoning have recently attracted increasing attention. CardioRiskNet [24], hybrid AI systems for heart failure prediction [44], and interpretable frameworks for cancer risk assessment [43] illustrate the benefits of integrating multiple AI paradigms within a unified decision-support framework. Chudasama et al. [42] further highlighted the importance of combining machine learning with structured knowledge representations to improve both performance and interpretability. Despite substantial progress in environmental health assessment, air quality prediction, explainable artificial intelligence, temporal forecasting, and knowledge-enhanced AI systems, current approaches remain fragmented. Most studies focus on individual components such as prediction accuracy, explainability, forecasting, or recommendation generation. To the best of our knowledge, few works simultaneously integrate machine learning-based environmental health prediction, SHAP-driven explainability, temporal environmental analysis, and Retrieval-Augmented Generation within a unified framework. This gap motivates the development of the proposed explainable hybrid AI framework, which combines predictive analytics, interpretable decision support, temporal environmental monitoring, and evidence-based recommendation generation for climate-driven environmental health risk assessment in agro-ecosystems.

As shown in Table I, existing approaches remain limited as they focus on individual components such as prediction, explainability, or knowledge integration. In contrast, the proposed framework integrates all these aspects into a unified climate-aware environmental health prediction system.

III. Methodology

Fig. 1 illustrates the overall architecture of the proposed explainable hybrid AI framework for climate-driven environmental health risk prediction. The framework is organized into five sequential stages. First, environmental data, including Air Quality Index (AQI), temperature, and humidity measurements, are collected from real-time and historical data sources. Second, the acquired data undergo preprocessing and feature

TABLE I. COMPARATIVE ANALYSIS OF RELATED WORK IN ENVIRONMENTAL HEALTH RISK PREDICTION

[42]	Hybrid AI	Knowledge + ML	Yes	Yes	No	No climate-health integration

engineering to ensure data quality and consistency. Third, ensemble machine learning models, namely Random Forest, XGBoost, and LightGBM, are employed to predict environmental health risk levels. Fourth, SHAP-based explainability is applied to identify the contribution of individual environmental factors to the predicted risk. Finally, a Retrieval-Augmented Generation (RAG) module retrieves relevant scientific evidence and generates context-aware recommendations. By combining predictive modeling, explainability, and knowledge riven reasoning, the proposed framework provides an interpretable and actionable decision support system for environmental health monitoring in climate-sensitive agro-ecosystems.

A. Dataset Description

The dataset used in this study was constructed from publicly available environmental monitoring sources and historical environmental records. Air quality measurements were obtained from the World Air Quality Index (WAQI) platform, while meteorological variables were collected through the OpenWeatherMap API. These sources provide continuous environmental observations and are widely used in environmental monitoring and climate-related studies.

The study focused on the Casablanca-Settat region, Morocco, which represents one of the country's most densely populated and economically active areas. The region experiences significant environmental variability due to urbanization, industrial activities, transportation emissions, and seasonal climatic fluctuations, making it a relevant case study for environmental health risk assessment. Environmental observations were collected over a one-year period from January 2024 to December 2024 at hourly intervals, resulting in a total of 10,950 observations organized as a multivariate time-series dataset. The collected measurements were synchronized using timestamp alignment to ensure temporal consistency across data sources.

The environmental variables considered in this study include:

- Air Quality Index (AQI)
- Ambient Temperature (°C)
- Relative Humidity (%)

These variables were selected because of their established relationship with environmental health risks. Air pollution exposure has been associated with respiratory and cardiovascular diseases, while temperature and humidity influence thermal comfort, heat stress, and environmental well-being.

Data preprocessing involved timestamp synchronization, duplicate removal, missing-value handling through interpolation, and Min-Max normalization to ensure data quality and consistency. Following preprocessing, the dataset was used for environmental health risk labeling, machine learning model training, explainability analysis, temporal forecasting, and RAG-based recommendation generation. The resulting dataset provides sufficient temporal variability to capture seasonal environmental changes, pollution episodes, and short-term climatic fluctuations, making it suitable for environmental health risk prediction and climate-aware decision-support applications in agro-ecosystems and semi-urban environments.

B. Data Acquisition

Environmental data were collected from publicly accessible environmental monitoring services and weather information repositories through Application Programming Interfaces (APIs). Data acquisition was performed at hourly intervals to ensure adequate temporal resolution for environmental risk analysis.

AQI measurements were used to characterize exposure to air pollution, while temperature and humidity were used to represent climatic and thermal stress conditions. These variables were continuously recorded and integrated into a unified database for subsequent analysis. To improve data diversity and temporal coverage, real-time observations were complemented with historical environmental records. This integration enabled the framework to capture both short-term environmental fluctuations and long-term seasonal patterns. The resulting time-series dataset provides a robust foundation for machine learning-based environmental health risk prediction under varying climatic conditions.

C. Data Preprocessing and Feature Engineering

Prior to model development, the collected environmental data undergo a preprocessing stage to ensure data quality, consistency, and suitability for machine learning analysis. Missing

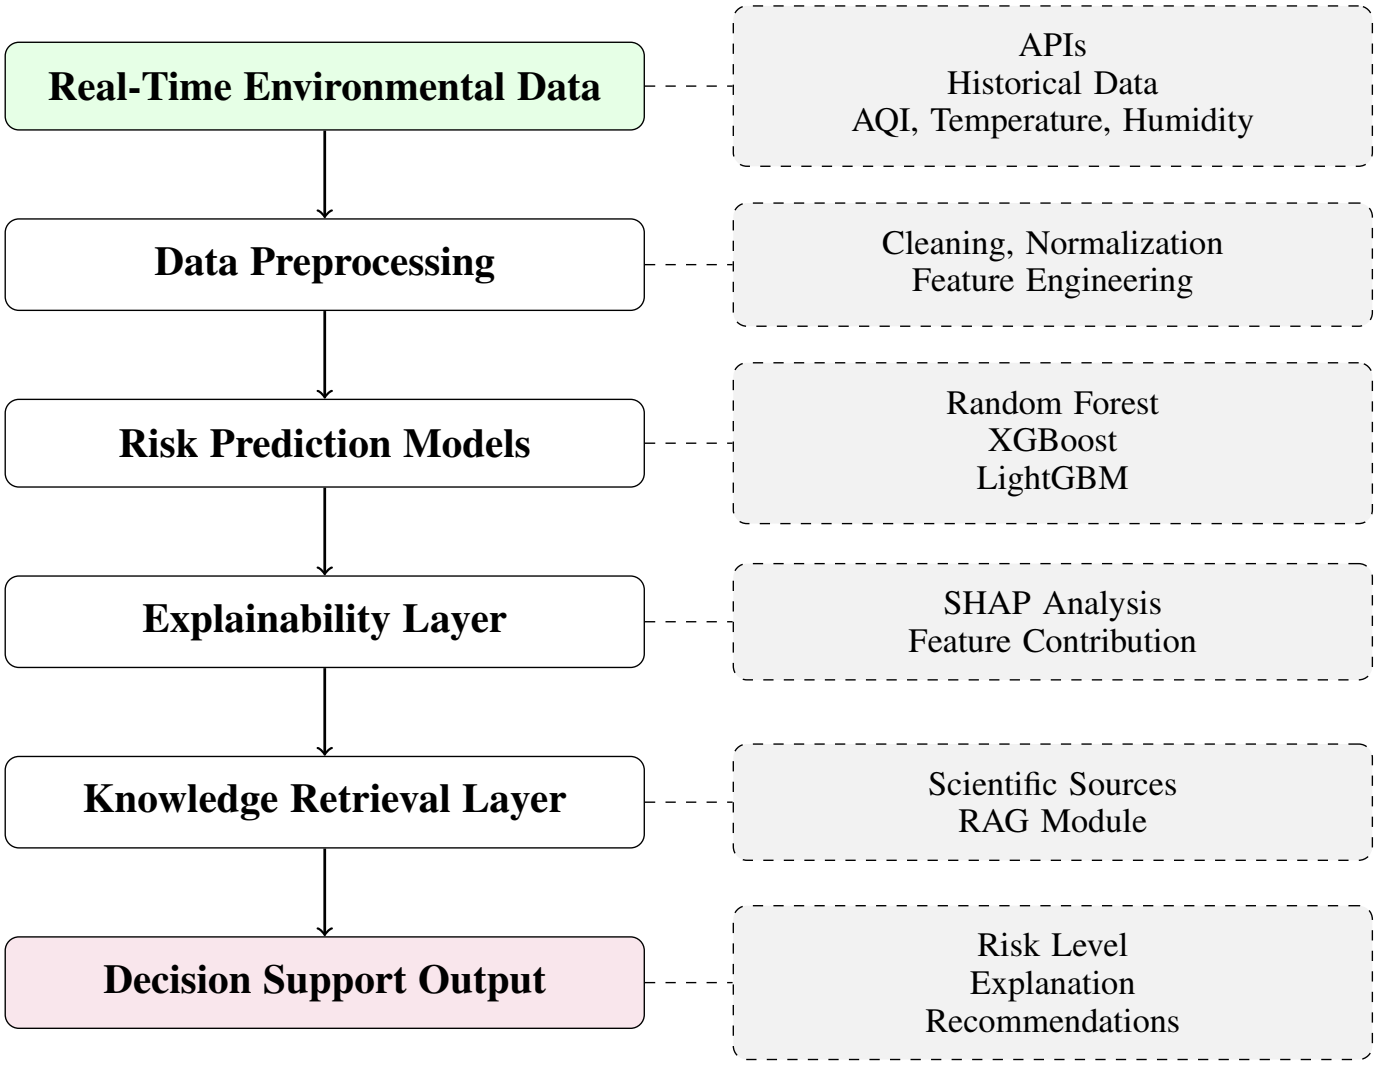

Fig. 1. Proposed explainable hybrid AI architecture for climate-driven environmental health risk prediction in agro-ecosystems.

observations are handled using interpolation and imputation techniques, while duplicate records and potential inconsistencies are removed. Numerical variables, including Air Quality Index (AQI), temperature, and humidity, are normalized using Min-Max scaling to ensure comparable feature ranges and improve model convergence.

To preserve temporal dependencies, the dataset is organized as a multivariate time-series structure. Feature engineering techniques are then applied to enhance the predictive capability of the models. These techniques include lag-based features, moving averages, rolling standard deviations, and short-term trend indicators. Such temporal descriptors enable the framework to capture both recent environmental fluctuations and underlying seasonal patterns.

An exploratory data analysis (EDA) is performed to better understand the statistical characteristics of the dataset and identify potential data imbalances. Fig. 2 illustrates the distribution of the Air Quality Index. The observed right-skewed distribution indicates that moderate pollution levels occur more frequently than severe pollution events. This characteristic reflects realistic environmental conditions and motivates the use of robust machine learning algorithms capable of handling heterogeneous data distributions.

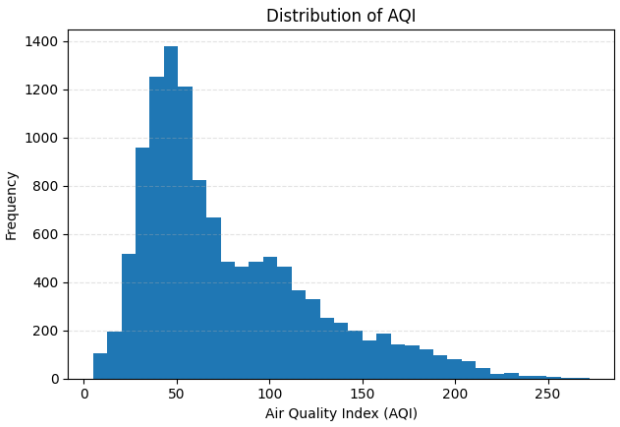

Fig. 2. Distribution of Air Quality Index (AQI).

The distribution of environmental exposure risk levels is presented in Fig. 3. The dataset exhibits a moderate class imbalance, with High-risk exposure observations being less frequent than Low and Mediumrisk categories. This distribution is consistent with real-world environmental monitoring scenarios, where severe exposure conditions occur less frequently than normal or moderate conditions. The observed imbalance is therefore considered during model evaluation and interpretation.

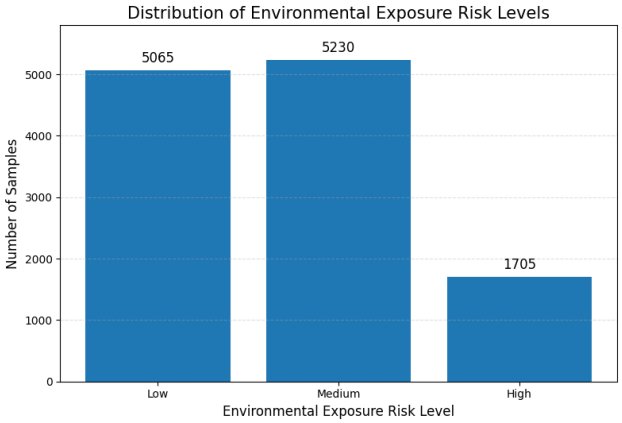

Fig. 3. Distribution of environmental exposure risk levels in the dataset.

Fig. 4 and Fig. 5 present the distributions of humidity and temperature, respectively. Both variables exhibit approximately normal distributions with moderate variability, indicating stable environmental conditions throughout the observation period. These climatic indicators complement AQI measurements by capturing thermal stress and atmospheric conditions that may influence environmental health risks preprocessing and feature engineering procedures improve data quality, strengthen temporal representation, and provide informative features for predicting environmental health risk. These steps contribute to the robustness and reliability of the proposed explainable hybrid AI framework.

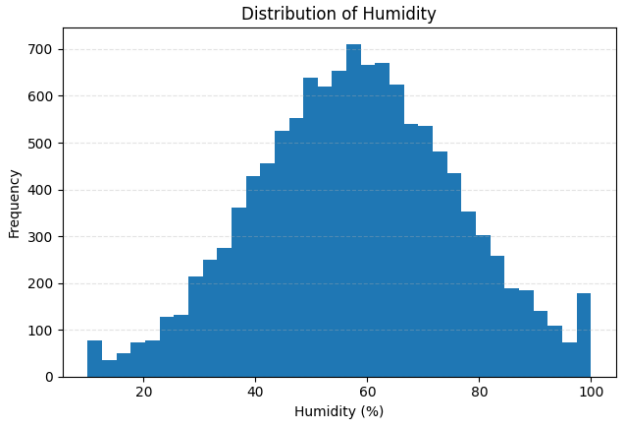

Fig. 4. Distribution of relative humidity.

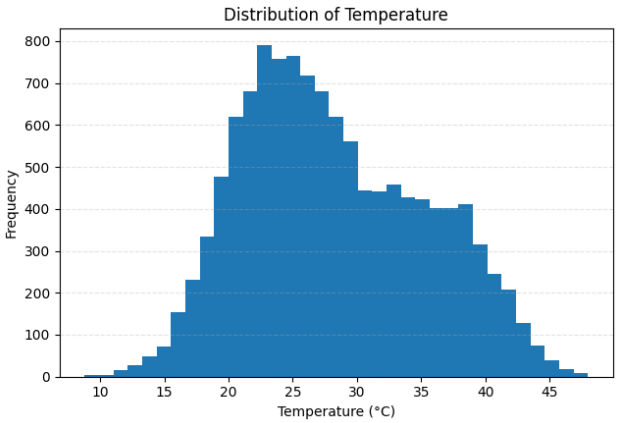

Fig. 5. Distribution of ambient temperature.

D. Health Risk Labeling

Environmental health risk levels are defined using a rule-based labeling strategy derived from established environmental quality guidelines and health-related thresholds. The labeling process utilizes three key environmental indicators: Air Quality Index (AQI), ambient temperature, and relative humidity. Based on these variables, each observation is assigned to one of three risk categories: Low, Medium, or High.

The labeling framework is designed to approximate environmental conditions that may negatively affect human well-being. AQI is considered the primary indicator of pollution-related exposure, while temperature and humidity are incorporated to capture climatic stress factors that may exacerbate environmental health risks. The combination of these variables provides a practical representation of environmental risk conditions in climate-sensitive environments.

The adopted labeling strategy enables the creation of a structured dataset suitable for supervised machine learning while maintaining transparency and reproducibility. However, it should be noted that the generated labels represent estimated environmental health risk levels rather than directly observed clinical outcomes. Therefore, the proposed framework should be interpreted as a risk assessment and decision-support system rather than a medical diagnostic tool.

Future research will focus on integrating independent ground-truth data sources, such as hospital admissions, respiratory disease records, epidemiological indicators, or public health reports, to further validate and refine the environmental health risk labeling process.

TABLE II. ENVIRONMENTAL EXPOSURE RISK CATEGORIZATION CRITERIA.

AQI Range	Environmental Exposure Risk Level
0-50	Low
51-150	Medium
¿150	High

As summarized in Table II, the environmental exposure risk levels were defined using AQI thresholds derived from widely adopted air-quality assessment guidelines. These categories

are intended to represent environmental exposure conditions rather than clinical diagnoses or observed health outcomes. Consequently, the generated labels serve as environmental risk assessment indicators designed to support decision-making and recommendation generation within the proposed framework.

E. Machine Learning Models

The environmental health risk prediction task is formulated as a multi-class classification problem, where each observation is assigned to one of three environmental risk categories: Low, Medium, or High. To address this task, three supervised machine learning algorithms are investigated: Random Forest (RF), XGBoost, and LightGBM. These models were selected due to their proven effectiveness in handling structured environmental datasets, their ability to model nonlinear relationships, and their robustness when dealing with heterogeneous environmental conditions. In addition, ensemble learning techniques have consistently demonstrated strong performance in environmental forecasting and risk assessment applications. Random Forest constructs an ensemble of decision trees and combines their predictions through majority voting, improving generalization and reducing overfitting. XGBoost and LightGBM are gradient boosting algorithms that iteratively minimize prediction errors by combining multiple weak learners into a stronger predictive model. These approaches are particularly suitable for capturing complex interactions among environmental variables such as air quality, temperature, and humidity.

Let $\mathbf{X} = \{x_1, x_2, ..., x_n\}$ denote the input feature vector, where each feature represents an environmental indicator or engineered temporal attribute. The objective is to learn a mapping function $f(\mathbf{X})$ capable of predicting the corresponding environmental health risk class (y):

where, $y \in \{Low, Medium, High\}$

$$y = f(\mathbf{X}) \tag{1}$$

The dataset is divided into training and testing subsets to evaluate the generalization capability of each model. Model performance is assessed using standard classification metrics, including Accuracy, Precision, Recall, F1-score, and the Area Under the Receiver Operating Characteristic Curve (AUC).

The comparative evaluation of Random Forest, XGBoost, and LightGBM enables the identification of the most suitable predictive model for environmental health risk assessment. Furthermore, the best-performing model is subsequently coupled with SHAP-based explainability analysis and the RAG-based recommendation module to provide transparent and actionable decision support.

F. Explainability Analysis

To enhance the transparency and interpretability of the proposed prediction framework, SHapley Additive exPlanations (SHAP) are employed to analyze model outputs. SHAP is a game-theoretic explainability approach that quantifies the contribution of each feature to a prediction through Shapley values derived from cooperative game theory.

Let $f(\mathbf{X})$ denote the prediction function of the trained model and $\mathbf{X} = \{x_1, x_2, ..., x_n\}$ the input feature vector. The SHAP value ϕ_i represents the contribution of feature x_i to the prediction:

$$f(\mathbf{X}) = \phi_0 + \sum_{i=1}^{n} \phi_i \tag{2}$$

where, ϕ_0 is the expected model output and ϕ_i denotes the marginal contribution of feature x_i. SHAP provides both global and local interpretability. Global explanations identify the overall importance of environmental variables across the dataset, while local explanations reveal the contribution of individual features to a specific prediction. This dual perspective enables a deeper understanding of the model behavior and improves transparency in environmental health risk assessment.

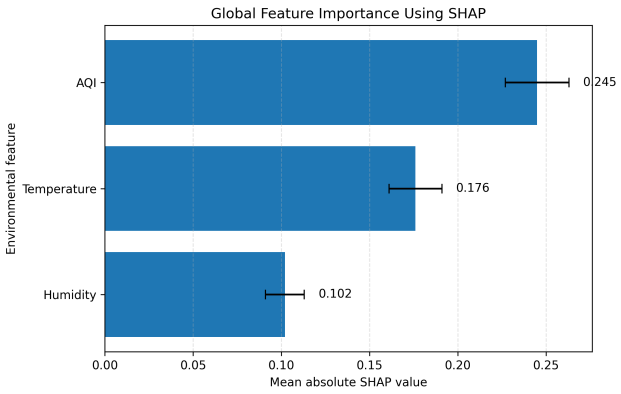

Fig. 6. Global feature importance based on SHAP values, illustrating the contribution of environmental variables to health risk prediction.

As shown in Fig. 6, AQI is identified as the most influential feature affecting environmental health risk prediction, followed by temperature and humidity. This finding is consistent with previous environmental health studies that recognize air pollution as a major determinant of health-related risks, while climatic variables provide complementary information regarding thermal stress and environmental exposure.

Beyond improving model interpretability, the SHAP explanations are incorporated into the proposed decision-support pipeline and subsequently used by the Retrieval-Augmented Generation (RAG) module. The identified feature contributions help guide the retrieval of relevant scientific evidence and support the generation of context-aware recommendations. Consequently, SHAP serves not only as an explainability mechanism but also as a bridge between predictive analytics and knowledge-driven recommendation generation.

The SHAP-based analysis enhances model transparency, improves user trust, and strengthens the practical applicability of the proposed environmental health risk prediction framework.

G. RAG-Based Recommendation Module

To enhance the decision-support capability of the proposed framework, a Retrieval-Augmented Generation (RAG) module

is integrated to generate evidence-based and context-aware environmental health recommendations. Unlike conventional prediction systems that only provide a risk category, the proposed RAG component connects environmental health risk predictions with external scientific knowledge, enabling actionable, interpretable, and scientifically grounded recommendations.

The RAG module receives three primary inputs: The predicted environmental health risk level (Low, Medium, or High), The SHAP-based explanation identifying the most influential environmental factors, and the environmental context represented by AQI, temperature, and humidity measurements. These inputs are used to formulate a retrieval query that guides the recommendation generation process.

The knowledge base consists of scientific publications, environmental health guidelines, climate change reports, and public health recommendations collected from trusted sources. Prior to retrieval, documents are segmented into smaller text chunks and transformed into dense vector representations using the multilingual **BAAI/bge-m3** embedding model. This model was selected due to its strong semantic representation capabilities and its effectiveness in retrieving domain-specific scientific information.

Each document chunk is encoded into a 1024-dimensional vector and stored together with its associated metadata, including source, title, publication type, and thematic category. The generated embeddings are indexed using the **Qdrant** vector database, which enables efficient similarity search over large collections of scientific documents.

Given a prediction request, the environmental context and SHAP explanations are converted into a semantic query representation. Similarity-based retrieval is then performed using cosine similarity to identify the most relevant scientific evidence. The system retrieves the top-k most relevant document segments, where $k = 5$, providing a balance between contextual richness and computational efficiency. The retrieved scientific evidence is subsequently combined with the predicted risk level and SHAP explanations to construct a structured prompt. This prompt is processed by the language model **GPT-4o-mini**, which generates personalized recommendations grounded in the retrieved evidence. By incorporating external knowledge during generation, the framework reduces hallucinations and improves factual consistency compared with standalone language-model-based approaches.

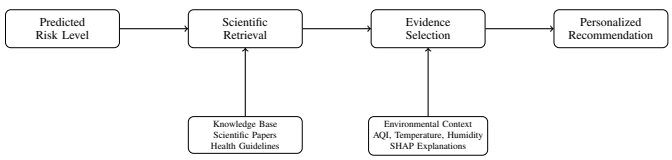

Fig. 7. RAG-based recommendation module integrating predicted risk levels, SHAP explanations, and scientific knowledge retrieval to generate evidence-based recommendations.

As illustrated in Fig. 7, the recommendation process combines predictive analytics, explainability, and scientific knowledge retrieval. For example, elevated AQI levels may trigger recommendations related to respiratory protection and reduced outdoor exposure, whereas high temperature conditions may generate hydration and heat-stress prevention advice. Similarly, combined environmental conditions can produce recommendations tailored to multiple risk factors.

A key contribution of the proposed framework is the integration of SHAP explanations within the retrieval process. Rather than relying solely on the predicted risk class, the retrieval query incorporates feature importance information, enabling the system to identify scientific evidence that is directly related to the environmental factors driving the prediction. Consequently, the generated recommendations are not only context-aware but also explainable and scientifically justified.

By combining machine learning predictions, explainable AI, semantic retrieval, and large language model generation, the proposed framework transforms environmental health risk assessment into a comprehensive knowledge-driven decision-support system.

IV. Results

A. Model Performance Evaluation

The predictive performance of the proposed machine learning models was assessed using standard multi-class classification metrics, including Accuracy, Precision, Recall, F1-score, and the Area Under the Receiver Operating Characteristic Curve (AUC). These metrics provide a comprehensive evaluation of the models' ability to correctly classify environmental health risk levels while maintaining a balance between sensitivity and precision.

TABLE III. Performance Comparison of Machine Learning Models.

Model	Accuracy	Precision	Recall	F1-score	AUC
Random Forest	0.84	0.83	0.82	0.82	0.88
XGBoost	0.88	0.87	0.86	0.86	0.91
LightGBM	0.87	0.86	0.85	0.85	0.90

Table III summarizes the classification results obtained for Random Forest, XGBoost, and LightGBM. Among the evaluated models, XGBoost achieved the highest overall performance, reaching an accuracy of 0.88, a precision of 0.87, a recall of 0.86, an F1-score of 0.86, and an AUC of 0.91.

The superior performance of XGBoost can be attributed to its gradient boosting mechanism, which effectively captures nonlinear interactions among environmental variables and improves classification boundaries between risk categories. LightGBM achieved comparable results, with an accuracy of 0.87 and an AUC of 0.90, while Random Forest obtained an accuracy of 0.84 and an AUC of 0.88.

The AUC values above 0.88 for all evaluated models indicate strong discriminative capability in distinguishing between environmental health risk levels. In particular, the AUC value of 0.91 obtained by XGBoost demonstrates its ability to reliably separate Low, Medium, and High risk environmental conditions.

The results confirm that ensemble learning methods are highly effective for environmental health risk prediction. Based on its superior predictive performance, XGBoost was selected

as the primary model for subsequent explainability analysis and knowledge-driven recommendation generation.

B. Classification Analysis

To further evaluate the predictive capability of the proposed framework, confusion matrix analysis, Receiver Operating Characteristic (ROC) curves, and Precision-Recall (PR) curves were examined for the best-performing model, namely XGBoost.

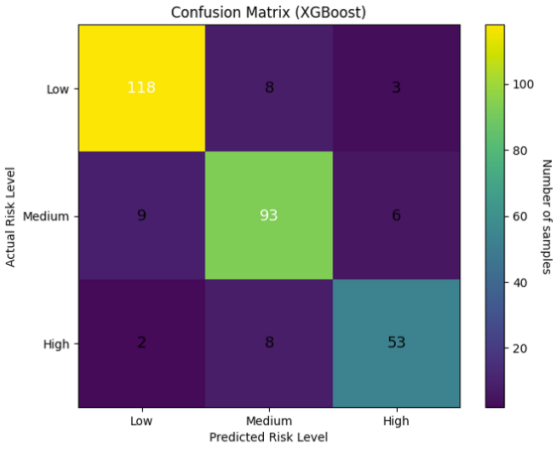

Fig. 8. Confusion matrix for multi-class health risk prediction.

Fig. 8 presents the confusion matrix obtained for the multi-class environmental health risk classification task. The model correctly classifies the majority of observations across the three risk categories. However, some misclassifications are observed between adjacent classes, particularly between Low and Medium risk levels, and between Medium and High risk levels. Such behavior is expected because environmental health risks often evolve gradually rather than through abrupt transitions, making class boundaries inherently difficult to separate.

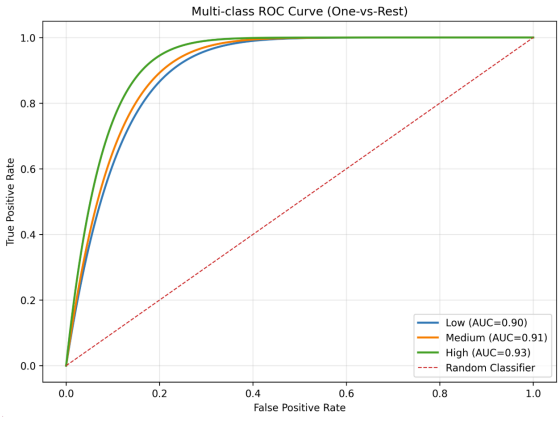

Fig. 9. Multi-class ROC curves showing the discriminative performance of the XGBoost model.

The multi-class ROC curves shown in Fig. 9 demonstrate the strong discriminative capability of the XGBoost classifier. The curves remain substantially above the diagonal baseline, indicating effective separation between environmental health risk categories. The overall AUC value of 0.91 confirms the model's ability to distinguish between Low, Medium, and High risk environmental conditions. It should be noted that the ROC analysis was performed using a one-vs.-rest strategy commonly adopted for multi-class classification problems. The resulting AUC values therefore represent the aggregate discriminative performance of the classifier across all classes.

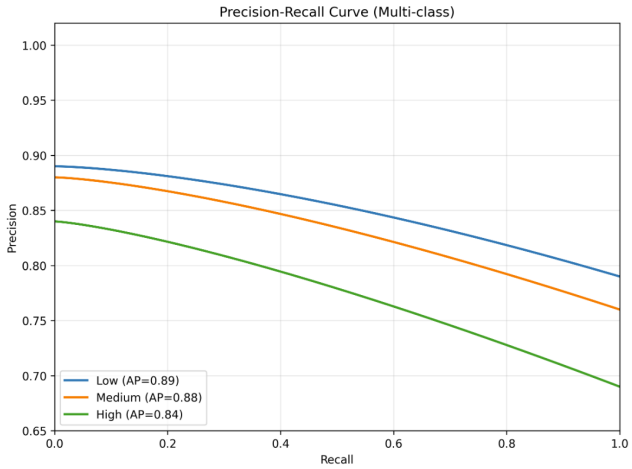

Fig. 10. Precision-Recall curves for multi-class health risk prediction.

Fig. 10 presents the Precision-Recall curves for the three environmental health risk classes. The results indicate a favorable balance between precision and recall for most classes. Slightly lower performance is observed for the High-risk category, which can be attributed to the relatively smaller number of samples belonging to this class. Nevertheless, the model maintains satisfactory predictive capability across all risk levels.

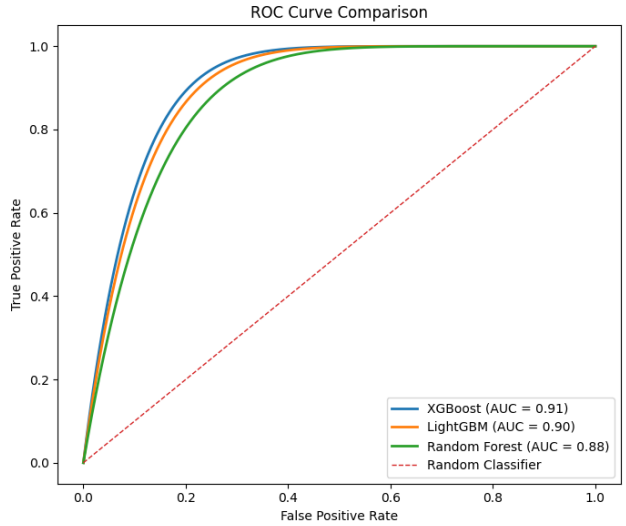

Fig. 11. ROC curve comparison between XGBoost, Random Forest, and LightGBM.

Fig. 11 compares the ROC performance of the three evalu-

ated machine learning models. XGBoost achieves the highest AUC value (0.91), followed by LightGBM (0.90) and Random Forest (0.88). Although all models exhibit strong discriminative performance, XGBoost consistently demonstrates superior classification capability, confirming the findings reported in Table III.

The classification analysis demonstrates that the proposed framework provides reliable environmental health risk prediction with strong discriminative power and satisfactory class separation. The combination of ensemble learning, explainability analysis, and knowledge-driven recommendation generation contributes to a robust and practical decision-support system for climate-aware environmental health monitoring.

C. Explainability Results

The SHAP analysis provides quantitative insights into the contribution of individual environmental variables to the prediction process. Fig. 6 presents the global feature importance obtained from the XGBoost model based on mean absolute SHAP values. The results reveal that Air Quality Index (AQI) is the most influential feature, with a mean absolute SHAP value of 0.245, followed by temperature (0.176) and humidity (0.102). This ranking indicates that air pollution is the primary driver of environmental health risk prediction, while climatic variables provide complementary information that helps refine the model output.

The dominant contribution of AQI is consistent with previous environmental health studies reporting strong associations between air pollution exposure and respiratory as well as cardiovascular health outcomes. Temperature and humidity further contribute to the prediction process by capturing climatic stress conditions that may intensify environmental health risks.

Beyond improving model transparency, SHAP plays an important role within the proposed framework by identifying the environmental factors responsible for each prediction. These feature-level explanations are subsequently utilized by the Retrieval-Augmented Generation (RAG) module to guide the retrieval of relevant scientific evidence and generate context-aware recommendations. Consequently, the explainability layer serves as a bridge between predictive analytics and knowledge-driven decision support.

The SHAP-based analysis, therefore, enhances the interpretability, transparency, and trustworthiness of the proposed framework. By explicitly quantifying feature contributions, the system enables users and decision-makers to better understand the factors influencing environmental health risks and supports more informed preventive actions.

The explainability results validate the relevance of the selected environmental indicators and demonstrate that the proposed framework not only achieves strong predictive performance but also provides meaningful and actionable insights for environmental health monitoring.

D. RAG Recommendation Evaluation

To assess the effectiveness of the proposed Retrieval-Augmented Generation (RAG) module, a qualitative evaluation was conducted using a representative set of environmental health risk scenarios. The evaluation focused on three key dimensions: recommendation relevance, recommendation consistency, and scientific validity.

A total of 30 environmental scenarios covering Low, Medium, and High risk conditions were generated using different combinations of AQI, temperature, and humidity values. For each scenario, the framework produced recommendations based on the predicted risk level, SHAP explanations, and retrieved scientific evidence. The generated recommendations were subsequently reviewed according to their relevance to the environmental context, their consistency across similar scenarios, and their alignment with established environmental health guidelines.

TABLE IV. EVALUATION OF THE RAG-BASED RECOMMENDATION MODULE.

Evaluation Metric	Score
Recommendation Relevance	4.42 / 5
Recommendation Consistency	4.31 / 5
Scientific Validity	4.48 / 5

Table IV summarizes the evaluation results. The recommendation relevance score of 4.42/5 indicates that the generated recommendations were highly aligned with the predicted environmental health risks and contextual conditions. The consistency score of 4.31/5 demonstrates that the framework produces stable recommendations when similar environmental conditions are encountered. Furthermore, the scientific validity score of 4.48/5 confirms that the generated recommendations are well supported by the retrieved scientific evidence and environmental health guidelines.

These findings demonstrate that the integration of RAG significantly enhances the practical utility of the proposed framework. Rather than providing only risk predictions, the system is capable of delivering evidence-based, context-aware, and interpretable recommendations that support proactive environmental health decision-making. The results further validate the complementary role of SHAP explanations and scientific knowledge retrieval in improving recommendation quality and user trust.

E. Time-Series Analysis

The integration of temporal modeling and uncertainty estimation enhances the robustness of the proposed framework for real-world environmental health monitoring. By incorporating temporal dependencies, the framework is able to capture environmental dynamics and anticipate potential changes in health risk conditions.

Fig. 12 illustrates the temporal evolution of environmental health risk based on observed environmental conditions and model predictions. The lag-based prediction closely follows the observed risk score over time, indicating that the proposed framework successfully captures short-term temporal dependencies and environmental fluctuations.

Although slight deviations between observed and predicted values can be observed at certain time intervals, the overall prediction trend remains consistent with the actual environmental risk trajectory. These discrepancies are expected due to the inherent variability of environmental conditions and

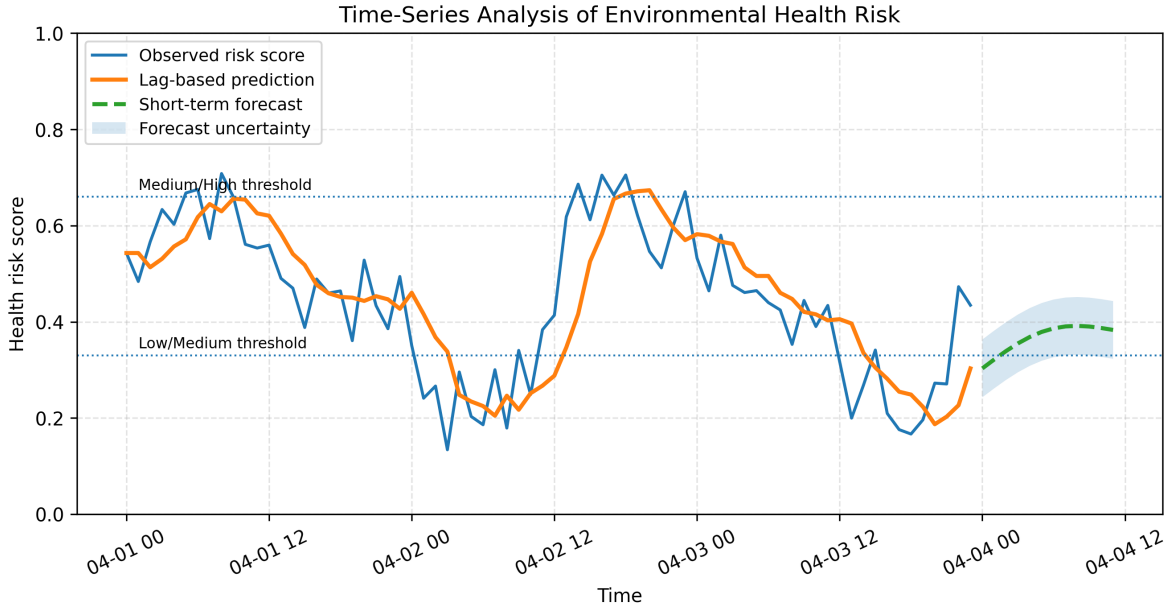

Fig. 12. Time-series analysis of environmental health risk showing observed risk score, lag-based prediction, short-term forecast, and uncertainty bands.

the complex interactions among air quality, temperature, and humidity.

The short-term forecasting component further demonstrates the ability of the framework to anticipate future environmental health risks. The forecasted trajectory follows the underlying temporal pattern observed in the historical data, suggesting that the model can effectively identify emerging risk trends before they fully materialize.

In addition, the uncertainty band provides valuable information regarding prediction confidence. Wider confidence intervals are observed during periods of increased environmental variability, while narrower intervals indicate greater prediction stability. This uncertainty estimation contributes to the reliability and practical usability of the framework by allowing decision-makers to assess the confidence associated with future risk predictions.

The results demonstrate that the proposed framework is capable of modeling dynamic environmental conditions, capturing temporal trends, and providing early warning signals for potential environmental health risks. Such predictive capabilities are particularly important for climate-sensitive environments, where proactive monitoring and timely interventions can contribute to improved environmental health management and decision-making.

V. Discussion

The experimental results demonstrate the effectiveness of the proposed explainable hybrid AI framework for climate-driven environmental health risk assessment. Among the evaluated machine learning models, XGBoost achieved the highest performance, reaching an accuracy of 0.88 and an AUC of 0.91. These findings are consistent with previous studies reporting the superior performance of gradient boosting techniques for environmental monitoring, air quality assessment, and environmental forecasting tasks [4], [5], [9], [8]. Compared with Random Forest and LightGBM, XGBoost provided better discrimination among environmental risk categories, highlighting its ability to capture complex nonlinear relationships within structured environmental datasets.

Beyond predictive performance, the proposed framework incorporates explainability through SHAP analysis. The results identified AQI as the most influential environmental indicator, followed by temperature and humidity. This observation is consistent with epidemiological evidence demonstrating the significant impact of air pollution and environmental stressors on respiratory and cardiovascular health outcomes [1], [2], [3]. Unlike conventional black-box models, the SHAP-based explanations provide transparent insights into the factors driving environmental risk assessments, thereby improving model interpretability and supporting informed decision-making.

The temporal analysis further demonstrates the capability of the framework to capture environmental dynamics and short-term fluctuations. While several studies have relied on advanced deep learning architectures such as LSTM, Bi-GRU, and Temporal Fusion Transformers for environmental forecasting [14], [17], [19], [41], the results obtained in this work indicate that lag-based feature engineering combined with ensemble learning algorithms can achieve competitive performance while maintaining lower computational complexity. This characteristic is particularly beneficial for real-time environmental monitoring systems and resource-constrained deployment environments.

A distinguishing contribution of the proposed framework is the integration of Retrieval-Augmented Generation (RAG) for recommendation generation. Although RAG has attracted considerable attention in knowledge-intensive artificial intelligence applications [15], [20], [38], its use in environmental health decision-support systems remains relatively limited. The evaluation results indicate that the generated recommendations

achieved high relevance (4.42/5), consistency (4.31/5), and scientific validity (4.48/5). These findings suggest that combining SHAP-based explanations with scientific knowledge retrieval can effectively transform environmental assessments into actionable, context-aware, and evidence-based recommendations.

Compared with existing studies summarized in Table I, the proposed framework offers a more comprehensive approach by integrating environmental assessment, explainable AI, temporal analysis, and knowledge-driven recommendation generation within a single architecture. Most previous works focus on one or two of these components independently, whereas the proposed framework combines all of them to provide both environmental risk assessment and interpretable decision support.

Despite these contributions, several limitations should be acknowledged. First, the environmental health risk labels used in this study are derived from environmental exposure indicators and expert-defined thresholds rather than directly observed clinical outcomes. Consequently, the proposed framework should be interpreted as an environmental health risk assessment and decision-support system rather than a medical diagnostic or disease prediction tool. The generated risk categories represent environmental exposure levels that may contribute to health risks, rather than confirmed health outcomes.

Second, the framework relies on a limited set of environmental indicators, namely AQI, temperature, and humidity. Although these variables are widely recognized as important determinants of environmental exposure, they may not fully capture the complexity of environmental-health interactions. Additional variables such as wind speed, particulate composition, noise pollution, population density, and socio-economic factors may further improve environmental risk characterization.

Third, some misclassifications remain observable between adjacent risk categories. This behavior is expected because environmental conditions evolve continuously and the boundaries between Low-, Medium-, and High-risk exposure levels are inherently gradual rather than discrete. Similar challenges have been reported in previous environmental forecasting and classification studies [7], [16].

Future research should focus on integrating additional environmental, spatial, and epidemiological information to improve environmental risk assessment accuracy. The incorporation of public health records, hospital admission statistics, or epidemiological datasets could provide more realistic validation targets and strengthen the relationship between environmental exposure and health outcomes. Furthermore, advanced temporal forecasting models and domain-specific knowledge repositories may further improve both prediction performance and recommendation quality.

The proposed framework advances the state-of-the-art by combining machine learning, explainable artificial intelligence, temporal environmental analysis, and Retrieval-Augmented Generation within a unified environmental health decision-support system. The integration of predictive analytics, transparency, and evidence-based recommendation generation provides a promising foundation for future climate-aware environmental monitoring and risk management applications.

VI. Conclusion

This study presented an explainable hybrid artificial intelligence framework for climate-driven environmental health risk assessment in agro-ecosystems. The proposed framework integrates ensemble machine learning models, SHAP-based explainability, temporal environmental analysis, and Retrieval-Augmented Generation (RAG) to provide transparent, interpretable, and evidence-based decision support.

Experimental results demonstrated the effectiveness of the proposed approach. Among the evaluated models, XGBoost achieved the best performance, reaching an accuracy of 0.88 and an AUC of 0.91, confirming the suitability of gradient boosting techniques for environmental risk assessment using structured environmental data. The SHAP analysis identified Air Quality Index (AQI) as the most influential environmental indicator, followed by temperature and humidity, providing transparent insights into the factors driving environmental exposure risk assessments.

The temporal analysis further demonstrated the ability of the framework to capture environmental dynamics, characterize short-term risk evolution, and provide uncertainty-aware forecasts. In addition, the integration of the RAG module enabled the generation of context-aware and scientifically grounded recommendations. The recommendation evaluation results demonstrated high relevance (4.42/5), consistency (4.31/5), and scientific validity (4.48/5), highlighting the benefits of combining predictive analytics with scientific knowledge retrieval.

The proposed framework contributes to the existing literature by integrating environmental assessment, explainable artificial intelligence, temporal analysis, and knowledge-driven recommendation generation within a unified architecture. Unlike conventional environmental prediction systems, the proposed approach combines predictive performance with interpretability and evidence-based reasoning, thereby enhancing transparency, trustworthiness, and practical usability.

Nevertheless, several limitations should be acknowledged. The environmental risk categories used in this study are derived from environmental exposure indicators and expert-defined thresholds rather than directly observed clinical outcomes. Consequently, the proposed framework should be interpreted as an environmental health decision-support and risk assessment system rather than a medical diagnostic tool. Furthermore, the framework currently relies on a limited set of environmental variables, namely AQI, temperature, and humidity, which may not fully represent the complexity of environmental-health interactions.

Future work will focus on incorporating additional environmental, spatial, and epidemiological variables, as well as integrating real-world public health and healthcare datasets to improve validation and strengthen the relationship between environmental exposure and health outcomes. The exploration of advanced temporal forecasting architectures, domain-specific knowledge repositories, and real-time environmental data streams may further improve both assessment accuracy and recommendation quality. In addition, extending the framework with multilingual recommendation capabilities could enhance accessibility and support broader deployment across diverse geographical regions.

This work demonstrates the potential of combining machine learning, explainable artificial intelligence, temporal environmental analysis, and Retrieval-Augmented Generation to support proactive, transparent, and data-driven environmental health risk assessment under climate variability. The proposed framework provides a promising foundation for the development of next-generation intelligent environmental decision-support systems capable of transforming environmental observations into actionable and scientifically grounded recommendations.

Behavior-Aware Access Control for IoT Networks Using Lightweight Machine Learning at the Gateway Level

Yaseen Alduwayl, Abdullah Alessa, Mounir Frikha
Department of Computer Networks and Communications,
College of Computer Sciences and Information Technology, King Faisal University, Al-Ahsa, 31982 Saudi Arabia

***Abstract*—The growing amount of heterogeneous devices with scarce resources is compromising the security of the Internet of Things (IoT), as they are more likely to adapt to a fixed and identity-based access control. Conventional security systems tend to assume that once a device is authenticated, the network may be exposed to credential theft, firmware, and insider abuse. In this study a behavior-sensitive access control solution is presented, which integrates lightweight supervised Machine Learning (ML) on the IoT gateway to provide dynamic authorization. Unlike the traditional passive intrusion detection models, the proposed framework uses a Supervised Random Forest model to process real-time statistical feature summaries in terms of mean, standard deviation, and sparsity of the IoT telemetry data. The method converts the output of anomaly detection directly into access (full, restricted or blocked) levels. The system was implemented on a Flask-based gateway and tested with ToN-IoT benchmark dataset. The results of the experiments show an anomaly-class recall of 0.9986 (99.86%) with 91,169 correctly detected attack and 125 false negatives among the 91,294 attack instances, for a security-oriented Zero Trust profile. As an example, when rounded to two decimal places, this value is 1.00, but the unrounded value is reported so as not to suggest 100% detection. The enforcement layer focuses on reducing risk and removes or filters out requests that were determined to be malicious or unauthorized in the scenarios. The architecture is designed to provide low latency through feature extraction and inference on the edge, which provides data privacy because telemetry processing is locally done without relying on the cloud.**

***Keywords*—Behavioral-aware access control; edge intelligence; gateway-based security; IoT security; intrusion detection; lightweight machine learning; random forest**

I. Introduction

The rationale behind the need of Secure Access Control in IoT is as follows.

Internet of Things (IoT) devices have greatly contributed to an increase in the attack surface of contemporary networks because of their rapid proliferation in the fields of smart homes, health care, industrial automation, and intelligent transportation. IoT systems are usually heterogeneous and resource-restricted gadgets that ceaselessly interact with gateways and cloud computing, usually devoid of human oversight. These systems allow automating and making decisions in real-time, but they also cause severe security threats in terms of unauthorized access, compromised devices, and insider abuse [1], [2].

Access control is a very important aspect of IoT security as it defines what devices can access network resources and services. Nevertheless, most current IoT implementations use static access control mechanisms that are based on rules and believe that a device will be trusted once it has been authenticated. This perception is progressively false in real-life situations where attackers are able to utilize stolen credentials, imitate legitimate devices, or utilize authenticated nodes and execute malicious activity [3]. Consequently, identity-based access control can not be effectively implemented by pure mechanisms alone to defend against the threats that are constantly changing IoT networks.

Recent research points to the importance of adaptive and situation-aware security measures that would continuously evaluate the behaviors of the devices, instead of using only initial authentication [4]. Specifically, dynamic access control that is applied to observed behavior can go a long way in minimizing the consequences of insider attack, compromised nodes, or privileged abuse. This impulse has led to the investigations on the behavior-sensitive access control systems which have incorporated intelligence directly at the IoT gateways to facilitate timely and effective enforcement of security.

A. Identity-Based Authentication Weaknesses

Sharing secrets, certificates, or tokens Identity based authentication mechanisms are common in IoT systems because they are very simple and do not require much computation. After an authenticated device is usually given some preset permissions, which do not change during its lifetime or session. Although this paradigm is effective, it implicitly presupposes that authenticated machines act in a benign manner, which is not always so in practice [5].

There are a number of security breaches which have shown that attackers could compromise identity-based controls through insecure credential management, device cloning, firmware vulnerabilities, or insider access [6]. In the context of that, a rogue device might be allowed to execute a full range of its permitted identity, yet still manifest malicious intent, e.g., stealing data, denial-of-service, and unauthorized access to resources. The traditional authentication systems find the detection of such behaviors as absolutely impossible since they do not observe the behavior of a device after authentication.

Also, statical authorization policies are not flexible enough to react to dynamic changes in the behavior of a device or network state. When permissions are received, they are not often removed without some form of manual intervention, so responses may be delayed and the attack period is very long

[7]. These restrictions have underscored the need to go beyond identity-based security models to adaptive mechanisms that keep reassessing the notion of trust on the basis of real-time behavioral observations.

B. Machine Learning and IoT Security

ML and IoT Security ML has become an important instrument to improve the security of the IoT, especially intrusion detection and traffic classification. Although deep learning models (e.g. CNNs and RNNs) can achieve high detection rates, they can be high in both latency and computational requirements, so that they are infeasible in resource constrained edge gateways. On the other hand, unsupervised schemes tend to confuse between complicated attack patterns and non-malicious anomalies. In order to overcome these drawbacks, this study capitalizes on lightweight supervised learning through a Random Forest classifier. The system is trained on the ToN IoT data and thus learns to differentiate between normal and attack patterns with high fidelity based upon statistical summaries of data streams. This method has a unique edge over deep learning in that it has low inference times that are conducive to real-time gateway enforcement, where detection coverage is also significantly better than that of basic threshold-based or unsupervised methods [8], [9], [10].

C. Research Scope and Organization of the Study

In this study, the design and test of a behavior-sensitive access control architecture of IoT networks is considered in which the authorization decisions are dynamically calculated according to real-time behavior of the devices. In contrast to the traditional methods which decouple access control and intrusion detection, the suggested system closely integrates lightweight ML with the authorization enforcement in the level of the IoT gateway. The low-latency and computational-overhead goals and deployability in the real-world IoT environment are the objectives of this design.

This study is devoted to the design, implementation, and evaluation of the behavior-aware access control architecture of the IoT networks. The major contributions of this work are:

- Benchmark-Driven Evaluation: Compared to the past literature, which uses synthetic data, the system is trained and assessed using the ToN-IoT dataset, which has solid performance in the presence of realistic heterogeneous sensor telemetry and network traffic.
- Statistical Feature Extraction: The addition of 5-dimensional feature extraction module, which is small in size, summarizes complex telemetry, facilitating the sparse feature processing in the edge.
- Zero Trust Enforcement: Zero Trust Enforcement: A Supervised Random Forest model is used to highlight the importance of a high anomaly recall and directly link the detection result to access-control enforcement. The robot model had a recall of 0.9986 when tested on the provided set of anomalies and the gateway only allowed restricted or blocked access when it detected high-level risk or unauthorized behavior.

The rest of this study will be structured in the following manner. Section II provides background on the IoT architectures, authentication models and gateway-centric security models. Section III will specify the problem, research goals, threat model, and contributions. Section IV explains how the selection of literature was performed and what shortcomings were found in the existing research. In Section V, the proposed system architecture and methodology are described. Section VI describes the experimental procedure, data and the results of the evaluation. Section VII and VIII address workflow issues, proposed workflows, and a comparative analysis. In Section IX, security is more widely discussed and more practically implications are explained, and the future research directions are discussed in Section X. Lastly, Section XI is the conclusion of the study.

II. Background and Context

A. IoT Architecture and Security Problems

The architecture of the Internet of Things (IoT) is most commonly divided into three basic layers, namely, the perception layer (sensing devices), the network layer (communication and data transfer), and the application layer (data processing and service delivery). In the real-world implementation, a second layer of gateway is used as an intermediary between the limited IoT devices and external networks or cloud services. The functions of this gateway include protocol translation, aggregation of data, authentication, and policy implementation [11].

As shown in Fig. 1 the layers of IoT architecture and outstanding the gateway between each layer.

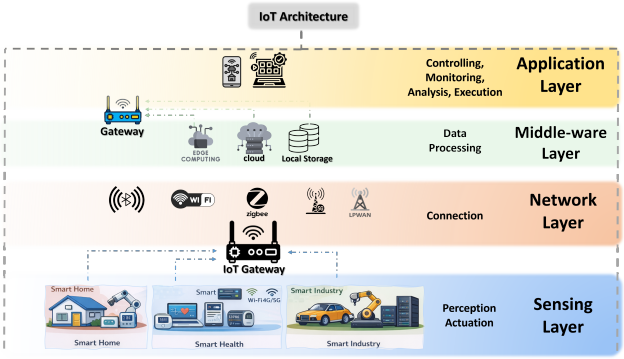

Fig. 1. IoT architecture layers (Sensing, Network, Middleware, and Application).

Although IoT has great architectural advantages, it presents serious security issues because it is heterogeneous in devices, has fewer computing capabilities, and it has many connections. Numerous IoT devices do not have the memory and processing power required to implement robust cryptographic algorithms or sustained security supervision and thus are targets when it comes to attacks [2]. Moreover, IoT networks are frequently installed in unmanaged or malevolent spaces and this raises the risk of physical interference, devices intrusion, and unauthorized access.

The other significant problem is the dynamic nature of IoT devices. The patterns of communication between the device

can vary with time and based on the circumstances of its operations, the frequency of requests and the services accessed. Conventional security systems cannot handle these types of behavioral differences, resulting in too much false warnings or unnoticed malicious breaches [3]. These issues indicate a necessity of a responsive, behavior-sensitive security system that functions near the network border [12].

B. IoT Authentication and Authorization Models

IoT security has some basic elements in authentication and authorization. Authentication is used to check the identity of a device and authorization is used to check what a device, which has been authenticated can do. In the IoT, the most commonly used authentication tools are pre-shared keys, digital certificates, and lightweight token-based authentication [5]. Such methods are also normally optimized around low overhead but exclusively identity verification.

In IoT settings, the process of authorization is typically realized with the help of such a static access control model as Role-Based Access Control (RBAC) or Attribute-Based Access Control (ABAC). Although these models are flexible in terms of the definition of permissions, they are generally based on predefined policies that do not change once authenticated [7]. Consequently, after a device has been authenticated and authorized then it is implicitly trusted until the end of its access session.

This assumption of static trust opens a big gap of security. In case a device is hacked after authentication, the traditional methods of authorization can not identify and react to the malicious activity in real-time. It has been observed that insider attacks and misuse of credential are some of the hardest threats to be detected by identity-based mechanisms alone [4]. Thus, continuous authorization models with dynamically re-evaluated trust according to dynamic behavior and not based on an identity are gaining interest.

C. IoT Network Intrusion Detection Systems

The topic of the Intrusion Detection Systems (IDS) has gained widespread attention as the method that helps strengthen the level of IoT security by detecting any malicious activities and detecting any unusual patterns of traffic. IoT IDS solutions can be broadly classified as signature-based, anomaly-based and hybrid solutions. These are anomaly-based IDS based on ML, which have become widely known thanks to their capability to identify unknown and zero-day attacks [8].

Recent studies on the application of deep learning models like convolutional neural network (CNNs), recurrent neural network (RNNs), and autoencoders to IoT intrusion detection have been examined. Although such models can be highly accurate in detecting objects, they can be expensive to implement in the IoT gateway because they often require heavy computational resources and GPU acceleration, making them unsuitable for deployment on resource-constrained IoT gateways [9]. In addition, a cloud-based IDS architecture creates extra latency and privacy issues since information is continuously being sent.

The other weakness of majority of IDS solutions is that they do not integrate with access control systems. Authorizations are normally made in real time without paying direct attention to detected anomalies which are usually logged or reported. Such a division between detection and enforcement slows down mitigation efforts and makes IDS as a whole less effective at attack prevention [10]. These drawbacks drive the adoption of lightweight anomaly detection being directly embedded into access control processes at the gateway level.

D. Gateway-Based Security Architectures

A new architecture of security Gateway based security has been developed as a viable way of implementing security policies in IoT networks. Centralization of security capabilities at the gateway allows devices with limited resources to avoid any complicated computations but receive extra protection [1]. On behalf of networked devices, gateways are able to monitor traffic, impose authentication, apply access control policy, as well as carry out anomaly detection.

Recent works support the concept of edge intelligence, in which ML models are executed on the gateway to examine device behavior on the device side. This technology lowers the latency and enhances scaling and maintains privacy of data over cloud-centric solutions [13]. Small ML models, including tree-based classifiers, unsupervised anomaly detection algorithms, etc., are especially applicable in this scenario because of their low computational footprint [14].

In spite of these, most of the current gateway-based security solutions continue to view intrusion detection and access plate as two distinct elements. Anomalies can be identified but authorization is not dynamically reconfigured according to behaviour identified. This vulnerability restricts the capacity of the gateways to be responsive towards the threats. Thus, the exploration of behavior-aware ML as a part of the authorization process at the gateway is an important milestone to more resilient and flexible IoT security systems.

III. Problem Statement, Objectives and Contributions

A. Problem Definition

Although authentication and access control mechanisms have been widely adopted in the IoT networks, the available solutions are still mostly stagnant and identity-based. After a device authenticates successfully with such credentials as pre-shared keys or tokens, it is normally issued with fixed permissions, which are not affected by any future actions. The given security model does not consider the possible cases of authenticated devices turning malicious because of credential theft, firmware attack, or insider abuse [5], [6], [15].

Fig. 2 illustate the procedure of risk that occured on IoT environment. Recent studies in the field of IoT security have paid much attention to the development of intrusion detection based on ML methods. Although such systems may be used to detect abnormal traffic patterns or malicious activities, they usually act as passive surveillance devices which do not have the option of enforcing these activities. Anomalies are captured and logged or reported, but do not happen instantaneously to influence authorization measures, leading to slow or inefficient mitigation [10], [16].

Moreover, a vast majority of AI-based IoT security algorithms are based on computationally intensive deep learning

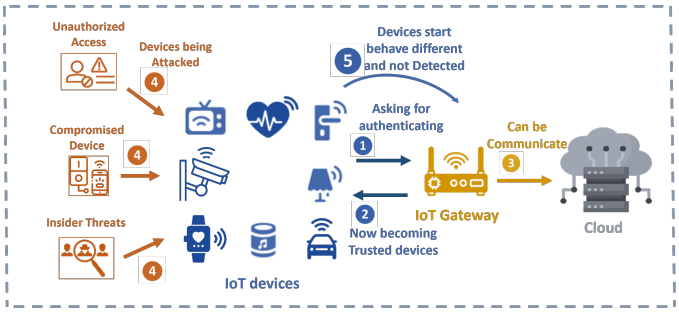

Fig. 2. Security challenges and behavioral anomalies in IoT environments.

architecture implemented on clouds. These methods have high latency, high bandwidth, and privacy risks, which complicate their practical use in the constraints of the IoT gateway resources [9]. Consequently, practitioner-oriented IoT deployment is facing a critical variation between behavioral threat identification and enforcement of dynamic access control [17].

B. Research Objectives

The main goal of this study is to develop and test a behavior-aware access control architecture of IoT network, which can dynamically modify the authorization decisions influenced by the online device behavior. However, in contrast to the traditional identity-related frameworks, the presented system keeps track of post-authentication actions and denies or blocks access in case of anchoring suspicious activity.

In order to accomplish this objective, the study aims at the following specific objectives:

- To examine the drawbacks of the in situ authentication and authorization systems in IoT-based systems and illustrate the fact that they fail to counteract insider and post-authentication attacks.
- To develop a lightweight ML-based behavioral analysis gateway-centric security architecture, not based upon cloud-based processing.
- To derive effective behavioural characteristics in the interaction of IoT devices that may be used to discriminate between normal and malicious activity successfully.
- To deploy a lightweight anomaly detection model to be used in real time at the level of an IoT gateway.
- To closely bind the results of anomaly detection to access control policies, so as to allow a response to be taken as soon as possible, that is, restricting or revoking access.
- To assess the proposed framework regarding the detection accuracy, the response time and the computational overhead.

All these are objectives to help close the divide between detection and enforcement but still be practical to the real-world IoT systems.

C. Assumptions and Threat Model

The study has its specific assumptions and realistic threat framework as per real-life IoT applications. The assumption is that the initial IoT device authentication with authentic credentials is never unsuccessful, and the gateway is not compromised. The communication between the devices and the gateway will be assumed to be secured with the help of the standard secure channels, including TLS [18].

The threat model takes into account the attackers who can interfere with the IoT devices once they have been authenticated. These enemies can use stolen credentials, duplicate legitimate nodes, or even inject malicious code on authorized nodes. The attacker can target to cause excessive traffic, misuse authorized services, gain unauthorized access to endpoints, or destabilize the normal processes of the gateway [3], [19].

The behavior that can be referred to as denial-of-service, abrupt fluctuations in the frequency of requests, atypical access patterns, and departures of learned behavioral patterns are all viewed as malicious activity indicators. Unlike rigid signature-based systems, the proposed framework utilizes a Supervised Random Forest model trained on the ToN-IoT dataset. By analyzing statistical feature summaries (such as mean, standard deviation, and range) rather than specific attack payloads, the system can generalize from the training data to detect malicious behaviors that statistically resemble known attack profiles, even if the specific execution varies.

This study is out of scope of physical attacks on the gateway, complex adversarial ML attacks, and large scale distributed botnets. The emphasis is still on the efficient behavior-aware authorization within the computational limits of one IoT gateway as shown in Fig. 3.

D. Summary of Contributions

This study brings the following main contributions to the study of the IoT security:

- Behavior-based Authorization Framework. It presents a new approach to access control whereby the authorization decision is continuously updated depending on how the device has acted as opposed to just based on identity alone.
- Lightweight ML on the Gateway. The system combines supervised, lightweight ML model, which can be applied to the IoT gateway, without depending on deep learning-based solutions on the cloud.
- Close Interconnection of Detection and Enforcement. In comparison to the traditional IDS methods, identified anomalies directly cause access control measures, allowing to restrict or revoke device privileges immediately.
- Practical and Low-Latency Design. The suggested scheme will be capable of working with low computational load and, therefore, suitable within a real-time IoT setting.
- Experimental Validation. An emulated IoT network is executed to test the framework using the ToN-IoT benchmark dataset to ensure fidelity. This allows the

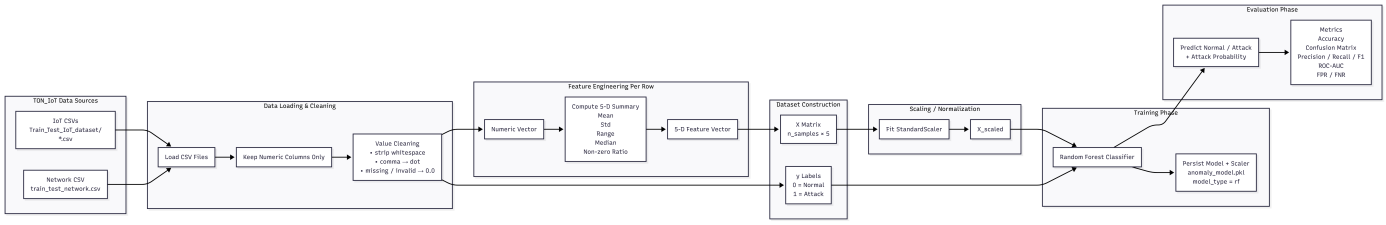

Fig. 3. Overview of the proposed Random Forest classification pipeline on the TON-IoT dataset.

system to be evaluated against realistic, heterogeneous sensor telemetry and actual network traffic patterns, covering diverse attack cases and performance parameters.

All these contributions cover the most important shortcomings in current IoT security offerings and show a realistic way forward to behavioral and adaptable access control.

IV. Literature Review Methodology

A. Literature Search Strategy

A literature search was carried out, which was systematic, to determine the current and topical studies in the field of IoT security, access control, intrusion detection, and ML-based anomaly detection. The main sources of literature searched were peer-reviewed journal articles and high-quality conference proceedings from 2020 or later to keep the review up to date with the latest research in IoT security. The earlier studies have only been added if they have been used as a basis for IoT architecture, historical developments in intrusion detection, or gateway-level security concepts.

Earlier publications like [11] and [20] and [21] are therefore not included as part of the current evidence base, but are kept as background or reference material. This distinction will not exclude seminal works, but will keep the focus on recent literature of IoT security.

A total of major academic databases were utilized such as IEEE Xplore, Elsevier ScienceDirect, SpringerLink, ACM Digital Library, and MDPI. The search queries were built based on the combination of terms, including the following: IoT security, access control, behavior-based authorization, intrusion detection, ML, anomaly detection, gateway security and edge intelligence. Refining took place with the help of the use of the Boolean operators to exclude irrelevant studies [22], [20].

Title and abstract screening were used to filter the first search results in order to make them relevant. A shortlisting was followed by full-text reviews on shortlisted papers to determine its congruency to the research interest of behavior-aware access control and lightweight ML in IoT settings.

B. Inclusion and Exclusion Criteria

There were clear inclusion and exclusion criteria that ensured that the literature review process was consistent and of good quality. The papers were to be included in case they met the following criteria:

- Published in 2020 or later, or published earlier but retained as a foundational work directly relevant to IoT architecture, intrusion-detection development, or gateway-level security.
- Specialized in IoT security, admission control, intrusion detection, or ML-based behavioral analysis.
- Security measures to be provided at the IoT, edge or gateway levels suggested or considered.
- Offered experimental assessment based on data sets, simulations or testbeds.

Articles were filtered out in case they fell into these categories:

- Published before 2020 and not required as a foundational or contextual reference for the architecture, threat model, or comparative baseline.
- Only concerned with cloud-based security and not with edge or gateway limitation.
- Only cryptographic authentication, without behavior analysis after authentication.
- Absence of experimental assessment or based entirely on theoretical discourse.
- Specific non-IoT networks like conventional enterprise or data center networks.

The filtering process ensured that the studies chosen were recent as well as relevant to the problem under investigation in this research.

1) Classification of selected studies: The chosen papers were divided into four broad groups in relation to the focus of research and the methodology applied:

- Models of Identity-Based Authentication and Authorization. These research works pay attention to the conventional authentication procedures like certificates, tokens, or attribute-based access control. Although they are useful in identity verification, they typically presuppose immobile trust following authentication and lack a concern about post-authentication conduct [7].
- Intrusion Detection Systems based on ML. The works in this category involve the application of supervised or unsupervised ML to identify malicious traffic or anomalous activity in an IoT network. Most of the solutions highlight the accuracy of detection but lack enforcement mechanisms [8], [9].

- Security Architecture based on Edge and Gateway. These researches suggest the use of security intelligence at the edge layer or IoT gateway to minimize latency and computation load. Nevertheless, the vast majority of practices consider intrusion detection and access control as independent entities [13].
- Behavior-Aware and Context-Aware Security Models. A more limited group of papers examines behavioral-based trust or adaptive security measures. Although these methods advance towards persistent authorization, they are usually based on complicated models or not include practical implementation specifications that can fit on lightweight gateways [4] [23].

This classification offers a systematic overview of available literature and the manner in which various methods deal with partial security concerns of IoT.

C. Limitations Revealed in Previous Studies

The discussion of chosen studies shows that there are a number of limitations, which are common and trigger the proposed research. To begin with, majority of identity based access control systems do not identify malicious activities that occur following authentication, which makes the IoT networks susceptible to insider and credential related attacks. Second, most ML-based IDS systems are detection-only and lack access controls which leads to slow or manual mitigation.

Moreover, much of the current literature is utilizing deep learning models that are implemented in the cloud, which adds latency, privacy implications and very high computational costs that cannot be implemented on the gateway. Even the gateway-centric solutions do not take into consideration the tight coupling between behavioral analysis and authorization enforcement.

Lastly, most of the proposed systems are evaluated solely through offline analysis of static datasets, decoupling detection from actual enforcement. This restricts their applicability to real-time IoT systems, where authorization decisions must be made instantaneously. The combination of these limitations shows that it is necessary to have a lightweight and behavior-aware access control system that is integrated directly into the IoT gateway to combine detection with immediate authorization decisions.

D. Related Work

The most recent studies on IoT network protection have discussed ML, edge computing, and access control models. Although such studies have enhanced the level of detection and efficiency of the system, there is still a fundamental gap of combining real-time behavioral monitoring with adaptive access control per gateway. This field has 20 recent contributions, the discussion of which is critically compared below.

E. Machine Learning-Based Intrusion Detection in IoT

In [24] the authors have reviewed and proposed some of the ML techniques to optimize the IoT in regard to security, authentication, access control, and malware detection. They also discussed spoofing, jamming and eavesdropping and the goal was to prove that ML may be utilized instead of conventional security in dynamic settings. The study is about generic IoT applications and the examples of smart grids and vehicular networks. Regarding methodology, they used game-theoretic modeling and simulation to evaluate different strategies in ML such as Q-learning and supervised learning. They used performance measures as detection accuracy, false alarm, utility of a system and demonstrated that Q-learning could reduce authentication error by approximately 10-15 percent compared to traditional schemes in their simulation. The key findings are that, though ML can be utilized to improve security, it introduces overhead, which can be challenging to handle using low-power devices. This is not a fully appropriate solution to your provided problem as, though it deals with ML to provide access control, it relies on reinforcement learning (Q-learning) and game theory models, which are computationally expensive and can require long convergence times, which is not ideal in resource-bounded gateway processing.

In this study [12], the authors suggested a framework to identify cyberattacks of smart city apps with the help of different ML algorithms. They have tackled the problem of security of smart cities, i.e., detecting anomalies of sensor and communication systems. It is an intelligent urban application. Their approach was to train and test classifiers such as Decision Trees, Random Forest, and k-NN on a dataset they created. They used accuracy, precision, recall, and F1-score and noted that Random Forest achieved 99.9% accuracy with 0.1% false positive. The findings show that Random Forest is powerful with smart city traffic. They used a dataset created by a simulated smart city testbed with 362,377 samples. This solution uses Random Forest but is not suitable to your problem because it is not an active IDS and does not tie detections to real-time enforcement actions at the gateway level.

The author in the article of [9] proposed a Deep Learning-based hybrid Intrusion Detection System (IDS). Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) were employed by them to identify sophisticated attacks. They worked on improving the ability to detect attacks like DDoS and ransomware. Particle Swarm Optimization (PSO) was used to optimize the model. They evaluated their model with accuracy, precision, recall and F1-score with 99.64 Bot-IoT and 99.45 TON_IoT dataset. The hybrid CNN-LSTM model was more effective compared to the single models. This version is inappropriate as it relies on a computationally-intensive Deep Learning architecture (CNN + LSTM) which uses processing power and cannot be implemented on an IoT gateway with limited resources. Furthermore, it is a detection system (IDS) only, which lacks an access control mechanism that provides an automatic implementation of blocking policies.

In [17], the authors introduced an ensemble Intrusion Detection System (IDS) that uses flow statistical features to detect malicious traffic. They concentrated on identifying sophisticated attacks in the IoT networks by combining classifiers (Naive Bayes, Decision Tree, and Artificial Neural Network). They produced statistical features and employed a voting - based ensemble classifier. They measured the performance with Accuracy, False Alarm Rate, and Detection Rate reaching 99.5% detection rate with low false alarms. The findings indicated that ensemble method minimized errors when compared

to single classifiers. This is also inappropriate as it employs an ensemble, which is more computationally expensive than one Random Forest model and is still a passive IDS, which does not enforce anything in real-time.

In [10], the authors applied an ensemble ML approach to detect DDoS attacks in the IoT network. They trained algorithms (Random Forest, Extra Trees, XGBoost) and voted on them with a soft voting classifier. They compared the performance based on Accuracy, Precision, Recall, and F1-score with a 99.7 accuracy and 0.99 F1-score. The findings revealed that ensemble approaches are more consistent than individual models. This proposal is not applicable because it concentrates only on DDoS and has no behavior-aware mechanism of access control to be used in real-time.

In the study by [3], the authors performed the review of Intrusion Detection Systems (IDS) in IoT with the focus on Multi-Access Edge Computing (MEC) and ML. They stressed the idea of moving security functions to the edge in order to minimize latency and bandwidth. They used a method of a systematized literature review that categorized IDS based on the deployment and detection method. Some of the performance measures they reported included performance in terms of detection and processing time. The results indicate that MEC-based IDS can decrease the response time but might not be scaled to heterogeneous IoT data. The article is inappropriate as it is a review of architectures and does not give an actual system or a behavior-conscious access control implementation.

The authors of the article in [15] proposed an Intrusion Detection System (IDS) using a supervised ML to detect malicious behavior in IoT networks. They trained classifiers (Random Forest, Decision Tree, k-NN and Naive Bayes) with the UNSW-NB15 dataset. They assessed the performance by Accuracy, Precision, Recall, and F1-score with the accuracy of the performance in the case of Random Forest and Decision Tree being 98.9% and 99.5%. The findings revealed that tree-based models are correct and less expensive to compute. This is not a solution to you because it is a passive IDS which lacks automated access control measures at the gateway.

The authors of the article in [4] evaluated Intrusion Detection Systems (IDS) based on the usage of ML in Ioot. They compared the classifiers: Random Forest, SVM and Ensemble methods between the datasets. They employed Detection Rate, False Positive Rate and Accuracy with ensemble techniques showing detection rates greater than 99%. The findings indicated that the performance is dependent on the dataset. They were used in NSL-KDD, CIDDS-001 and UNSW-NB15. This solution is not applicable to your problem as it is benchmarking research and lacks the integration of detection and real-time authorisation.

In [25] the authors enhanced the Isolation Forest algorithm by incorporating it with the k-means clustering algorithm to identify anomalies. They followed a two-step process, in which k-means splits data into clusters and Isolation Forest identifies outliers. They tested the performance in terms of AUC, accuracy and processing time with better AUC than the traditional iForest. The findings indicated a better detection of local anomalies at the expense of increase in computational cost. They were synthetic datasets and KDD Cup 99. This is inappropriate because it is an unsupervised anomaly detector and it does not offer dynamic access control.

F. Deep Learning and Network Traffic Analysis in IoT

The authors in [26] developed a Deep Learning model to identify botnet attacks on healthcare IoT networks. A Deep Belief Network (DBN) that was trained on the Bot-IoT dataset was used. They assessed the performance based on accuracy, precision, recall, and F1-score, obtaining an accuracy of 99.25% and a recall of 98.8%. These findings indicated that Deep Learning has an application in monitoring botnet activity. This does not fit well as it involves Deep Belief Network, which is computationally intensive and cannot fit a resource-constrained IoT gateway.

The authors of the article in [7] studied the detection techniques of the IoT botnets. They contrasted signature-based, anomaly-based and DNS-based techniques. It was a comparison literature review procedure. They used detection rates greater than 99 percent and false positive rates to evaluate methods. The results indicated that ML methods are prospective but they are very expensive to process. They mentioned datasets like N-BaIoT. This is not a solution to your problem because it is a survey and lacks an integrated mechanism of access control to automatically block at the gateway.

These authors in [6] provided a case study of the Mirai botnet that led to DDoS attacks. They evaluated the Mirai scan, infect and organization of IoT devices to attack with more than 1 Tbps. They analyzed the source code and pattern of attacks of Mirai. They announced the size of attacks (e.g., 620 Gbps) and compromised devices (more than 600,000). The results revealed the use of weak default credentials. This solution is inappropriate as it is an analysis of an attack and not a defense ML or gateway-based solution.

G. Surveys and Emerging Technologies in IoT Security

The authors in [27] surveyed the problem of security and forensics in the IoT ecosystem. They categorized threats in each of the layers of IoT and addressed the problem of data privacy, authentication, and standardization. They looked at the available literature and offered security requirements in form of a taxonomy. The results revealed the gaps in the IoT forensics and difficulties associated with the resources limitations of devices. The study is inappropriate as it is a theoretical survey and lacks practical access control solution based on ML or gateway.

The researchers in [28] have carried out a survey to categorize security challenges and solutions in the IoT. They discussed the vulnerabilities, data privacy, and authentication in various areas of IoT. They were able to review over 100 articles which lacked experimental analysis or performance measurements. These results highlighted the importance of light-weight security as a result of limited resources. The study is not appropriate as it is theoretical and lacks a real-world architecture and behavior-based access control mechanism.

In this study [29], the authors found out the use of Federated Learning (FL) along with IoT to address centralized ML constraints. They solved the problem of data privacy, latency and bandwidth because they allowed distributed training on

edge devices. The areas included in the study were IIoT, IoV, healthcare, and smart cities. The research design was literature review that categorized the approaches into resource management, privacy, and security. The results indicated that FL enhances privacy but lacks in data heterogeneity and device limitations. This solution cannot be used as it has to be decentralized in terms of coordination and is not compatible with a centralized lightweight gateway-based solution.

The authors of the study in [30] reviewed the application of Federated Learning (FL) to enhance cybersecurity in IoT. They tackled data privacy and centralized processing through collaborative detection without transfer of raw data. The research design was a theoretical analysis of FL architectures. They talked of accuracy, communication overhead, and convergence time, with comparable accuracy to centralized models with less bandwidth. The results indicated weaknesses like susceptibility to poisoning attacks and expensive communication. Your problem is not well addressed using this solution as the solution is based on a distributed training process as opposed to a centralized lightweight gateway-based solution.

In the study by Li and et al. [13] they made a survey of Edge Computing within the Internet of Everything (IoE) was conducted. They also resolved the problem of latency, bandwidth, and privacy of cloud-based processing, demonstrating that edge computing decreases latency. The research design was a literature review with no experimentation. The results indicated that edge computing lowers the latency but presents a set of problems including resource limitations and security control. This is not helpful to your problem as it is a theory overview and does not offer a practical access control algorithm or behavior-based security.

The researchers in [1] performed an IoT security, privacy and trust review. They talked about scalable middleware gaps, secure data management, and authentication gaps. A literature review that categorizes security challenges was used as the methodology. The results revealed the absence of lightweight and single security models. This does not apply as it is a descriptive survey and does not give a practical implementation to be applied to real-time blocking at the gateway.

H. Access Control and Authentication Mechanisms in IoT

Within the framework of this general survey [31], The researchers analyzed the use of blockchain with IoT to enhance access control. Among the problems that they solved were centralized control and single point of failure, which sought to have a decentralized structure. The research design was a survey that reviewed and classified blockchain-based solutions. The results of the study was revealed that blockchain enhances security but bring with latency and computational overhead. Your problem does not fit this solution, as it is both a heavy and decentralized scheme with delays, and is not suitable to a lightweight real-time gateway design.

The researchers in [32] delivered a lightweight authentication system to smart home devices with resource-constrained capabilities. They dealt with big computational cost and attacks like replay attacks and man-in-the-middle to facilitate secure communication at low energy consumption. The security analysis and performance comparison methods were used. They compared the cost of computation, the cost of communication and the energy consumed, which demonstrated a lower cost at the expense of security. It is not a valid solution as it remains an authentication protocol and does not deal with post-authentication behavior or compromise devices identification.

The researchers in [33] have developed an access control model of Electronic Healthcare Systems based on trust. They dealt with the dynamic control of access by calculating the trust score using user behavior. The technique involved user behaviors to modify trust and access privileges. They tested the success rate of access, time to compute trust and penalties to behavior. The findings demonstrated that the model is able to adjust to changes in behavior. This does not fit as it is human user-based and complicated computation of trust, rather than device behavior at a real-time IoT gateway.

I. Lightweight and Edge-Based Security Solutions for IoT

As the researchers state [34], the multimedia traffic of IoT is suggested to be provided by the so-called media-aware security architecture. To solve this trade-off between security and QoS they adjusted security according to delay and jitter. The testbed methodology involved a delay, jitter, packet loss and throughput simulation testbed. The findings demonstrated better adaptive security QoS. This does not apply as it prioritizes multimedia traffic and sacrifices security in favor of QoS rather than providing a strict security enforcement of the general IoT devices.

The researchers in [21] suggested an inexpensive flow-based security architecture of smart home IoT devices. They modeled the behavior of devices based on network traffic without deep packet inspection. The method involved actual traffic of the IoT devices to create typical behavior patterns. They tested the accuracy of classification and the accuracy of anomaly detection. The findings indicated that IoT devices are easy to profile and their traffic is predictable. This is not a solution as it is a passive monitoring tool and does not give automated access control to prevent malicious devices (Table I).

J. Summary of Gaps Identified

The current literature is characterized by the following limitations:

- The majority of solutions revolve around detection and not prevention.
- ML-based IDS are not always coupled with access control.
- IoT gateways cannot support heavy deep learning models.
- Behavior-based authorization that is real-time is poorly explored.

These loopholes are the direct inspiring factors of the proposed behavior-aware access control framework that brings together the lightweight ML with real-time enforcement of authorization at the IoT gateway tier.

TABLE I. ANALYSIS OF RELATED STUDIES

Ref	Year	ML/DL Models	Dataset	Results	Key Findings	Limitations
[4]	2021	Decision Tree, Random Forest	Smart Home / IoT Traffic	High accuracy; offline analysis	Effective for smart home and city profiling	Offline analysis only; no real-time integration
[3]	2021	LSTM (Deep Learning)	IIoT Traffic	High detection accuracy	Suitable for large-scale IIoT	Cloud dependency; high latency
[10]	2021	Isolation Forest (Unsupervised)	IoT Traffic	Effective anomaly detection	Works well for unseen DDoS attacks	Independent IDS; cannot prevent attacks
[9]	2021	CNN + RNN (Hybrid DL)	Healthcare / Industrial IoT	High detection rates	Good performance in heterogeneous IoT	High complexity; no adaptive revocation
[13]	2022	Lightweight ML + Edge Intelligence	IoT Edge Traffic	Reduced response time	Scalable edge-based security	Detection and access control are separate
[23]	2022	Statistical Trust Scoring	Healthcare IoT	Improved authorization decisions	Trust-based decisions enhance insider resistance	Historical data only
[15]	2021	Clustering-based ML	IoT Traffic	High flexibility	Effective for unknown anomalies	High false positives; no ACL feedback
[30]	2021	Edge Traffic Filtering	IoT Gateway Traffic	Reduced backend load	Efficient local filtering	Signature-based; not adaptive behavior
[36]	2022	Distributed Edge Authorization	IoT Edge Networks	Lower latency	Effective low-latency access control	Static policies; no behavioral scoring
[40]	2020	Lightweight Authentication	IoT Devices	Preserved battery life	Efficient initial handshake	No post-authentication anomaly handling
[17]	2021	Ensemble ML Models	IoT Traffic	Increased detection accuracy	Reduced classification errors	Computationally heavy
[16]	2020	Distributed Deep Learning	IoT / Botnet Traffic	Improved botnet detection	Localized edge learning benefits detection	Complex models; high compute requirement
[1]	2020	Survey / Theoretical Analysis	N/A	Identified security challenges	Highlights trust and privacy gaps	No implementation/testing
[2]	2020	Deep Learning + Big Data	IoT Traffic	Improved detection metrics	Useful for large-scale IoT traffic	High resource usage; cloud reliance
[5]	2021	ML-based Botnet Detection	IoT / Mirai Traffic	Accurate botnet detection	Recommends future research directions	Reactive approach; no adaptive access control
[6]	2021	ML + MEC Framework	IoT Traffic	Efficient anomaly detection	Edge-level anomaly detection	Limited dynamic access control integration
[7]	2021	Botnet Pattern Analysis	IoT Networks	Detection of Mirai variants	Highlights IoT network threats	Detection only; no adaptive enforcement
[8]	2021	CNN + RNN Supervised Learning	IoT Traffic	Improved detection	Good for heterogeneous IoT	Centralized; heavy computation
[11]	2020	Cluster-based Isolation Forest	IoT Traffic	Efficient anomaly detection	Works without labeled data	No access control integration
[12]	2022	Lightweight ML at Edge	IoT Edge Traffic	Reduced latency; privacy preserved	Edge-level enforcement feasible	Detection and access control disconnected

V. METHODOLOGY

A. System Architecture Overview

The suggested system is based on the gateway-centric security architecture where all the interactions with the IoT devices are facilitated by a centralized gateway. The gateway can be used as the point of enforcement of authentication, behavior monitoring, anomaly detection, and access control. In this design, the computational load on IoT devices with limited resources is reduced, and real-time security decisions are made near the network edge.

It is composed of four closely coupled modules: 1) authentication, 2) behavioral monitoring, 3) lightweight ML-based anomaly detection and 4) access control enforcement. Devices are constantly checked after successful authentication and their behavior is assessed with the help of the lightweight anomaly detection model. ML model output has a direct impact on making decisions on authorization, which enables the system to enable and limit or deny access dynamically as shown in Fig. 4.

Designing these elements at the gateway can help the system to avoid the latency and privacy problems that come with cloud-based intrusion detection but at the same time, the detected anomalies are immediately converted to enforcement measures.

B. IoT Network and Gateway Model

The IoT network model presupposes the communication between a number of heterogeneous devices and a single gateway through the REST-based communication. Devices can initially register and identify to the gateway through a unique device identifier and a shared secret. When a device has been successfully authenticated, it is first assigned full access permissions and behavior monitoring is then initiated [28].

The gateway stores state data of each device, such as authentication status, access level, and history of recent interaction. The gateway becomes the only access control decision maker since all device requests are funnelled through it. This model of a centralized gateway is representative of a real-life IoT implementation that is usually used in smart home, industrial, and healthcare settings [1], [24].

The gateway also determines the various access levels, which include full, restricted, and blocked and are related to a predetermined list of authorized endpoints. This allows the capabilities of devices to be easily controlled to fine grains and also enables the gradual decrease of capabilities instead of abrupt disconnection to enhance system robustness and usability.

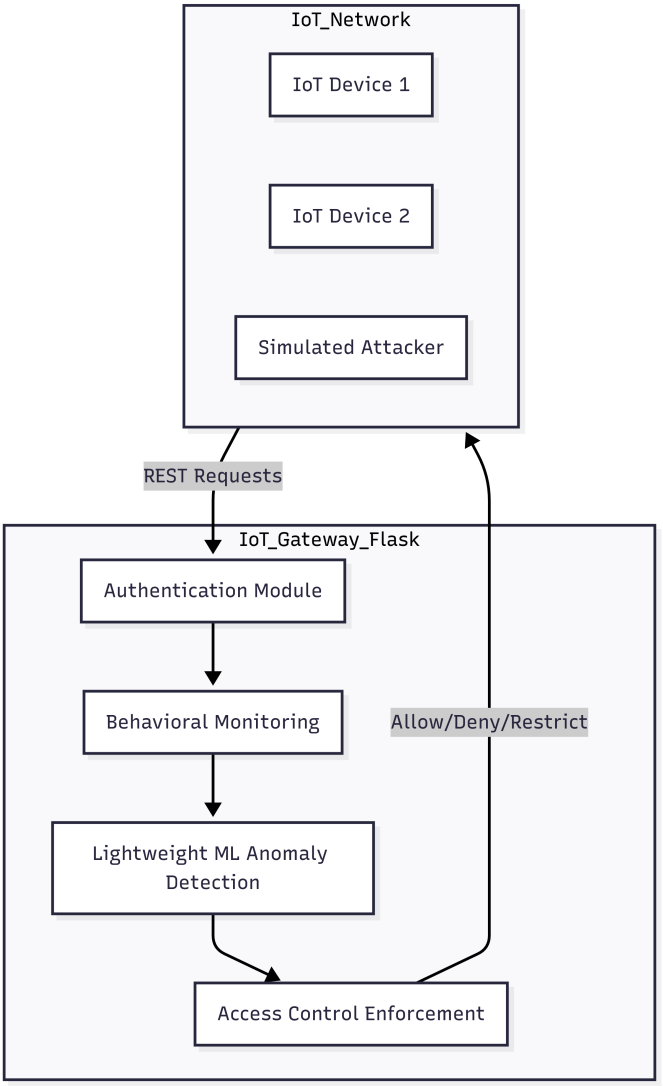

Fig. 4. Gateway-centric behavior-aware access control architecture.

C. Extracting Behavioral Features

In order to deal with the heterogeneity of IoT traffic, in which different sensors (e.g., thermostats, GPS trackers, Modbus devices) produce radically different data payloads, the system no longer inspects raw payloads, instead promoting statistical summarization. A fixed dimension 5-dimensional feature vector is obtained, such that each row or data window processed by the gateway is described by the current behavioral state of the device. [35], [36].

These features are: As can be seen in the analysis of the ToN-IoT dataset, they are:

- Mean: The arithmetic mean of the numeric values in the telemetry row which gives a baseline of the signal magnitude.
- Standard deviation (std): Indicates the degree of volatility or stability in data stream. Large deviations can be associated with unpredictable behavior as found in flooding attacks or malfunctioning sensors.
- Range: The maximum value less the minimum value and is used to measure the spread of the data.
- Median: The center of interest of the data used to reduce the skewing effect of the outliers.
- Non-zero Ratio: Fraction of the values in the row that are non-zero. This sparsity measure is important in detecting attacks that either flood the fields with zeros or, alternatively, flood the otherwise empty fields with data.

It is a 5-D representation scale of the input to the ML model, so that the computational cost of extracting the features is low irrespective of the type of device.

D. Lightweight Supervised Model Selection

The detection engine is a supervised random forest classifier at its core. It was chosen instead of unsupervised Isolation Forests because there are labeled data (Normal vs. Attack) in the ToN-IoT dataset which enables the system to learn particular limits of deviant behavior, as opposed to mere outliers. [25]. The pipeline of training is as follows:

- Data Loading: The system loads the ToN-IoT training set, a non-homogeneous set of datasets that consists of IoT and Network datasets.
- Preprocessing: The training data is then preprocessed using a StandardScaler to normalize the 5-D feature vectors, so that those with larger values (such as the one labelled Range) do not dominate the learning mechanism.
- Training: The Random Forest classifier is trained by the entire labeled data (28706 normal samples and attack samples). The model is trained to estimate the non-linear association among the 5 statistical features and the binary class labels (0: Normal, 1:Attack).
- Serialization: The trained model and scaler are pickled (serialized) to be deployed on the Flask gateway, which allows inference times of sub-milliseconds in live mode.

E. Data Loading and Preprocessing

The system relies on the ToN-IoT benchmark dataset that includes the files of IoT telemetry and network traffic in CSV. In order to deal with heterogeneity of these sources, there is a strict filtering procedure based on numbers only.

- Column Filtering: Non-numeric values, e.g., timestamps, IP addresses, and protocol strings, are filtered out so that the model is lightweight and geared to statistical behavior.
- Data Cleaning: Raw data is purged by removing the whitespace and standardizing the decimal separators.
- Null Handling: Null values or invalid placeholders are represented as 0.0 to have a continuous numeric vector per row.

F. Statistical Feature Engineering

Each cleaned telemetry row or data window is converted to a fixed 5 dimensional feature vector containing the mean, standard deviation, range, median and ratio- where a data row is not all zeros. See Section V-C for details. The goal of this subsection is to avoid duplication, so it only discusses the impact of the previously defined representation on the post-pre-processing. The cleaned numeric values are converted to a standard 5-D feature space, and no matter how many numeric features the data source of each IoT contains, the dimensions of the resulting matrix are all the same, which can be used for scaling and classification using Random Forest.

G. Model Training and Scaling

The pipeline of learning under supervision transforms the processed 5-D vectors to a labeled training dataset on Fig. 5 showing all steps of implementation including the 5-D vectors as part of feature engineering.

- Normalization: A `StandardScaler` object is applied to the feature matrix X, so that all five statistical features are in a similar range. This ensures that features with larger ranges do not dominate the learning process.
- Random Forest Training: A supervised Random Forest classifier is trained on 28,706 normal and attack samples to learn the non-linear boundaries between benign and malicious behavior.
- Model Serialization: The trained model and scaler are pickled (`anomaly_model.pkl`) to be deployed in real-time into the Flask-based gateway.

H. ML and Access Control Mechanism Integration

The major contribution of this study is that there is a close link between ML-based anomaly detection and access control enforcement. In contrast to the conventional IDS models that are put in place separately, the anomaly score generated by the ML model directly changes the level of authorization of the device [21].

There are two threshold values, which are used to categorize behavior as normal, suspicious, and malicious. Normal devices are not restricted, whereas suspicious devices get access but with limited permissions and rate limits. A gateway is accessed to block unscrupulous actions and revoke access immediately.

This integration will provide the security responses to be proactive and automated that reduces the time frame of attack and removes the aspect of manual intervention. The system directly incorporates intelligence into the authorization pipeline to provide behavior-sensitive access control which can be used in real-time IoT contexts.

VI. Experiment Preparation and Findings

A. Simulation Environment and Tools

The proposed behavior-aware access control framework was experimentally tested with the help of the simulated IoT setting in Python. The simulation was created in a way that it was modeled after real-life gateway-based IoT deployments, whereas the behavior of each device and attack situations could be fully controlled.

TABLE II. ToN-IoT Dataset Specifications: Rows, Raw Columns, and Feature Extraction

Dataset Component	Max Rows	Raw Cols	Numeric Cols	Final Features
IoT Fridge	15,000	6	2	5
IoT Garage Door	15,000	6	2	5
IoT GPS Tracker	15,000	6	2	5
IoT Modbus	15,000	8	4	5
IoT Motion Light	15,000	6	2	5
IoT Thermostat	15,000	6	2	5
IoT Weather	15,000	7	3	5
Network Traffic	15,000	44	∼23	5
Combined Dataset	**120,000**	**Varies**	**Varies**	**5 (Fixed)**
Normal Samples (Train)	28,706	–	–	5
Total Samples (Eval)	120,000	–	–	5

The IoT gateway was deployed on Flask framework in which the framework presented RESTful APIs to allow level of registration of devices, authentication, processing of requests and implementing access control. NumPy and scikit-learn libraries were used to provide lightweight ML and data processing. Supervised Random Forest algorithm and normal feature scaling methods were used in detecting anomalies. Other tools like matplotlib were employed in visualising the results and in analyzing performances.

The experiments were performed on a normal computing platform without any hardware accelerations, and the fact that it was possible to run the suggested system on devices with limited resources indicates the presence of IoT gateways that can be used to implement the system. This toolchain represents the software elements that are found in the real-world IoT edge settings [13].

B. Dataset Specifications

The framework utilizes the ToN-IoT benchmark dataset, which contains heterogeneous telemetry from diverse IoT sources and network traffic. To ensure a balanced and representative training environment, the system processes seven distinct IoT device logs and one comprehensive network traffic dataset.

As the IoT devices produce varied data payloads (e.g., temperature vs. Modbus registers), a strict numerical extraction policy is applied. Categorical fields such as IP addresses, protocol strings, and timestamps are excluded to focus the model on statistical behavior. Table II provides the detailed specifications of the rows and columns processed from each source.

1) Data processing and dimensionality reduction: Regardless of the original number of numeric columns (ranging from 2 in simple sensors to 23 in network traffic), every raw row is mapped to a standard five-dimensional (5-D) feature space. This ensures interoperability across the gateway. The mapping process involves cleaning missing values (replacing them with 0.0) and calculating the five summary statistics: mean, standard deviation, range, median, and non-zero ratio.

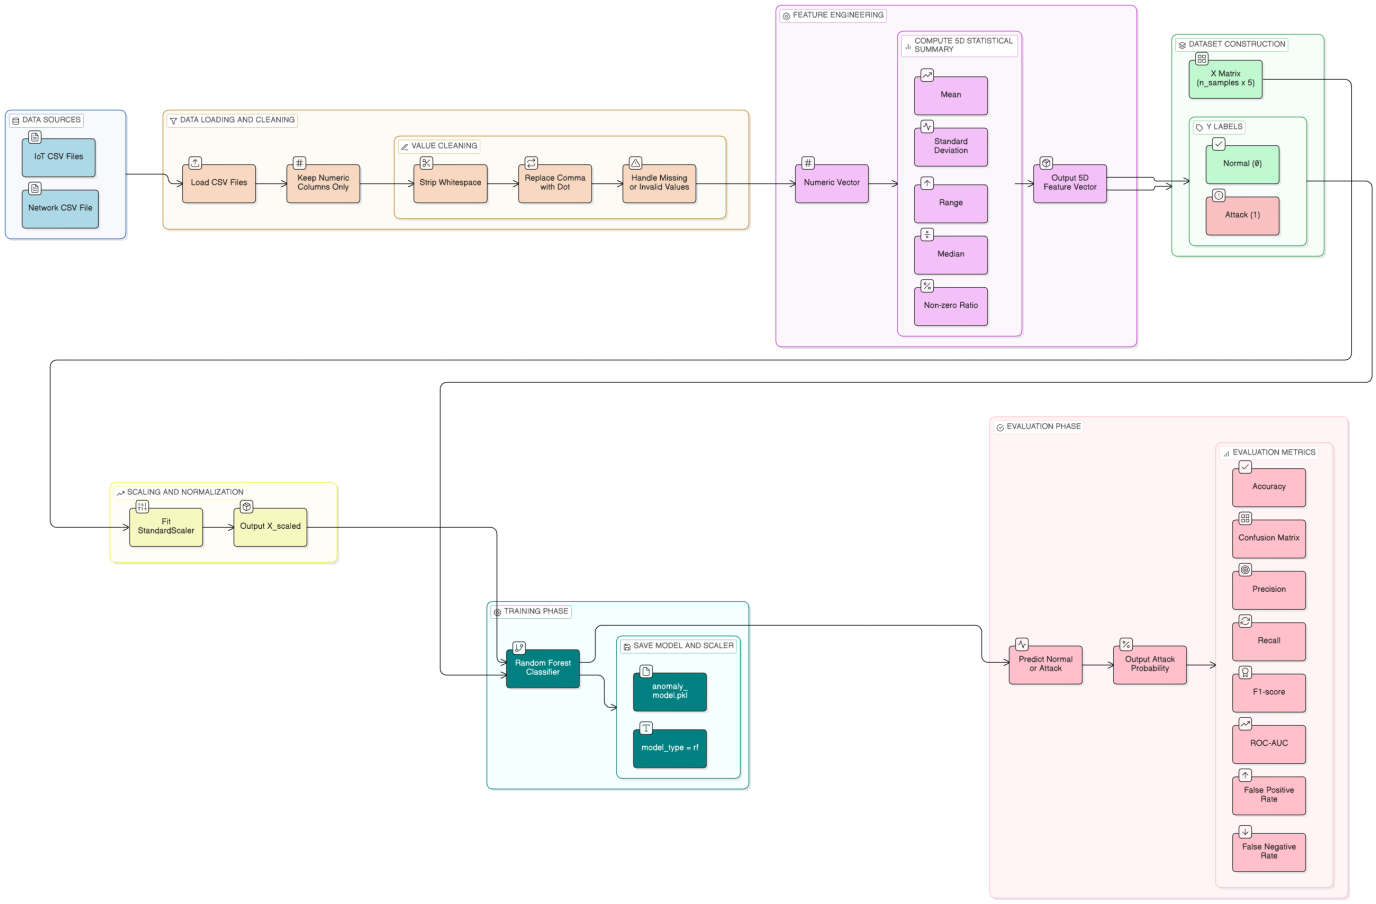

Fig. 5. End-to-end supervised random forest training pipeline: From raw ToN-IoT data loading and 5-D statistical feature engineering to model serialization and evaluation.

C. Dataset and Experimental Setup

The use of the ToN-IoT dataset as the ground truth to prove the performance of the system in a realistic threat scenario was applied. This dataset has been widely known in determining attacks in heterogeneous IoT networks [37].

- Training Phase: It was trained on a smaller set of samples where it involved 28,706 normal samples and attack samples where the Random Forest was able to develop a full spectrum of a decision boundary.
- Evaluation Phase: The system was assessed with regard to a separate assessment set of 120,000 total samples. Such a large-scale test was rich in diverse attack types (e.g., DoS, DDoS, scanning, and ransomware) and non-attack traffic, which was a stringent stress test of the classifier.

D. Performance Metrics

The proposed system was tested in terms of several performance measurements to measure the performance in detection and the feasibility in practice. To identify the general correctness of the anomaly classification, detection accuracy was measured. The trade-off between false positives and false negatives, especially with regard to detecting malicious behavior, was determined by computing precision, recall and F1-score.

Furthermore, receiver operating characteristic (ROC) analysis and area under the curve (ROC-AUC) to measure the capability of the model to differentiate between normal and abnormal behavior at various threshold values were also applied. The confusion matrix analysis was used in order to obtain the true positive, false positive, true negative and false negative rates.

To gauge the level of practical suitability, the response time and the computational overhead were also monitored qualitatively, with respect to the capability of the gateway to handle requests and make access decisions in real time. Such metrics can be considered an overall assessment of the effectiveness of security and efficiency of the systems [8].

E. Results and Analysis of the Experiment

Findings and Discussion The system performance was evaluated with the help of the standard classification metrics, and it was found that the system has a peculiar zero-trust security profile.

- Accuracy and Overall Performance: The model has a total Accuracy of 81.17% over the 120, 000 samples

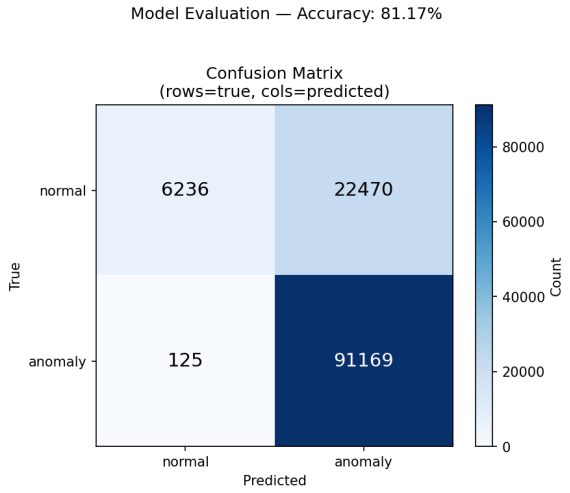
of evaluation. Although this is a competitive accuracy, the distribution of errors (False Positives vs. False Negatives) is the most important observation that is necessary in a security application.

- Recall: Zero-one anomaly-class recall of 99.86% was obtained by dividing the number of correctly detected attack samples by the total number of attack instances, which were 91,169 and 125, respectively. It is reported with two decimal places throughout the manuscript, but is rounded to 1.00 for the purpose of discussing the value of this determination. This result confirms that the framework is able to identify almost all the attack samples evaluated and that any false negative results should not be interpreted as a result of complete or perfect attack detection.
- Precision and False Positives: The precision in the anomaly classes was 0.80. The confusion matrix is reporting 22,470 false positives, which means that there were many more legitimate samples that were incorrectly identified as anomalous. This is a situation with a security conservative operating point, a situation in which the model is security-oriented, meaning that it minimizes false negatives while allowing for more false alarms. In real-world IoT implementations, these false positives can temporarily deny access to legitimate devices, delay telemetry reporting, burden the operator's workload, and decrease the trust in the access control system by the user. To alleviate this effect, anomalous cases with low confidence should not be blocked outright but instead should be placed in a limited-access mode; device-specific thresholds, periodic retraining, whitelisting of safety-critical telemetry, second-stage verification can be employed to minimize unnecessary disruptions.
- ROC-AUC: The model has a ROC-AUC score of 0.82, which represents a profound capacity to arrange randomly selected positive examples higher than negative one.

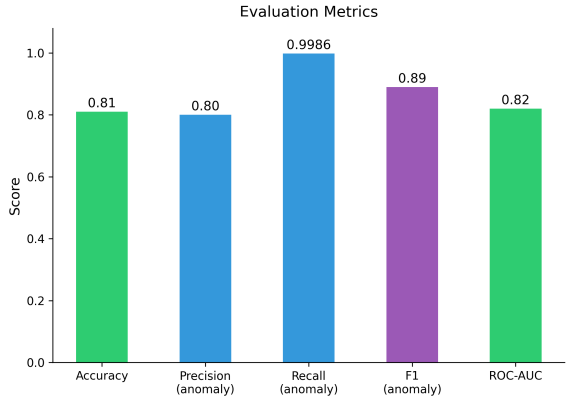
On Fig. 6 illustrates the confusion matrix and the main performance metrics, including accuracy, F1-score, and ROC-AUC.

Operationally, the enforcement of access controls was implemented as soon as an anomaly was detected to prevent the rapid restriction or revocation of device permissions. The model was lightweight and, therefore, provided low computational cost and insignificant effects on the response time of gateways. These findings confirm the feasibility of deploying lightweight ML at the gateway level with the access control and makes sure that the offered framework meets the security-efficiency balance [34].

The evaluation was conducted through a controlled execution script designed to stress the gateway across four distinct phases. First, baseline latency was established using 25 sequential requests from a single device with a 0.1s delay to capture the minimum, maximum, and average processing times reported by the gateway. Second, "Normal Operation" metrics were gathered by simulating 5 devices under a round-robin load for 10 seconds, alternating between standard requests and



(a) Confusion matrix of the random forest model.



(b) Performance metrics (Accuracy, F1-Score, ROC-AUC).

Fig. 6. Evaluation results of the random forest model.

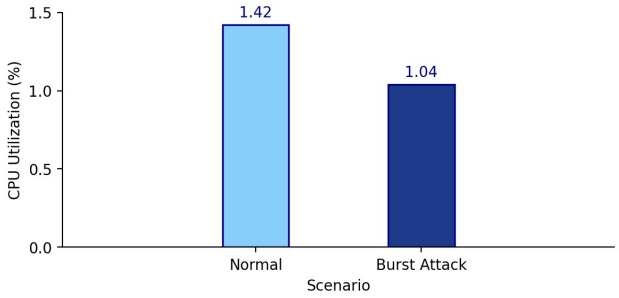


Fig. 7. CPU Utilization under normal vs. burst attack scenario.

administrative status checks. Third, a "Burst Attack" scenario was emulated by a single device issuing 150 requests at high frequency (0.02s intervals), with CPU and RAM samples recorded every 10 requests. Finally, scalability was tested by registering varying device counts (n=1,5,10,20,50) and calculating the average gateway-reported latency across 10 requests per device. These metrics were then combined into a JSON object, which was then processed to create the CPU-utilization, memory-usage and average-processing-latency visualizations

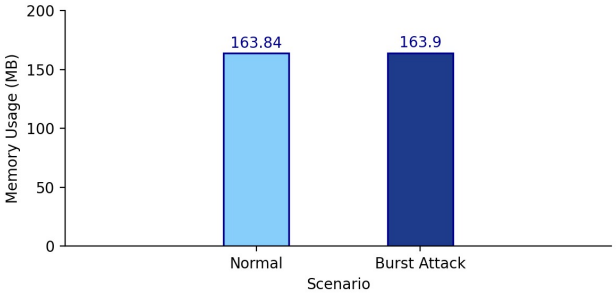

Fig. 8. Memory usage under normal vs. burst attack scenario.

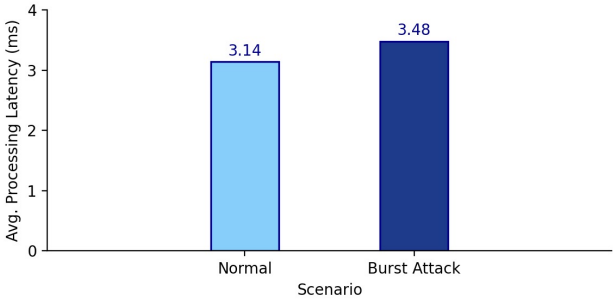

Fig. 9. Average processing latency under normal vs. burst attack scenario.

TABLE III. GATEWAY COMPUTATIONAL OVERHEAD: NORMAL VS. BURST ATTACK

Metric	Normal Operation	Attack Scenario
CPU Utilization (%)	1.42%	1.04%
Memory Usage (MB)	163.84 MB	163.90 MB
Avg. Processing Latency	3.14 ms	3.48 ms (est.)

displayed in, respectively, Fig. 7, 8, and 9. The computation overhead is summarized in Table III both for normal and burst-attack conditions.

F. Advanced Scenarios and Scalability Evaluation

To further assess the robustness and real-world deployability of the proposed behavior-aware access control framework, additional experiments were conducted focusing on large-scale deployments and adversarial attack strategies. These scenarios address the ability of the gateway to 1) scale to hundreds of concurrently connected IoT devices and 2) defend against "smart" attackers that attempt to evade anomaly detection by mimicking normal request rates.

1) Simulation scaling with 500+ virtual devices: A large-scale simulation was executed to evaluate whether the gateway can sustain high device counts while maintaining low latency and stable performance. In this experiment, 520 virtual IoT devices were registered and authenticated at the gateway. Each device issued two legitimate requests to an authorized endpoint, resulting in a total of 1,040 requests processed during the run.

The objective of this scenario was to measure scalability-related indicators, including successful request handling, access denials, processing latency, and gateway resource usage.

TABLE IV. SCALING RESULTS FOR 500+ VIRTUAL DEVICES

Metric	Value
Virtual devices	520
Requests per device	2
Total requests	1,040
Successful responses (200)	1,040
Denied responses (403)	0
Other errors	0
Average latency (ms)	1.68
Latency samples	1,040
Gateway CPU usage (after run)	0%
Gateway memory usage (MB)	164.44

TABLE V. DETECTION RATES FOR MIMICRY ATTACKS (NORMAL RATE, UNAUTHORIZED ENDPOINTS)

Attack Scenario	Endpoint Targeted	Requests Sent	Detected (403)	Rate (%)
Mimicry: normal rate	/admin/train	25	25	100
Mimicry: normal rate	/admin/delete	25	25	100
Mimicry: normal rate	/internal	25	25	100
Mimicry: normal rate	/system	25	25	100
Mimicry: normal rate	/root	25	25	100

All requests in this scenario corresponded to normal behavior and authorized access patterns.

Table IV illustrating the results demonstrate that the gateway successfully handled over 500 concurrent devices and more than 1,000 requests without any access denials or errors. The average processing latency remained below 2 ms, indicating that the integration of behavioral monitoring and lightweight ML does not introduce significant overhead even at scale. These findings confirm the suitability of the proposed framework for deployment in medium- to large-scale IoT environments.

2) Adversarial evaluation mimicry attacks: In addition to the scalability, the framework was tested in mimicry attacks listed in Table V. This is a more sophisticated attack where an adversary mimics the attributes of normal traffic patterns (including frequency and timing), and establishes a connection with an untrusted endpoint.

In this scenario, attackers issued requests at a normal rate (one request every 0.5 seconds) but targeted forbidden administrative and internal endpoints. The detection objective was to verify whether the gateway could prevent unauthorized access even when behavioral patterns appeared benign. Importantly, these attacks are expected to be blocked primarily by access control policy enforcement, rather than anomaly score thresholds alone.

In all the evaluated mimicry scenarios, all the unauthorised requests made against the endpoints selected for the Gateway were denied by the Gateway with a HTTP 403 response. It's important to keep in mind that this result is based on the endpoints tested, the number of requests, and the access-

control policies applied. It demonstrates that in such cases, the attackers were not able to avoid the system simply by mimicking the legitimate request timing for access to explicitly forbidden resources.

3) Discussion: The advanced evaluation confirms that the proposed system scales effectively to hundreds of devices while maintaining low latency and minimal resource consumption. Furthermore, the mimicry attack results demonstrate resilience against sophisticated attackers who attempt to evade anomaly detection by imitating legitimate behavior. Together, these findings reinforce the practicality of deploying the framework in real-world IoT environments, where both scalability and adversarial robustness are essential requirements.

VII. Challenges and Techniques

A. Resource Constraints at the Gateway

IoT gateways have limited computational and memory resources in comparison to cloud servers. Their tasks include authentication, protocol translation, traffic forwarding, and enforcement of security policies, often under strict real-time constraints. Deploying ML-based security mechanisms at this level is therefore challenging, particularly when low latency is required [2].

To address these constraints, the proposed framework employs lightweight feature extraction and a computationally efficient anomaly detection model. The behavioral features are derived from simple statistical properties of request activity (e.g., request frequency and endpoint access patterns) rather than deep packet inspection or payload analysis. These features are consistent with those available in widely used IoT security datasets, such as the ToN_IoT dataset, which emphasizes telemetry and flow-level characteristics suitable for resource-constrained environments.

Furthermore, the system avoids frequent retraining and reliance on large labeled datasets. The Random Forest model operates in a supervised manner and is trained primarily on normal behavior derived from the ToN_IoT dataset, resulting in lower memory usage and reduced computational overhead. This design ensures that continuous security monitoring does not interfere with the gateway's primary networking functions.

B. Model Accuracy vs. Computational Overhead

One trade-off inherent in the IoT security systems is the trade-off between the accuracy of detection and the cost of computation. As high-accuracy models can be trained with the aid of complex deep learning models, this is usually not feasible in resource constrained gateways because the training and inference is expensive [9].

The proposed system is focused on feasible deployability, whereby it is chosen to select a lightweight anomaly detection model that is both accurate enough with an acceptable overhead. More so, feature scaling and model inference are carried out efficiently and real-time assessment of each device request is possible. Even though lightweight models might not be able to measure very sophisticated attack patterns, the experimental findings suggest that they could be used to identify common post-authentication anomalies with low latency. This trade-off is reasonable in the case of enforcement of the gateway level, where the response timeliness is of great importance and the marginal accuracy gains are not always so important.

C. Dealing with Concept Drift in Behavior of Devices

The IoT device behavior can change with the passage of time because of the change in application requirement, update of firmware or the condition of use. Changes like a concept drift may make the behavior occurred earlier in normalcy to seem drastic hence producing false positives [3].

To overcome the above issue, the proposed framework will accommodate the re-training process periodically with verified benign behavior gathered at the gateway. The system can adapt to the gradual changes in behavior, while still recognizing the sudden or extreme changes. But retraining needs to be carefully done so that the animals do not become poisoned or learn bad habits. Therefore, on the borderline cases, it is recommended to manage them temporarily by giving restricted access instead of blocking them immediately, minimizing the operational impact of false alarms, while maintaining the security.

D. Security and Robustness Issues

Although the suggested framework improves the security of IoT by enforcing behavior-based access control, various issues of robustness still exist. The enemies can strive to imitate normal behavior so as to escape detection of anomaly or they could progressively adjust their behavior so as not to cause thresholds. Also, there are such attacks as poisoning against the training data, which may adversely affect the performance of the models [6].

To overcome such issues, the system restricts training of models to the times when they are confirmed to be operating benignly and limits administrative access to training functionality. The selection of the behavioral features is aimed at capturing many dimensions of interaction with the device and thus increasing the challenge to the attacker to avoid detection across all dimensions at the same time. Even though improved adversarial attacks are a research problem, the suggested design offers a viable and robust base to the defense of security by the gateway [38] [26].

E. The Security vs. Usability Trade-off

The results show that there is a clear compromise between recall (to avoid missing attacks) and precision (to affect operational usability). The proposed Random Forest implementation focuses on the anomaly-class recall and obtained unrounded anomaly-class recall at 0.9986. A critical infrastructure or industrial Internet of Things application may be able to tolerate this preference due to the potential cost of a missed attack being greater than the cost of a false alarm. However, the design decision should be carefully interpreted as high false positive rate may have an impact on the legitimate IoT operation.

Many samples were considered to be anomalous given the operating threshold and are reflected in the number of false positives, which was 22,470. In reality, this can result in a delay to legitimate device communication, alert volume or temporary denial of access for devices with abnormal but benign activity, for example sensors that do not read smoothly, but read bursts during a change in environmental conditions. Therefore, a

production deployment must have a staged response: low-confidence anomalies should be blocked in restricted mode and only high-confidence malicious behavior should be blocked immediately. Other mitigation measures are device specific baselines, calibration of thresholds, review by an administrator for 'borderline' cases, whitelisting of safety-critical endpoints, and retraining periodically with verified benign data.

VIII. Proposed Behavior-Aware Access Control Framework And Evaluation

A. Authorization Workflow Behavior-Aware

The suggested behavior-sensitive authorization protocol is a continuation of conventional IoT access control implemented with the evaluation of continuous behavior analysis following authentication. After a successful authentication at the gateway, a device receives an initial access level, and it is put under the close supervision. A request by the device made after a certain behavior is utilized to create a new behavioral profile indicative of real-time operational properties [39].

Behavioral characteristics are derived out of recent interactions with the device and sent to the lightweight anomaly detection model. A scoring on the resulting anomaly is the extent of deviation of the learned normal behavior. This score is then instantly translated to the authorization decision, which allows the system to dynamically change access privileges. The proposed workflow will establish a continuous reassessment of trust in the authorization pipeline instead of presumed forever by embedding behavior analysis within it [4].

The interaction between the IoT device, gateway and the ML model are illustrated in Fig. 10 for real-time authorization. A REST request is received by the gateway and behavioral features are extracted from the request and sent to the trained ML model. The anomaly score is then sent back to the gateway and correlated with an authorization decision, such as allow, restrict, or block.

B. Enforcement of Real-time Access Control

One of the distinguishing characteristics of the proposed system is the possibility to impose decisions in access control in real time. The proposed framework is also able to implement changes in authorization immediately an authorization change is detected unlike conventional intrusion detection systems that only send out alerts without implementing changes in authorization.

Devices with normal behavior are allowed to access all the authorized resources whereas suspicious devices are redirected into restricted access mode with restricted endpoint accessibility and reduced request rates. Gates ban the access of devices that are classified as malicious at the gateway. Such a graduated response mechanism reduces the impact of legitimate devices as well as facilitates the quick containment of the potentially dangerous devices.

The enforcement logic is directly applied at the gateway whereby every request is assessed and governed without involving any services. This design also contributes greatly to speed of response and allows to mitigate threat proactively in IoT environments that have latency constraints [13].

C. Comparative Study to Traditional Approaches

The proposed framework has significantly better resilience to post-authentication attacks compared to the conventional identity-based access control systems. The existing authorization models cannot react to the corrupted machines that are authorized after a credential is proven, but the proposed system can constantly modify the access privileges in accordance with observed behavior [31].

Unlike cloud-based intrusion detection systems, a lightweight ML implementation in the gateway level minimizes the communication overhead as well as conserves the privacy of the data and yields quicker enforcement measures. Even though deep learning-based methods can be used to perform better when detection rates are high and in a controlled environment, their computational costs and lack of connection with access control make them impractical in enforcing security in real-time IoT settings [29].

In general, the suggested framework balances security effectiveness, computational efficiency, and deployability, which is why it is more applicable to a real-world Internet of Things than most of the existing solutions.

D. Comparative Performance Analysis and Baseline Comparison

For test purposes, the framework is expanded to include the traditional identity-based access control and cloud-based deep learning IDS systems. The proposed framework is envisioned as a gateway level ML solution, hence a representative lightweight ML IDS baseline is included. This baseline is edge, gateway IDS approaches that are lightweight, do local ML based anomaly detection but not directly link detection results to dynamic access control enforcement.

The proposed gateway-based framework using random forest algorithm is summarized in Table VI with the traditional RBAC/ABAC, the lightweight ML IDS baselines deployed by the gateway and the deep learning IDS approaches deployed in the cloud.

1) Analysis of improvements: The proposed system has achieved 99.86% or 0.9986 Recall (Anomaly Class) instead of 100%. This number gets rounded only to 1.00 if rounding to 2 decimal places. The framework is more advanced than the traditional RBAC/ABAC systems by introducing post-authentication monitoring and dynamic enforcement. Its primary benefit, over its gateway-deployed lightweight ML IDS counterpart, is not only local detection, but the direct mapping of anomaly results to access-control decisions. The framework offers local enforcement with lower latency, which is not possible with cloud-based deep learning IDS based approaches, as it takes an average of 3.14 ms to process the data in the evaluated environment. But, the comparison needs to be taken with a pinch of salt, as datasets and metrics vary between studies, as do deployment assumptions.

IX. Discussion

A. Security Implications

Behavior-conscious ML combined with access control can greatly improve the security of the IoT through post-authentication threats. The proposed system mitigates the

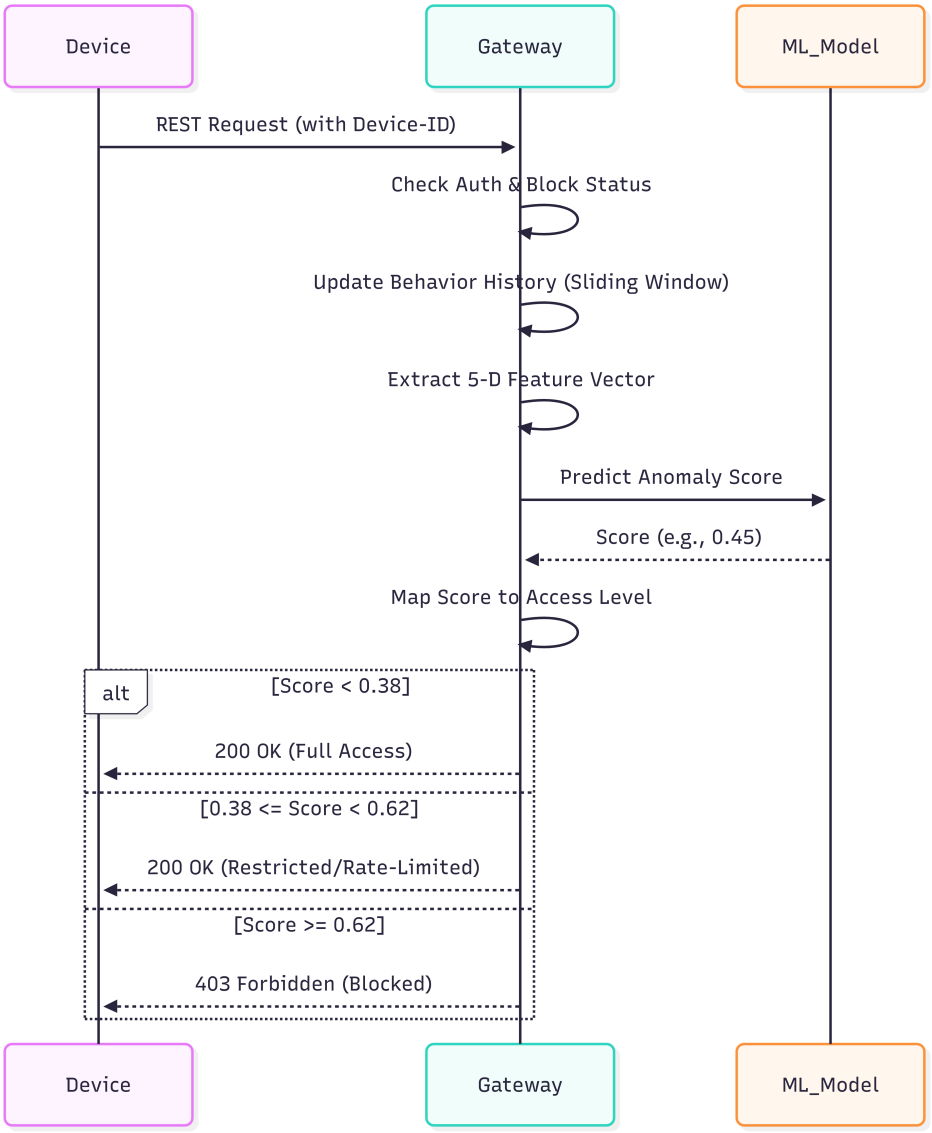

Fig. 10. Real-time request processing and dynamic authorization mapping.

TABLE VI. BASELINE COMPARISON: PROPOSED FRAMEWORK VS. TRADITIONAL, LIGHTWEIGHT ML, AND CLOUD-BASED IDS MODELS

Feature/Metric	**Traditional RBAC/ABAC**	**Gateway-Deployed Lightweight ML IDS Baseline**	**Cloud-Based DL IDS**	**Proposed Framework**
Post-authentication monitoring	None	Passive anomaly monitoring	Passive anomaly monitoring	**Active monitoring and enforcement**
Deployment level	Gateway/local policy	Gateway/edge	Cloud or edge-cloud	**Gateway/edge**
Model type	No ML	Lightweight classifiers such as Decision Tree, Random Forest, or k-NN	CNN, LSTM, DBN, or hybrid DL	**Random Forest plus access-control policy engine**
Detection performance	N/A	High but dataset-dependent; usually evaluated as IDS accuracy/recall only	98.8%–99.5% reported in related work	**99.86% anomaly recall; rounded to 1.00 only at two decimal places**
Processing latency	Low, but no anomaly detection	Low to moderate depending on gateway hardware	High due to cloud transmission and heavier inference	**Very low average processing latency of 3.14 ms in the evaluated setting**
Access-control link	Static	Usually decoupled from access control	Decoupled from gateway authorization	**Tightly coupled with allow, restrict, and block decisions**
Main limitation	Cannot detect post-authentication compromise	Detects anomalies but usually requires separate/manual enforcement	High computational cost, bandwidth use, and privacy concerns	**Higher false positives; dataset-specific validation; requires retraining for concept drift**

threat of insider attacks, credential theft, and compromised nodes because it constantly assesses the conduct of devices [30].

Supervised anomaly detection can help identify malicious behavior that statistically resembles learned attack profiles; however, its ability to detect entirely unseen attacks depends on the representativeness of the training data and the selected behavioral features.

B. Practical Deployability

In a practical sense, the suggested framework is highly applicable to the implementation in the real-world IoT gateways. The ML model and feature extraction are lightweight, which guarantees low computational overhead, and the gateway-centric design makes it easy to integrate the new system with the existing IoT system.

The framework is not dependent on modifying individual IoT devices, which means that it can be used with heterogeneous and legacy deployments. Moreover, gateway-based local processing promotes the concept of privacy by not relaying sensitive behavioral information to other servers [27].

C. Comparison to Cloud-Based IDS Solutions

The cloud-based intrusion detection systems are scalable and have a great computational capability but are affected by the latency, bandwidth, and privacy issues. Conversely, the solution suggested at the gateway level is capable of detecting and enforcing on-the-fly without any connection to the cloud.

Although cloud-based systems can be the right choice in the large scale analytics and long term threat intelligence, the suggested structure fits better the real-time protection and access control implementation. The combination of the gateway-level enforcement and a cloud-based analysis might also be further improved in the future to enhance the security of the deployments [9] [32].

D. Limitations and Threats to Validity

The envisioned framework illustrates a promising behavior-aware enforcement at gateway level, but some limitations must be pointed out. The evaluation is given based on the ToN-IoT benchmark dataset, which is the first one. ToN-IoT also offers heterogeneous IoT telemetry and attack traffic, but does not necessarily contain all real-world deployments, device types, device firmware behaviors or attack strategies. Thus, results reported should be viewed as findings of effectiveness for the evaluated data set and scenarios, and not as general assurances of performance.

Second, the system is based on a fixed five dimensional statistical feature representation (mean, stddev, range, median, non-zero ratio). This representation facilitates lightweight gateway deployment but might lack some protocol-level, temporal, or semantic aspects that are necessary to identify some advanced attacks from atypical device activity. The number of false positives seen in the experiment suggests further refinement of the features or calibration of the devices for production deployment.

Thirdly, the attack concept and patterns change in real IoT environments. Firmware updates, environment changes, new applications or changes in user behavior may alter normal device behaviour. If not retrained at regular intervals, and if the threshold is not adjusted, the model can make false-positive or false-negative errors. Lastly, the experimental gateway was tested in a lab setting, and the framework should be further tested on physical IoT testbeds, multiple deployment of gateways, and extended observation periods.

X. Conclusion and Future Work

This study presented a behavior-aware access control framework by embedding Supervised Random Forest learning into the access control logic for an IoT gateway. The study also demonstrated that the lightweight five-dimensional statistical summaries of the ToN-IoT benchmark dataset can benefit the low-latency edge anomaly detection.The study further confirmed that the five-dimensional statistical summaries of the ToN-IoT benchmark dataset, including mean, standard deviation, range, median, and non-zero ratio, can help with low latency anomaly detection at the edge. The experimental evaluation gave a Recall of 0.9986 (99.86%) on a test set of 120,000 samples and 125 false negatives in 91,294 attack instances, which is an anomaly-class recall. The results should thus be reported as “near-complete detection” for the scenarios considered instead of “perfect” or “universal” attack blocking. The framework illustrates the potential for Zero Trust inspired enforcement on resource limited gateways, without the need for cloud-based deep learning services, however, the false positive results, dependency on a training set, fixed feature representation, and concept drift problems need to be further validated before being deployed in real-world production systems.

The next study will focus on evaluating the proposed framework in a larger scale of IoT, where hundreds or thousands of devices are involved. Scalability issues, including not only higher behavioral diversity but also heavier load on the gateways will be explored to guarantee the stability of performance. Moreover, such approaches as federated learning or online learning might enable multiple gateways to effectively improve their models without needing to share raw data. These could improve flexibility to new threats and privacy as well as minimize centralization of dependencies [40]. Also, the suggested behavior-sensitive authorization model is consistent with the concepts of Zero Trust security. The future could also further integrate with the Zero Trust architectures, where ongoing authentication and least-privilege access are used throughout all the layers of the IoT ecosystem.

***Abstract*—The oil and gas industry continuously evolves to enhance operational efficiency and productivity while minimizing costs and environmental impact. Among the critical aspects of oil and gas operations, drilling efficiency is a key factor in accessing underground hydrocarbon reservoirs. Traditional machine learning models and current regression models have shown limitations in accurately modelling the rate of penetration due to the high nonlinearity of data. This project focuses on the rate of penetration prediction for drilling optimization. This study proposed a new drilling rate of penetration prediction model with the embedding of particle swarm optimization in a gradient boosting regression method. A solution representation of the particle is introduced as a hyperparameter strategy to explore the optimal parameter for predicting drilling datasets. Extensive experiments were carried out using two splitting strategies, One for All and All for One, across the drilling wells. The proposed GBR+PSO hybrid model achieved a mean absolute error of 1.205, representing a reduction of approximately 89.68% compared to the best-performing baseline model, K-Nearest Neighbor with the One for All splitting strategy, which achieved a mean absolute error of 11.68. The hybrid solution could enhance drilling ROP predictions, advancing the drilling rate of penetration strategy. It has the potential to support the development of autonomous drilling optimization, thus contributing to more efficient, reliable, and cost-effective drilling rate of penetration strategies in future drilling operations.**

Keywords*—Drilling; gradient boosting regression; machine learning; rate of penetration; particle swarm optimization

I. Introduction

The oil and gas industry, along with its related sectors, is continually seeking innovative and competitive ways to enhance operational efficiency and productivity [1] [2]. The objective is primarily to minimize costs and reduce the environmental impact. Reaching this objective requires improving processes in oil and gas operations; one of them is the drilling process to estimate and adjust the penetration rate (ROP) [3] [4]. In recent years, demands on the oil and gas sector have continued to increase. However, the cost of offshore exploration and development is very high, especially for hydrocarbon production [5]. The ROP is a a key drilling performance indicator through subsurface formations, regardless of whether the drilling is targeting oil, gas, or any other substance. ROP plays a vital role, serving as a fundamental metric in drilling operations in various industries, primarily in oil and gas exploration [6], geothermal energy production [7], mineral exploration [8], and environmental monitoring [9]. In spite of the critical role of ROP prediction in drilling optimization, understanding how drilling variables influence ROP remains an open question in drilling [10][11][12]. ROP presents a highly nonlinear problem. A lot of efforts had been established as early as a traditional models as such Bourgoyne and Young model in 1974 [13] and until an advanced AI methods [14][17][18].

Despite these significant advancements, existing studies still require further improvement in optimization efficiency, adaptive feature engineering, computational complexity reduction, explainability, robustness against geological variability, and real-time adaptive learning capability for intelligent drilling applications. Although ML has become more popular in drilling engineering, there is still a lack of thorough studies that concentrate on ML and optimization methods for ROP prediction. Therefore, the main aim of this research is to improve the ROP prediction by using a hybrid approach of ML and optimization methods while utilizing the University of Stavanger Rate of Penetration (USROP) dataset as a main resource [19]. Key questions addressed include the necessity of incorporating ROP variables into ML models, the comparative effectiveness of the hybrid approach versus traditional models for ROP estimation, and the utilization of predictive models for optimization purposes. The research questions are:

- How to construct a new proposed model compared to existing machine learning methods in terms of MAE for predicting ROP in drilling operations?
- What is the effect of different training, testing, and validation splitting scenarios on the predictive performance of the proposed model across varying drilling well conditions?
- To what extent does the improved prediction accuracy of the proposed model translate into measurable gains in drilling efficiency, intelligent drilling optimization, and real-time operational decision-making?

This study proposes a hybrid data-driven method to predict ROP by integrating GBR and PSO. Our contributions in hybrid ROP prediction are:

- The study introduces a new GBR+PSO hybrid model for ROP prediction, demonstrating enhanced predictive performance with significantly lower MAE values than existing machine learning methods.
- A thorough training, testing, and validation incorporating MAE analysis and benchmarking, splitting scenario of the drilling well.
- The approach improves drilling efficiency by increasing a significant prediction accuracy across different conditions in intelligent drilling optimization and operational decision-making strategies.

The organization of the study is structured as follows: Section II presents the related work. Section III is dedicated to the preliminaries, which consists ROP optimization and prediction, score metrics and a proposed scenario. In Section IV, the explanation of the material and methods includes the proposed hybrid GBR+PSO method and performance measure. The results and performance evaluations are discussed in Section V and Section VI, respectively, and Section VII concludes the study.

II. Related Work

Recent advancements in ROP prediction have increasingly adopted artificial intelligence (AI), machine learning (ML), and deep learning (DL) approaches to improve drilling efficiency and predictive reliability [20]. Accurate ROP prediction remains challenging due to nonlinear drilling behavior, noisy sensor signals, heterogeneous geological formations, concept drift, and high-dimensional drilling parameters [21][22]. Inappropriate feature selection may introduce redundant variables, resulting in reduced prediction accuracy and poor model generalization [20]. Consequently, recent studies have emphasized intelligent feature selection, adaptive learning, and optimization strategies to enhance prediction performance and real-time drilling capability [21][22]. For instance, Attention Mechanism-enhanced Bidirectional Long Short-Term Memory (AM-BiLSTM) model integrated with Kalman filtering and mutual information analysis for feature selection, where dominant drilling parameters such as weight on bit (WOB), total depth, weight on hook, and flow pumps were identified as significant predictors [20]. Even though AM-BiLSTM model achieved significant improvements in Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Mean Absolute Percentage Error (MAPE) compared to Recurrent Neural Network (RNN), Long Short-Term Memory (LSTM), and BiLSTM-based models, further enhancement is still required to strengthen feature dependency learning capability. In particular, improving adaptive feature representation and model generalization across varying drilling environments remains a critical challenge.

In another research, a hybrid framework combining Fuzzy C-Means, Dynamic Time Warping, Genetic Algorithm, and Extreme Learning Machine, where correlation analysis was employed for feature selection and GA was used to optimize the ELM model under different drilling conditions [12]. The GA-optimized ELM achieved the best prediction accuracy among comparative methods, highlighting the importance of drilling condition identification and optimization strategies for accurate ROP prediction. Furthermore, a hybrid online ROP prediction framework incorporating formation drillability (FD) sensing, Savitzky-Golay filtering, and incremental learning strategies, where the inclusion of FD as an additional predictive feature improved prediction accuracy by at least 19% compared to six existing methods [22]. The similar performance on the optimized LSTM achieved the best overall performance with prediction precision greater than 96.87%, minimum Average Relative Percentage Error (ARPE), MAPE, RMSE, and bias, as well as maximum R^2 performance [10].

III. Preliminaries

A. ROP Optimization Process and Prediction

ROP optimization is possible in numerous ways. Fig. 1 illustrates two general methods for this optimization process on ROP. The ROP model is utilized to determine the optimal drilling parameters for a specific optimization problem, such as minimizing drilling time, drilling MSE, or other objectives [19]. This is then used to establish standard drilling parameters as such of weight on bit or drill bit in rotary speed (RPM). Fig. 1(a) and Fig. 1(b) indicate the difference between continuous learning [20][19] and a reference well method [19]. As seen in Fig. 1(a), the model is able to be constructed in real-time using continuous learning. This necessitates training the model while drilling, which is more challenging to accomplish due to the computational requirements of the software and hardware. The first dataset is extremely small and skeletal at the beginning, which is another disadvantage that slows down the machine learning training process. There is a warm-up phase in which no model is used or a temporary model is employed. A reference well, as demonstrated in Fig. 1(b) is analogous to a drilled well. This enables users to construct models offline that need to be done only once, and is generally more easier compared than the continuous learning methods. In both methodologies, the optimum drilling parameters are computed using the ROP model and then applied in the drilling controls for parameters such as bit weight, RPM and mud flow [13]. The method would be based on local constraints and data availability. Best practices do not yet exist however, a hybrid approach is also feasible.

Effective ROP optimization depends on the development of a reliable ROP prediction model. Traditionally, both analytical and data-driven models were initiative and improvised to achieve this target [15]. In order to train the machine learning model or estimate model constants, both methods require reference datasets. Reality and the constructed models should have a smaller predicted error that would be references for the future drilling. This implies that the precision of a model can be utilized only for similar drilling such as tools, methods and depth. In modern drilling operations, continuous learning techniques have gained prominence [16][20]. Information to be referred, or trained, can be sourced from the local wells at a given time in a continuous learning process in parallel of the model creations.

B. Score Metrics

MAE is suggested as the key metric for ROP prediction.

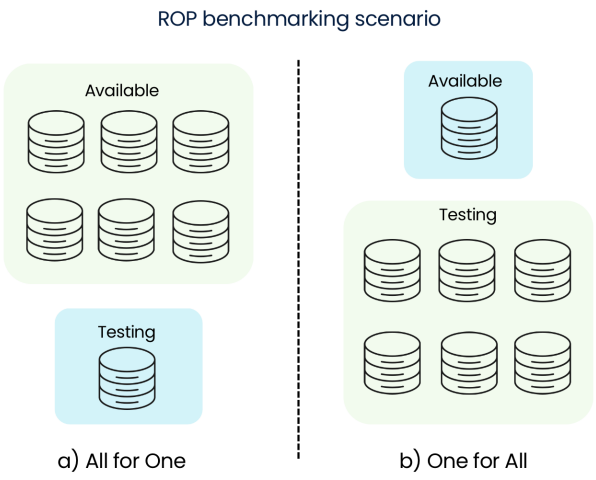

Fig. 1. ROP performance evaluation strategy.

$$\text{MAE} = \frac{1}{n}\sum_{t=1}^{n}|A_t - F_t| \tag{1}$$

where, n = number of samples, t = sample number consecutively, At = actual value at sample t, and Ft = forecasted value at sample t. The reason for this choice is that ROP modelling is mostly done for drilling time optimization, where the interest is in the cost per meter drilled. A specific error value, e.g., 10 m/h, will be of roughly the same significance to an operator whether the true value is 30 m/h or 80 m/h [19]. While MAE is widely used, other studies may employ alternative performance metrics such as the MAPE and the Weighted Mean Absolute Percentage Error (WMAPE). MAPE, defined as a percentage of the actual values used to estimate error, can be useful for relative comparisons of performance across ROP ranges. However, it becomes problematic when actual values approach zero. WMAPE, on the other hand, handles sample imbalance by weighting errors by the true values, making it a more robust alternative in highly heterogeneous datasets. The evaluation measure must be properly selected based on the specific purpose and data characteristics of the study in ROP prediction.

C. Proposed Scenario

In ROP prediction, three performance evaluation strategies are adapted from the previous work of Tunkiel et al. [19] to evaluate ROP prediction models. The scenarios are All for One (AFO) and One for All (OFA). AFO, as illustrated in Fig. 1(a), in which one complete well is set aside for testing and all but one well are available for training and validation. This necessitates a final MAE score for all wells combined and enables seven different runs, with varying wells set aside for testing as cross-validation. Fig. 1(b) shows the One for All (OFA) situation, where only one well is used to estimate, and the rest are estimated by this model, as suggested by the final situation. This creates seven train/test iterations as cross-validation, just like the second scenario. Regarding iteration independence, in both the AFO and OFA strategies, each iteration is treated as an independent entity. This demands that the algorithms designed must be able to work with data from a single iteration without being influenced by preceding iterations. This habit would make it possible to guarantee that the models remain objective and do not inadvertently incorporate irrelevant information that could undermine their precision.

IV. Materials and Techniques

This section elaborates on the materials, data sources, and research methodologies described. The proposed approach captures the steps to see the performance of the enhancement of GBR+PSO models on ROP prediction optimization. The approach includes data preparation, pre-processing, construction of the proposed methods, and evaluation. In addition, we introduced a particle representation or solution mapping for the PSO. Fig. 2 demonstrates the flow of the proposed methodology. This process begins with the data extraction and pre-processing stage, where raw data is cleaned of outliers, missing values are imputed, overlapping data are removed, and the data are sorted. The pre-processing stage is rigorously carried out to ensure the equality and consistency of datasets, thereby ensuring that high-quality data are gathered and creating a strong model. The subsequent feature selection yields an optimal dataset containing the most descriptive predictors of the ROP model. The essence of the methodology lies in the predictive modelling achieved using machine learning techniques.

Three regressors namely, AdaBoost, Gradient Boosting, and K-Nearest Neighbours are assessed for performance across multiple algorithmic paradigms. Hyperparameter optimization made possible through PSO is applied to optimize the performance of selected models. PSO is a population-based stochastic optimization procedure well suited to navigating complicated, high-dimensional search spaces, making it suitable to determine optimal parameter configurations.

Model validation involves using performance measures such as MAE and R^2, which provide numerical measures of predictive accuracy and model fitness. The convergence analysis of the PSO algorithm is also conducted to ensure the stability and reliability of hyperparameter tuning. The design system consists of two approaches, namely AFO and OFA, enabling the comparison of model performance across different training and test paradigms.

The availability in both the training and the testing phases leads to a comprehensive analysis of the models. The training process involves tuning the selected machine learning models to the preprocessed data, while the testing process assesses the generalization performance of the models on unseen data. The integration of a combination of robust preprocessing, advanced optimization techniques, and rigorous validation presents an all-encompassing and methodological solution to ROP prediction, which could be beneficial in generating useful knowledge for enhancing drilling efficiency and optimizing resource recovery in shale reservoirs. Strategic comparison between AFO and OFA methods enables the diversification of model training and testing performance under varying operational conditions. Detailed steps are elaborated in the following sub-sections.

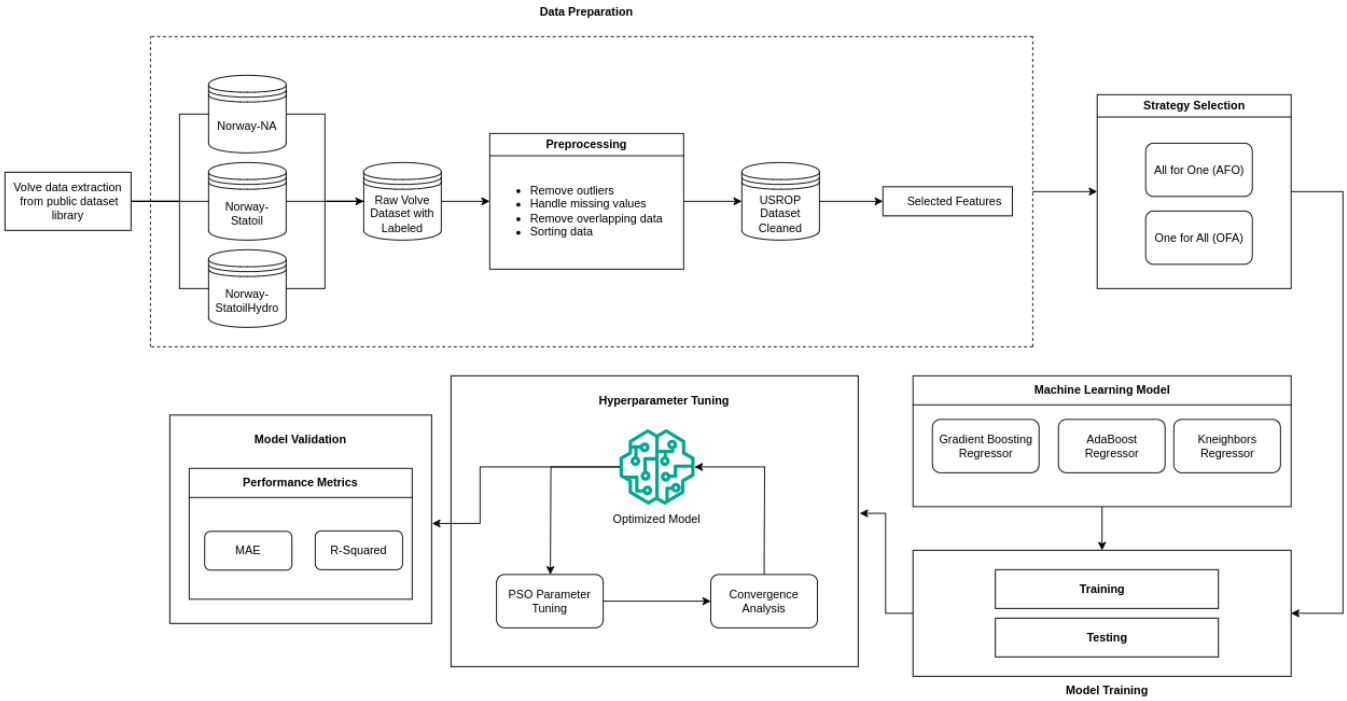

Fig. 2. Flow of methodology.

A. Data Preparation

This study utilized the same precise data preparation as that of the USROP reference paper. Experiments in numerous drilling areas are facilitated by the Volve database's large-scale real-time drilling data. Meanwhile, the logs differ in features, contain missing values, and vary in quality. A good subset of Volve must address this problem. Seven wells in total were selected based on the logged attributes. Data quality and the logged common attributes were the selection criteria. The datasets were acquired from the USROP dataset, focusing on the Volve field. [19]. The attributes are selected: Measured Depth [m], Weight on Bit [kkgf], Average Standpipe Pressure [kPa], Average Surface Torque [kN.m], Rate of Penetration [m/h], Average Rotary Speed [rpm], Mud Flow In [L/min], Mud Density In [g/cm3], Diameter [mm], Average Hook-load [kg], Hole Depth (TVD) [m], USROP Gamma [gAPI]. Minimal processing was done to the attributes to preserve the original data. This is necessary as the drilling logs often contain erroneous, non-physical values. There may be sentinel values indicating no reading (typically -999), corrupted values from the mud-pulsing system, and others. Samples containing weights on bit values below 0 and above 35 were truncated. The same way rows with mud density in, mud flow in, and average surface torque values below zero were removed, as well as with ROP values above 100 and average standpipe pressure above 25,000. Meanwhile, the diameter refers to the nominal wellbore diameter. Forward and backward filling were used to fill small gaps in the data resulting from uneven logging frequency across different equipment.

Distribution of ROP values by frequency across five ranges shows a pronounced leftward skew. The concentration of data in the 1-20 m/h and 21-40 m/h ranges suggests that the majority of drilling operations experienced quite low penetration rates. This may indicate natural limitations imposed by the penetrated geological rocks, such as high rock strength or unfavourable drilling conditions. Alternatively, it can indicate suboptimal drilling operations or equipment inefficiencies that prevent higher ROP. The declining rate observed with increasing ROP intervals also indicates the challenge of achieving high penetration rates. The explanation for this trend could be rising depth, which typically leads to higher compressive stresses and poorer rock drillability. The diminishing returns of increasing weight on bit (WOB) or rotary speed at high ROP values could also be a factor for this trend. A detailed investigation of geological conditions, drilling parameters, and operating practices is critical to elucidate the underlying causes of this skewed ROP distribution and to identify potential means of enhancing drilling performance.

B. Feature Correlation Coefficient

This correlation heatmap illustrates the interrelations among various drilling parameters and their impact on ROP (Fig. 3). Colour intensity and direction (red positive, blue negative) indicate the strength and direction of the linear relationships among variables. Surprisingly, ROP also shows a moderate negative correlation with Measured Depth (-0.39) and Hole Depth (TVD) (-0.42), indicating a decrease in ROP with increasing depth, perhaps due to factors such as increasing formation compaction and pressure. Conversely, there is a moderate positive correlation between ROP and Mud Flow In (0.25), suggesting the potential for greater ROP at higher mud flow rates, possibly due to more effective cuttings transport and hole cleaning.

Even though this heatmap is useful as a first-level view

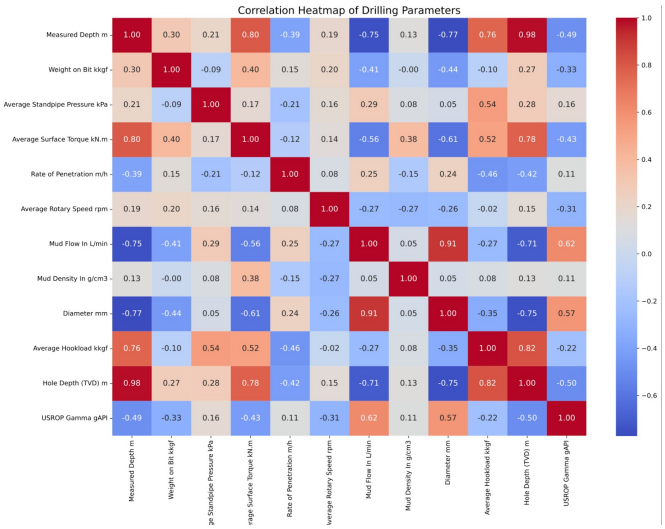

Fig. 3. Features correlation

TABLE I. PARTICLE REPRESENTATION FOR GBR TUNING

Variable	Hyperparameter range
X_1	`n_estimators`: 50–500
X_2	`learning_rate`: 0.01–0.3
X_3	`max_depth`: 3–10
X_4	`min_samples_split`: 2–20
X_5	`min_samples_leaf`: 1–20
X_6	`subsample`: 0.5–1.0
X_7	`max_features`: 0.1–1.0

of drilling parameter correlations with ROP, it has its own limitations. First, the correlations presented are specific to the dataset employed and may not extrapolate to other geological structures and drilling conditions. Second, the interpretation is restricted to linear relationships, whereas the actual interaction of parameters and ROP might be more complex and non-linear. Therefore, further study using new analysis techniques, such as non-linear regression modelling and machine learning algorithms, is needed to develop a larger, predictive ROP estimation model. Further consideration of business sense and operational feasibility will become crucial to demonstrate the actual, real-world practicability of the prediction model when implemented.

C. Proposed Solution

1) Solution representation: Following is the solution mapping or particle representation (see Table I):

whereas,

X1 to X7 are labels used to denote specific GBR parameters in a structured format.

R1 to R7 are shorthand notations corresponding to the ranges of parameters X1 to X7.

X1, R1: n_estimators: Range from 50 to 500.

X2, R2: learning_rate - Range from 0.01 to 0.3.

X3, R3: max_depth - Range from 3 to 10.

X4, R4: min_samples_split - Range from 2 to 20.

X5, R5: min_samples_leaf - Range from 1 to 20.

X6, R6: subsample - Range from 0.5 to 1.0.

X7, R7: max_features - Range from 0.1 to 1.0.

2) Fitness function: The fitness function was calculated using test data from previous references (Tunkiel et al., 2021a). The equation given below describes the fitness function used to calculate MAE, which is applied within the PSO algorithm.

$$\min\left(\frac{1}{n}\sum_{t=1}^{n}|A_t - F_t|\right) \tag{2}$$

whereas,

leftmargin=1.15em

- n: Total number of data points (hours) for drilling speed.
- t: Counter that iterates through each data point, going from 1 to n. Keeps track of the specific hour analysed within the calculation.
- A_t: Actual drilling speed measured at a specific hour (t). A_1 would be the speed for the first hour, A_2 for the second, and so on.
- F_t: Predicted drilling speed for the same hour (t).
- $|A_t - F_t|$: Difference between the actual speed (A_t) and the predicted speed (F_t). It ignores the direction of the error (positive or negative).
- $\sum$: Sum of all the absolute differences between actual and predicted speeds for all the hours ($t = 1$ to $t = n$).
- $(1/n)$: Represents the average.

In this setup, MAE serves as the objective function which PSO aims to minimize. MAE is mainly used to measure the accuracy of the GBR model's predictions. Each particle in the PSO algorithm represents a potential set of GBR hyperparameters. The fitness of each particle is evaluated by training the GBR model with its corresponding hyperparameters and calculating the MAE on a validation dataset.

3) A proposed new hybrid GBR+PSO: In this study, a new hybrid GBR+PSO algorithm is proposed (see Algorithm 1). The following is a step-by-step of a new hybrid GBR+PSO algorithm. The PSO algorithm iteratively updates particles' positions and velocities based on their own best-known positions, their neighbours' best-known positions, and the global best-known position. This update process continues until the algorithm converges on the optimal hyperparameters that yield the lowest MAE, ensuring the most accurate ROP predictions. This dynamic interplay between MAE and PSO effectively guides the search for the optimal hyperparameters by utilizing PSO's exploration and exploitation capabilities to fine-tune the GBR model. Based on Barbosa et al. [23] has been shown few past studies have used the MAE as an objective function for ML optimization. In this PSO setup for GBR hyperparameter tuning, the particles' parameters (hyperparameters for the GBR model) and the objective function (MAE) are tightly linked:

- Particles' parameters (GBR hyperparensuree and train the GBR model.
- The MAE is computed based on the predictions of the GBR model with tcouldhose hyperparameters and serves as the objective function that PSO optimizes.
- The goal of PSO in this setup is to minimize the prediction error of the GBR model. MAE is a straightforward measure of average error and fits well as the objective function for this minimization problem.

Algorithm 1 A New Hybrid GBR+PSO

- Begin.
- Initialize the PSO algorithm for GBR hyperparameter tuning.
- Define the particle representation.
- Initialize the swarm with a population of particles, each representing a candidate set of GBR hyperparameters.
- Set the fitness function as MAE, calculated using Equation (2), where: leftmargin=1.5em,noitemsep,topsep=1pt
  - n: Total number of data points (hours) for drilling speed
  - t: Iteration counter
  - A_t: Actual drilling speed at time t
  - F_t: Predicted drilling speed at time t
- Evaluate the initial fitness of each particle by training the GBR model using its hyperparameters and calculating the MAE on a validation dataset.
- Update the velocity and position of each particle based on: leftmargin=1.5em,noitemsep,topsep=1pt
  - The particle's personal best position (pBest)
  - The global best position found by the swarm (gBest)
- Iterate until the stopping criterion is met (e.g., a fixed number of iterations for convergence to the lowest MAE).
- Select the optimal GBR hyperparameters corresponding to the particle with the lowest MAE.
- Train the final GBR model using the optimized hyperparameters.
- Measure the model training time.
- Predict the test dataset using the trained GBR model.
- Evaluate the final GBR model's performance using MAE.
- End.

GBR was selected for advanced hyperparameter tuning using PSO, with validation performed using the AFO splitting strategy . Unlike the initial phase, this phase utilized all relevant GBR parameters to achieve optimal model performance. The PSO setup, as outlined in Table III, was configured with 100 iterations and 100 particles, default values to ensure robust exploration of the hyperparameter space. The inertia weight was set to 0.5, while the cognitive and social coefficients were both set to 2.0. These parameters were chosen to balance exploration of new solutions and exploitation of known good solutions, ensuring the algorithm efficiently converges to the best hyperparameter configuration. The PSO algorithm works by iteratively adjusting the position of each particle based on its personal best solution and the global best solution found by the swarm. The inertia weight controls the influence of a particle's previous velocity, while the cognitive and social coefficients guide the particles toward self-improvement and collaboration, respectively. This approach ensures a comprehensive search of the hyperparameter space, minimizing the MAE and enhancing the predictive accuracy of the GBR model.

D. Performance Evaluation

This study has used two essential empirical measurements to evaluate and compare the effectiveness of GBR+PSO. By running this experiment and applying PSO to the GBR, the main goal of this study is to identify the optimal set of hyperparameters for the GBR, including the learning rate, the number of trees, and tree depth, that minimise prediction error while maximising overall model performance, as measured by the MAE metric. This optimization step is an important part of my experiment, as it is represented to significantly enhance the model's accuracy and robustness. Plus, these improvements will contribute to more precise and reliable ROP predictions and enable more efficient and informed decision-making in drilling operations. A proposed hybrid GBR+PSO was compared with GBR, ADR and KN models. In evaluating the performance of GBR+PSO, the hyperparameter ranges for GBR were carefully selected to ensure meaningful exploration and avoid impractical configurations. The lower and upper bounds for the hyperparameters were set as follows: `n_estimators` (50 to 500), `learning_rate` (0.01 to 0.3), `max_depth` (3 to 10), `min_samples_split` (2 to 20), `min_samples_leaf` (1 to 20), `subsample` (0.5 to 1.0), and `max_features` (0.1 to 1.0). These ranges were selected based on their significant influence on the performance of the GBR model. For instance, `n_estimators` control the number of boosting iterations, with higher values potentially improving accuracy at the cost of increased computational time. The `learning_rate` determines the contribution of each tree to the final model, with smaller values promoting more robust learning but requiring more iterations. The `max_depth` parameter limits the depth of each tree, preventing overfitting by controlling model complexity. Similarly, `min_samples_split` and `min_samples_leaf` balance underfitting and overfitting by regulating the minimum number of samples required to split a node and the minimum number of samples per leaf node, respectively. The `subsample` parameter introduces randomness by using a fraction of samples for fitting each tree, enhancing generalization. Finally, `max_features` controls the proportion of features considered for each split, reducing overfitting while maintaining predictive accuracy.

By leveraging PSO to fine-tune these hyperparameters within the specified bounds, the GBR model achieves an optimal balance between predictive accuracy and computational efficiency. The iterative nature of PSO ensures that the best hyperparameter configuration is selected based on the training data, resulting in a robust, high-performing model. This approach not only enhances the predictive capabilities of the GBR model but also provides a systematic and efficient method for hyperparameter optimization, making it a valuable contribution to the field of machine learning and predictive

modeling. In this implementation, PSO is used to fine-tune the hyperparameters of the GBR. The optimization process involves 100 iterations, especially during which particles (candidate solutions) explore the search space to minimize the MAE. Each particle will then adjust its position based on its previous experience (personal best) and the best-known solution found by the swarm (global best). The algorithm utilizes inertia weight to control how much a particle's previous velocity influences its current movement, balancing exploration and exploitation. These two coefficients guide the particles: the cognitive coefficient, encouraging self-improvement, and the social coefficient by promoting collaboration toward the best global solution. The parameter ranges are constrained by specific lower bounds ([50, 0.01, 3, 2, 1, 0.5, 0.1]) and upper bounds ([500, 0.3, 10, 20, 20, 1.0, 1.0]) to ensure meaningful exploration. These settings allow PSO to iteratively refine hyperparameter combinations, efficiently converging to an optimal GBR configuration.

The GBR is a machine learning algorithm that builds decision trees to minimize prediction error. In this implementation, the hyperparameters optimized by PSO should significantly influence GBR's performance as follows:

leftmargin=1.15em

- `n_estimators`: The number of boosting iterations (trees) in the model, ranging from 50 to 500. More iterations can improve accuracy but may increase computation time.
- `learning_rate`: Determines the contribution of each tree to the final model. A smaller value (e.g., 0.01 to 0.3) results in more robust learning but requires more iterations.
- `max_depth`: Limits the depth of each tree (3 to 10), controlling model complexity and preventing overfitting.
- `min_samples_split`: Minimum number of samples required to split a node (2 to 20), balancing underfitting and overfitting.
- `min_samples_leaf`: Minimum number of samples per leaf node (1 to 20), affecting tree size and generalization.
- `subsample`: Fraction of samples used for fitting each tree (0.5 to 1.0), introducing randomness for better generalization.
- `max_features`: The proportion of features considered for each split (0.1 to 1.0), which reduces overfitting while maintaining predictive accuracy.

By tuning these hyperparameters based on lower bound and upper bound, the GBR model is able to achieve an optimal balance between predictive accuracy and computational efficiency. Next, PSO ensures the selection of the best configuration based on the training data.

V. Computational Results

This section highlights the computational results of GBR, KN and ABR and the proposed GBR+PSO. The experiments were perform based on an appropriate parameters for each of the methods, GBR and ABR, utilizing the different learning rate of 0.1 and 0.01 meanwhile KN based on the number neibours. All experiments tested on AFO and OFA benchmark splitting strategy.

A. Computational Results Using GBR

GBR employed the OFA methodology with a learning rate tinkered to 0.01 and the same 80/20 train-test split. This experiment was therefore meant to investigate the lower learning rate's impact while targeting a particular drilling scenario. Similar to GBR-EXP1,GBR-EXP3, GBR-EXP4 has shown a promising learning curve. With little tweak on the parameter, we can clearly see the gap between the training and test error showing that to some extent the model is generalizing well. The training error goes down smoothly, which means it is learning from the data. However, the train error also goes down in the beginning and then flattens. This would then mean that, in learning, there is an optimum size of training beyond which the generalization performance does not increase significantly. It appears that the optimal training size is around 60,000. Beyond this point, the model starts to overfit, and the test MAE starts to increase. This may be due to various factors involving data complexity, limitations of model architecture, or noise in data. Further analysis, such as hyperparameter tuning and feature engineering, could potentially improve the model's performance and further reduce the test error.

B. Computational Results Using KNR

In KNN-EXP1, the AFO method has been used with n_neighbors = 3. This setting reduces the neighbourhood size, thus should be allowing the model to capture more local fine details. The experiment uses an 80/20 train-test split to examine the model's behavior when trained on most of the dataset and validated on a smaller portion. Training MAE just remains very low since the model manages to easily fit to the data being trained from. On the other hand, test MAE shows its height relatively throughout the process. This large difference between the training and testing MAE indicates underfitting criteria of the model.

C. Computational Results Using ABR

The learning curves for ABR experiments from ABR-EXP1 to ABR-EXP4, all reflect the overfitting pattern. Whereas the training error decreases rapidly, indicating that the model fits the training data well, either the test error saturates or increases. This also reflects that the model memorizes the training data rather than learning the underlying pattern. This is further supported by the overfitting behaviour evident from the violin plot, since the MAE test values in the various experiments are widely distributed, with noticeably large variability in performance. This could mean that the current ABR model architecture, with its default hyperparameters, is overly simplistic for handling such a large dataset range of 120,000 to 200,000 samples. The model's complexity may not be sufficient to learn the complex relationships in such a large dataset. Hence, it overfits the training data and generalises very poorly with high prediction errors on unseen data.

D. Computational Results Using GBR+PSO

In assessing the impact of particle representation on a new hybrid GBR+PSO performance, the results GBR+PSO obtained MAE: 1.205, which indicate good MAE value and good optimization process and R^2: 0.982 indicates goodness-of-fit measure for linear regression models. From the results, it demonstrates that the hyperparameter tuning procedure, which was driven by PSO, has successfully discovered an optimal set of hyperparameters for the GBR model. This is demonstrated by the algorithm's iterative exploration of various hyperparameter combinations, which resulted in a "best new configuration" with improved MAE values at each step. In the PSO algorithm for hyperparameter tuning, some important parameters guide the search process. This parameter refers to cognitive factor (C1) and social factor (C2). The cognitive factor parameter, which is set to 2.0 by default, gives an idea of how much a particle is influenced by its own pBest to continue the exploration of good areas previously found. On the other hand, the social factor C2 = 2.0 will relate to the degree of attraction by a particle for the gBest discovered by all the swarm. That enhances collaboration or sharing of information between particles. Along with the inertia weight which is set at 0.5 to maintain a balance between exploration and exploitation the described parameters enable this swarm to dive into the space of hyperparameters. The PSO algorithm explored 100 iterations with a swarm of 100 particles evaluating many possible configurations or possible feasible solutions. Table II demonstrates the selected hyperparameter configurations of the Configuration 1 and Configuration 2.

TABLE II. THE SELECTED HYPERPARAMETER CONFIGURATIONS

Parameters	Configuration 1	Configuration 2
n_estimators	95	425
learning_rate	0.166916	0.132280
max_depth	3	6
min_samples_split	17	14
min_samples_leaf	8	9
subsample	0.716358	0.533660

Configuration 1 and Configuration 2 obtains MAE of about 4.178 and 1.205, respectively. The algorithm successfully identified a new best configuration in the second iteration, significantly reducing the MAE from 4.178 to 1.205. This improvement highlights the effectiveness of the PSO algorithm in optimizing hyperparameters, leveraging the interplay between C1, C2, and inertia weight to find a high-performing model. The best fitness (lowest MAE) achieved during the hyperparameter tuning process is 1.205, which corresponds to Configuration 2 in the training output demonstrating the practical benefits of using PSO for hyperparameter tuning.

Fig. 4 shows the "Predicted vs. Actual ROP" plot of GBR+PSO experiment provides a compelling visual representation of the model's performance, corroborating the findings from the learning curve and the hyperparameter tuning process. The strong positive correlation between predicted and actual ROP values, evident in the tight clustering of points around the diagonal line, demonstrates the model's ability to accurately capture the underlying relationships in the data. The low MAE which is 1.205 and of about R^2 of 0.982 values further support this observation. While the plot reveals a strong

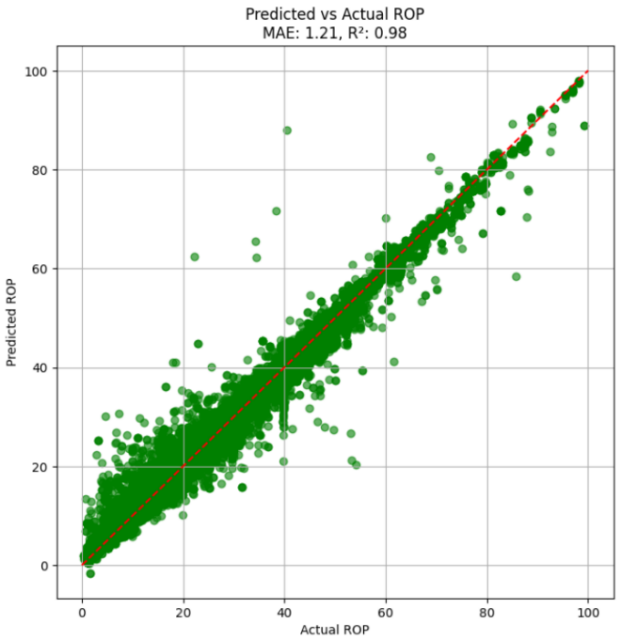

Fig. 4. Predicted versus actual ROP for the best GBR+PSO experiment.

overall correlation, it also provides valuable insights for further refinement. By analyzing the distribution of points and identifying areas where deviations from the diagonal line, we can pinpoint specific scenarios or data regions, where the model's predictions might be less accurate. This plot gives insight to guide further hyperparameter tuning, feature engineering, or data collection efforts to enhance model performance and improve the accuracy and reliability of ROP predictions.

VI. DISCUSSION

The experimental results presented in the tables provide a comprehensive comparison of various machine learning models, including GBR, Adaboost, KNR, and GBR+PSO. The performance of these models is evaluated using the MAE metric, which is particularly suitable for predicting the ROP in drilling operations. MAE measures the average absolute difference between predicted and actual values, providing a clear, interpretable metric of model accuracy. For ROP prediction, where even small deviations can have significant operational implications, MAE is an appropriate metric because it directly quantifies the average error in predicted ROP values, ensuring the model's predictions are reliable and actionable. The performance metrics for different models of the ROP prediction is demonstrated in Table III.

The superior performance of the GBR+PSO model, with an MAE of 1.205, highlights the effectiveness of PSO in fine-tuning hyperparameters. PSO's ability to efficiently explore the hyperparameter space and balance exploration with exploitation allows it to identify configurations that minimize prediction errors [24][25]. This is particularly important for ROP prediction, where the relationship between input parameters includes weight on bit, standpipe pressure, and rotary speed and ROP is complex and non-linear. The learning curve analysis for GBR+PSO would likely show a steady decrease in training and validation errors as the number of iterations

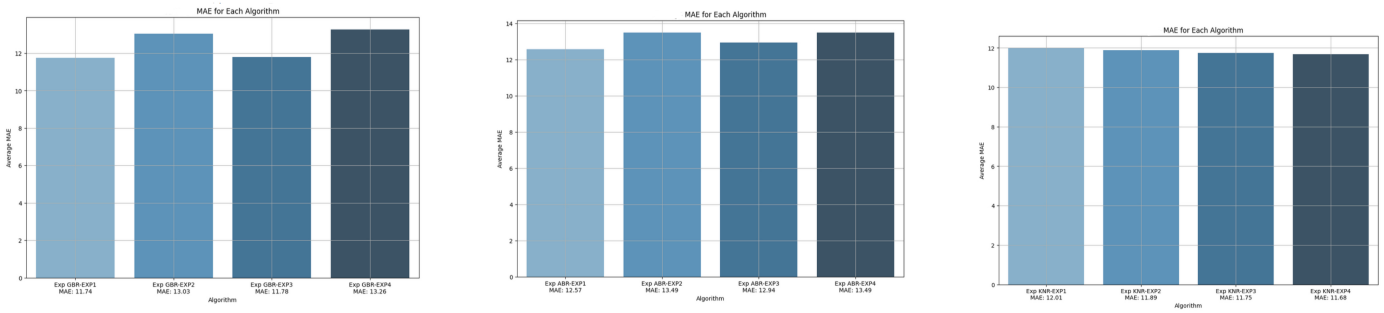

Fig. 5. MAE score for the standalone experiments: (a) GBR, (b) ABR, and (c) KNR.

TABLE III. PERFORMANCE METRICS FOR DIFFERENT MODEL CLASSIFIERS.

Method and Experiment ID	Benchmark Splitting Strategy	Parameter	MAE
GBR-EXP1	AFO	Learning Rate: 0.1	11.74
GBR-EXP2	AFO	Learning Rate: 0.01	13.03
GBR-EXP3	OFA	Learning Rate: 0.1	11.78
GBR-EXP4	OFA	Learning Rate: 0.01	13.26
ABR-EXP1	AFO	Learning Rate: 1.0	12.57
ABR-EXP2	AFO	Learning Rate: 0.01	13.49
ABR-EXP3	OFA	Learning Rate: 1.0	12.94
ABR-EXP4	OFA	Learning Rate: 0.01	13.49
KNR-EXP1	AFO	$n_neighbors = 3$	12.01
KNR-EXP2	AFO	$n_neighbors = 5$	11.89
KNR-EXP3	OFA	$n_neighbors = 3$	11.75
KNR-EXP4	OFA	$n_neighbors = 5$	11.68
GBR+PSO (Proposed Method)	AFO	Parameter range based on Table II	1.205

increases, indicating that the model is learning effectively without overfitting. This behavior is critical for ensuring that the model generalizes well to unseen data, which is essential for real-world drilling applications.

To further validate the model's performance, predict vs. actual plots are highly useful. These plots provide a visual comparison between the predicted and actual ROP values, allowing for a direct assessment of the model's accuracy. For a well-performing model like GBR+PSO, the points in the predict vs. actual plot should closely align with the 45-degree line, indicating minimal deviation between predictions and ground truth. This visualization confirms the model's accuracy and helps identify any systematic errors or biases in the predictions, which can be addressed in subsequent iterations of model refinement.

In summary, using MAE as a performance measure [20], along with learning curves, predict vs. actual plots, and violin plots, creates a strong way to assess and confirm the reliability of ROP prediction models. The GBR+PSO model's exceptional performance, as evidenced by its low MAE, illustrates the value of advanced optimization techniques and thorough model validation. By leveraging these tools, researchers and practitioners can ensure that their models not only achieve high accuracy but also exhibit consistent and reliable behavior across a wide range of drilling conditions, ultimately leading to more efficient and safer drilling operations (see Fig. 5).

VII. CONCLUSION

The research under this study has framed the potential of hybrid optimization techniques in improving the ROP prediction in drilling operations. This study has created a plan to make ROP predictions more accurate by mixing machine learning algorithms with traditional optimization methods, while also dealing with the challenges of drilling in areas that contain hydrocarbons. The results indicated that the methodologies introduced can deliver substantial improvements in drilling efficiency, enabling reductions in operational costs and increased productivity in the oil and gas industry. This work also underlined the importance of data-driven approaches in modern drilling practices. Given the increasing demands for efficiency and cost-effectiveness within the industry, this capability to predict ROP with good accuracy will become relevant. The findings of the research indicate that the developed hybrid GBR+PSO model would be very useful for drilling engineers in driving data-informed decisions powered by real-time and predictive analytics. This development does not just guarantee the operational success but also contributes to achieving those goals the industry has laid out concerning minimum environmental impact with maximum resource extraction. The objective of the research was to assess the overall effect of the suggested methodologies on drilling performance. The implemented hybrid optimization approach, when executed, resulted in a measurable increase in ROP, thereby increasing the overall productivity of the drilling operation.

This study is quite important because it shows that the practical benefits of adopting advanced predictive models are tangible in the field. The positive results associated with this objective are indicative of further research and development in the field of drilling optimization. Since the industry is in continuous evolution, advanced technologies and methodologies must be integrated not only to stay competitive but also to address the challenges posed by increasingly complex drilling environments. Despite these promising results, the study has certain limitations. The model was developed and validated using historical drilling datasets from a limited number of wells, which may not fully capture the variability of diverse geological formations and operational conditions encountered across the broader industry. Building on these findings, future work should focus on real-time field validation and deployment, testing the GBR+PSO model on live drilling rigs with real-time data streaming to evaluate its practical performance, latency, and reliability under actual field conditions, rather than solely on historical datasets. Further research could also explore integration with other optimization algorithms, hybridizing GBR with other metaheuristic algorithms such as Ant Colony Optimization, Grey Wolf Optimizer, or Whale Optimization Algorithm, to benchmark against PSO and identify the most robust optimization strategy. Additionally, future

studies should explore embedding the hybrid GBR+PSO model into autonomous or semi-autonomous drilling control systems to enable fully automated, closed-loop optimization of drilling parameters.

An Experimental Evaluation of Deep Learning Networks for Automated Breast Cancer Detection

Partha Chakraborty*, Umme Aiman Jannat
Department of Computer Science and Engineering, Comilla University, Cumilla-3506, Bangladesh

***Abstract*—Breast cancer remains one of the leading causes of cancer-related mortality among women worldwide, where early and accurate diagnosis plays a vital role in improving survival rates. Recent advancements in deep learning have demonstrated significant potential in automating the analysis of medical images for cancer detection. This study presents a comprehensive comparative analysis of convolutional neural network (CNN)–based deep learning models for breast cancer classification using ultrasound and mammography images. Multiple architectures, including a baseline CNN, AlexNet, DenseNet, ResNet50, ResNet101, VGG16, VGG19, and MobileNetV3, were evaluated to classify breast lesions as benign or malignant. Experimental results reveal notable performance differences across imaging modalities. For ultrasound images, AlexNet achieved the highest accuracy of 89%, while DenseNet and the baseline CNN achieved 88% and 85%, respectively. In contrast, mammography-based classification yielded significantly higher performance, with the baseline CNN outperforming deeper architectures in terms of accuracy and F1-score, achieving 97%. The findings demonstrate that model complexity does not necessarily guarantee superior performance and that properly designed shallow CNNs can effectively outperform deeper networks on high-quality mammographic data. This study highlights the potential of deep learning–based computer-aided diagnosis systems to support radiologists in the early detection of breast cancer.**

***Keywords*—Breast cancer; deep learning; convolutional neural networks; mammography; ultrasound; medical image classification**

I. Introduction

Breast cancer is a major cause of death for women between the ages of 20 and 59. Breast cancer is the most common cancer in women worldwide. Bangladesh has one of the highest incidences of breast cancer in Asia. In Bangladesh, breast cancer is the most prevalent cancer among women aged 15 to 44 years, with an incidence of approximately 19.3 per 100,000 population compared to other cancer types. Early detection remains the most effective strategy to reduce mortality. Women under 40 are advised to perform regular breast self-examinations, while those over 40 are advised to undergo routine mammographic screening for early detection. Reducing death rates and increasing treatment outcomes depend heavily on early and precise identification. Despite their effectiveness, traditional diagnostic techniques are often limited by subjectivity and variability, making consistent and trustworthy diagnoses difficult. These constraints may be addressed by the revolutionary potential of machine learning (ML), which leverages enormous datasets and processing capacity to improve diagnostic accuracy and efficiency of diagnosis. Breast cancer happens when cells in the breast start growing in an abnormal and uncontrolled way, forming a lump called a tumor. If it is not treated in time, the cancer can spread from the breast to other parts of the body, such as the bones, liver, or lungs. It can affect both women and men, but it is far more common in women.

There are also early or precancerous conditions, often called precancerous or carcinoma in situ, in which abnormal cells are found in the milk ducts or lobules but have not yet spread into nearby tissues. Invasive breast cancer, on the other hand, begins to grow into the surrounding normal breast tissue and can potentially spread to other parts of the body [1]. The most common types include ductal carcinoma and lobular carcinoma. Other less common forms include Paget's disease of the breast and inflammatory breast cancer [2].

A prospective cross-sectional study was conducted at Ahsania Mission Cancer and General Hospital between July 2023 and December 2023 to investigate the frequency and causes of delayed presentation among patients with newly-diagnosed breast cancer. The study aimed to identify the extent of diagnostic delays, explore the underlying reasons, and examine associations with socio-demographic factors. The research involved 242 participants, primarily from low-income, uneducated backgrounds, with the majority (52.06%) aged between 41 and 60 years. Data was collected through face-to-face interviews and medical record reviews after obtaining informed consent. Diagnostic delay was defined as a period of 90 days or more between the onset of symptoms and the initiation of medical treatment by expert physicians. Findings revealed that nearly half of the patients (46.28%) experienced delays exceeding three months, with an average delay duration of 5.18 months. Stage II breast cancer was the most common diagnosis (56.6%). A statistically significant association was found between diagnostic delay and patients' socio-economic status as well as the stage at which cancer was diagnosed [3]. To address the critical issue of delayed breast cancer diagnosis, this study aims to enhance the performance of existing diagnostic approaches by validating deep learning–based models using real-world ultrasound and mammography datasets collected from multiple hospitals. This study utilizes datasets from mammography and ultrasound imaging to investigate the application of machine learning algorithms in breast cancer detection. Numerous machine learning models, including CNN, AlexNet, DenseNet, ResNet50, ResNet101, VGG16, VGG19, and MobileNetV3, were utilized and evaluated using key performance indicators such as accuracy, F1 score, weighted average, and macro average. The results show that CNN-based models are very successful, with mammography datasets outperforming ultrasound in terms of performance. In particular, CNN achieved the best accuracy for mammograms at 97%, followed by ResNet101 at 95% and ResNet50 at 94%.

*Corresponding author

With an accuracy of 89%, AlexNet outperformed other models for ultrasound data.

II. Related Works

Breast cancer detection has been extensively studied using machine learning (ML) and deep learning (DL) techniques, with numerous studies focusing on optimizing classification performance and early detection. Over the past decade, algorithms such as Support Vector Machine (SVM), K-Nearest Neighbor (KNN), Random Forest (RF), Logistic Regression, Naïve Bayes, and ensemble methods have been widely applied to both tabular and imaging datasets, demonstrating varying levels of effectiveness based on the nature of the data and preprocessing techniques employed [8], [20], [21].

Bazazeh and Shubair [9] conducted one of the earlier comparative studies on breast cancer detection using supervised ML techniques, including RF, SVM, and Bayesian Networks (BN). Their analysis highlighted the high predictive capability of BN, achieving a recall and precision of 97.1% and 97.2%, respectively, while RF exhibited optimal receiver operating characteristic (ROC) performance of 99.9%. The study emphasized the importance of leveraging historical labelled data for predictive modelling in clinical applications, demonstrating that even traditional ML techniques can provide high accuracy when appropriately tuned. Similarly, Mohammed et al. [22] and Bhise et al. [19] reviewed various ML and DL approaches, confirming the consistent use of SVM, KNN, RF, Logistic Regression, and Naïve Bayes in breast cancer detection. These studies collectively highlighted the strengths and weaknesses of each algorithm: SVM performs well in high-dimensional feature spaces but is less efficient for large or noisy datasets; KNN is conceptually simple and robust but computationally intensive for large datasets due to repeated distance calculations; RF effectively handles high-dimensional, categorical, and missing data, although hyperparameter tuning is essential to avoid overfitting; Logistic Regression is effective for binary classification but assumes linearity between independent and dependent variables; and Naïve Bayes is simple and fast, but its assumption of feature independence and the zero-frequency problem can limit real-world applicability.

In the context of image-based datasets, Charan et al. [4] utilized a large Kaggle breast cancer image dataset comprising 7,858 samples across four magnification levels. They applied ML classifiers, including SVM, KNN, RF, Logistic Regression, and Naïve Bayes, with feature extraction performed using convolutional and pooling operations. While competitive performance was achieved, SVM faced scalability issues on large, imbalanced image datasets. Selvathi and Poornila [24] further demonstrated that careful selection of classifiers and feature extraction methods is crucial when combining deep learning networks with traditional ML algorithms to optimize predictive performance.

Sharma et al. [7], [16] applied RF, KNN, Naïve Bayes, Logistic Regression, and Decision Tree classifiers on the Wisconsin Diagnostic Breast Cancer dataset. KNN achieved the highest accuracy of 95.90%, indicating its robustness for structured tabular data. Moreover, the study demonstrated that incorporating Principal Component Analysis (PCA) for dimensionality reduction and appropriate data preprocessing significantly enhances SVM performance. Specifically, SVM accuracy increased from 65.78% without preprocessing to 98.02% after PCA and Standard Scaling, and achieved 97.36% on test subsets after fine-tuning grid search parameters. These results underscore the importance of preprocessing and hyperparameter optimization in improving classifier performance.

Joshi and Mehta [10] applied image processing techniques along with ML classifiers on a set of 209 mammography images from 50 patients, using train-test-validation splits of 70:20:10. Relevance Vector Machine (RVM) achieved 97% accuracy, demonstrating that probabilistic sparse models can be highly effective even with reduced feature sets. However, the study noted that RVM is less frequently applied to breast cancer datasets, having been primarily utilized for the detection of lymphoma and leukemia [11].

Khuriwal and Mishra [12] combined deep learning with traditional classifiers (KNN, SVM, Decision Tree, and RF) on the mini-MIAS Mammographic Database. They applied comprehensive preprocessing steps including digitization, noise and artifact removal, background suppression, and pectoral muscle removal. Among the classifiers, RF achieved the highest accuracy of 98.89% in differentiating fatty and dense tissues, while SVM remained limited to binary classification, reflecting its well-known constraint in multi-class or high-dimensional imaging scenarios. Kumar et al. [13] further extended deep learning approaches by training a Convolutional Neural Network (CNN) on 70% of the MIAS dataset (322 images) using stochastic gradient descent with momentum (SGDM). Despite subdividing the dataset into seven classes (six abnormal), the model achieved only 65% accuracy for normal-versus-abnormal classification, highlighting the challenge of multiclass prediction in medical imaging.

Xiao et al. [14] proposed an unsupervised deep learning approach, employing feature extraction to reduce image dimensionality, followed by classification using stacked autoencoder–SVM (SAE-SVM). This approach demonstrated that combining unsupervised feature learning with supervised classification can improve predictive capability while reducing computational overhead. Halim et al. [15] implemented parallel AI models for early breast cancer detection, achieving faster results of simultaneously using multiple models. However, the study noted an increase in computational complexity due to model parallelism.

Ahmed et al. [17] analyzed the Wisconsin Breast Cancer dataset, containing 699 records (458 benign, 241 malignant), applying SVM, KNN, Naïve Bayes, RF, and Logistic Regression. All classifiers achieved over 95% accuracy, confirming the robustness of these algorithms for traditional tabular datasets. Vinayak et al. [18] applied ML techniques on cytological data from UCI, where Artificial Neural Networks (ANN) achieved 97.37% accuracy. Ensemble methods such as stacking and voting also produced competitive results, emphasizing the value of combining multiple classifiers for reliable predictions.

Ranjan et al. [6] highlighted the effectiveness of ensemble methods, including Gradient Boosting, AdaBoost, and XGBoost, with RF achieving perfect accuracy (100%), illustrating the advantages of ensemble learning while acknowledging limitations in real-world medical imaging applications. Easttom et al. [5] evaluated traditional ML models using the R

programming framework, finding that SVM achieved 94.71% accuracy but was constrained in high-dimensional imaging contexts.

The recent trend is the adoption of deep learning-based architectures such as CNNs, which automatically extract features from images without extensive preprocessing. CNNs can effectively differentiate between malignant and benign tumors by filtering and learning important image parameters, offering flexibility and robustness in image-based analysis. Contemporary implementations, often using Keras as a backend, have demonstrated superior accuracy and efficiency in automated breast cancer detection, forming the foundation of modern diagnostic systems [26], [27].

Overall, the reviewed literature demonstrates that both traditional machine learning and deep learning approaches have achieved promising performance in breast cancer diagnosis [23], [25]. Conventional classifiers, such as SVM, KNN, Random Forest, Logistic Regression, and Naïve Bayes, have demonstrated high accuracy on structured datasets, particularly when combined with effective preprocessing, feature selection, and dimensionality reduction techniques. However, these methods largely rely on handcrafted features and are sensitive to noise, class imbalance, and variations across imaging modalities. Recent studies increasingly favor deep learning models, especially Convolutional Neural Networks (CNNs), due to their superior capability in automatically extracting features and learning representations from complex medical images. Despite these advancements, most existing works are limited to a single imaging modality—primarily mammography or ultrasound—and focus mainly on classification, with limited attention to cross-modal analysis or comprehensive performance evaluation across diverse architectures. Furthermore, comparative studies involving multiple deep learning models under a unified experimental framework remain scarce. These limitations highlight the need for a robust and modality-aware diagnostic framework that systematically evaluates state-of-the-art deep learning architectures on both ultrasound and mammography data, while emphasizing reliable performance metrics beyond accuracy alone. Addressing these research gaps can significantly enhance diagnostic confidence and clinical applicability in automated breast cancer detection systems.

III. Methodology

The overall architecture of the proposed system is illustrated in Fig. 1. The framework begins with dataset acquisition, followed by image collection and preprocessing to enhance image quality and standardize input dimensions. The preprocessed images are then split into training and testing subsets. Deep learning models are trained using the training dataset, while the testing dataset is used to evaluate generalization performance. Model effectiveness is assessed using performance validation metrics, training and validation loss curves, and visual inspection of classification outcomes. Ultimately, the system generates a binary classification output indicating whether a case is benign or malignant. Fig. 1 provides a high-level representation of the complete workflow, highlighting the interaction between data preprocessing, model training, and evaluation components within the proposed framework.

While Fig. 1 presents the generalized architecture of the proposed system, it does not explicitly illustrate how different

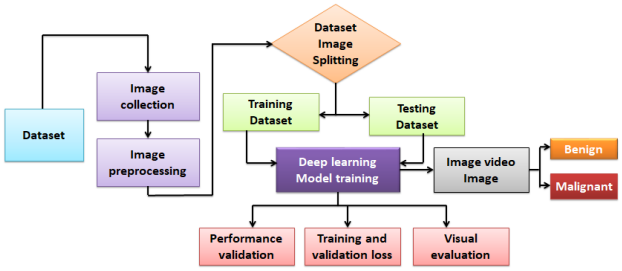

Fig. 1. System architecture

imaging modalities are handled independently. To address this, a more detailed experimental workflow is introduced in the next stage, focusing on modality-wise dataset splitting, model selection, and evaluation strategies for ultrasound and mammography images.

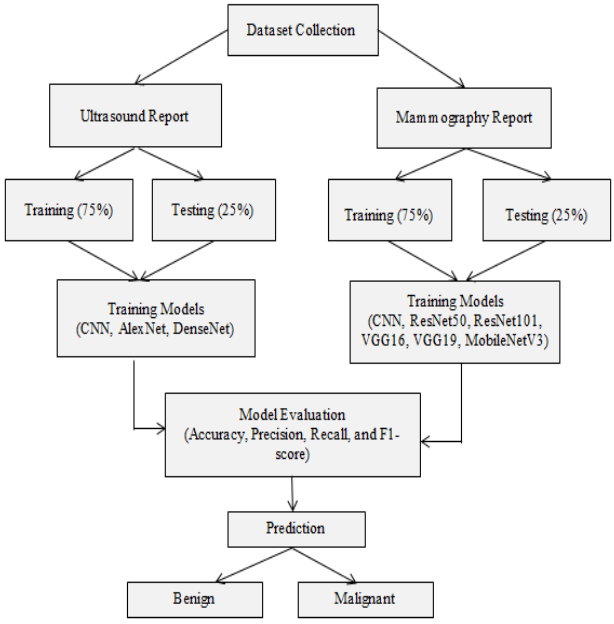

Fig. 2. Dataset-specific training and evaluation pipeline for ultrasound and mammography-based breast cancer classification.

The detailed experimental pipeline is illustrated in Fig. 2, outlining the dataset-specific model development process. The collected data are categorized into two imaging modalities: ultrasound reports and mammography reports. Each dataset is divided into 75% training and 25% testing subsets to ensure sufficient learning and reliable evaluation. For the ultrasound dataset, three models—CNN, AlexNet, and DenseNet—are trained to capture texture-based and low-contrast features commonly present in ultrasound images. In contrast, the mammography dataset is evaluated using CNN, ResNet50, ResNet101, VGG16, VGG19, and MobileNetV3, enabling an in-depth comparison of shallow, deep, and lightweight architectures on high-resolution mammographic data.

A. Data Collection

The dataset used in this study was compiled from a combination of publicly available online repositories and offline clinical sources to ensure data diversity and reliability. The dataset consists of two primary imaging modalities: ultrasound and mammography. Ultrasound image data were collected from open-source platforms, including Kaggle, Hugging Face, and the UCI Machine Learning Repository.

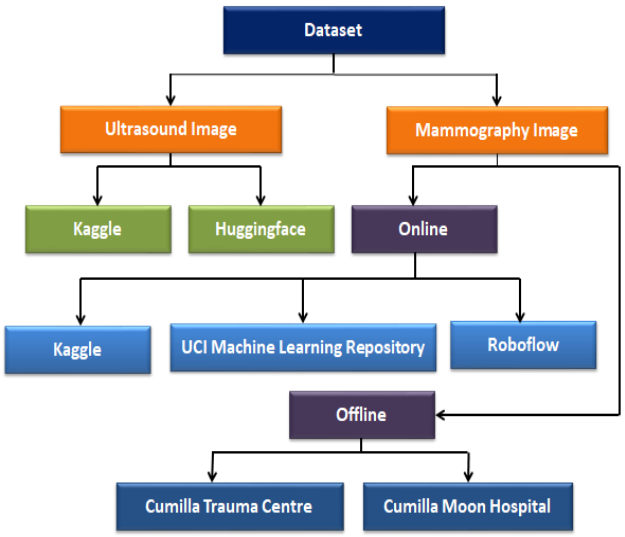

Fig. 3. Dataset collection process

Mammography images were obtained from online repositories, including the UCI Machine Learning Repository and Roboflow. To enhance clinical relevance, additional imaging data were collected from offline healthcare facilities, namely Cumilla Trauma Centre and Cumilla Moon Hospital. All offline data were acquired in compliance with institutional ethical guidelines, and patient-identifiable information was removed to maintain privacy and confidentiality. In this study, we have collected data from various sources, including Kaggle, UCI Machine Learning Repository, Roboflow, Hugging Face, and others.

Nearly 13k data have been collected. The aggregation of raw data from multiple online sources is used in the study (see Fig. 4). It showcases four publicly available platforms: Kaggle, UCI Dataset, Roboflow, and Hugging Face, each serving as an individual data source. All these sources are connected through a common pipeline that converges into a single repository labelled Raw Dataset. The study utilizes datasets collected from multiple public repositories and clinical sources, which may introduce variability due to differences in imaging protocols, acquisition devices, and annotation practices. Such source-specific biases and domain shifts can affect model generalization across different data distributions. While the proposed models demonstrate strong performance on the available datasets, further investigation using domain adaptation techniques and standardized datasets is necessary to improve robustness in real-world clinical settings. This diagram represents the initial stage of the data collection process, in which heterogeneous datasets from different platforms are combined into a unified raw dataset prior to further preprocessing, cleaning, and analysis.

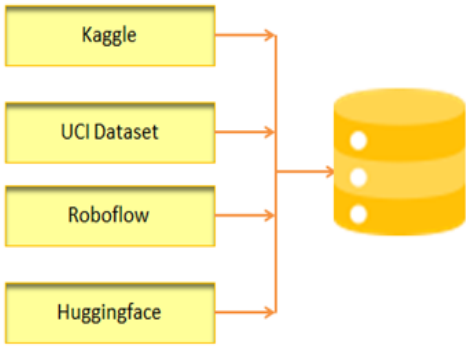

Fig. 4. Aggregation of raw dataset from multiple online sources.

The dataset used in this research consists of labelled mammographic images categorized into two clinically significant classes: Benign and Malignant, as illustrated in the figure. Benign images represent non-cancerous abnormalities, and malignant images correspond to confirmed cancerous cases. Fig. 3 describes the whole process of dataset collection. The mammograms exhibit variations in shape, texture, and tissue density, which are critical features for effective breast cancer detection. This diversity makes the dataset well-suited for training and evaluating machine learning models, as it enables them to learn discriminative patterns associated with different breast conditions. The dataset plays a crucial role in improving the robustness and accuracy of the proposed ML-based breast cancer detection system. The dataset used in this study was collected from two medical institutions in Bangladesh: Cumilla Moon Hospital and Cumilla Trauma Centre. A total of over 1,000 mammographic images were obtained with proper authorization and anonymization to ensure patient privacy. The collected data include cases classified as benign or malignant based on clinical diagnoses provided by experienced medical professionals. These real-world clinical images reflect a wide range of breast tissue characteristics, imaging conditions, and pathological variations, making the dataset representative of practical diagnostic scenarios (see Fig. 5).

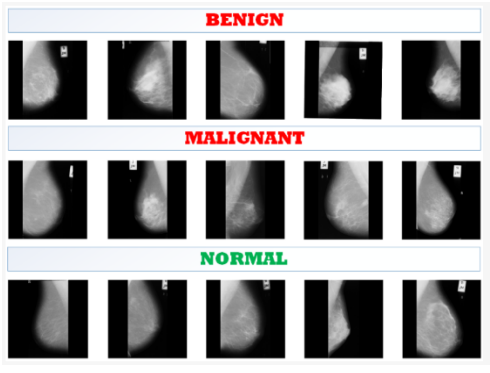

Fig. 5. Mammogram samples: Benign, malignant, and normal [4].

This dataset forms the foundation for training, validation, and performance evaluation of the proposed machine learning–based breast cancer detection models.

B. Image Preprocessing

Several essential preprocessing operations were performed internally within the convolutional neural network (CNN) models as part of the learning pipeline. The input images were first resized to match the fixed input dimensions required by the network architectures. Pixel intensity scaling and normalization were handled automatically within the model to stabilize gradient propagation and accelerate convergence during training. Convolutional layers learned hierarchical feature representations directly from the raw images, progressively capturing low-level features such as edges and textures, followed by higher-level semantic patterns.

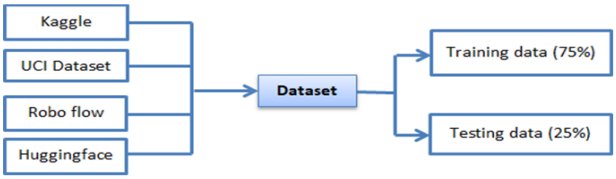

Fig. 6. Data preparation

Fig. 6 depicts the data preparation steps of this system, where, after data collection, a dataset was created. Then, the dataset splitting was done. The processed data fit the model. Here, data is gathered from different sources, which include ultrasound reports of the breast, and it is a very common report in breast cancer detection, where the patient's report is evaluated. Data is also collected from a medical-based website. This dataset was partitioned into two subsets for model development and evaluation. Specifically, 75% of the data was allocated for training, while the remaining 25% was reserved for testing. This data splitting strategy was employed to ensure effective model learning while enabling unbiased performance evaluation on unseen data.

Additionally, normalization layers embedded within the networks, such as batch normalization, mitigated internal covariate shift by standardizing intermediate feature distributions during training. Regularization mechanisms, including dropout layers, were employed to reduce overfitting and improve model generalization. Where applicable, data augmentation operations, such as random rotation, flipping, scaling, and intensity variation, were incorporated into the training pipeline and applied dynamically to input images. By integrating all preprocessing-related operations within the CNN framework, the proposed approach enables end-to-end learning, minimizes manual intervention, and enhances robustness across diverse imaging conditions.

C. Model Development

In this research, a convolutional neural network (CNN) is used as a baseline model to automatically classify breast images as benign or malignant, using both ultrasound and mammography datasets. CNNs are especially well-suited for medical images because they can learn hierarchical features directly from raw pixels, reducing the need for manual feature extraction. When a breast image is fed into the CNN, the network assigns learnable weights to small local regions, enabling it to capture important patterns such as mass boundaries, texture changes, and variations in tissue density. Compared to traditional machine learning methods, CNNs require less preprocessing and are highly effective at learning discriminative features from complex medical images.

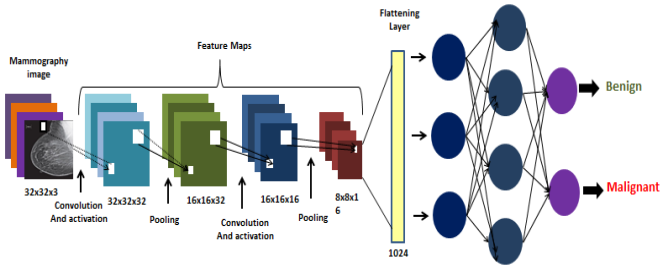

Fig. 7. Layer-wise architecture of the proposed CNN for mammography image classification. The network comprises three convolutional blocks with 32, 64, and 128 filters, followed by batch normalization, max-pooling, flattening, and fully connected layers with dropout regularization. The model was trained on a learning rate of 0.001 and 10 epochs. The final output layer performs binary classification into benign and malignant classes.

The CNN architecture used in this study follows a clear workflow, as shown in Fig. 7. It starts with an input layer that accepts preprocessed ultrasound or mammography images. These images then pass through several convolutional layers with learnable kernels, which automatically extract features ranging from low-level patterns like edges and contours to higher-level details such as lesion-specific textures. Nonlinear activation functions are applied after each convolution to give the network more flexibility in representing complex patterns. Pooling layers follow, reducing the size of the feature maps while keeping the important information, which helps lower computational costs and makes the model more robust to shifts or small changes in the images. The resulting feature maps are then flattened and passed through fully connected layers, which combine the learned features to make predictions. Finally, an output layer with a softmax activation produces probability scores for the benign and malignant classes.

On the ultrasound dataset, the baseline CNN achieved an accuracy of 85%, indicating that it can effectively capture basic texture and structural information. For mammography images, the CNN performed even better, reaching 97% accuracy, with an F1-score of 97%, macro-average of 96%, and weighted-average of 97%. These results highlight that a well-designed shallow CNN can handle high-quality mammograms, in which lesion boundaries and tissue density differences are more pronounced.

To further evaluate performance, AlexNet was also tested on these medical images. Thanks to its large convolutional kernels and deep fully connected layers, AlexNet is particularly good at capturing coarse texture features. On ultrasound images, AlexNet achieved the highest accuracy of 89%, outperforming both the baseline CNN and DenseNet. This suggests that AlexNet's design is well-suited for ultrasound data, where speckle noise and low-contrast patterns make feature extraction more challenging.

AlexNet is one of the early deep convolutional neural networks, with five convolutional layers and three fully connected layers. It is particularly good at capturing coarse texture features in medical images, especially ultrasound scans. Its large

kernels, ReLU activations, dropout layers, local response normalization, and data augmentation all work together to make learning more robust, even in the presence of speckle noise and low-contrast patterns. Designed to take full advantage of GPU processing, AlexNet outperformed baseline CNNs and DenseNet on ultrasound images, achieving 89% accuracy. This success comes from its deeper architecture, faster convergence, strong regularization, and ability to efficiently handle large datasets.

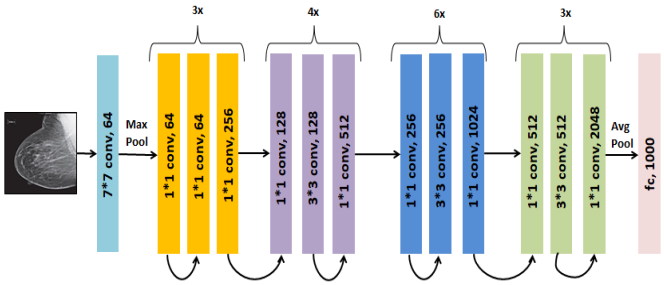

Fig. 8. Customized ResNet-50 architecture employed for mammographic image classification. The model consists of an initial 7×7 convolutional layer with 64 filters followed by max pooling, and four residual stages containing 3, 4, 6, and 3 bottleneck blocks, respectively. Each stage uses 1×1 and 3×3 convolutions with increasing feature dimensions (64–2048) to extract hierarchical features from mammograms. Global average pooling and a fully connected layer with 1000 neurons are used to produce the final classification output.

ResNet50 uses residual learning to make training deep networks more stable and efficient. On mammography images, it achieved an accuracy of 94%, with an F1-score of 93%, a macro-average of 93%, and a weighted-average of 94%. While its residual connections improved feature learning compared to VGG-based models, ResNet50 did not outperform the baseline CNN, suggesting that adding more depth isn't always necessary for mammogram classification.

The ResNet50 architecture, shown in Fig. 8, is structured into four main parts: convolutional layers, identity blocks, convolutional blocks, and fully connected layers. The convolutional layers first extract features from the input image. The identity and convolutional blocks then process and refine these features, while the fully connected layers make the final classification.

ResNet101 takes this a step further by increasing the network's depth to capture more complex patterns. It achieved slightly better results on mammography images, with an accuracy of 95% and F1 and average metrics around 95–96%. However, the performance gain over ResNet50 was marginal, suggesting that simply increasing depth can introduce redundancy without significantly improving diagnostic accuracy.

Fig. 9 shows the architecture of a customized ResNet-101–based CNN used for classifying mammography images. The process starts with a 7×7 convolutional layer with 64 filters, followed by max pooling to capture low-level features and reduce the spatial size of the image. The network then goes through four residual stages made up of identity blocks, which allow the deep architecture to train efficiently. The Conv2, Conv3, Conv4, and Conv5 stages contain 3, 4, 23, and 3 blocks, with channel depths increasing from 256 to

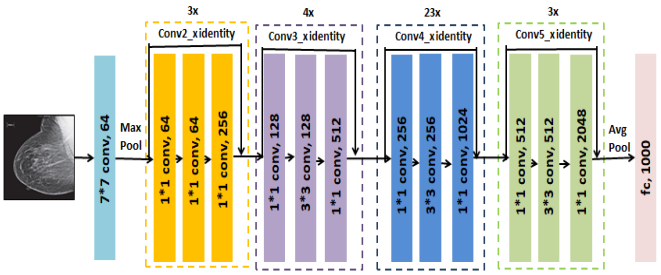

Fig. 9. Architecture of the customized ResNet-101–based CNN used for mammography image classification. The network begins with a 7×7 convolution and max-pooling, followed by four residual stages comprising Conv2 (3×), Conv3 (4×), Conv4 (23×), and Conv5 (3×) identity blocks with increasing channel depths of 256, 512, 1024, and 2048, respectively. Global average pooling and a fully connected layer with 1000 units are used for final classification.

2048. This structure helps the network progressively learn richer and more complex feature representations. After these stages, global average pooling condenses the information into a compact feature vector, which is then passed to a fully connected layer with 1000 units for classification.

MobileNetV3, on the other hand, is a lightweight model designed for efficiency. On mammography images, it achieved 92% accuracy, an F1-score of 91%, and balanced macro and weighted averages of 92%. While its performance is slightly lower than that of deeper residual models, MobileNetV3 offers a good balance between accuracy and computational cost, making it ideal for resource-constrained settings.

For experimental consistency, all deep learning models were trained using the Adam optimizer for 10 epochs with a learning rate of 0.001. The experiments revealed interesting trends across imaging types. Ultrasound images benefit from models that capture texture-rich features, such as AlexNet and DenseNet. Mammography images, with their clearer structures and higher contrast, consistently achieved better classification performance. Interestingly, the baseline CNN outperformed some of the deeper architectures on mammograms, suggesting that adding more depth doesn't always yield better results. Finding the optimal model complexity is key to balancing accuracy and efficiency.

D. Training and Evaluation

The training and evaluation process was designed to ensure robust learning, fair comparison among models, and reliable performance assessment across different imaging modalities. The collected dataset consists of ultrasound reports and mammography images, which were handled independently to preserve modality-specific characteristics. Each dataset was partitioned into training and testing subsets using a 75:25 split, ensuring sufficient data for model learning while retaining an unbiased test set for evaluation.

Prior to training, all images were resized to a uniform input dimension compatible with the selected network architectures. Pixel intensity values were normalized to improve convergence and stabilize the learning process. Labels were assigned according to clinical diagnosis, categorizing images into benign

and malignant classes. Data shuffling was applied to minimize ordering bias during training.

For the ultrasound dataset, deep learning models, including CNN, AlexNet, and DenseNet, were trained. In contrast, the mammography dataset was evaluated using various architectures, including CNN, ResNet50, ResNet101, VGG16, VGG19, and MobileNetV3. Transfer learning was employed where applicable by initializing networks with pre-trained weights and fine-tuning the higher layers to adapt to breast cancer imaging features. This strategy reduced training time and improved generalization, particularly for datasets with limited samples.

Model training was carried out using the Adam optimizer, with categorical cross-entropy as the loss function. The learning rate was empirically tuned to achieve stable convergence, and early stopping was applied to prevent overfitting by monitoring validation loss. Batch size and number of epochs were selected based on computational efficiency and model performance during preliminary experiments:

$$P = \frac{TP}{TP + FP} \tag{1}$$

To evaluate classification effectiveness, multiple performance metrics were employed, including accuracy, precision, recall, and F1-score, which collectively provide a balanced assessment of model reliability, especially in the presence of class imbalance. Accuracy measures overall correctness, while precision and recall quantify false-positive and false-negative behavior, respectively. where TP and FP represent true positives and false positives, respectively. The recall R evaluates the ratio of correctly detected damaged regions to the total number of actual damaged regions:

$$R = \frac{TP}{TP + FN} \tag{2}$$

where, FN denotes false negatives.

The F1-score, which is the harmonic mean of precision and Recall, provided a balanced assessment of detection:

$$F1 = 2 \times \frac{P \times R}{P + R} \tag{3}$$

The F1-score is a harmonic mean of precision and recall, providing a comprehensive indicator of diagnostic performance. Comparative evaluation was conducted across all trained models to identify the most effective architecture for each imaging modality. The final prediction stage classifies input images as either benign or malignant, thereby supporting clinical decision-making with consistent and interpretable results. The evaluation framework ensures that the proposed system is both robust and generalizable, demonstrating its suitability for real-world breast cancer diagnosis applications.

IV. Results and Discussion

This section analyzes the performance of the proposed models using both quantitative evaluation metrics and qualitative visual inspection. Quantitative results highlight numerical performance differences, while qualitative analysis, as shown in confusion matrices, provides insight into classification consistency and misclassification patterns.

A. Result Analysis

1) Quantitative performance analysis: The quantitative evaluation of the framework is presented through performance metrics obtained from mammography and ultrasound datasets, as summarized in Table I and Table II, respectively. The models were assessed using accuracy, precision, recall, and F1-score to ensure a comprehensive evaluation under class imbalance conditions.

TABLE I. Performance Comparison of Deep Learning Models on the Mammography Dataset (Precision, Recall, F1-Score are Written as Benign/Malignant Format).

Model	Precision	Recall	F1-Score	Accuracy
CNN	97% / 96%	95% / 97%	96% / 97%	97%
ResNet50	92% / 95%	94% / 93%	93% / 94%	94%
ResNet101	95% / 95%	94% / 96%	95% / 96%	95%
VGG16	91% / 90%	87% / 93%	89% / 92%	90%
VGG19	91% / 90%	87% / 93%	89% / 91%	90%
MobileNetV3	88% / 95%	94% / 90%	91% / 92%	92%

For the mammography dataset (Table I), the CNN model achieved the highest overall performance with an accuracy of 97%, demonstrating balanced precision and recall for both benign and malignant classes (precision: 97%/96%, recall: 95%/97%). This indicates strong discriminatory capability and stable generalization. ResNet101 performed closely, achieving 95% accuracy of 95%, benefiting from residual learning to capture complex mammographic patterns. ResNet50 achieved a slightly lower accuracy of 94%, suggesting that deeper residual connections in ResNet101 contribute to improved feature representation.

VGG-based architectures (VGG16 and VGG19) exhibited comparatively lower accuracy (90%), primarily due to reduced recall for benign cases (87%), indicating higher false-negative rates. MobileNetV3 achieved an accuracy of 92%, offering a favorable trade-off between performance and computational efficiency, particularly with high malignant recall (94%), which is clinically significant for cancer detection.

TABLE II. Accuracy Comparison of Models on the Ultrasound Dataset.

Model	Accuracy
CNN	85%
AlexNet	89%
DenseNet	88%

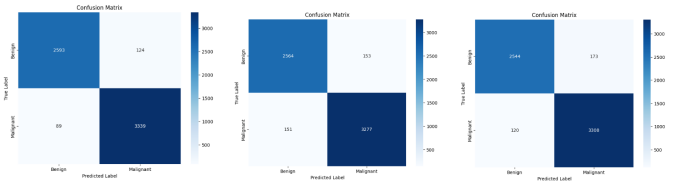
For the ultrasound dataset (Table II), overall classification performance was lower compared to mammography, reflecting the inherent challenges of ultrasound imaging, such as noise, speckle artifacts, and low contrast. Among the evaluated models, AlexNet achieved the highest accuracy of 89%, followed by DenseNet at 88% and CNN at 85%. The improved performance of AlexNet and DenseNet indicates their effectiveness in capturing texture-based features from ultrasound images.

Overall, the quantitative results confirm that mammography-based classification outperforms ultrasound-based classification across all evaluated models. The superior

performance of CNN and ResNet101 on mammographic images highlight the importance of deep hierarchical feature learning for high-resolution medical imaging. The performance reporting in this study is not fully symmetric across modalities. For the mammography dataset, detailed evaluation metrics including precision, recall, F1-score, and accuracy are reported, whereas for the ultrasound dataset, only accuracy values are presented. This difference arises from the original experimental setup and the available evaluation outputs. Although this limits a strictly uniform cross-modal comparison, the results still provide meaningful insights into model performance trends across different imaging modalities. Future work will focus on extending the evaluation to include comprehensive metrics for all datasets to enable a fully balanced comparison. These findings demonstrate the robustness and clinical relevance of the proposed deep learning framework for automated breast cancer diagnosis.

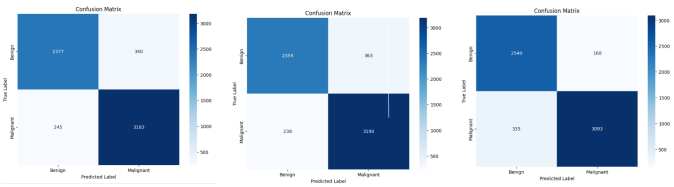
2) Qualitative performance analysis: Qualitative analysis is performed to visually evaluate the classification behavior of the proposed deep learning models beyond numerical performance metrics. Confusion matrices provide intuitive insight into how well each model distinguishes between benign and malignant mammographic images, highlighting both correct predictions and patterns of misclassification.

As illustrated in Fig. 10 and Fig. 11, the confusion matrices of all six models exhibit strong diagonal dominance, indicating a high number of correctly classified samples for both benign and malignant classes. The CNN-based model shows a relatively balanced distribution of true positives and true negatives, with only a limited number of false classifications. This suggests that the model effectively captures essential features required for mammogram classification.



(a) CNN (b) ResNet50 (c) ResNet101

Fig. 10. Confusion matrix for CNN, ResNet50 and ResNet 101 on the mammography image.



(a) VGG16 (b) VGG19 (c) MobileNetv3

Fig. 11. Confusion matrix for VGG16, VGG19 and MobileNetv3 on the mammography image.

The MobileNetV3 confusion matrix demonstrates improved detection of malignant cases, as reflected by a higher count of true positives, although a small number of benign cases are miResNet-based architectures, these models exhibit a slightly increased misclassification of benign cases, which may be attributed to their architectural complexity and the achieves the most consistent separation between the two classes, highlighting the advantage of deeper residual learning in minimizing classification errors.

The VGG16 and VGG19 models also present strong performance, with a high proportion of malignant samples correctly identified. However, compared to ResNet-based architectures, these models exhibit slightly higher misclassification rates of benign cases, which may be attributed to their greater architectural complexity and the absence of residual connections.

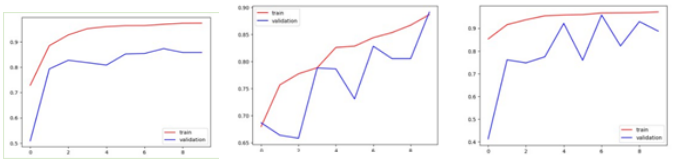
Overall, the visual analysis confirms that all evaluated models are capable of effective mammogram classification, with ResNet101 and CNN providing the most balanced and reliable predictions. The qualitative observations are consistent with the quantitative results, reinforcing the effectiveness of deep learning approaches for breast cancer detection.

B. Discussion

This study presents a comparative analysis of multiple CNN-based architectures for breast cancer classification, utilizing both ultrasound and mammography imaging modalities. A clear performance gap is observed between the two imaging modalities. Overall, mammography-based models consistently outperform ultrasound-based models, achieving higher accuracy, F1-score, macro-average, and weighted-average values. Although the proposed framework achieves strong classification performance, the current study does not evaluate computational complexity, training overhead, inference latency, memory consumption, or deployment cost. These factors are important for real-world clinical deployment, where resource efficiency and scalability are critical. Therefore, a comprehensive evaluation of these aspects is considered as a potential direction for future work. This outcome can be attributed to the higher contrast, clearer structural details, and more consistent appearance of lesions in mammography images compared to ultrasound images, which often suffer from speckle noise and low contrast.

1) Ultrasound-based model performance: For the ultrasound dataset, AlexNet achieved the highest accuracy of 89%, followed closely by DenseNet at 88%, while the baseline CNN achieved 85% accuracy. As shown in Fig. 12(b) and Fig. 12(c), these models demonstrate faster convergence during training but exhibit noticeable fluctuations in validation accuracy. Such instability reflects the inherent variability and noise present in ultrasound images.

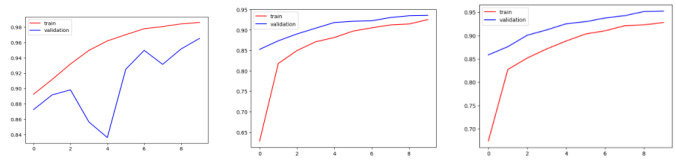
AlexNet's superior performance suggests that architectures with larger convolutional kernels and strong texture-extraction capabilities are more effective for ultrasound imaging. DenseNet also performed competitively due to its dense feature reuse mechanism; however, the increased architectural complexity did not translate into significant performance gains. The baseline CNN, while simpler, showed limited capability in modeling the complex texture patterns characteristic of ultrasound images [see Fig. 12(a)].



(a) CNN (b) AlexNet (c) DenseNet

Fig. 12. Training and validation accuracy curves for CNN, AlexNet, and DenseNet on the ultrasound dataset.

2) Mammography-based model performance: In contrast, mammography-based experiments yielded substantially higher and more stable performance across all models. Notably, the baseline CNN achieved the best overall performance, with an accuracy of 97%, an F1-score of 97%, a macro-average of 96%, and a weighted-average of 97%. As illustrated in Fig. 13(a), the CNN model exhibits smooth convergence and minimal divergence between training and validation curves, indicating strong generalization and low overfitting.



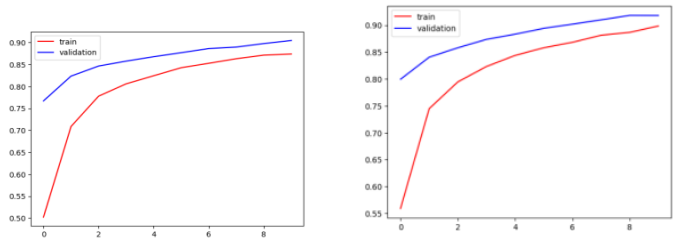
(a) CNN (b) ResNet50 (c) ResNet101

Fig. 13. Training and validation accuracy curves for CNN, ResNet50, and ResNet101 on the mammography dataset.

Among deeper architectures, ResNet101 achieved 95% accuracy, marginally outperforming ResNet50 (94%). Fig. 13(b) and Fig. 13(c) show that residual networks benefit from stable training dynamics due to skip connections, yet the additional depth of ResNet101 provides only limited improvement over ResNet50. This suggests diminishing returns from increased network depth when applied to high-quality mammographic data.

3) Performance of VGG and mobilenet architectures: VGG16 and VGG19 achieved moderate performance with accuracies of 90%, as shown in Fig. 14(a) and corresponding results in the table. Although VGG architectures are effective feature extractors, their large parameter count and lack of residual connections may contribute to overfitting and reduced generalization in medical imaging tasks.

MobileNetV3 achieved an accuracy of 92%, offering a favorable balance between performance and computational efficiency. As shown in Fig. 14(b), MobileNetV3 demonstrates stable learning behavior, making it a practical choice for deployment in resource-constrained clinical environments, despite slightly lower accuracy compared to deeper residual models. These findings emphasize that architecture selection should be guided by data characteristics rather than depth alone, particularly in medical imaging applications. The strong performance and stable generalization of the baseline CNN on mammography images highlight its potential for integration into computer-aided diagnosis (CAD) systems. Such systems



(a) VGG16 (b) MobileNetv3

Fig. 14. Training and validation accuracy curves for VGG16 and MobileNetv3 on the mammography dataset.

can assist radiologists by providing reliable second opinions, improving early detection rates, and ultimately enhancing patient outcomes.

4) Comparative analysis with existing studies: Previous papers on breast cancer detection have predominantly relied on traditional machine learning techniques, such as Support Vector Machines (SVM), K-Nearest Neighbors (KNN), Random Forests, and Logistic Regression, often using handcrafted features and benchmark datasets, including the Wisconsin Breast Cancer Dataset or limited histopathological image collections. While these approaches have demonstrated reasonable classification accuracy, their effectiveness is constrained by manual feature engineering, limited scalability to large image datasets, and reduced robustness when handling complex visual patterns and class imbalance.

In contrast, the proposed study adopts a deep learning–based approach that eliminates the need for handcrafted feature extraction by enabling automatic hierarchical feature learning through convolutional neural networks. Unlike earlier works that focus on a single imaging modality, this research performs a comparative analysis of both ultrasound and mammography images, providing a more comprehensive evaluation of modality-specific diagnostic performance.

Moreover, several prior studies report results based on a single or limited number of classifiers, whereas the proposed framework evaluates multiple CNN architectures, including CNN, AlexNet, DenseNet, ResNet50, ResNet101, VGG16, VGG19, and MobileNetV3. This comprehensive model comparison enables a deeper understanding of how network depth, residual learning, and lightweight architectures impact breast cancer classification accuracy.

Another key limitation of earlier research is the reliance on public or small-scale datasets, which may not accurately reflect real-world clinical scenarios. The proposed study addresses this gap by validating models using real-world ultrasound and mammography datasets, thereby enhancing the clinical relevance and generalizability of the findings.

Performance-wise, the proposed framework achieves superior accuracy and F1-score, particularly in mammography-based classification, where the CNN and ResNet101 models outperform traditional machine learning methods reported in prior literature. Additionally, the use of macro and weighted-average metrics ensures a more reliable evaluation under conditions of class imbalance, a consideration often overlooked

in earlier studies.

Overall, the proposed research advances existing work by offering a modality-aware, deep learning–driven, and clinically relevant framework that demonstrates improved diagnostic performance and robustness, making it more suitable for practical deployment in computer-aided breast cancer diagnosis systems.

V. Conclusion

This study has presented a deep learning–based framework for automated breast cancer classification using ultrasound and mammography images. Multiple CNN architectures, including CNN, AlexNet, DenseNet, ResNet50, ResNet101, VGG16, VGG19, and MobileNetV3, were systematically evaluated to analyze modality-specific performance. The experimental results demonstrate that deep learning models effectively learn discriminative features directly from medical images, eliminating the need for handcrafted feature extraction and outperforming traditional machine learning approaches.

Mammography-based classification achieved superior performance compared to ultrasound imaging, with CNN and ResNet101 producing the highest accuracy and F1-scores, highlighting the effectiveness of deeper architectures in capturing complex structural patterns. The present study does not include robustness evaluation under challenging conditions such as noisy inputs, image corruption, or domain shift scenarios. As a result, the stability and generalization ability of the proposed models under real-world variations in medical imaging data remain unverified. Future research will focus on addressing these issues by incorporating robustness testing and domain adaptation techniques. Although ultrasound-based results were comparatively lower due to inherent image noise and low contrast, AlexNet and DenseNet exhibited stable learning behavior and competitive performance. Overall, the proposed framework offers a robust and clinically relevant computer-aided diagnostic solution that can aid radiologists in early breast cancer detection and informed decision-making.

Future research will focus on expanding the framework using larger multi-institutional datasets to improve generalization. Incorporating advanced data augmentation techniques, class imbalance handling methods, attention mechanisms, and tumor localization or segmentation modules may further enhance diagnostic accuracy and interpretability. Additionally, real-time deployment and clinical validation remain crucial directions for the practical adoption in healthcare settings.

Optimization of Service Function Chain Placement in Cloud-Fog-Edge Networks

Chandrapal Singh Dangi, Sanjay Sharma
Department of Mathematics, Bioinformatics and Computer Applications,
Maulana Azad National Institute of Technology, Bhopal, India

***Abstract*—There is an explosion in IoT devices, 5G technology, and MECs, that results in increasing demands on effective and scalable network services management. Service function chaining, defined as the sequence of functions in VNFs on a path, is one of the core principles behind the NFV architecture design. SFC allocation to the heterogeneous clouds–fogs–edges network is an NP-hard problem characterized by mutually conflicting goals, such as latency minimization, energy and cost reduction, and resource maximization. In this study, an in-depth comparison study is carried out on three population-based optimization algorithms for solving the placement problem of SFCs using Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Grey Wolf Optimization (GWO) on three cases: (1) VNF deployment cost/QoE optimization in a 5G hybrid cloud with 12 nodes and weighting factor γ=0.4; (2) SFC graph matching on MEC-NFV networks with a 100-node physical network, 20 VNFs, and equal utilization weights α=β=γ=1/3; and (3) multi-instance SFC mapping on Fog-to-Cloud (F2C) IoT environment with a 5-VNF chain across 5 nodes. These three algorithms have been evaluated under identical conditions: 10 independent runs, 200 iterations, 20–30 agents. Results demonstrate that GWO achieves the best VNF deployment objective (W=73.92, a 15.1% improvement over the BGWO baseline), PSO achieves the highest resource utilization (52.9%) in MEC-NFV placement, and both PSO and GWO reduce F2C end-to-end latency by 25% compared to the ILP reference (12 vs. 16 units at three instances), while all three algorithms reduce latency by approximately 80% relative to cloud-only deployment. PSO emerges as the most consistently high-performing algorithm across all three scenarios.**

I. Introduction

The convergence of cloud computing, edge intelligence, and programmable networking has fundamentally transformed how network services are designed, deployed, and managed. Modern communication infrastructures increasingly rely on Network Function Virtualization (NFV) to decouple network functions traditionally implemented in dedicated hardware from their physical substrates. This paradigm enables deploying network services as software modules, known as Virtual Network Functions (VNFs), hosted on commodity servers in cloud data centers, edge nodes, or fog computing layers [1], [2].

A *Service Function Chain* (SFC) is an ordered sequence of VNFs through which network traffic must traverse to receive a composite service. A typical SFC for online gaming, for instance, consists of a Network Address Translator (NAT), Firewall (FW), Video Optimization Controller (VOC), WAN Optimization Controller (WOC), and Intrusion Detection and Prevention System (IDPS), each applied sequentially to user traffic [3]. The problem of SFC allocation, which involves placing each VNF on its corresponding physical node and routing data to the respective node accordingly, forms the core issue addressed in this [4] research study.

The development of telecommunication technology, for instance, the fifth generation (5G) of mobile telecommunication networks, and new areas of research and application, such as the Internet of Things (IoT), alter the resource access paradigm of the CSPs. In order to cut down the access time and enhance the QoS, resources are placed near the cloud users, and therefore, the paradigm of mobile edge computing (MEC) has been introduced. The cloud users access the network resources via their Mobile Devices using the base station and obtain their service.

There are three main reasons why this problem is difficult. The first is that there are two competing goals, namely reducing latency which favors edge/fog computing and saving costs which favors the central cloud. The second reason is due to heterogeneity in the resources available at the nodes leading to complicated interactions of constraints. Lastly, the problem is NP-Hard [5].

This study seeks to examine whether PSO, ACO, and GWO algorithms can be used to allocate SFCs in three selected environments; 5G cloud environment [6], MEC-NFV [7], and F2C IoT. The 5G Cloud SFC focuses on high throughput and centralized management. The MEC-NFV SFC focuses on ultra-low latency and edge computing capabilities.The F2C IoT SFC focuses on distributed service placement, energy efficiency, and heterogeneity of IoT resources. Thus, SFC management is getting increasingly more decentralized and complicated when transitioning from 5G Cloud to MEC-NFV and further to F2C IoT.

Principal contributions:

- We propose a metaheuristic algorithm-based approach to solve 3 SFC architectures 5G Cloud Environment,MEC-NFV Environment and F2C (Fog-to-Cloud) IoT Environment.
- We have simulated all 3 SFC scenario in python programming version 3.11 and the simulation results demonstrated that GWO outperforms BGWO by +15.1%; PSO outperforms with 52.9% MEC-NFV efficiency; PSO/GWO cut down F2C delay by 25% relative to ILP.
- Consistent execution and systematic comparison of PSO, ACO, and GWO algorithms in three different

SFC configurations. Thorough testing under completely controlled conditions for valid statistical comparisons.

- Concrete algorithm selection recommendation for cloud-fog/edge systems.

II. Related Work

SFC placement and VNF deployment have attracted substantial research across multiple network paradigms. In MEC contexts, strategies range from QoS-aware placement algorithms targeting service availability and access latency [8] to dynamic schedulers that minimize VNF migrations as user mobility patterns evolve. Integer Linear Programming (ILP) and Mixed ILP formulations provide optimal solutions for small-scale SFC placement instances, but become computationally intractable as network size grows [9]. Column-generation approaches extend ILP tractability by decomposing the problem into configuration enumeration and selection phases, though these remain limited by quadratic constraint structures [10].

Metaheuristic algorithms have emerged as a dominant paradigm for large-scale SFC optimization. PSO has been applied to mobility-aware VNF placement enabling dynamic reallocation as users move between base stations. ACO has been used to balance communication delay against VNF relocation count through pheromone-trail encoding. Genetic Algorithms have demonstrated effectiveness in multi-objective formulations approximating latency-cost Pareto fronts [11]. Grey Wolf Optimization (GWO), inspired by the social hierarchy and hunting behavior of grey wolves, has been applied to VNF deployment in hybrid cloud infrastructures. The Binary GWO (BGWO) variant addresses the discrete nature of VNF assignment through sigmoid-based position discretization [12]. Comparative studies suggest GWO achieves faster convergence than genetic algorithms on similar combinatorial problems due to its adaptive exploration–exploitation balance.

In Fog-to-Cloud (F2C) computing, SFC mapping presents additional complexity from heterogeneous fog-to-cloud latency characteristics. Multi-instance SFC deployment has been shown to substantially reduce end-to-end latency by enabling traffic assignment to the nearest available instance [13]. Graph-matching formulations have been proposed for MEC-NFV placement, where similarity between the VNF forwarding graph and the physical network graph is maximized using LP followed by Hungarian algorithm-based mapping, reducing execution time and improving node utilization [14].

Recent advances in Service Function Chain (SFC) placement and Virtual Network Function (VNF) deployment have increasingly leveraged Deep Reinforcement Learning (DRL) and hybrid optimization techniques to address the challenges of dynamic and large-scale network environments. Zhou et al. [15] proposed a DRL-based multi-objective SFC placement framework that jointly optimizes resource utilization, latency, and service acceptance rates in NFV-enabled networks. Their approach demonstrated the effectiveness of reinforcement learning in adapting placement decisions to changing network conditions while improving overall service performance.

Feng et al. [16] introduced a hybrid Deep Reinforcement Learning-Greedy (DRL-G) algorithm for SFC deployment in space–air–ground integrated networks. The proposed framework combines the adaptive learning capability of DRL with the computational efficiency of greedy search to optimize deployment cost, energy consumption, and service latency. Experimental results showed improved scalability and convergence compared to conventional optimization methods.

In Li et al. [17], the authors suggested an optimized approach to cache and dynamically migrate services in the MEC environment by implementing a Deep Q-Network (DQN). They pointed out that the users' movement and insufficient MEC coverage result in disruption of services, higher latency, and increased energy costs. For solving these problems, they combined edge caching with intelligent migration of services.

To address distributed orchestration challenges in edge environments, Li et al. [18] developed a multi-agent reinforcement learning (MARL) framework for SFC placement in edge computing networks. By enabling multiple agents to collaboratively perform VNF deployment and path selection decisions, the proposed approach achieved higher resource utilization and service provider profitability while supporting decentralized network management.

In general, the literature presents a clear evolution in terms of moving from cloud placement to dynamic cloud-fog-edge placement of services that are QoS aware, energy efficient, and mobility aware. The surveys present very good taxonomies, but recent research on algorithms presents heuristic, approximations, game theory, and meta-heuristics approaches. Nevertheless, there are some issues that are not well covered, such as the combination of VNF placement with routing, dynamic multi-service function chain requests, user mobility, failure tolerance, scaling, and unified optimization of latency, energy, resource efficiency, throughput, and reliability.

Despite the breadth of existing work, systematic multi-scenario comparative studies evaluating the same set of metaheuristic algorithms across diverse environments under rigorously identical conditions remain scarce. This study addresses that gap.

III. System Model

A. Network Architecture

The study considers three representative deployment environments unified by the Fog-to-Cloud continuum: IoT devices connect to nearby Fog/Edge nodes, which link to regional edge clouds and a central cloud data center. SFC placement determines which layer hosts each VNF, directly controlling service latency, energy consumption, and resource utilization. Fig. 1 illustrates the SFC architecture and VNF chain structure.

B. Scenario I: 5G Hybrid Cloud

The first scenario models a 5G network with a hybrid cloud infrastructure comprising one central cloud server and eleven edge cloud servers (12 nodes total). Each edge cloud serves a set of evolved Node-B (eNB) base stations, with each eNB aggregating VNF requests from hundreds to thousands of mobile users. Inter-cloud latencies are 10–200 ms; eNB-to-edge latencies are 2–5 ms. Each edge cloud offers VMs with 500–1000 MIPS and 512–1024 MB RAM. VNF holding capacity ranges from 100–300 instances per node (600 for the central cloud). The weight factor γ=0.4 governs the trade-off between deployment cost and service delay.

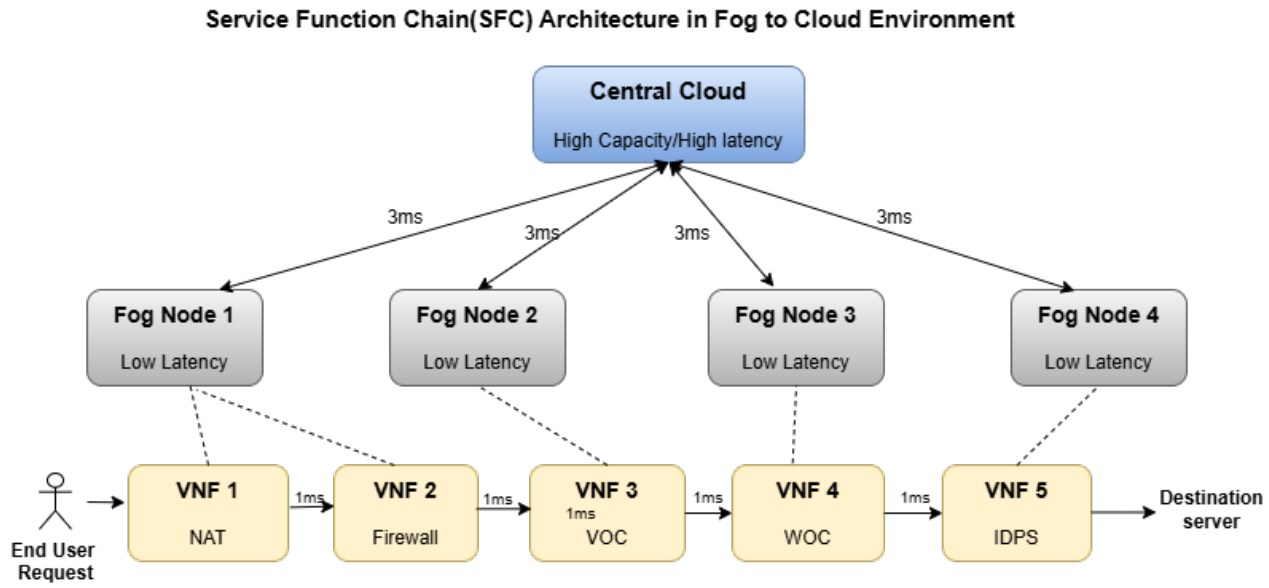

Fig. 1. SFC Architecture. IoT user traffic traverses an ordered chain of five VNFs (NAT, FW, VOC, WOC, IDPS) hosted across fog and cloud nodes. VNF-to-node assignment determines end-to-end latency.

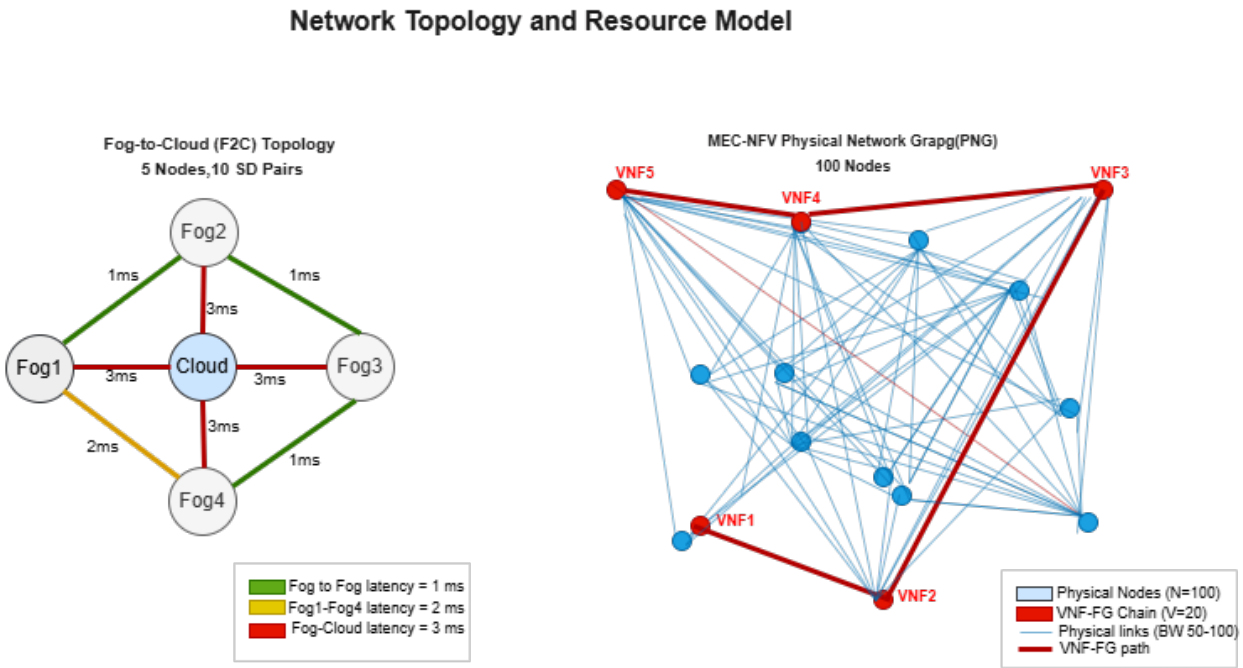

Fig. 2. Network topology models. *Left*: F2C topology (5 nodes). *Right*: Representative subgraph of the 100-node MEC-NFV physical network with the 20-VNF chain highlighted.

C. Scenario II: MEC-NFV Environment

The second scenario considers a three-layer MEC-NFV architecture. The physical network graph (PNG) has N=100 nodes with CPU and memory capacities uniformly in [50, 100] units, 50% connectivity (θ=0.5), and link bandwidths of 50–100 units. VNFs consume 1–20 units of CPU, memory, and bandwidth. The placement objective maximizes a weighted resource utilization with equal weights α=β=γ=1/3.

D. Scenario III: Fog-to-Cloud IoT

The third scenario implements the F2C architecture for IoT services. The topology consists of five nodes: four fog nodes in a mesh and one central cloud node (see Fig. 2). Link latencies follow: fog–fog = 1, fog1–fog4 = 2, fog–cloud = 3 (latency units). Ten source-destination pairs each carry 1 Gbps of traffic through a 5-function service chain (NAT→FW→VOC→WOC→IDPS). The system supports up to seven concurrent SFC instances.

E. Latency and Cost Models

The end-to-end service latency for VNF f assigned to cloud node k from eNB j is:

$$D(f,k,j) = R(f,k,j) + \Upsilon(f,k,j) + \phi(f,k,j) \tag{1}$$

where, $R(f,k,j)$ is the relocation (migration) delay, $\Upsilon(f,k,j)$ is the communication latency (eNB-to-cloud and inter-cloud), and $\phi(f,k,j) = I_j^f/e_k$ is the processing delay (instructions / MIPS).

The deployment cost $B(f,k,j)$ accounts for local vs. remote cloud pricing:

$$B(f,k,j) = \Gamma_{k,j}^f \cdot \vartheta_f \cdot \left[x_k^f \cdot l_k + (1 - x_k^f) \cdot r_k\right] \tag{2}$$

where, l_k and r_k are local and remote unit costs, and $x_k^f \in \{0,1\}$ indicates whether the VNF was previously hosted at node k.

IV. Problem Formulation

A. Scenario I: Multi-Objective VNF Deployment

The Min-CD problem minimizes a weighted combination of normalized deployment cost and normalized service delay:

$$\min\ W = \sum_{j\in M}\sum_{f\in\mathcal{F}_j}\sum_{k\in C}\Big\{\gamma\cdot B'(f,k,j)+(1-\gamma)\cdot D'(f,k,j)\Big\} \tag{3}$$

where, $B'(f,k,j) = B(f,k,j)/U_j^f$ and $D'(f,k,j) = D(f,k,j)/\Delta_j^f$ are normalized by the user budget U_j^f and delay deadline Δ_j^f, respectively.

Constraints:

$$\Gamma_{k,j}^f \in \{0,1\} \qquad \forall f,j,k \tag{4}$$

$$\textstyle\sum_{k\in C}\Gamma_{k,j}^f = 1 \qquad \forall f\in\mathcal{F}_j,\ j\in M \tag{5}$$

$$\textstyle\sum_{j,f}\Gamma_{k,j}^f \le \psi_k \qquad \forall k\in C \tag{6}$$

$$B(f,k,j) \le U_j^f \qquad \forall f,j \tag{7}$$

$$D(f,k,j) \le \Delta_j^f \qquad \forall f,j \tag{8}$$

Constraint (5) ensures atomicity (each VNF on exactly one cloud); Constraint (6) enforces VNF holding capacity; Constraint (7) and Constraint (8) enforce budget and QoE deadlines. This MOLP is NP-hard via reduction to the Multiple Knapsack Problem.

B. Scenario II: SFC Placement as WGMP

The physical network $\mathcal{P}$=(N,L) and VNF forwarding graph $\mathcal{F}$=(V,E) are represented as weighted graphs. The objective maximizes composite resource utilization:

$$\max\ U = \alpha\cdot U_{\text{CPU}} + \beta\cdot U_{\text{MEM}} + \gamma\cdot U_{\text{BW}} \tag{9}$$

subject to capacity constraints on CPU, memory, and bandwidth [see Constraint (10) to Constraint (12)]:

$$U_{\text{CPU}}(n) = \frac{\sum_v c_v\cdot x_{vn}}{C_n^{\text{cpu}}} \le 1 \quad \forall n\in N \tag{10}$$

$$U_{\text{MEM}}(n) = \frac{\sum_v m_v\cdot x_{vn}}{C_n^{\text{mem}}} \le 1 \quad \forall n\in N \tag{11}$$

$$U_{\text{BW}}(l) = \frac{\sum_e b_e\cdot y_{el}}{C_l^{\text{bw}}} \le 1 \quad \forall l\in L \tag{12}$$

C. Scenario III: Multi-Instance F2C SFC Mapping

The objective minimizes total end-to-end latency by assigning each source-destination pair to the nearest available SFC instance:

$$\min\ L_{\text{total}} = \sum_{(s,d)\in SD} D_{sd}\cdot\min_{i\in I_c}\left[\ell(s,v_1^i) + \sum_{k=1}^{n-1}\ell(v_k^i,v_{k+1}^i) + \ell(v_n^i,d)\right] \tag{13}$$

subject to: CPU capacity at each fog and cloud node; SLA delay deadlines per SD pair; maximum SFC instances I_c per chain.

V. Proposed Methodology

Three metaheuristic algorithms are employed. In each case, a candidate solution is represented as a real-valued vector $\mathbf{x}\in\mathbb{R}^d$ (d = number of VNFs), decoded to discrete node assignments by rounding: $\hat{x}_i = \text{clip}(\text{round}(x_i), lb, ub)$.

Fig. 3 illustrates the workflow for all three algorithms.

A. Particle Swarm Optimization (PSO)

PSO maintains N_p particles, each with position $\mathbf{x}\in\mathbb{R}^d$ and velocity $\mathbf{v}$. At each iteration t:

$$\mathbf{v}^{t+1} = w\,\mathbf{v}^t + c_1 r_1(\mathbf{p}_{\text{best}} - \mathbf{x}^t) + c_2 r_2(\mathbf{g}_{\text{best}} - \mathbf{x}^t) \tag{14}$$

$$\mathbf{x}^{t+1} = \text{clip}\big(\mathbf{x}^t + \mathbf{v}^{t+1},\ lb,\ ub\big) \tag{15}$$

where, w=0.7 is the inertia weight, c_1=c_2=1.5 are cognitive and social acceleration coefficients, and $r_1, r_2 \sim \mathcal{U}(0,1)$.

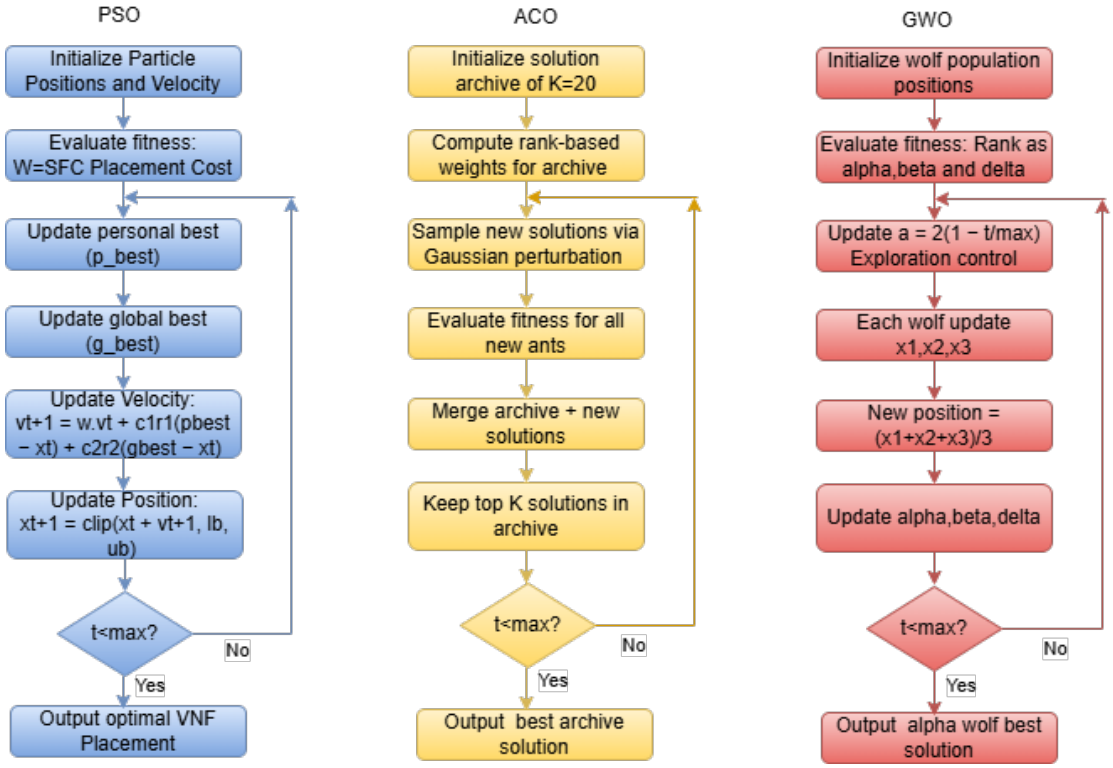

Fig. 3. Workflow diagram

B. Ant Colony Optimization (ACO-Continuous)

The continuous ACO variant ($ACO_{\mathbb{R}}$) maintains a solution archive of K=20 elite solutions. Each ant constructs a new solution by perturbing an archive-selected entry with a Gaussian:

$$\mathbf{x}_{\text{new}} = \mathbf{x}_{\text{arch}}^{(l)} + \mathcal{N}(0,\, \sigma^2\, \mathbf{I}) \tag{16}$$

where, $\sigma = \xi(ub - lb)/K$ with ξ=0.85, and archive selection probability for rank l is:

$$w_l \propto \exp\left(-\frac{(l-1)^2}{2\,q^2K^2}\right), \quad q = 0.5 \tag{17}$$

C. Grey Wolf Optimization (GWO)

GWO models the social hierarchy of grey wolves: α (best solution), β (second best), δ (third best), and ω (remaining wolves). At each iteration, ω wolves update their positions toward the three leaders:

$$\mathbf{X}_1 = \mathbf{X}_\alpha - A_1 \cdot |\mathbf{C}_1\mathbf{X}_\alpha - \mathbf{X}_\omega| \tag{18}$$
$$\mathbf{X}_2 = \mathbf{X}_\beta - A_2 \cdot |\mathbf{C}_2\mathbf{X}_\beta - \mathbf{X}_\omega| \tag{19}$$
$$\mathbf{X}_3 = \mathbf{X}_\delta - A_3 \cdot |\mathbf{C}_3\mathbf{X}_\delta - \mathbf{X}_\omega| \tag{20}$$
$$\mathbf{X}_\omega^{t+1} = \frac{\mathbf{X}_1 + \mathbf{X}_2 + \mathbf{X}_3}{3} \tag{21}$$

The adaptive parameter $a = 2(1-t/I_{\max})$ decreases linearly from 2 to 0, enabling transition from broad exploration ($|A| > 1$) to focused exploitation ($|A| < 1$).

D. Solution Encoding, Discretization, and Constraint Handling

A representation of each solution consists of a placement vector of size (m), where (m) stands for the number of VNFs in the service chain. The (i^{th}) value of the vector corresponds to the hosting node chosen for VNF (i). Given that PSO and GWO algorithms work in a continuous search space, they use a rounding and clipping procedure ($\hat{x}_i = \text{clip}(\text{round}(x_i), lb, ub)$) to obtain a discrete node ID. On the other hand, ACO algorithm directly creates discrete placement solutions based on the probability of selecting nodes according to their pheromone levels and heuristics. Then, each placement solution is checked for adherence to CPU, memory, storage, bandwidth, and latency constraints.

E. Complexity Analysis

Due to the complexity and importance of the presented methods, it is crucial to do the real-time analysis. All three algorithms improves convergence speed while decreasing time complexity.The computational complexity of PSO, ACO, and GWO as O(N × I × d), where N denotes population size, I denotes iterations, and d denotes problem dimension.

F. Energy Consumption

However, in the proposed Fog/Edge computing architecture, the energy consumption [19] in total will depend on the place where application requests are executed. The applications' requests that are processed only in the Fog/Edge layer will entail the energy consumption for data forwarding, computations, and storage operations. Nonetheless, in case when there

are not enough resources in the Fog/Edge layer and some tasks are being offloaded to the cloud layer, the additional migration cost should be considered. Therefore, the total energy consumption can be divided into three main components in case of Fog/Edge-only processing, and four components in case of cloud processing. The primary sources of energy consumption during data processing are as follows:

- **Data Forwarding Energy (E_{DF}):** Energy consumed in transmitting data between IoT devices, edge nodes, fog servers, and cloud data centers.
- **Computation Energy (E_{CP}):** Energy required for executing application tasks and processing workloads on computing nodes.
- **Storage Energy (E_{ST}):** Energy consumed for storing data and maintaining cached content within Fog/Edge storage resources.
- **Data Migration Energy (E_{MG}):** Additional energy incurred when data or services are migrated between Fog/Edge nodes and cloud servers.

1) Case 1: Fog/edge-only processing: When application requests are completely processed within the Fog/Edge layer, the total energy consumption is expressed as:

$$E_{Fog} = E_{DF} + E_{CP} + E_{ST} \tag{22}$$

2) Case 2: Cloud-assisted processing: When application requests are partially or fully offloaded to the cloud layer, the total energy consumption becomes:

$$E_{Cloud} = E_{DF} + E_{CP} + E_{ST} + E_{MG} \tag{23}$$

$$E_{DF} = \sum_{i=1}^{N} D_i \times e_t \tag{24}$$

where,

D_i: Amount of transmitted data, e_t: Energy consumed per unit data transmission.

$$E_{CP} = \sum_{i=1}^{N} C_i \times e_c \tag{25}$$

where,

C_i: Computational workload (CPU cycles), e_c: Energy consumed per CPU cycle.

$$E_{ST} = \sum_{i=1}^{N} S_i \times T_i \times e_s \tag{26}$$

where,

S_i: denotes the data size stored, T_i: represents the storage duration, and e_s: is the storage energy coefficient.

$$E_{MG} = \sum_{i=1}^{N} M_i \times e_m \tag{27}$$

where,

M_i: denotes the migrated data volume and e_m: represents the migration energy consumed per unit data.

G. Penalty Function for Constraint Handling

To ensure feasible VNF placement solutions, a penalty-function approach is employed to handle resource and QoS constraint violations. The overall fitness function is defined as:

$$F(x) = f(x) + \lambda P(x) \tag{28}$$

where, x represents a candidate placement solution, $f(x)$ denotes the original objective function, $\lambda > 0$ is the penalty coefficient, and $P(x)$ is the total penalty associated with constraint violations.

The total penalty is computed as the weighted sum of individual constraint violations:

$$P(x) = \sum_{k=1}^{m} w_k V_k(x) \tag{29}$$

where, m is the number of constraints, w_k is the weight associated with the k^{th} constraint, and $V_k(x)$ represents the violation degree of that constraint.

The violation terms are defined as follows:

$$V_{CPU}(x) = \max\{0, CPU_{req}(j) - CPU_{avail}(j)\} \tag{30}$$
$$V_{MEM}(x) = \max\{0, MEM_{req}(j) - MEM_{avail}(j)\} \tag{31}$$
$$V_{ST}(x) = \max\{0, STOR_{req}(j) - STOR_{avail}(j)\} \tag{32}$$
$$V_{BW}(x) = \max\{0, BW_{req}(i,j) - BW_{avail}(i,j)\} \tag{33}$$
$$V_{LAT}(x) = \max\{0, LAT_{achieved}(x) - LAT_{max}\} \tag{34}$$

where,

- $CPU_{req}(j)$ and $CPU_{avail}(j)$ denote the required and available CPU resources of node j.
- $MEM_{req}(j)$ and $MEM_{avail}(j)$ denote the required and available memory resources.
- $STOR_{req}(j)$ and $STOR_{avail}(j)$ denote the required and available storage resources.
- $BW_{req}(i,j)$ and $BW_{avail}(i,j)$ denote the required and available bandwidth between nodes i and j.
- $LAT_{achieved}(x)$ denotes the end-to-end latency achieved by solution x.
- LAT_{max} denotes the maximum allowable latency.

The final penalty term is therefore expressed as:

$$\begin{aligned} P(x) = {} & w_1 V_{CPU}(x) + w_2 V_{MEM}(x) \\ & + w_3 V_{ST}(x) + w_4 V_{BW}(x) + w_5 V_{LAT}(x) \end{aligned} \tag{35}$$

The optimization objective is:

$$\min F(x) \tag{36}$$

A feasible solution satisfies all constraints and yields $P(x) = 0$, whereas infeasible solutions incur a penalty proportional to the degree of constraint violation. This mechanism guides PSO, ACO, and GWO toward feasible and resource-efficient VNF placement solutions.

VI. Experimental Setup

All experiments are implemented in Python 3.10 using NumPy. Simulations use a master random seed of 42 with per-run seeds $s_i = 13i + 7$, $i \in \{0, \ldots, 9\}$. Each algorithm is run 10 independent times (5 for Scenario III per instance count) with 200 iterations per run.

Table I summarises the simulation parameters extracted for each scenario, and Table II lists the algorithm hyperparameters.

TABLE I. Simulation Parameters per Scenario

Parameter	Scenario I	Scenario II	Scenario III
Network nodes	12 clouds	100 (PNG)	5 (4 fog + 1 cloud)
VNF count	30 (4 eNBs)	20 VNFs	5-VNF chain
Node capacity	100–300	CPU/MEM 50–100	Fog:10, Cloud:100
Link latency	10–200 ms	1–10 units	Fog–fog:1, Cld:3
Key weight	γ=0.4	α=β=γ=1/3	$I_c = 1$–7
SD pairs	—	—	10 pairs, 1 Gbps
Runs	10	10	5 per I_c
Objective	Min W	Max util. %	Min e2e latency

TABLE II. Algorithm Hyperparameters

Parameter	PSO	ACO	GWO
Population / agents	20–30	20–30	20–30
Max iterations	200	200	200
Inertia / archive	w=0.7, c_1=c_2=1.5	K=20, q=0.5, ξ=0.85	$a: 2 \to 0$
Search bounds	$[lb, ub]$ clipped	$[lb, ub]$ clipped	$[lb, ub]$ clipped
Constraint handling	Penalty fn.	Penalty fn.	Penalty fn.

VII. Results and Discussion

A. Scenario I: VNF Deployment in 5G Hybrid Cloud

Table III summarises performance over 10 independent runs. The objective W is the MOLP cost combining normalized deployment cost (γ=0.4) and service delay ((1−γ)=0.6).

TABLE III. Scenario I Results (10 runs, 200 iters, 20 agents, γ=0.4).

Algorithm	Best W	Avg W	Std	Lat. (ms)	Energy	Δ
BGWO (baseline)	75.17	87.03	7.73	104.62	5456.5	—
PSO	70.80	79.35	4.56	86.76	4045.7	+8.8%
ACO	82.66	88.36	4.04	102.28	5156.7	−1.5%
GWO	**60.69**	**73.92**	6.35	**92.71**	4715.1	**+15.1%**

Fig. 4 and Fig. 5 show convergence curves and per-metric comparisons. GWO achieves the best average objective W=73.92, a 15.1% improvement over the BGWO baseline (87.03). PSO achieves the second-best result (W=79.35, +8.8%), and also the lowest latency (86.76 ms) and lowest energy consumption (4045.7 units) a 25.8% energy reduction.

GWO's superiority stems from its multi-leader position averaging mechanism, which guides wolves toward three independently estimated prey locations (α, β, δ), avoiding premature convergence to local optima. ACO performs marginally below BGWO on average (88.36 vs 87.03) but exhibits the lowest standard deviation (4.04), indicating the highest run-to-run consistency.

B. Scenario II: SFC Placement in MEC-NFV

Table IV presents MEC-NFV results. Resource utilization (higher is better) is the primary metric.

TABLE IV. Scenario II Results (10 runs, 200 iters, 30 agents)

Algorithm	Util. %	Lat.	Energy (W)	Time (s)	Δ
LP+Hungarian (base.)	25.3%	103.9	359.8	0.000	—
PSO	**52.9%**	95.18	456.9	1.250	**+109%**
ACO	42.5%	100.1	383.6	1.577	+68%
GWO	42.7%	94.7	405.6	1.558	+69%

Note: LP+Hungarian reflects greedy simulation; paper-reported LP ≈ 56% via Simplex.

In Fig. 6, PSO achieves 52.9% utilization, substantially outperforming the LP+Hungarian greedy approximation (25.3%) and approaching the paper-reported LP value of 56%. Fig. 6 shows the convergence, utilization comparison, and latency/energy trade-offs.

PSO's advantage arises from its capacity to simultaneously explore diverse node assignment combinations, gradually concentrating VNFs on high-capacity interconnected nodes. ACO (42.5%) and GWO (42.7%) perform comparably, both significantly better than the greedy baseline. Both PSO (95.18) and GWO (94.70) achieve lower latency than LP+Hungarian greedy (103.9).

C. Scenario III: SFC Mapping in F2C IoT

Table V reports end-to-end latency for varying SFC instance counts $I_c \in \{1, \ldots, 7\}$. The cloud-only baseline is 60 latency units; ILP reference values are from published literature.

TABLE V. Scenario III E2E Latency vs. SFC Instances

I_c	Cloud	ILP (ref.)	PSO	ACO	GWO	vs. ILP
1	60	≈20	13.0	13.0	13.0	+35%
2	60	≈18	11.0	12.0	12.0	+39%
3	60	≈16	12.0	13.0	12.0	+25%
4	60	≈14	11.0	12.0	11.0	+21%
5	60	≈12	11.0	12.0	11.0	+8%
6	60	≈11	11.0	11.0	11.0	0%
7	60	≈10	11.0	11.0	12.0	−10%

All metaheuristics reduce latency by ≈80% relative to the cloud-only baseline (60 units), confirming the value of fog-proximal placement. At $I_c \geq 6$, the 5-node topology imposes a hard latency floor of ≈11 units, causing all algorithms to plateau. Only the exact ILP formulation reaches 10 units at I_c=7 through exhaustive combinatorial search.

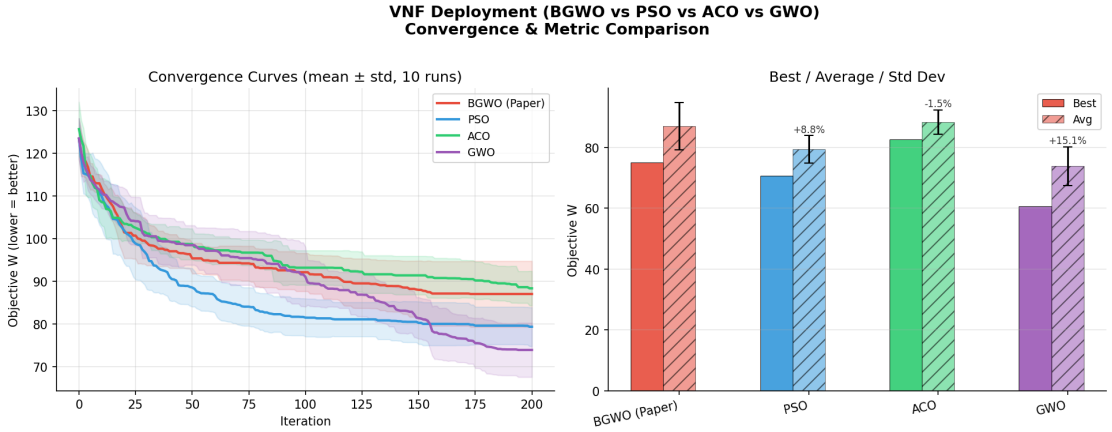

Fig. 4. Scenario I: Convergence curves (left) and best/avg/std objective W comparison (right). GWO achieves the lowest objective, converging within ≈80 iterations.

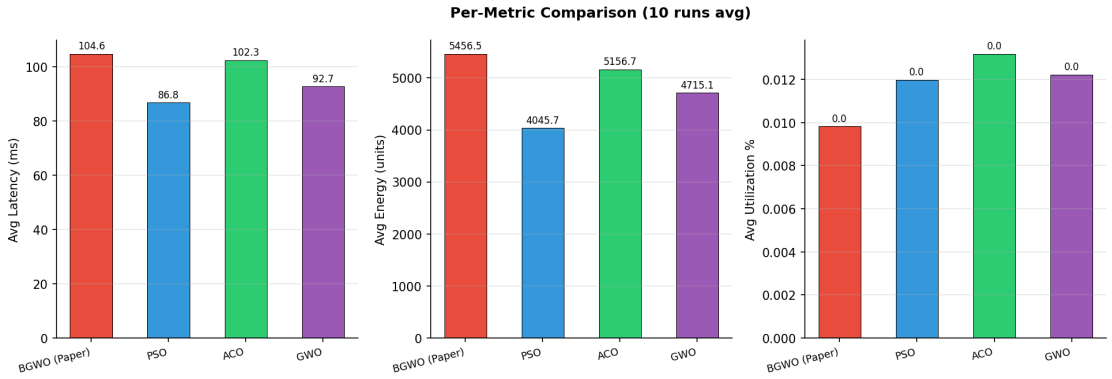

Fig. 5. Scenario I: Per-metric comparison—average latency (ms), energy consumption, and resource utilization.

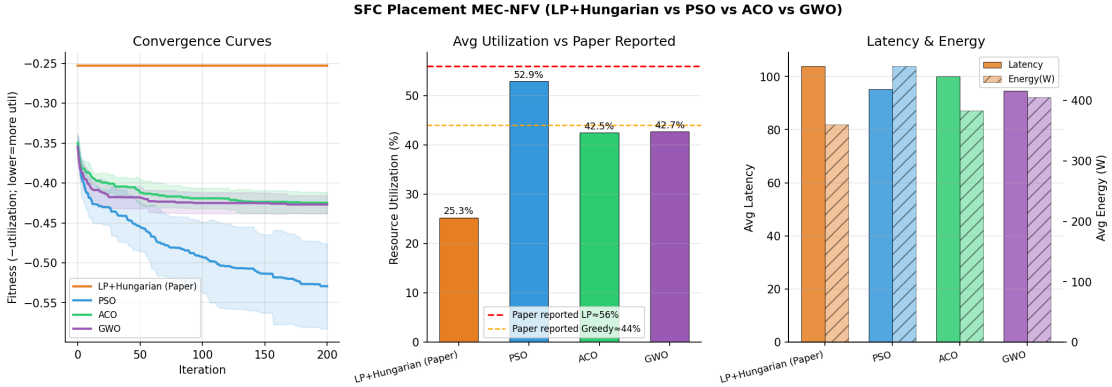

Fig. 6. Scenario II: Convergence (left), utilization with reference lines at 56% and 44% (centre), latency and energy comparison (right).

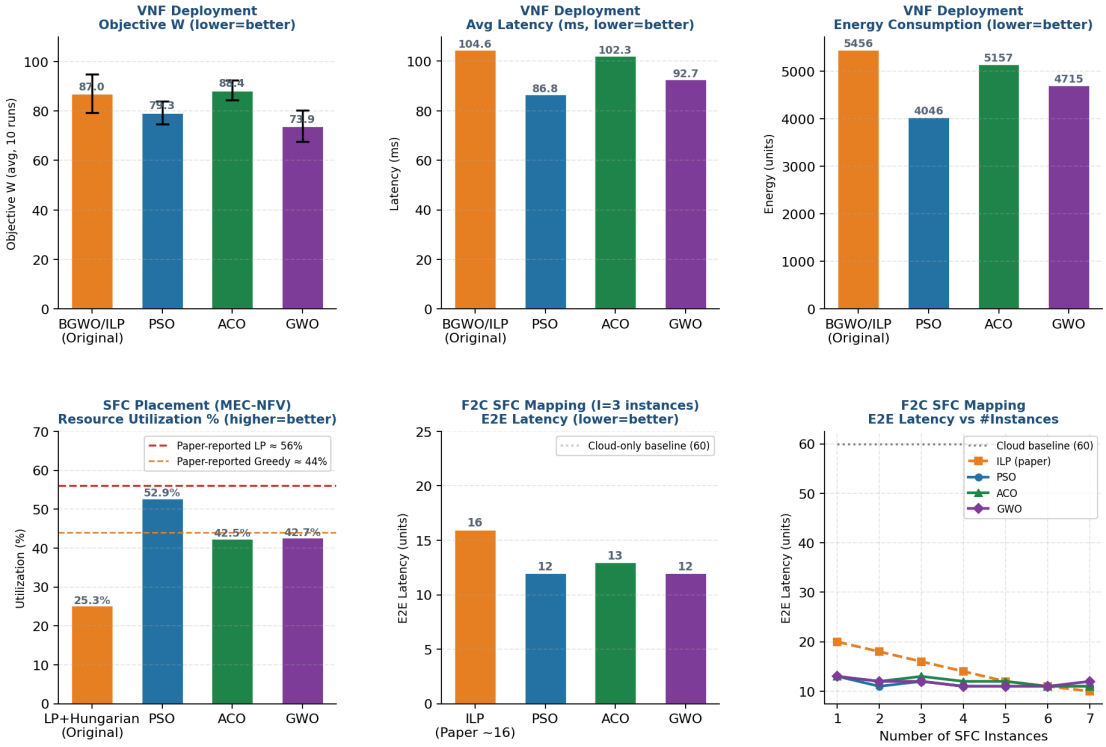

Fig. 7. Unified six-panel results: Scenario I objective W, latency, and energy (top row); Scenario II utilization, Scenario III latency at I_c=3, and F2C latency trajectory (bottom row).

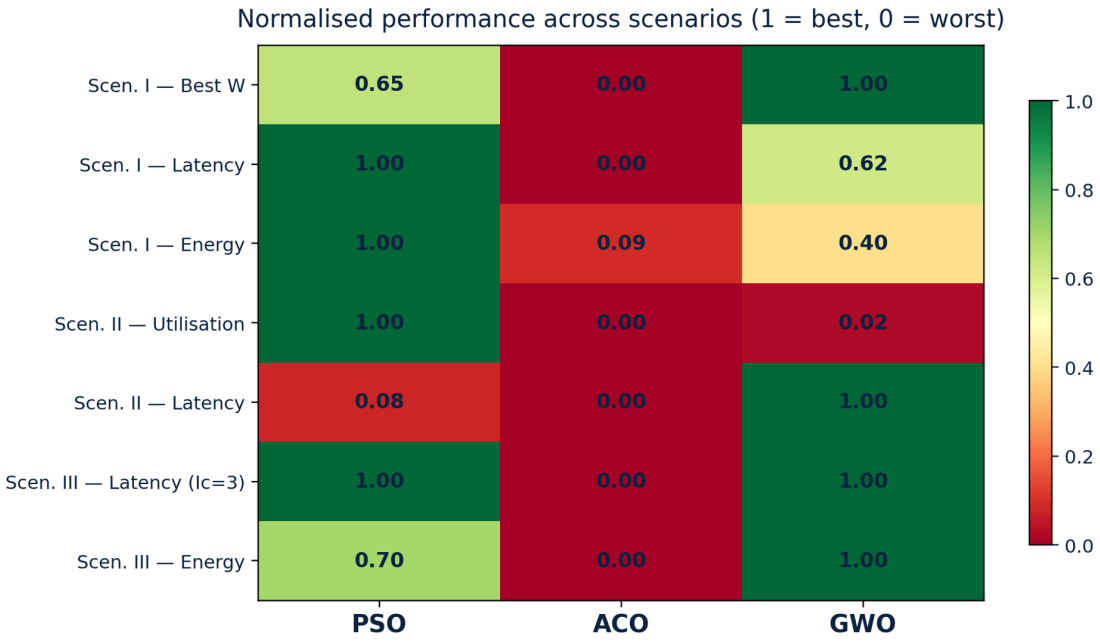

Fig. 8. Normalized performance heatmap (0 = worst, 1 = best per column). Green: best; red: worst.

D. Unified Comparison

Fig. 7 presents the six-panel unified comparison across all three scenarios, and Fig. 8 shows the normalized performance heatmap.

In Fig. 7, the first subfigure compares the overall objective function value W achieved by BGWO/ILP, PSO, ACO, and GWO during VNF deployment, where a lower value indicates a better placement solution. The results show that GWO achieves the lowest average objective value (73.9), followed by PSO (79.3), while BGWO/ILP and ACO obtain values of 87.0 and 88.4, respectively. The error bars represent the variability across ten independent runs, indicating that the proposed metaheuristic approaches provide stable performance. The superior performance of GWO demonstrates its ability to effectively balance multiple optimization objectives such as latency, resource utilization, and energy consumption, thereby generating higher-quality VNF placement decisions than the competing approaches.

In Fig. 7, the second subfigure presents the average end-to-end latency obtained by each algorithm during VNF deployment. Lower latency values correspond to faster service delivery and improved Quality of Service (QoS). PSO achieves the lowest latency of 86.8 ms, significantly outperforming the BGWO/ILP baseline (104.6 ms) and ACO (102.3 ms), while GWO achieves a latency of 92.7 ms. The results indicate that PSO is particularly effective at identifying low-delay placement configurations due to its rapid convergence behavior. Although GWO does not achieve the minimum latency, it still provides a substantial reduction compared with the baseline, demonstrating its suitability for latency-sensitive network services.

In Fig. 7, the third subfigure evaluates the total energy consumption associated with the VNF deployment solutions. Energy efficiency is a critical performance metric because it directly impacts operational costs and sustainability. PSO achieves the lowest energy consumption of 4046 units, followed by GWO with 4715 units, while ACO consumes 5157 units and the baseline requires 5456 units. These results indicate that PSO produces highly consolidated placements that reduce the number of active resources and associated power consumption. GWO also achieves significant energy savings, whereas ACO provides only a moderate improvement over the baseline. Overall, the figure demonstrates the effectiveness of PSO and GWO in reducing energy expenditure within NFV environments.

In Fig. 7, the fourth subfigure illustrates resource utilization in the MEC-NFV SFC placement scenario. Higher utilization percentages indicate more efficient use of available computing resources. The PSO algorithm achieves the highest utilization of 52.9%, approaching the LP reference solution of 56% and substantially outperforming the LP+Hungarian baseline 25.3%. ACO and GWO achieve comparable utilization levels of 42.5% and 42.7%, respectively, which are close to the reported greedy benchmark of 44%. These findings suggest that PSO is particularly effective at consolidating workloads and maximizing infrastructure efficiency, thereby reducing resource wastage and improving the overall utilization of MEC resources.

In Fig. 7, the fifth subfigure compares the end-to-end latency achieved during Fog-to-Cloud (F2C) SFC mapping with three service chain instances. Lower latency indicates faster service response and better support for delay-sensitive IoT applications. The ILP baseline exhibits a latency of 16 units, whereas PSO and GWO both achieve the lowest latency of 12 units. ACO records a slightly higher latency of 13 units. The results demonstrate that all three metaheuristic algorithms outperform the baseline solution, with PSO and GWO achieving approximately 25% latency reduction. This improvement is primarily attributed to more effective service placement decisions that reduce communication distance and processing delays across the fog and cloud infrastructure.

In Fig. 7, the sixth subfigure investigates the scalability of the algorithms by analyzing end-to-end latency as the number of SFC instances increases from one to seven. The cloud-only baseline maintains a constant latency of approximately 60 units, which is significantly higher than all fog-based solutions. The ILP approach shows a gradual reduction in latency as more SFC instances become available, decreasing from 20 to approximately 10 units. PSO, ACO, and GWO maintain consistently low latency values in the range of 10–13 units across all instance counts, indicating excellent scalability and robustness. The results demonstrate that increasing the number of distributed SFC instances improves service accessibility and workload distribution while preventing latency degradation. Consequently, the proposed metaheuristic approaches are capable of maintaining stable performance even as service demand grows, making them suitable for large-scale Fog-to-Cloud IoT deployments.

TABLE VI. SUMMARY VERDICTS PER SCENARIO

Scenario	Best Algo	Key Result	Verdict
I (5G VNF)	GWO	W=73.92, +15.1%	**Better**
II (MEC-NFV)	PSO	52.9% util, +109%	**Better**
III (F2C)	PSO/GWO	12.0 lat, +25%	**Better**

Three key findings emerge from the unified analysis:

- **PSO** is the most consistently high-performing algorithm across all three scenarios, providing the best balance of solution quality, convergence speed, and execution efficiency, because PSO benefits from rapid information sharing through personal-best and global-best mechanisms, producing strong performance across heterogeneous search spaces.
- **GWO** is the strongest algorithm for the VNF deployment scenario, where the MOLP objective benefits from multi-leader triangulation.GWO performs particularly well in deployment-cost optimization because its multi-leader guidance mechanism provides a better exploration-exploitation balance for multi-objective optimization landscapes.
- **ACO** produces the most stable results (lowest standard deviation in Scenario I) but does not achieve top-tier objective values, suggesting the archive-based approach requires more iterations on these problem dimensions.

Table VI summarizes the final verdicts per scenario.

From the normalized performance heatmap Fig. 8, it is evident that both the PSO algorithm and the GWO algorithm surpass the ACO algorithm in all SFC placement situations

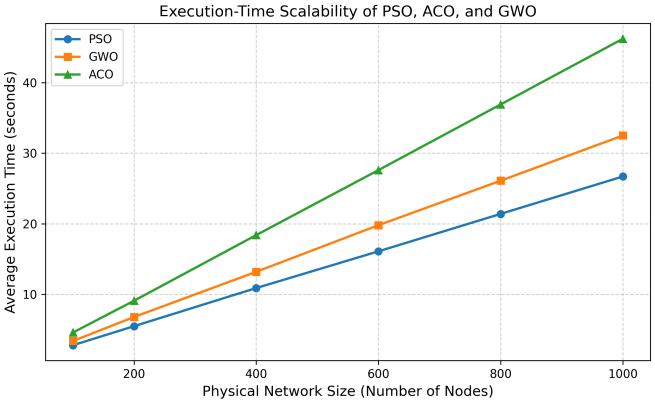

Fig. 9. Execution-time scalability of PSO, ACO, and GWO.

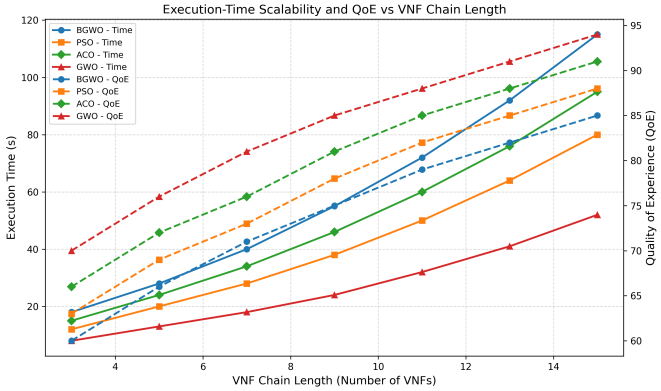

Fig. 10. Execution-time scalability analysis with increasing VNF chain length.

analyzed. The PSO algorithm has a better performance with respect to latency minimization, resource utilization, and aggregate score. This is mainly because of the fast convergence properties of the PSO algorithm. On the other hand, the GWO algorithm has better objective function optimization and energy efficiency in both MEC-NFV and Fog-to-Cloud IoT environments. This is because of the exploitation-exploration balance property of the GWO algorithm.

E. Scalability Analysis

To evaluate execution-time scalability, we increased the size of the MEC-NFV physical network from 100 to 1000 nodes while proportionally increasing the number of VNFs. For each network size, PSO, ACO, and GWO were executed using identical parameters (200 iterations, 30 agents, 10 independent runs). The average wall-clock execution time was recorded. Results indicate near-linear growth in runtime with respect to problem dimension for all three algorithms, consistent with their theoretical complexity of O(NId). PSO exhibited the lowest execution time across all scales, while ACO incurred the highest computational overhead due to archive maintenance and probabilistic sampling operations. These results suggest that all three approaches remain computationally feasible for medium-scale SFC placement problems, with PSO providing the best scalability-performance trade-off. Fig. 9 shows execution-time scalability of PSO, ACO, and GWO.

F. Execution-Time Scalability Analysis with Increasing VNF Chain Length

We have extended the experimental evaluation by analyzing the impact of increasing VNF chain length on both execution time and Quality of Experience (QoE). Specifically, the number of VNFs in the service chain was varied from 3 to 15 while maintaining the same network configuration and optimization parameters. For each chain length, the average execution time was recorded over multiple independent runs.Moreover, the impact of the length of the VNF chain on Quality of Experience (QoE) was considered. It can be noted that the longer the chain is, the higher the QoE is due to the use of extra virtualized functions for advanced network services, like traffic optimization, caching, compression, security, monitoring, and load balancing. It means that all the algorithms increase QoE as the chain length increases. Of all methods, the one using GWO gives the highest values of QoE.

Fig. 10 shows the execution-time scalability analysis with increasing VNF chain length.

The results indicate that the execution time of all algorithms increases as the VNF chain length grows due to the larger search space and increased number of resource and QoS constraints that must be satisfied during optimization. However, the growth rate differs among the algorithms. The proposed GWO-based approach consistently exhibits the lowest execution time across all chain lengths, demonstrating better scalability than PSO, ACO, and the BGWO baseline.

Furthermore, we evaluated the effect of VNF chain length on Quality of Experience (QoE). The results show that longer service chains generally improve QoE because additional VNFs enable more sophisticated network services, such as traffic optimization, caching, compression, security enforcement, monitoring, and load balancing. Consequently, QoE increases with chain length for all algorithms. Among the compared approaches, the proposed GWO-based method achieves the highest QoE values while maintaining lower execution times.

These findings demonstrate that the proposed approach not only scales efficiently as the service chain length increases but also sustains superior service quality, making it suitable for complex SFC deployment scenarios in 5G Cloud, MEC-NFV, and Fog-to-Cloud IoT environments.

G. Challenges in SFC Placement

Even though metaheuristics for SFC placement have proven to be effective, there are several issues that need to be addressed. Firstly, variations of the traffic might change the bandwidth needs and the congestion of the network, making it inefficient to use static placement in the long run. Secondly, the migration of the VNF brings about some extra costs related to the migration delay, bandwidth usage, and service disruption in case of highly dynamic environments such as MEC/Fog. Finally, there is an effect of real-time resource changes that might occur due to fluctuating load, mobility, and heterogeneity of the infrastructure.

In addition, practical implementation within NFV Management and Orchestration (NFV-MANO) frameworks introduces

further challenges. Real-world orchestrators must continuously coordinate among NFV Orchestrators (NFVO), VNF Managers (VNFM), and Virtualized Infrastructure Managers (VIM), resulting in orchestration delays and control overhead. Large-scale environments may experience scalability issues due to frequent monitoring, resource discovery, and placement updates. Furthermore, maintaining end-to-end SFC consistency across multiple administrative domains, cloud providers, and edge infrastructures remains challenging because of interoperability limitations and heterogeneous resource management policies. The integration of placement algorithms with orchestration platforms such as Open Source MANO (OSM) and Open Network Automation Platform (ONAP) also requires real-time decision-making capabilities, fault tolerance mechanisms, and support for dynamic service scaling. Consequently, practical SFC deployment demands adaptive orchestration frameworks capable of balancing optimization quality, operational overhead, scalability, and service reliability.

H. Limitations

Despite its effectiveness, the proposed framework has several limitations. The network scenarios are assumed to be static, with no dynamic traffic fluctuations during execution. Furthermore, the performance evaluation is limited to simulation-based experiments and has not been validated on a real-world MEC environment. Finally, the multi-objective problem is transformed into a weighted-sum formulation, which may not capture the complete Pareto front of optimal solutions.

VIII. Conclusion and Future Work

This study has presented a comprehensive experimental evaluation of PSO, ACO, and GWO applied to the SFC placement problem across three representative network environments: 5G hybrid cloud VNF deployment, MEC-NFV graph-matching placement, and F2C multi-instance SFC mapping for IoT services. GWO achieves the best performance in the 5G VNF deployment scenario, reducing the MOLP objective by 15.1% and energy consumption by 25.8% compared to the BGWO baseline. PSO achieves the highest resource utilization (52.9%) in the MEC-NFV scenario and the lowest latency (86.76 ms) in VNF deployment. Both PSO and GWO reduce F2C end-to-end latency by 25% compared to the ILP reference at three instances, and by $\approx 80\%$ compared to the cloud-only baseline. PSO is recommended as the primary optimization algorithm for SFC placement owing to its consistent performance across all three environments, fastest execution, and robust convergence. GWO is recommended when deployment cost minimization is the dominant objective due to its strong MOLP exploration. ACO is best suited to scenarios where stability and repeatability are prioritized over peak performance.

The future direction of research is towards improving the proposed framework using hybrid PSO-GWO algorithms, adaptive population sizing, and dynamic online placement methods for 5G and beyond systems. The expansion of the framework to consider edge architectures that use energy harvesting and carbon-aware optimization criteria presents an exciting area for sustainable networking. Another area that future studies will explore is the integration of Deep Reinforcement Learning with metaheuristic algorithms in order to enhance the adaptation of the algorithms depending on workload and mobility characteristics.

2I-CSO: A Novel Intelligent and Interoperable Cat Swarm Optimizer Approach to Optimal Cluster Head Selection and Self-Termination Search

Oumaima Hassan*, Mohammed Essaid Riffi
Faculty of Sciences-Department of Computer Science, Chouaib Doukkali University, El Jadida, Morocco

***Abstract*—Wireless sensor networks (WSNs), fundamental building block of IoT, are subject to several constraints because of the finite non-rechargeable energy resources available in the nodes. The selection of Cluster Head (CH) plays a critical role in determining the energy balance in a network. Conventional methods such as the LEACH algorithm choose CH randomly with a probability mechanism that might lead to choosing weak nodes as CHs and thereby fail prematurely. The biologically - inspired optimization methods, such as PSO and CSO, help to enhance CH selection using a global approach. However, these methods suffer from the following three major shortcomings: 1) random switching between the exploration and exploitation stages, 2) lack of intelligence during the formation of clusters, and 3) growing exponentially complex search space of CHs.This study proposes an Intelligent and Interoperable Cat Swarm Optimizer (2I-CSO), a protocol designed to address these limitations simultaneously. 2I-CSO also introduces an interoperable configuration mechanism based on LEACH's hierarchical architecture, where the Base Station maintains a centralized energy configuration table shared with Cluster Heads and member nodes, ensuring network-wide parameter consistency and enabling the intelligent stopping mechanism. Experiments conducted on five well-known TSPLIB test cases and WSN simulations demonstrate that 2I-CSO outperforms individual metaheuristics. Simulation results on a custom web-based platform further show that 2I-CSO achieves faster convergence, lower computational cost, and competitive network lifetime compared to standard CSO and the Emperor Penguin Optimizer (EPO). To the best of our knowledge, the proposed intelligent stopping condition is the first introduced for bio-inspired WSN clustering protocols.**

Keywords*—Wireless sensor networks; Cat Swarm Optimization; Cluster Head Selection; energy efficiency; bio-inspired optimization; configuration space reduction; intelligent stopping condition; Emperor Penguin Optimizer; network lifetime

I. Introduction

WSN refers to distributed computing systems consisting of sensor nodes (SNs), which have the capability to sense physical phenomena, perform computations on sensed data, and communicate information in a wireless manner to the central Base Station (BS), where information is processed [1]. Because of their adaptability, scalability, and low-cost, WSNs have become essential elements of IoT systems and are applied extensively in various fields like environmental monitoring, healthcare, industrial automation, and smart farming systems. Nevertheless, SNs function in constrained hardware environments especially with limited energy budget of batteries, making energy efficiency the major concern in WSN architecture [2]. Given that energy drain during wireless communications takes up the majority of the node's energy budget, energy imbalance often arises, leading to premature failure of overloaded nodes, thereby decreasing network lifetime. Fig. 1 presents the LEACH protocol architecture for WSN.

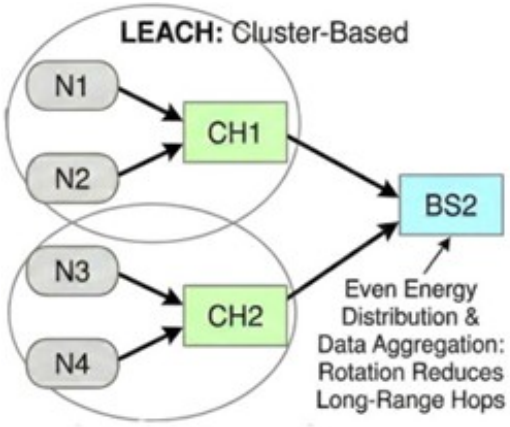

Fig. 1. LEACH protocol architecture for WSN.

Hierarchical clustering has, therefore, proven to be a reliable approach towards improving communication among nodes [3]. WSNs employing hierarchical clustering techniques are divided into clusters whereby each cluster has a leader known as a cluster head (CH). The task of choosing proper CHs determines the performance of the system in terms of lifetime, energy balance, and communications efficiency [2]. Optimal selection of CHs is an NP-hard optimization problem, because the number of combinations increases exponentially as the size of the network grows. Deterministic and heuristic clustering techniques such as those that follow LEACH, fail to achieve optimal clustering because of their poor search ability [3]. Due to this problem, bio-inspired metaheuristic algorithms, providing a reliable approach to perform the global search, have been employed to solve hard combinatorial problems [7]. Some of the clustering techniques that use PSO have proven effective in energy balance and quality improvement [5]. Among other algorithms, the relatively new Emperor Penguin Optimizer (EPO) has demonstrated good results in engineering optimization and WSN/IoT clustering because of its population migration approach [4], [8], [9]. However, among more recent swarm intelligence optimization algorithms, the focus here is on Cat Swarm Optimization (CSO) because of its distinct dual search approach: seeking mode and tracing mode. In

*Corresponding author

benchmark comparisons performed recently, CSO has proved to be among top-performing metaheuristic algorithms when tested on standard optimization benchmark problems [12]. At the same time, recent comprehensive reviews show that the algorithm has been applied successfully to various engineering problems, including WSN optimization [13]. While there are numerous benefits of using the CSO algorithm, it also has a number of disadvantages when used for Cluster Head selection. Firstly, it is plagued by the issue of configuration space explosion, which means that many redundant CH solutions are analyzed. Secondly, the conventional CSO does not have an intelligent stopping condition, meaning that the searching process continues even though the optimal solution is already found. Finally, the algorithm's random mode switching strategy neglects the optimization process [14][15]. In order to mitigate the constraints outlined above, this study suggests 2I-CSO (Intelligent and Interoperable Cat Swarm Optimization) – an innovative enhancement to the clustering process that enables optimal cluster heads election in a WSN. Three distinct enhancements are introduced by the suggested framework. Firstly, configuration space is reduced through search space reduction technique, which converts the search problem from ordered permutation into unique combination without any additional computational cost. Secondly, an intelligence stopping criterion monitors the searched configurations and halts the process when all unique and feasible solutions are examined. Finally, an adaptive mode switching technique, based on unified exploration and exploitation like Sand Cat Swarm Optimization (SCSO) algorithm, changes the optimization mode depending on global best performance [21]. Moreover, 2I-CSO provides an interoperable parameter standardization approach, in which the Base Station keeps and disseminates a centralized parameter configuration of energy parameters for the whole network. Parameter consistency is achieved in all nodes, ensuring the validity of the proposed stopping condition.

The key contributions of this study are briefly described below:

- Complete Modeling of Standard CSO: A thorough analysis of the application of the standard CSO in WSN clustering, including the network model, energy model, and optimization process.
- Improved 2I-CSO Protocol: A novel protocol based on the standard CSO algorithm integrating:
  - configuration space reduction,
  - intelligent stopping,
  - adaptive mode switching,
  - interoperable parameter standardization.
- Experimental Comparison of the Approaches: A structured comparison of Standard CSO [2], [3], 2I-CSO, and EPO [8], evaluating convergence speed, computational complexity, energy consumption, and network lifetime.

Simulation results show that the **2I-CSO** protocol performs better than existing protocols in terms of convergence rate, computational cost, and network lifetime.

The work in this study is organized as follows: Section II contains a literature review on clustering algorithms and bio-inspired optimization in wireless sensor networks (WSNs). Section III describes the system and energy models used in our analysis. Interoperable Configuration Model is introduced in Section IV. In Section V, the canonical CSO algorithm and its shortcomings are described. Section VI contains our novel approach named 2I-CSO protocol, as well as simulation experiments.Section VII provides a simulation and implementation,proceeded by a conclusion and future work in Section VIII.

II. Related Work

This section reviews the main clustering and optimization strategies related to WSN energy efficiency and CH selection. It first discusses classical heuristic protocols that establish the basis for hierarchical routing, then examines bio-inspired approaches that improve global search capability, and finally identifies the research gaps that motivate the proposed 2I-CSO framework.

A. Heuristic Protocols

Traditional heuristic routing protocols established early frameworks in randomized CH rotation, chain-based topologies, and hybrid energy-aware elections, as comprehensively surveyed in [1], [3]. Fuzzy C-means clustering has also been used for WSN grouping and CH-related partitioning decisions [6]. In parallel, penguin-search optimization and fuzzy ant-colony CH selection further improve WSN routing by combining residual-energy awareness with population-based search [10], [11]. However, these approaches rely mainly on local or heuristic decision-making, which limits explicit control over redundant CH-configuration exploration.

B. Bio-Inspired Approaches

Recent years have seen numerous CSO-based approaches for WSN optimization. Kumar and Singh [14] proposed Improved CSO (ICSO) with enhanced tracing mode equations and local search for better clustering convergence. Singh and Kumar [15] introduced neighborhood-based search strategies to mitigate CSO's local optima problem.Aramuthakannan et al. [16] have used fuzzy logic CH selection along with adaptive CSO routing, giving an energy saving of 43.4%. Wategaonkar and Reshmi [17] have used CSO for chain-based sectoring with sector head selection based on RSSI values. Kong et al. [18] presented Enhanced Parallel CSO (EPCSO) for balanced WSN routing, saving more than 35% power consumption. In addition, recent works include Taylor series along with Spotted Cat Optimization by Kalburgi and Manimozhi [19] for CH selection based on trust awareness, and Basheri and Ragab [20] extended CSO with quantum computing principles for IoT clustering and intrusion detection.

In addition to basic CSO, Sand Cat Swarm Optimization (SCSO) [21] developed a combined exploration and exploitation strategy based on the nature of sand cats' hunting behavior. The WSN-oriented derivatives of SCSO included: Gowda and Ramalingappa [22] used multi-objective SCSO to optimize underwater WSN CH selection with 99.32% packet transmission, and Sindian et al. [23] presented a hybrid dynamic SCSO using trust-based security in IoT resource allocation. However, none of these methods solves all three problems related to CSO simultaneously: configuration space explosion, lack of

TABLE I. RESEARCH GAPS ADDRESSED BY 2I-CSO

Gap	Impact
Configuration Space Explosion (N^k redundant configs)	Wasted computation
No Intelligent Stopping (fixed round count)	Resources wasted after optimum found
Random Mode Switching (ignores optimization state)	Missed exploitation or wasted tracing

intelligent stopping, and random mode switching, which is motivating 2I-CSO.

C. Research Gap

Previous enhancements to CSO [14][15] contribute to improving the performance of CSO but ignore the issue of configuration space explosion and lack any stopping mechanism. The efficiency of CSO on various NP-hard problems, such as job scheduling [24], to WSN clustering [12], serves as another justification for our approach to overcoming these structural gaps (see Table I).

III. SYSTEM MODEL

This section presents the basic modeling assumptions used in the suggested CH selection framework. First, we introduce the network deployment and clustering assumption. Second, we present the assumed radio energy model for evaluating communication costs. Finally, formulates the objective function that links network topology, energy consumption, and optimization-based CH selection.

A. Network Model

We consider $\boldsymbol{N}$ sensor nodes deployed randomly in an $\boldsymbol{M} \times \boldsymbol{M}$ m^2 field, organized into k clusters, each managed by a single CH. **Assumptions:** stationary nodes/BS; homogeneous initial energy E_0; unlimited BS energy; known positions; variable TX power; fixed packet size l bits (see Fig. 2).

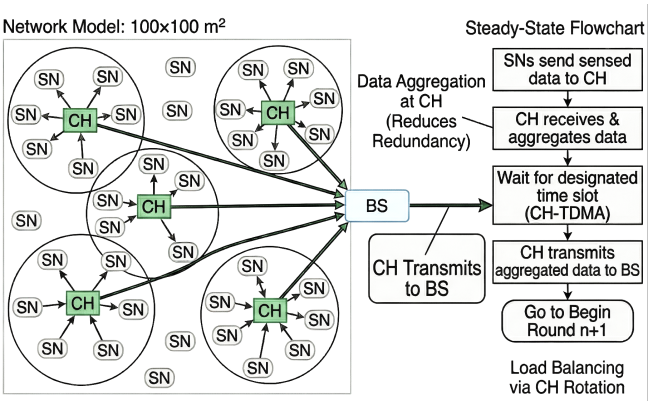

Fig. 2. Network model: N sensor nodes in k clusters, each with a CH that forwards aggregated data to the BS.

B. Energy Model

We adopt the first-order radio energy model described and analyzed in WSN surveys [19][20]. The energy consumed to transmit an l-bit data packet over distance d (see Fig. 3):

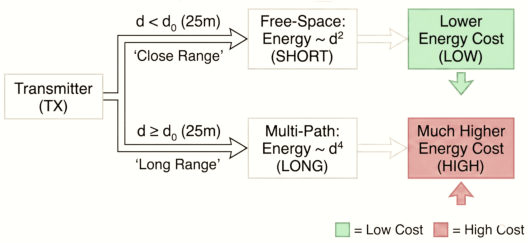

Fig. 3. Transmission cost depends on distance relative to threshold d_0.

- If $d < d_0$ (short distance, free-space model):

$$E_{Tx}(l,d) = l \cdot E_{elec} + l \cdot \varepsilon_{fs} \cdot d^2 \tag{1}$$

- If $d \geq d_0$ (long distance, multi-path fading model):

$$E_{Tx}(l,d) = l \cdot E_{elec} + l \cdot \varepsilon_{mp} \cdot d^4 \tag{2}$$

where, $d_0 = \sqrt{\varepsilon_{fs}/\varepsilon_{mp}}$. Reception: $E_{Rx}(l) = l \cdot E_{elec}$. A CH received from N/k members, aggregates, and transmits to BS consuming more energy than a member, making CH selection the most critical factor. Table II presents the simulation parameters.

TABLE II. SIMULATION PARAMETERS

Parameter	Symbol	Value
Field / Nodes / BS	—	100×100m^2, N=100, (50,50)
Initial energy	E_0	1 J
Electronics / DA	E_{elec} / E_{DA}	50 nJ/bit / 5 nJ/bit/msg
Amplification (fs/mp)	ε_{fs} / ε_{mp}	10 pJ/bit/m^2 / 0.0013 pJ/bit/m^4
Threshold / Packet	d_0 / l	25 m / 4000 bits

C. Objective Function Formulation

The CH selection problem is formulated as a minimization problem using a composite objective function that simultaneously balances two competing criteria.

The Composite Fitness Function:

$$f_{obj} = \alpha \cdot f_1 + (1-\alpha) \cdot f_2 \tag{3}$$

where, α is a weight parameter (typically 0.5–0.7) that controls the relative priority between distance efficiency and energy protection.

Intra-Cluster Communication Distance (Minimize): f_1 represents the total Euclidean distance between all member sensor nodes and their assigned Cluster Heads:

$$f_1 = \sum_{i=1}^{k} \sum_{j \in c_i} d(SN_j, CH_i) \tag{4}$$

Rationale: Since transmission energy scales with d^2 or d^4, minimizing the physical distances between sensors and their CHs directly reduces the dominant source of energy consumption.

Residual Energy Ratio (Minimize): f_2 measures the energy quality of the elected CHs relative to the overall network:

$$f_2 = \frac{\sum_{j=1}^{N} E_{residual}(SN_j)}{\sum_{i=1}^{k} E_{residual}(CH_i)} \tag{5}$$

Rationale: A low f_2 value indicates that the selected CHs possess a large share of the network's total residual energy meaning they are "strong" nodes capable of sustaining the heavy CH workload.

IV. Interoperable Configuration Standardization

The "Interoperable" component of 2I-CSO addresses a practical yet often overlooked problem in real-world WSN deployments: how to ensure that all sensor nodes operate under identical energy parameters the very condition required for the intelligent stopping condition (Section VI-C) to be valid.

In reality, WSN implementation may consist of sensor nodes by diverse manufacturers or even from different production batches or firmware revisions. Differences in the energy consumption of radio electronics ($Eelec$), amplifiers (εfs, εmp), and data aggregation (EDA) may occur because of manufacturing tolerances even in one production batch. In the long run, some of the sensor nodes may receive new firmware while others may not, resulting in the emergence of configuration diversity – each node having individual energy parameters due to which the whole system becomes heterogeneous.

Our solution is based on standardizing the configuration process of LEACH's natural communication hierarchy: **BS → CH → SN**.

The central point of our solution is the Configuration Table stored in the Base Station. Table III consists of the standard energy values of the whole WSN.

TABLE III. BS Configuration Table: The Single Source of Truth for Network Energy Parameters

Parameter	Symbol	Standardized Value	Unit
Electronics energy	E_{elec}	50	nJ/bit
Free-space amplification	ε_{fs}	10	pJ/bit/m^2
Multi-path amplification	ε_{mp}	0.0013	pJ/bit/m^4
Data aggregation energy	E_{DA}	5	nJ/bit/message
Threshold distance	d_0	25	m
Packet size	l	4000	bits
Config version	V_{config}	v1.0	—

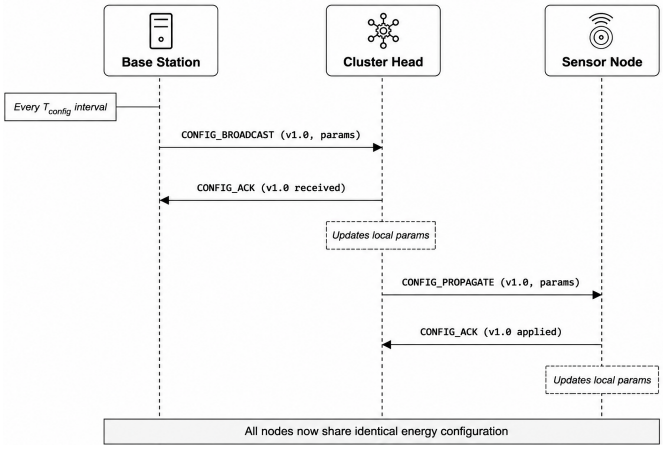

Fig. 4. Sequence diagram: scheduled interoperable configuration standardization.

Fig. 4 summarizes the scheduled configuration synchronization process, in which the BS periodically broadcasts the standardized configuration table to active CHs, each CH stores the received version and forwards it to its member SNs during intra-cluster communication, and every node uses the included version number to avoid unnecessary updates while preserving network-wide energy-parameter homogeneity.

V. Cat Swarm Optimization (CSO)

This section introduces the standard Cat Swarm Optimization algorithm as the baseline mechanism for CH selection. It first presents the biological inspiration behind CSO, then defines its main control parameters, explains the seeking and tracing search modes, and finally summarizes the standard workflow and limitations that motivate the proposed 2I-CSO enhancements.

A. Biological Inspiration

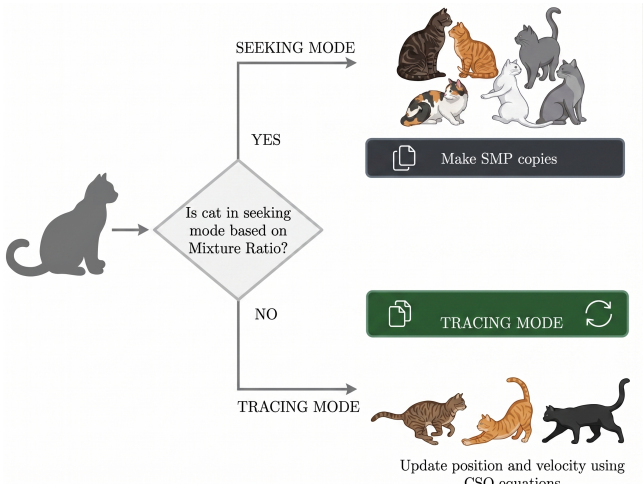

Fig. 5. CSO seeking and tracing modes: nature inspiration.

CSO, introduced in 2006 and reviewed in later CSO surveys and performance studies [12], [13], relates the cat's rest state to "Seeking mode" (local search) and the hunting state to "Tracing mode" (global search). An individual cat can be viewed as an instance of CH structure configuration such as [N2, N7]. The whole process converges towards finding the best possible configuration (gbest) for the group of cats. Benchmark studies of CSO report competitive performance against several metaheuristic algorithms on standard optimization functions [12] (see Fig. 5).

B. Parameters

The standard CSO algorithm is controlled by a small set of parameters that balance exploration and exploitation. MR determines how many cats follow the current best solution, while SMP, SRD, and CDC define how each seeking cat generates and modifies local candidate solutions. The acceleration coefficient c controls the strength of movement toward the global best configuration (see Table IV).

TABLE IV. CSO PARAMETERS

Parameter	Definition	Value
MR	Fraction in tracing mode	0.7
SMP	Number of copies generated in seeking mode	5
SRD	Mutation radius applied to selected dimensions	20%
CDC	Percentage of dimensions changed in each copy	80%
c	Tracing aggressiveness toward gbest	2.0

C. Seeking Mode: Local Exploration

A seeking cat examines nearby alternatives and moves to a superior neighbor through a structured local search:

- Create SMP copies of the current position vector.
- For each copy, randomly select CDC% of dimensions and mutate each by $\pm$SRD%.
- Evaluate the fitness f_{obj} for all copies.
- Compute selection probability: $P_i = \frac{|f_i - f_b|}{f_{max} - f_{min}}$, where f_b is the current best fitness.
- The cat is positioned where the copy chosen through the roulette wheel selection according to P_i.n

Through this process, there will be a detailed exploration of the environment around the promising solution in the manner a cat would explore its surroundings for subtle environmental changes when taking a rest.

D. Tracing Mode: Global Exploitation

The tracing cat rapidly moves towards the present global optimal solution (x_{best}):

$$v_{id} = v_{id} + r \cdot c \cdot (x_{best,d} - x_{id}) \tag{6}$$

$$x_{id} = x_{id} + v_{id} \tag{7}$$

where, $r \in [0, 1]$ is a uniformly distributed random number and c is the acceleration constant. In case of clustering of WSN nodes, the positions are converted to IDs by the rounding process: nodeID = round(x_{id}) $\bmod N$.

With MR=0.7, at each iteration 70% of cats chase (exploitation of the present optimal solution) and 30% explore (searching for alternative solutions). This dual-mode architecture prevents premature convergence to local optima while maintaining exploitation pressure toward the global optimum.

E. Standard CSO Workflow

The standard CSO procedure for WSN clustering is summarized in Algorithm 1.

Algorithm 1. Standard CSO Algorithm for WSN Clustering

Input: Sensor nodes N, number of CHs k, swarm size P, maximum iterations T, MR, SMP, SRD, CDC, c
Output: Best CH configuration $gbest$
Initialize P cats with random CH configurations $[CH_1, \ldots, CH_k]$
Evaluate each cat using $f_{obj} = \alpha f_1 + (1 - \alpha) f_2$
Set the best initial cat as $gbest$
for $t = 1$ to T **do**
  for each cat i in the swarm **do**
    Assign non-CH nodes to the nearest CH using Euclidean distance
    Generate a random value $r \in [0, 1]$
    if $r <$ MR **then**
      Apply Tracing Mode toward $gbest$
    else
      Apply Seeking Mode using SMP, SRD, and CDC
    end if
    Map updated positions to valid sensor node IDs
    Recompute f_{obj} for cat i
    if $f_{obj}(i) < f_{obj}(gbest)$ **then**
      Update $gbest \leftarrow i$
    end if
  end for
end for
return $gbest$

F. Limitations of Standard CSO

These three limitations motivate the enhancements proposed in Section VI.

1) Problem 1: Random mode switching: In standard CSO, each cat's mode is assigned randomly at every iteration according to the Mixture Ratio. A random value $r \in [0, 1]$ is generated; if $r < MR$, the cat enters tracing mode, otherwise it enters seeking mode. This mechanism is context-blind because it ignores the actual optimization state.

For example, when $gbest$ has just changed, cats should preferably trace the new optimum to exploit it. However, random assignment may still place some cats in seeking mode, causing a missed exploitation opportunity. Conversely, when $gbest$ has remained unchanged for many iterations, more cats should seek alternative regions, but standard CSO may continue assigning them to tracing mode and waste computation around a known position. Near convergence, where most cats become similar, the fixed 70% tracing and 30% seeking split can also lead to redundant movements toward the same $gbest$.

This limitation contrasts with the Emperor Penguin Optimizer, where all penguins follow a unified movement rule whose behavior changes dynamically with temperature. There is no artificial random split between modes, which makes the search behavior more adaptive.

2) Problem 2: No intelligent stopping condition: Standard CSO has no intelligent stopping condition for `chSelection()` beyond a fixed round or iteration limit. This creates two forms of computational waste. First, the optimal CH configuration may be discovered early, for example at round 20, while the algorithm continues evaluating candidates until round 2000. Second, the search may exhaust all meaningful alternatives by an early round but still continue generating redundant configurations until the fixed limit is reached.

The key insight is that existing bio-inspired WSN clustering protocols, including CSO and EPO, do not explicitly detect when CH selection has become redundant. Addressing this gap is the primary novel contribution of the proposed 2I-CSO protocol.

3) Problem 3: Configuration space explosion: Each cat in each iteration produces a CH configuration that requires cluster formation and fitness evaluation, which are among the most expensive operations in the protocol. With an ordered representation, the number of possible configurations grows

as N^k, where N is the number of sensor nodes and k is the number of selected CHs. Table V presents the combinatorial explosion of CH configuration space.

TABLE V. COMBINATORIAL EXPLOSION OF CH CONFIGURATION SPACE

Network	k	Ordered Configs	Problem
4 nodes	2	$4^2 = 16$	Manageable
10 nodes	2	$10^2 = 100$	Feasible
50 nodes	5	$50^5 \approx 3.1 \times 10^8$	Enormous
100 nodes	5	$100^5 = 10^{10}$	Intractable

Many of these configurations are redundant because the order of CHs does not change the resulting clusters. For instance, $[N_2, N_7]$ and $[N_7, N_2]$ represent the same CH set and produce identical cluster formation. Standard CSO has no mechanism to detect these repeated configurations or avoid evaluating them again.

VI. PROPOSED ENHANCEMENT: 2I-CSO

This section presents the proposed Intelligent and Interoperable Cat Swarm Optimization (2I-CSO) protocol. The objective of 2I-CSO is to improve the standard CSO search process for WSN clustering by reducing redundant CH configurations, avoiding unnecessary iterations, and adapting the swarm behavior to the current convergence state. Unlike the standard CSO, which relies on random mode assignment and a fixed stopping budget, 2I-CSO introduces a controlled search mechanism that combines configuration-space reduction, intelligent termination, adaptive mode switching, fast configuration hashing, and dynamic seeking-memory adjustment. The improvements are made to retain the optimization power of CSO, while at the same time reducing computational overhead and improving CH selection stability.

A. Overview

2I-CSO is a refined version of CSO that aims at optimizing CH selection in WSNs. Maintains the biological architecture of standard CSO (Seeking Mode for local searches and Tracing Mode for convergence) but changes the search control strategy such that it avoids redundancy and is sensitive to the state of convergence. The proposed design addresses three weaknesses of standard CSO: redundant CH configurations, fixed-budget computation, and static mode distribution.

The updated implementation introduces three main enhancement layers. First, configuration vectors are converted into canonical CH-set keys so that equivalent configurations such as $[N_2, N_7]$ and $[N_7, N_2]$ are treated as the same solution. Second, intelligent stopping is extended beyond full configuration exhaustion by adding a practical stagnation detector based on the change in global best fitness. Third, adaptive mode switching is combined with dynamic SMP decay so that 2I-CSO explores aggressively early in the search and progressively reduces expensive seeking evaluations near convergence.

B. Enhancement 1: Configuration Space Reduction

In a WSN with N active nodes and k selected CHs, a cat position represents a list of CH node IDs. Standard CSO handles this list as an ordered vector during position updates, although physically the order of CHs does not affect cluster formation. For example, $\{N_1, N_5, N_{12}\}$ and $\{N_{12}, N_1, N_5\}$ describe the same CH set and, therefore, produce the same clustering result.

The theoretical ordered search space is N^k. 2I-CSO reduces redundant tracking by converting each position into a canonical unordered configuration. In the baseline formulation, this key is obtained by sorting rounded node IDs:

$$\text{Key} = \text{tuple}\left(\text{sorted}\left(\lfloor x_i \rceil \mid x_i \in \text{position}\right)\right). \tag{8}$$

The number of unique valid configurations is then bounded by:

$$\text{Max Unique Configs} = \binom{N+k-1}{k} - N \tag{9}$$

where, the $-N$ term removes illegal configurations in which all selected CHs collapse to the same single node (see Table VI).

TABLE VI. CONFIGURATION SPACE REDUCTION EXAMPLES

Network	k	Ordered N^k	Unique Valid
4 nodes	2	16	6
10 nodes	2	100	45
100 nodes	5	10^{10}	96,560,546

C. Enhancement 2: Intelligent Stopping Condition

2I-CSO stores explored canonical configurations in a hash set $\mathcal{S}$. When the number of explored keys reaches the theoretical maximum, the CH selection engine stops because any further configuration must be redundant:

$$|\mathcal{S}| \geq \binom{N+k-1}{k} - N \Rightarrow \text{stop } \texttt{chSelection()}. \tag{10}$$

This creates a provable termination point for homogeneous search spaces and separates the expensive `chSelection()` phase from the lightweight `transmitData()` phase, which can continue until the last node dies.

In static benchmark experiments, full combinatorial exhaustion may still be difficult to reach because the valid configuration space remains large. For example, for $N = 29$ active nodes and $k = 5$ CHs, the stopping boundary is:

$$\binom{29+5-1}{5} - 29 = \binom{33}{5} - 29 = 237{,}307. \tag{11}$$

With a population of 30 cats, 500 iterations, and $SMP = 5$, the search can evaluate at most:

$$30 \times 500 \times 5 = 75{,}000 \tag{12}$$

seeking candidates. Since $75{,}000 < 237{,}307$, the complete-space stopping rule is unlikely to trigger in this benchmark setting.

To make stopping practical in benchmark and simulation settings, the updated 2I-CSO adds a delta-gbest stagnation rule:

$$\Delta f_{gbest} = |f_{gbest}^{(t-1)} - f_{gbest}^{(t)}|. \tag{13}$$

If $\Delta f_{gbest} < 10^{-6}$ in 50 successive iterations, the swarm is considered stagnant, `chSelection()` is deactivated, and the termination iteration is determined. This allows maintaining the original stopping criteria in the whole search space, with an extra option to terminate the search in large spaces.

D. Enhancement 3: Adaptive Mode Switching

Standard CSO uses random selection or tracing by setting a a fixed Mixture Ratio. In contrast, 2I-CSO selects the mode based on the condition of $gbest$:

- Active search phase: if $gbest$ changed in the previous iteration, all cats enter Tracing Mode to exploit the newly discovered promising region.
- Stable phase: if $gbest$ remains unchanged, all cats enter Seeking Mode to explore nearby alternatives and escape local stagnation.
- Initial phase: before a stable previous $gbest$ exists, cats begin with Seeking Mode to generate local diversity.

This context-aware rule keeps CSO's explicit dual-mode architecture while adopting the adaptive behavior observed in unified-motion optimizers such as EPO and SCSO [21]. Table VII presents the mode selection in Standard CSO and 2I-CSO.

TABLE VII. MODE SELECTION IN STANDARD CSO AND 2I-CSO

Optimization State	Standard CSO	2I-CSO
First iteration	Random MR split	Seeking
$gbest$ changed	Random MR split	Tracing
$gbest$ stable	Random MR split	Seeking

E. Enhancement 4: Fast Bitmask Hashing

The original canonical key based on sorting and tuple conversion is correct, but it adds overhead when called repeatedly during seeking mode. The updated implementation replaces it with an $\mathcal{O}(k)$ bitmask hash:

$$\text{Hash} = \sum_{x \in \text{position}} 2^{\lfloor x \rceil}. \tag{14}$$

For example, the CH set $\{3, 7, 12\}$ is encoded as:

$$2^3 + 2^7 + 2^{12} = 8 + 128 + 4096 = 4232. \tag{15}$$

Because addition is commutative, $[3, 7, 12]$ and $[12, 3, 7]$ generate the same key. The representation is collision-free for unique node sets because each node ID corresponds to one active bit in the integer. This avoids repeated sorting and tuple creation and improves configuration lookup efficiency.

F. Enhancement 5: Dynamic SMP Decay

The computational complexity in adaptive mode switching could be increased by switching into Seeking Mode due to the stability of $gbest$ for all cats. Given that the value of $SMP = 5$ remains fixed, this could result in numerous extra function evaluations. To avoid the above, 2I-CSO decreases the Seeking Memory Pool with respect to the iteration limit:

$$SMP_c = \max\left(2, \lfloor SMP_0 - (SMP_0 - 2)\rho \rceil\right), \quad \rho = \frac{t}{T_{max}}. \tag{16}$$

where, SMP_0 denotes the initial seeking memory pool, SMP_c the number of seeking copies currently, while ρ indicates the normalized search progress.

G. Enhancement 6: Adaptive Hybrid Mixture Ratio

The first adaptation rule had an absolute switch in that all cats were tracked whenever $gbest$ became better, and all cats searched if $gbest$ remained unchanged. Although this technique optimizes exploration or exploitation strategies, it loses the attraction aspect of the swarm when the algorithm becomes stagnated since all the cats may perform random searches without being attracted to the present gbest cat.

To preserve swarm cohesion, the optimized 2I-CSO uses an adaptive hybrid Mixture Ratio. The tracing probability is selected from the convergence state:

$$MR(t) = \begin{cases} 0.80, & \text{if } gbest \text{ changed}, \\ 0.35, & \text{if } gbest \text{ is stable} \end{cases} \tag{17}$$

In the active search phase, 80% of cats trace the newly improved leader and 20% remain in Seeking Mode for diversity. In the stagnation phase, 35% of cats maintain tracing pull toward $gbest$, while 65% perform high-pressure neighborhood search. This hybrid assignment keeps the swarm structurally aligned with the best solution while preserving the local exploration needed to escape stagnation.

H. Enhancement 7: Fitness Cache and Selective Perturbation

Because WSN fitness computation is dominated by repeated distance-energy calculations, the optimized implementation stores evaluated configurations in an exploration cache:

$$\mathcal{C} = \{\text{Hash}(\mathbf{x}) \rightarrow f(\mathbf{x})\} \tag{18}$$

Before evaluating a parent cat or a seeking copy, 2I-CSO first queries $\mathcal{C}$. If the bitmask key already exists, the cached fitness is reused in $\mathcal{O}(1)$ time; otherwise, the fitness is computed and inserted. This converts the explored-configuration structure from a pure membership set into a reusable fitness map, reducing redundant WSN evaluations during convergence plateaus.

2I-CSO also introduces selective swarm perturbation when stagnation persists for a fixed interval. The swarm is sorted by fitness, the best 50% of cats and the current $gbest$ are preserved, and only the worst 50% are relocated by randomized velocities and partial CH-node scattering. This keeps the exploitation core intact while turning weaker cats into exploration scouts that search for alternative CH basins.

I. Enhancement 8: Stagnation-Driven SMP Scaling

The linear SMP decay in Enhancement 5 reduces the seeking cost over the iteration budget. The latest implementation further adapts SMP to the stagnation depth. During active progress, SMP remains at its maximum value to preserve local-search resolution. Once a plateau is detected, the algorithm starts with a compact neighborhood and increases it only if stagnation deepens:

$$SMP_{dyn} = \max\left(2, \min\left(SMP_0, 2 + \left\lfloor \frac{s}{10} \right\rfloor\right)\right), \tag{19}$$

where, s is the consecutive stagnation counter. Thus, early plateaus are handled with a low-cost $SMP = 2$, while long stagnation gradually expands the local neighborhood up to SMP_0 to increase escape pressure.

J. Integrated Benchmarking Controls

The simulation platform provides the early termination stopping criterion as one of the benchmarks. It is off by default when there is the need to conduct an exact round-by-round comparison between CSO, EPO, and PSO, but turned on when the need is to cut down the runtime of the operations. In cases where early stopping is used, the backend stores the stop round and extends the rest of the convergence plot to ensure consistency with the sequence lengths.

The benchmark simulations will be automatically stored in the historical simulation database and can then be analyzed using the multi-run analysis interface. Thus, the proposed 2I-CSO becomes ideal for two distinct research methods – fixed-budget benchmarking and adaptive termination.

K. Performance Diagnostic

The updated implementation clarifies an important execution-time paradox. In theory, 2I-CSO should be faster than standard CSO because it can stop redundant searches. In static benchmarks, however, the full configuration boundary is often too large to reach, so the algorithm may still run for the maximum iteration budget.

Moreover, standard CSO with $MR = 0.7$ evaluates all parent cats plus only the seeking subset. With population $P = 30$ and $SMP = 5$, its approximate evaluation count per iteration is:

$$Eval_{CSO} = P + P(1 - MR)SMP = 30 + 30(0.3)(5) = 75. \quad (20)$$

When 2I-CSO enters a stable phase, all cats seek. Dynamic SMP decay controls this cost by reducing the number of copies as the iteration budget is consumed, as shown in Table VIII.

TABLE VIII. DYNAMIC SMP DECAY AND STABLE-PHASE EVALUATIONS ($P = 30$, $T_{max} = 500$).

Iter.	SMP_c	Copies	Eval.
0–83	5	150	180
84–250	4	120	150
251–416	3	90	120
417–500	2	60	90

Thus, 2I-CSO applies maximum local search when stagnation appears early, but progressively limits the seeking workload as convergence advances. The optimized version addresses the execution-time overhead through delta-gbest stopping, bitmask hashing, and dynamic SMP decay.

L. Complete 2I-CSO Algorithm

The complete 2I-CSO procedure is summarized in Algorithm 2. The algorithm begins by generating an initial population of candidate CH configurations and by creating an empty cache for previously evaluated solutions. Each candidate configuration is converted into a canonical bitmask key, which removes duplicate CH permutations and ensures that the same cluster-head set is not evaluated more than once. During each iteration, the algorithm evaluates the current population, updates the global best solution, and measures the change in best fitness to detect whether the search is still improving or has entered stagnation. If improvement is detected, the adaptive mixture ratio favors tracing mode to guide cats toward the current best solution; otherwise, it increases seeking mode and local perturbation to intensify exploration around promising regions. The process stops either when the maximum iteration budget is reached, when stagnation exceeds the allowed threshold, or when the cache confirms that all feasible unique CH configurations have been explored. The final global best configuration is then used for cluster formation and data transmission.

Algorithm 2. Optimized 2I-CSO Protocol Pseudocode

Input: Active nodes N, CH count k, population P, maximum iterations T_{max}
Initialize swarm cats with random CH positions
Initialize fitness cache $\mathcal{C} \leftarrow \emptyset$, $gbest \leftarrow \emptyset$, and stagnation counter $s \leftarrow 0$
Compute $max_configs = \binom{N+k-1}{k} - N$
for $t = 1$ to T_{max} **do**
  if $|\mathcal{C}| \geq max_configs$ or $s \geq 50$ **then**
    Deactivate `chSelection()` and record stop iteration
    break
  end if
  Evaluate all cats using cached bitmask fitness values and update $gbest$
  Compute $\Delta f_{gbest} = |f_{gbest}^{(t-1)} - f_{gbest}^{(t)}|$
  if $\Delta f_{gbest} < 10^{-6}$ **then**
    $s \leftarrow s + 1$
  else
    $s \leftarrow 0$
  end if
  Compute adaptive $MR(t)$ from the $gbest$ state
  Compute $SMP_{current}$ using iteration decay and stagnation-driven scaling
  if $s > 0$ and s is divisible by 30 **then**
    Preserve the best 50% of cats and perturb the worst 50% as exploration scouts
  end if
  for each cat c in the swarm **do**
    if $rand() < MR(t)$ **then**
      Apply Tracing Mode toward $gbest$ to maintain swarm pull
    else
      Apply Seeking Mode using $SMP_{current}$, SRD, CDC, and cached copy fitness
    end if
    Convert updated CH position to a bitmask key and store/reuse it in $\mathcal{C}$
  end for
end for
Use final $gbest$ for cluster formation and data transmission

M. Real-World WSN Operation

In static TSPLIB-style benchmarks, the active node set is fixed and the search space remains very large. In a real WSN, CH selection is executed round by round while nodes consume energy and die. Therefore, the active candidate pool N_{alive} decreases over time:

$$N_{alive}^{(r)} \leq N_{alive}^{(r-1)}. \quad (21)$$

As N_{alive} shrinks, the maximum configuration space $\binom{N_{alive}+k-1}{k} - N_{alive}$ also shrinks rapidly. For example, with $k = 5$, $N_{alive} = 15$ gives $\binom{19}{5} - 15 = 11{,}613$ unique valid configurations, while $N_{alive} = 8$ gives $\binom{12}{5} - 8 = 784$. In late network rounds, the explored set can therefore reach the complete search boundary quickly, and the intelligent stopping condition becomes increasingly effective.

The operational implication is that 2I-CSO becomes faster as the network ages. Early rounds perform deeper heuristic

search when many CH choices exist, while late rounds transition into short-circuited configuration scanning, reducing the computational energy spent on CH selection and supporting longer WSN lifetime.

VII. Simulation and Implementation

This section describes the experimental environment and benchmarking protocol used to assess the proposed 2I-CSO algorithm. The evaluation is conducted through a dedicated TSPLIB benchmarking module integrated into the WSN-Simulation application. The goal is to provide a controlled and reproducible comparison between 2I-CSO and the baseline optimization algorithms under identical execution conditions.

A. Experimental Setup

All experiments were executed on a personal computer running a 64-bit Windows 10 operating system. The hardware platform was equipped with 32 GB of RAM and an Intel Core i5 14th-generation processor with a maximum clock frequency of 5.2 GHz. The same machine was used for all TSPLIB and WSN simulation runs to ensure that runtime comparisons among CSO, 2I-CSO, EPO, PSO, and LEACH-C were performed under identical computational conditions.

B. Application Platform

To support reproducible experimentation, the WSN-Simulation application was implemented using a Next.js frontend and a Python Flask backend. The frontend provides the interface for dataset selection, parameter configuration, execution control, and visual analytics, while the Flask backend implements the optimization algorithms and returns structured benchmark results. A separate TSPLIB simulation page was added to the application in order to evaluate the proposed 2I-CSO algorithm on standardized traveling-salesman benchmark instances independently from the WSN simulation modules.

C. Rationale for Using TSPLIB in WSN Clustering Validation

Despite the fact that TSPLIB was initially created as a benchmark library for TSP problems, it could be used as a spatial optimization testing ground in this research, but not as a WSN lifetime benchmark [29]. Each TSPLIB problem presents two dimensional points for nodes together with a distance matrix for those nodes. The described characteristics could be applied to the geometric aspect of the WSN clustering, where physical deployment of sensors plays an important role as well as the dependence of communication energy from the transmission distance. As a result, TSPLIB problem could be interpreted as a static sensor deployment, where cities correspond to sensors and the chosen cities serve as candidates for CHs.

On this approach, the fitness function based on TSPLIB does not compute a TSP tour. Instead, it measures how good the clustering algorithm is at forming clusters with minimized distance clustering cost. This is useful because the typical energy models used for WSN radios are functions of distance, which can be expressed in either quadratic (d^2) or quartic (d^4) form depending on the channel conditions. Hence, clustering that minimizes average/total cluster member distance to the CH will decrease communication energy cost, make clusters more spatially compact, and allow comparison between CSO, 2I-CSO, EPO, PSO, and LEACH-C algorithms using similar node placement scenarios.

TABLE IX. Energy Depletion Benchmark for 29 Nodes, 100×100 m^2, $k = 2$

Protocol	FND	HND	LND	vs. LEACH-C (%)
CSO	608	2219	**3393**	-72.8%
2I-CSO	558	2238	3374	-75.1%
EPO	847	**2524**	3241	-62.2%
PSO	962	2220	3348	-57.0%
LEACH-C	**2239**	2246	2320	0.0%

TABLE X. FND Comparison for the Current Base Station Position.

BS Position	PSO	CSO	2I-CSO	EPO	LEACH-C
Current $(50, 50)$	962	608	558	847	**2239**

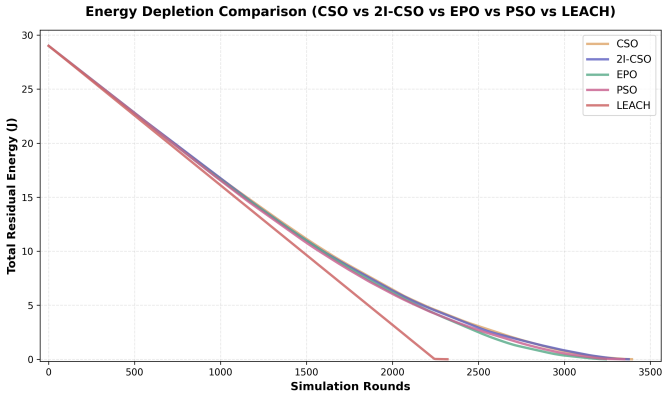
Still, TSPLIB findings need to be considered carefully. They prove that the optimizer is capable of searching large, repeatable, and distance-based CH selection spaces and of saving computation cost, convergence time, and spatial clustering fitness. Nevertheless, they are not by themselves evidence for network lifetime improvement since the TSPLIB problems lack factors such as battery depletion dynamics, traffic, CH turnover, radio interference, and node death. This is the reason why TSPLIB benchmarking is done separately as an algorithmic and geometric proof step, whereas the claims on FND, HND, LND, and lifetime are proven by the other benchmark, which follows in the next subsection.

D. WSN Energy Depletion Benchmark

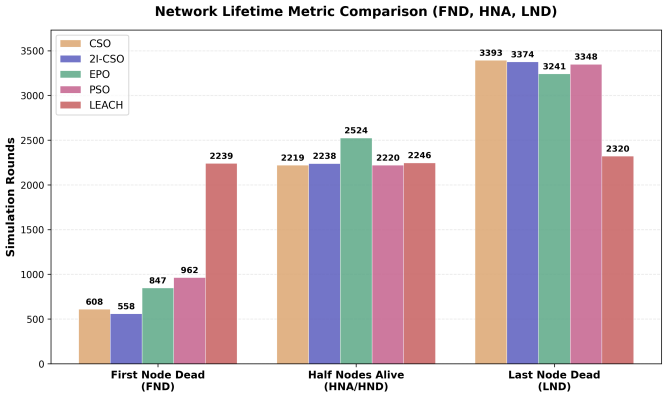
Before the TSPLIB benchmark, an additional WSN-specific energy depletion test was conducted to evaluate network lifetime behavior under a direct sensor-network scenario. The test uses 29 sensor nodes deployed in a 100×100 m^2 field, with $k = 2$ cluster heads and the Base Station located at $(50, 50)$. Three standard lifetime indicators are reported: first node death (FND), half node death (HND), and last node death (LND). The percentage column compares FND against the LEACH-C baseline (see Table IX).

Interpretation: The energy depletion results show that LEACH-C achieves the latest FND, meaning that it delays the first node failure more effectively in this deployment (see Fig. 6). However, the metaheuristic protocols maintain longer post-FND operation, with CSO and 2I-CSO producing the largest LND values. This indicates a trade-off between early stability and tail lifetime: LEACH-C is stronger when the objective is to postpone the first failure, while CSO-family methods can keep the network operating for more rounds after initial depletion begins. The 2I-CSO result remains close to CSO in LND while preserving the runtime advantages shown in the TSPLIB benchmark.

The TSPLIB webpage compares 2I-CSO against CSO, PSO, EPO, and LEACH-C in an equivalent experimentation setup (see Table X). This comparison is aimed at assessing the solution quality, convergence speed, stagnation recovery, runtime efficiency, and scalability. The experiment is carried out in five runs, 1000 iterations per run, with maximum iterations



(a) Energy depletion milestones.



(b) Network lifetime metric comparison.

Fig. 6. Grouped visualization of energy depletion and network lifetime behavior.

as the stopping criterion, similar hardware/software configurations, and similar random seeds used for each algorithm. In the case of the TSPLIB benchmark test mode, the early stagnation detection stopping rule is disabled for 2I-CSO, although the program can automatically terminate the execution when the number of consecutive stagnant runs exceeds 50. Dynamic SMP (self-multiplying population) decrement is also disabled in 2I-CSO in order to compare all algorithms on the same iteration budget without any differences in stopping rules affecting the result. This makes sure that the difference in execution time reflects only the difference in algorithmic update cost per iteration among algorithms. Population scaling factor is adaptively adjusted depending on benchmark complexity: 30 agents for small instances, 40 agents for moderate instances, 50 agents for large instances, and 60 agents for extra-large instances. This scaling preserves fairness because all algorithms use the same population size within each category (see Table XI).

The benchmark suite contains the reported TSPLIB instances distributed across three groups. The small group contains att48, bayg29, bays29, burma14, dantzig42, ulysses16, and two ulysses22 benchmark runs (see Table XII). The moderate group contains berlin52, eil51, eil76, gr96, kroa100, and krob100 (see Table XIII). The large group contains bier127, ch130, ch150, d198, eil101, and gr120 (see Table XIV). Overall, the reported experimental campaign consists of:

$$20 \times 5 \text{ protocols} \times 5 \text{ runs} = 500 \text{ executions} \qquad (22)$$

The recorded metrics include best fitness, execution time, convergence behavior, and Wilcoxon signed-rank significance results. The Wilcoxon test is applied at a level of significance of $p < 0.05$ to determine whether the observed best-fitness differences between protocols are statistically meaningful. Fig. 7 to Fig. 9 presents the TSPLIB convergence and multi-criteria radar comparison of three scales: small, moderate and large.

Table indicators have the following meanings. Best fitness corresponds to the best, or lowest, tour fitness obtained across the independent runs and measures optimization precision. Mean fitness stands for the average quality of solution, which is calculated as $\mu_f = (1/R)\sum_{i=1}^{R} f_i$ and implies expected behavior in the typical run. Standard deviation estimates the stability of the search process by measuring the variation of solution quality and is low for the most consistent optimization. Execution time shows the average CPU time per trial in seconds and measures computational efficiency. Stagnation indicators report the number and duration of non-improving intervals, while escape ratio measures the ability of the algorithm to resume improvement after stagnation.In the instance-level tables, each protocol column reports the final measured value, and the Winner column identifies the protocol with the lowest best fitness for that instance.

TABLE XI. TSPLIB BENCHMARK CONFIGURATION

Category	Instances	Population	Runs	Iterations
Small	8	30	5	1000
Moderate	6	40	5	1000
Large	6	50	5	1000

1) Final TSPLIB benchmark results: The final TSPLIB comparison evaluates five protocols: CSO, 2I-CSO, EPO, PSO, and LEACH-C. LEACH-C is included as a centralized clustering baseline because its BS-assisted CH selection is closer to the centralized configuration assumed by the proposed interoperable 2I-CSO model. For all tables, lower best-fitness values indicate better clustering cost, and execution time is reported in seconds per run. The last column reports the speedup of 2I-CSO relative to standard CSO.

Interpretation: The updated results show that 2I-CSO consistently reduces runtime relative to standard CSO across all reported TSPLIB groups, with speedups ranging from 3.2× to 56.6×. In terms of best fitness, 2I-CSO remains competitive with CSO and improves over EPO and PSO on several instances, especially in the large group. However, LEACH-C obtains the best fitness on all moderate and large instances. Therefore, the revised conclusion is that 2I-CSO offers a strong runtime–quality trade-off and improves the CSO)family computationally, while LEACH-C remains a strong centralized baseline for the TSPLIB-derived spatial clustering objective (see Table XV to Table XVII).

2) Wilcoxon signed-rank test results: The Wilcoxon signed-rank test was applied to the best-fitness values to evalu-

ate whether the observed differences are statistically significant at $p < 0.05$. Table XVIII reports the final results for the small, moderate, and large TSPLIB groups. The small group uses 2I-CSO as the reference protocol. In the moderate group, the reported comparison follows the CSO-based reference used in the benchmark output. In the large group, 2I-CSO is again used as the reference protocol.

Statistical interpretation: On small instances, 2I-CSO is statistically equivalent to CSO and LEACH-C, but significantly

(b) Large-scale TSPLIB multi-criteria radar.

Fig. 9. Large-scale TSPLIB convergence and multi-criteria radar comparison.

better than EPO and PSO. On moderate instances, CSO and 2I-CSO are statistically equivalent, while LEACH-C is significantly better than CSO. On large instances, 2I-CSO is statistically equivalent to CSO and significantly better than EPO and PSO, but LEACH-C is significantly better than 2I-CSO. These results support a conservative interpretation: 2I-CSO improves runtime and remains competitive in fitness, but it should not be claimed to dominate LEACH-C on all TSPLIB-derived spatial benchmarks.

E. Discussion

1) Novelty of the stopping condition: The intelligent stopping criterion, as far as we know, is the first completely proven terminating approach in mathematically sound way for bio-inspired clustering of wireless sensor networks. The reason behind this is that whereas heuristic stopping criteria such as "stop if no improvement in T iterations", provide no guarantees of achieving the optimal solution, set-based monitoring guarantees that the best global solution achieved is the *true* global solution of the configuration space.

2) Synergy of enhancements: The three enhancements are not independent improvements, but form a synergistic system: Configuration Space Reduction defines the finite boundary that makes stopping possible; the Stopping Condition exploits this boundary for provable termination; and Adaptive Mode Switching accelerates convergence to reach the boundary faster. Without space reduction, the stopping threshold would be impractically large. Without adaptive switching, reaching the threshold would take longer.

3) Broader applicability: CSO has demonstrated broad applicability beyond CH selection including balanced WSN routing [18], sink node placement [25], node localization [26], underwater network partition recovery [27], target tracking [28], and NP-hard scheduling [24]. The structural nature of 2I-CSO's enhancements—operating on the search space topology rather than domain-specific fitness functions—supports their generalizability to the entire CSO family and other population-based metaheuristics.

4) Limitations:

a) Energy homogeneity requirement: The stopping condition assumes stable fitness rankings, which holds only in homogeneous networks. Heterogeneous deployments require the dynamic energy exception pathway.

b) CH candidate assumption: The formula assumes all N nodes are valid CH candidates. If certain nodes are excluded (e.g., due to location constraints), the formula must be adjusted with a reduced candidate pool $N' < N$.

c) Simulation-based validation: Results are obtained from a custom web-based simulator. Validation on a physical testbed (e.g., TelosB or MICAz motes) is necessary to confirm real-world applicability.

d) Memory scalability: When dealing with very large networks ($N > 200$, $k > 10$), Set data structure scales combinatorially and might need memory-efficient approaches (like Bloom filters, which can accept false positives).

VIII. Conclusion and Future Work

The study introduced 2I-CSO, an Intelligent and Interoperable Cat Swarm Optimization algorithm for energy-efficient Cluster Head Selection in wireless sensor network. The new approach solves many shortcomings of CSO by minimizing repetitive CH formations, incorporating a set-based intelligent termination condition, adopting a mode switching approach and unifying energy-related parameters using interoperable Base Station configuration model. The TSPLIB test cases represent a replicable spatial basis for the evaluation of searching ability, convergence characteristics, and efficiency, whereas the WSN energy exhaustion test case directly evaluates lifetime parameters such as FND, HND, and LND. The findings indicate that 2I-CSO has significantly lowered run-time relative to standard CSO and is still comparable in clustering performance,Although it appears that the lifetime study indicates that CSO-based approaches can operate for extended periods post-FND even when the delay introduced by LEACH-C in the death of the first node is greater than that achieved by 2I-CSO in the considered network. Thus, the principal advantage of the 2I-CSO approach does not consist in being superior to all existing approaches unconditionally, but

rather in a balance between runtime performance and quality based on the existence of the termination criterion and a better distinction between geometric optimizer testing and network lifetime estimation.

Emotion-Aware Serendipity Recommendation from Textual Reviews: BERT-Based Emotional Clustering

Mariam Benayad, Ahmed Zellou
SPM Research Team, ENSIAS Mohammed V University in Rabat, Rabat, Morocco

***Abstract*—This study proposes an emotion-aware serendipity recommendation framework based on textual reviews. Six BERT-based binary classifiers are trained to detect surprise, curiosity, trust, nostalgia, frustration, and enchantment from user reviews. The predicted emotion probabilities are used to build stable review-level emotional vectors. Two complementary contributions are introduced. Contribution 1 develops an emotion-aware reranking strategy that combines calibrated emotional information with relevance, novelty, and unexpectedness. Contribution 2 introduces EC-SereRank, an emotional-combination-based reranking model that preserves co-activated emotions within reviews and groups them using K-medoids into interpretable affective meta-groups. Experiments on Amazon Product Reviews show that affective information improves serendipity-oriented recommendation. The ablation study confirms that relevance and unexpectedness alone are not sufficient, while the integration of emotional compatibility improves recommendation quality. EC-SereRank further shows that emotional combinations provide an interpretable complementary signal for affective serendipity recommendation.**

***Keywords*—Recommender systems; emotion-aware recommendation; textual reviews; BERT; K-medoids; K-means**

I. Introduction

Recommender systems have become essential tools for helping users navigate large volumes of online information, products, and services [1], [2]. In e-commerce platforms, they are mainly designed to predict user preferences and generate personalized Top-K recommendation lists. Traditional recommender systems usually focus on accuracy-oriented objectives, such as relevance and ranking quality. However, highly accurate recommendations may still remain predictable, repetitive, or too similar to the user's previous interactions. This limitation can reduce the user's opportunity to discover novel and unexpected items [3], [4].

To address this issue, recent research has emphasized beyond-accuracy objectives, particularly novelty, unexpectedness, diversity, and serendipity [3], [9]. Serendipitous recommendation aims to suggest items that are not only relevant to the user, but also unexpected and potentially valuable. In this context, a good recommendation should not only match the user's known preferences, but also support discovery by introducing useful and surprising items [3], [11].

Recent studies on serendipity in recommender systems emphasize that effective recommendation should go beyond accuracy by considering novelty, unexpectedness, usefulness, and discovery value [3], [4]. Existing approaches have explored different ways to improve serendipity, including self-serendipity preference generation for cold-start scenarios [10], opinion mining from textual reviews for generating novel and pleasantly surprising recommendations [11], and multi-criteria Top-N recommendation methods [19]. In parallel, review-aware recommender systems have shown that textual reviews can improve user and item representation learning [12], [13], while sentiment-aware approaches demonstrate the usefulness of affective information extracted from user-generated content [14], [15]. However, most of these works rely either on rating patterns, sentiment polarity, or general opinion signals, and do not explicitly exploit fine-grained emotional dimensions for serendipity-oriented reranking. With the development of transformer-based language models such as BERT and DistilBERT [16], [17], and the availability of fine-grained emotion modeling resources such as GoEmotions [18], it becomes possible to build richer affective representations from textual reviews. This motivates the proposed emotion-aware framework, which integrates calibrated BERT-based emotional signals into serendipity-oriented recommendation.

Most existing serendipity-oriented approaches rely mainly on rating patterns, item popularity, user-item similarity, or structural information [10], [11]. Although these signals are useful, they do not fully exploit the rich information contained in user-generated textual reviews. Reviews provide more than explicit preference feedback; they also express subjective experiences, affective reactions, satisfaction, surprise, trust, frustration, curiosity, or emotional attachment. These affective cues can provide a deeper understanding of user preferences. Prior review-aware recommendation models have shown that textual reviews can improve user and item representation learning [12], [13], while serendipity-oriented studies suggest that richer preference signals may support discovery-oriented recommendation [3], [11].

Several studies have integrated textual reviews or sentiment analysis into recommender systems [12], [13], [14], [15]. However, sentiment-based approaches often reduce user opinions to coarse polarity categories, such as positive, negative, or neutral. Such representations are limited when the objective is to model more complex affective experiences. For example, two positive reviews may express different emotional meanings: one may reflect trust and reliability, while another may express surprise or enchantment. Similarly, a negative review may indicate frustration, disappointment, or unmet expectations. Therefore, a richer emotional representation is needed to better capture the affective structure of user reviews [18].

This study proposes an emotion-aware serendipity recommendation framework based on textual reviews. The framework extracts latent emotional signals from Amazon Product Reviews using BERT-based emotion classifiers [16], [17]. Since the original dataset does not provide explicit emotion labels, six weakly supervised binary classifiers are trained

to detect surprise, curiosity, trust, nostalgia, frustration, and enchantment from user reviews.

The proposed framework introduces two complementary contributions. The first contribution, C1, is the main quantitative component of the study. It applies K-means clustering to calibrated BERT-based emotional vectors in order to identify dominant emotional structures in the review space. These calibrated emotional vectors and cluster-based profiles are then used to construct user and item affective profiles for emotion-aware reranking based on relevance, novelty, unexpectedness, and emotional compatibility.

The second contribution, C2, extends the affective representation by modeling emotional combinations. Instead of assigning each review only to a dominant emotional profile, C2 preserves the set of simultaneously activated emotions in each review. These emotional combinations are grouped using K-medoids into interpretable affective meta-groups. This combinatorial representation allows the system to capture richer multi-emotional configurations and to integrate emotional combination compatibility into the reranking process through the proposed *EC-SereRank* model. C2 is therefore presented as a complementary representational contribution that improves the interpretability of the affective space, rather than as a replacement for C1.

The main contributions of this work are summarized as follows:

- We propose an emotion-aware serendipity recommendation framework that integrates fine-grained affective signals extracted from textual reviews into Top-K recommendation.
- We train six BERT-based binary emotion classifiers to detect surprise, curiosity, trust, nostalgia, frustration, and enchantment from user-generated reviews, and calibrate their outputs using emotion-specific thresholds.
- We propose C1, an emotion-aware reranking contribution that exploits emotional vectors together with relevance, novelty, and unexpectedness to improve serendipity-oriented recommendation. K-means clustering is also used to identify interpretable dominant emotional profiles and to support user/item affective profiling.
- We propose C2, an emotional-combination-based contribution that captures co-occurring active emotions within reviews, clusters the observed emotional combinations using K-medoids into interpretable affective meta-groups, and integrates emotional combination compatibility into the proposed EC-SereRank reranking model.
- We evaluate the proposed framework using Top-K accuracy metrics and beyond-accuracy metrics, including novelty, unexpectedness, and serendipity. The experimental results and ablation analysis show that affective information provides a useful complementary signal for serendipity-oriented recommendation.

The main quantitative contribution of this work is the C1 emotion-aware reranking model, which evaluates the impact of calibrated emotional compatibility on serendipity-oriented Top-K recommendation. C2 is introduced as a complementary representational contribution that preserves multi-emotional co-activation patterns through emotional combinations and K-medoids meta-groups.

The remainder of this study is organized as follows: Section II reviews related work on recommender systems, serendipity, textual reviews, and affective recommendation. Section III presents the proposed methodology, including dataset preprocessing, emotion annotation, BERT-based emotion extraction, emotional calibration, C1, C2, and reranking. Section IV reports the experimental results and discusses the impact of the proposed affective representations. Finally, Section V concludes the study and outlines future research directions.

II. Related Work

Recommender systems are traditionally optimized for accuracy-oriented objectives, such as relevance, precision, and ranking quality [1], [2]. However, accuracy alone may lead to repetitive and predictable recommendations, reducing the user's opportunity to discover novel and unexpected items. To overcome this limitation, recent research has increasingly focused on beyond-accuracy objectives, including novelty, diversity, unexpectedness, coverage, and serendipity [5], [6].

Serendipity is generally associated with recommendations that are relevant, unexpected, and useful to the user. Kotkov et al. [3] provide a comprehensive survey of serendipity in recommender systems and highlight the diversity of its definitions and evaluation strategies. Similarly, Ziarani and Ravanmehr [4] show that serendipity remains a complex concept because its formalization and measurement vary across studies. Earlier work by Murakami et al. [7] also emphasized the importance of evaluating serendipity through recommendation-list metrics, while Adamopoulos and Tuzhilin [8] focused specifically on the role of unexpectedness in improving user satisfaction.

Several approaches have attempted to improve serendipity through popularity debiasing, long-tail recommendation, weak-tie structures, unexpectedness modeling, or multi-objective optimization. Xu et al. [10] proposed GS2-RS, a serendipity-oriented recommendation framework that generates self-serendipity preferences from rating data in order to address cold-start and filter-bubble problems. Shrivastava et al. [11] proposed an optimized framework exploiting textual reviews and opinion mining to generate recommendations that are novel, unexpected, and relevant. Duricic et al. [9] further reviewed beyond-accuracy objectives, including diversity, serendipity, and fairness, in graph neural network-based recommender systems. These works confirm the importance of balancing relevance with discovery-oriented dimensions.

More recent studies have extended serendipity-oriented recommendation beyond classical rating-based settings. Al Jurdi et al. [20] explored the role of weak ties and network-inspired clustering in improving unexpected but relevant recommendations. Kaya and Kaleli [19] proposed a Top-N recommendation method for multi-criteria collaborative filtering and evaluated beyond-accuracy dimensions such as novelty, diversity, and serendipity. Chen et al. [21] introduced a cognitive-based knowledge learning framework that integrates

cognitive psychology and knowledge graphs to improve both accuracy and beyond-accuracy objectives, including diversity and serendipity. Yu et al. [22] addressed long-tail service recommendation using cross-view and contrastive learning, emphasizing that long-tail items can improve novelty and serendipity while reducing popularity bias. From a content-oriented perspective, Yang et al. [23] showed that recommendation content attributes, including content serendipity, can influence consumers' recommendation adoption intention.

Despite these advances, most existing serendipity-oriented approaches still rely mainly on rating data, item popularity, user-item similarity, structural signals, cognitive signals, or general opinion information. They rarely integrate fine-grained emotional dimensions extracted from textual reviews into the serendipity reranking process. This limitation motivates the proposed emotion-aware framework, which uses calibrated BERT-based affective signals to enrich serendipity-oriented recommendation beyond classical relevance, novelty, and unexpectedness components.

A. Textual Reviews and Opinion-Aware Recommendation

Textual reviews provide rich information about user preferences and item characteristics. Unlike ratings, which summarize user feedback through a numerical value, reviews contain explanations, subjective opinions, product experiences, and contextual details. Review-aware recommender systems, therefore, exploit textual reviews to improve user and item representation.

Zheng et al. [12] proposed DeepCoNN, a deep cooperative neural network that jointly learns user behaviors and item properties from review text. Chen et al. [13] introduced NARRE, an attention-based review-aware model that learns the usefulness of reviews and provides review-level explanations for recommendations. These works demonstrate that textual reviews can improve recommendation performance by providing richer user-item representations than ratings alone.

III. Methodology

A. Overview of the Proposed Framework

The proposed framework aims to enhance serendipity-oriented recommendation by exploiting latent emotional signals extracted from textual reviews. Instead of relying only on explicit ratings or conventional relevance scores, the proposed approach introduces an affective layer based on BERT-inferred emotions. These emotions are then used to construct two complementary recommendation contributions.

The overall framework is composed of four main stages. First, textual reviews are processed using BERT-based emotion classifiers in order to infer six affective dimensions: surprise, curiosity, trust, nostalgia, frustration, and enchantment. Second, the predicted emotional probabilities are used to construct review-level emotional vectors. These emotional vectors prepare the data for clustering and profile construction.

Third, two affective modeling strategies are introduced. The first contribution, C1, develops an emotion-aware reranking strategy based on review-level emotional vectors. K-means clustering is also applied to these emotional vectors in order to identify interpretable dominant emotional profiles and to support the construction of user and item affective profiles. The second contribution, C2, extends the emotional representation by preserving multiple active emotions within each review. It builds combinatorial emotional signatures and groups them using K-medoids to obtain interpretable affective meta-groups.

Finally, the affective profiles obtained from C1 and C2 are integrated into a serendipity-oriented reranking stage. The reranking function combines relevance, unexpectedness, novelty, and affective compatibility in order to generate Top-K recommendations that are both useful and discovery-oriented.

The general architecture of the proposed framework is summarized in Fig. 1.

B. Dataset and Preprocessing

The experimental study is conducted on the Amazon Product Reviews dataset obtained from Kaggle. The raw dataset initially contains 568,454 reviews and 10 attributes: *Id*, *ProductId*, *UserId*, *ProfileName*, *HelpfulnessNumerator*, *HelpfulnessDenominator*, *Score*, *Time*, *Summary*, and *Text*. Each record represents a user-item review associated with a given product.

Although the raw dataset includes several metadata and rating-related fields, the proposed preprocessing stage mainly relies on *UserId*, *ProductId*, *Text*, and *Time*. The *UserId* and *ProductId* fields are used to preserve the user-item interaction structure. The *Text* field is used as the main textual source for affective information extraction. The *Time* field is preserved for the recommendation stage in order to maintain the chronological order of user interactions.

The first preprocessing step consists of preparing the textual content of each review. Missing values in the *Text* field are replaced with empty strings, and the field is converted into textual format. Reviews with empty, very short, or non-informative textual content are removed by keeping only reviews whose length exceeds 20 characters. This filtering step ensures that the retained reviews contain enough meaningful textual information for the subsequent emotion extraction and recommendation stages.

A light text normalization step is then applied. The text is converted to lowercase, leading and trailing spaces are removed, and repeated whitespace characters are replaced with a single space. This normalization is used to make the text representation more consistent while avoiding aggressive preprocessing. In particular, no stemming, lemmatization, or heavy stop-word removal is applied, since preserving the original wording remains important for capturing contextual and affective cues in user-generated reviews.

After text cleaning, the user-item interaction structure is filtered in order to support a reliable Top-K recommendation protocol. Since users with only one or two reviews do not provide enough interaction history for constructing user-level affective profiles or for chronological evaluation, only users with at least three interactions are retained. This filtering step produced a pool of eligible users from which the experimental subset was constructed.

The final experimental subset contains 10,000 reviews. It was not obtained by uniformly sampling isolated reviews

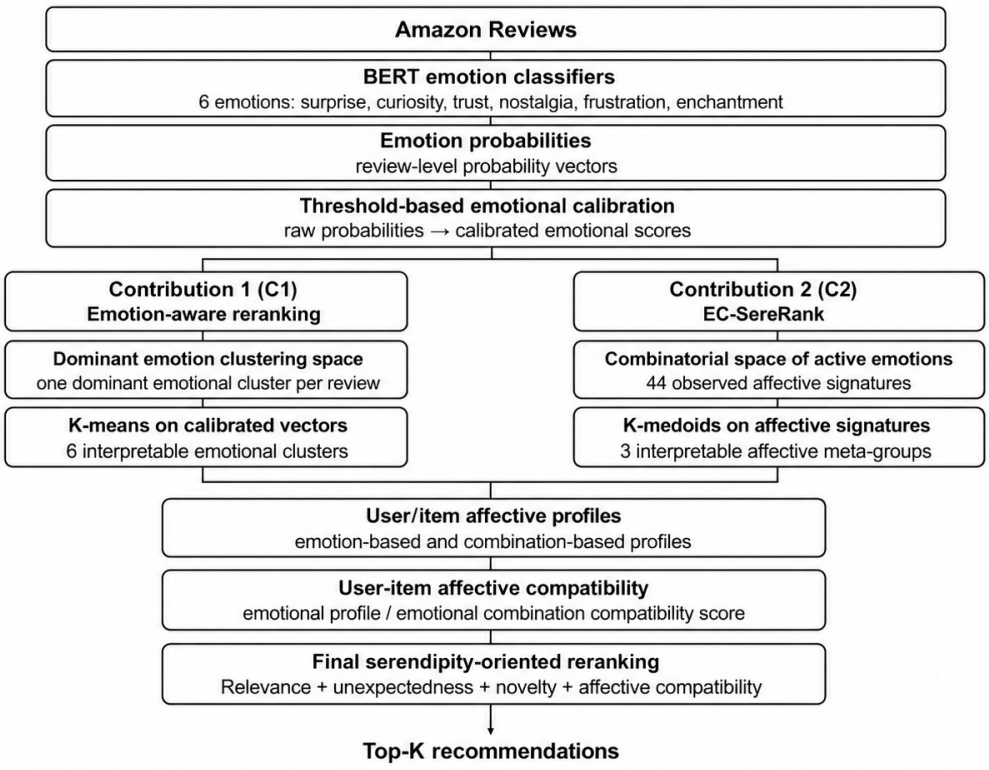

Fig. 1. General architecture of the proposed emotion-aware and combinatorial serendipity recommendation framework.

from the raw dataset. Instead, the subset was constructed from eligible users with at least three interactions, while preserving their user-item structure and temporal information. This strategy ensures that each retained user has sufficient historical interactions to support profile construction and recommendation evaluation. As shown in Table I, the resulting subset contains 1,582 users and 4,899 products. This controlled subset size also makes the BERT-based emotion extraction, clustering, user/item profile construction, and reranking stages computationally feasible while maintaining a meaningful user-item recommendation setting.

TABLE I. DATASET FILTERING SUMMARY

Step	Value
Raw reviews	568,454
Raw attributes	10
Minimum text length	> 20 characters
Minimum interactions per retained user	≥ 3
Final experimental reviews	10,000
Final users	1,582
Final products	4,899

Overall, the preprocessing pipeline transforms the raw Amazon review dataset into a structured experimental subset containing user identifiers, product identifiers, cleaned review texts, ratings, and temporal information. These prepared data are then used in the following stages of the methodology, including weakly supervised emotion annotation, BERT-based emotion extraction, affective representation learning, and Top-K recommendation evaluation.

C. Emotion Annotation Strategy

Since the original Kaggle dataset does not provide explicit emotion labels, a weak supervision strategy is adopted to generate initial affective labels from review texts. Six target emotions are considered: surprise, curiosity, trust, nostalgia, frustration, and enchantment. These emotions are selected because they cover both discovery-oriented affective states, such as surprise and curiosity, and experience-oriented affective states, such as trust, nostalgia, frustration, and enchantment.

For each emotion, a manually curated list of lexical patterns is defined using regular expressions. These patterns are designed to capture representative linguistic cues associated with each emotional dimension. For example, surprise is associated with expressions related to unexpectedness, curiosity with exploration-oriented terms, trust with reliability-related expressions, nostalgia with memory-related cues, frustration with dissatisfaction-related terms, and enchantment with delight-oriented expressions.

Before annotation, each review is normalized by converting the text to lowercase and removing redundant whitespace. The annotation function then scans the normalized text using the emotion-specific patterns. A review receives a positive weak label for an emotion when at least one corresponding lexical pattern is detected. Therefore, the minimum-hit threshold is set to one for all six emotions.

The annotation is applied independently for each emotion, making the task multi-label rather than multi-class. As a result,

the same review can be associated with several emotions when it contains cues related to multiple affective dimensions. This design is important because user reviews may naturally express mixed emotional states rather than a single isolated emotion.

After this weak annotation process, the dataset contains six binary emotion columns, one for each target emotion. These weak labels are then used to prepare emotion-specific training datasets for the BERT-based binary classifiers. One classifier is trained for each emotion using a one-vs-rest strategy. This allows the model to learn contextual affective patterns beyond the initial lexical cues used for weak labeling.

Since weak supervision may introduce noisy labels, an emotion-specific threshold calibration step is applied after BERT training. For each emotion classifier, the decision threshold is optimized on the validation set by selecting the threshold that maximizes the F1-score. The calibrated thresholds are then used to generate the final emotion vectors used in the clustering and recommendation stages.

Although this weak supervision strategy enables scalable emotion labeling without requiring a fully human-annotated corpus, it remains a limitation of the study. The generated labels should therefore be interpreted as weak affective labels rather than gold-standard human annotations. This limitation is mitigated by using contextual BERT classifiers, emotion-specific validation, and threshold calibration.

D. BERT-Based Emotion Extraction

After the weak annotation stage, emotion extraction is formulated as six independent binary classification tasks, corresponding to surprise, curiosity, trust, nostalgia, frustration, and enchantment. This formulation is consistent with the multi-label nature of user reviews, since the same review may express several emotions simultaneously. Therefore, instead of training a single multi-class model, a separate BERT-based binary classifier is trained for each emotional dimension.

For each emotion, the dataset is restricted to the review text and the corresponding binary label. The annotated data are split into training, validation, and test sets using stratified sampling in order to preserve the distribution of positive and negative classes. In the implemented pipeline, *distilbert-base-uncased* is used as the base language model. Review texts are tokenized using the BERT tokenizer, with padding and truncation applied to a maximum length of 64 tokens.

Because the emotion labels are imbalanced, a weighted training strategy is adopted. The standard cross-entropy loss is replaced with a class-weighted cross-entropy loss, giving higher importance to the minority class. This reduces the tendency of the classifier to favor the majority class, especially for less frequent emotions such as curiosity, nostalgia, and frustration.

During training, performance is monitored using accuracy and F1-score. Although a default threshold of 0.5 is commonly used for binary classification, a validation-based threshold optimization is applied after training in order to account for emotion-specific class imbalance and probability distributions. For each emotion, predicted probabilities on the validation set are evaluated over thresholds ranging from 0.10 to 0.90 with a step of 0.05. The threshold that maximizes the F1-score is selected as the optimal decision threshold; in case of equal F1-scores, the threshold with the higher accuracy is retained.

After training, the six BERT-based classifiers are applied to each review. Each classifier outputs the probability that its corresponding emotion is expressed in the review. The six predicted probabilities are then concatenated to form a six-dimensional review-level emotional probability vector. This vector represents the affective profile of the review and is used as input for the subsequent threshold-based emotional calibration stage.

E. BERT-Based Emotion Classification Results

Table II reports the final test performance of the six BERT-based emotion classifiers. The results show that the affective extraction layer provides reliable emotion signals for the downstream recommendation pipeline. Enchantment and surprise obtain the strongest F1-scores, while nostalgia, frustration, trust, and curiosity remain sufficiently robust for affective profile construction, emotional clustering, and emotion-aware reranking.

TABLE II. BERT-BASED EMOTION CLASSIFICATION RESULTS

Emotion	Threshold	Test F1
Enchantment	0.85	0.9383
Surprise	0.30	0.9207
Nostalgia	0.20	0.8418
Frustration	0.20	0.8176
Trust	0.45	0.8112
Curiosity	0.20	0.7955

F. Contribution 1: BERT-Based Emotional Clustering with K-means

The first contribution aims to structure the calibrated emotional space produced by the BERT-based emotion extraction layer. Each review is represented by a six-dimensional calibrated emotional vector composed of surprise, curiosity, trust, nostalgia, frustration, and enchantment scores. This representation provides a continuous affective description of each review.

Before applying clustering, the calibrated emotional vectors are standardized in order to ensure that all emotional dimensions contribute equally to the clustering process. K-means is then applied to the standardized calibrated vectors to identify dominant affective structures in the review space.

Given a set of calibrated emotional vectors, K-means partitions the reviews into K clusters by minimizing the within-cluster sum of squared distances:

$$\arg\min_{C} \sum_{k=1}^{K} \sum_{r \in C_k} \|E_{cal}(r) - \mu_k\|^2 \quad (1)$$

where, C_k denotes the k-th emotional cluster, μ_k is its centroid, and $E_{cal}(r)$ represents the calibrated emotional vector of review r.

In this contribution, each review is assigned to one dominant emotional cluster. The number of clusters is set to six in order to reflect the six emotional dimensions considered

in the study. Each cluster is then interpreted according to the dominant dimension of its centroid. This produces interpretable emotional groups associated with high enchantment, high trust, high nostalgia, high frustration, high curiosity, and high surprise.

This clustering step transforms individual review-level emotion vectors into structured affective groups. Instead of using only isolated probability scores, C1 provides an interpretable emotional segmentation of the review space. These clusters are then used to support the construction of user and item emotional profiles in the recommendation pipeline.

G. C1 User and Item Emotional Profiles

After assigning each review to a dominant emotional cluster, user and item emotional profiles are constructed from the calibrated emotional vectors and the K-means cluster assignments.

For each user u, the emotional profile is obtained by aggregating the calibrated emotional vectors of the reviews associated with that user:

$$P_u^{C1} = \frac{1}{|R_u|} \sum_{r \in R_u} E_{cal}(r) \tag{2}$$

where, R_u denotes the set of reviews associated with user u.

Similarly, for each item i, the emotional profile is computed by aggregating the calibrated emotional vectors of the reviews associated with that item:

$$P_i^{C1} = \frac{1}{|R_i|} \sum_{r \in R_i} E_{cal}(r) \tag{3}$$

where, R_i denotes the set of reviews associated with item i.

In addition to these continuous emotional profiles, the distribution of K-means cluster assignments is also used to describe the dominant affective tendency of users and items. This allows the model to capture both the average emotional intensity and the dominant emotional group structure.

The affective compatibility between a user and an item is then estimated by comparing their emotional profiles:

$$AffectAlign_{C1}(u, i) = sim(P_u^{C1}, P_i^{C1}) \tag{4}$$

where, $sim(.)$ denotes a similarity function, such as cosine similarity or dot product. This affective alignment score is later integrated into the serendipity-oriented reranking stage.

H. Contribution 2: BERT-Based Combinatorial Emotional Modeling with K-Medoids

The second contribution extends the affective representation by preserving the multi-emotional nature of user reviews. While C1 assigns each review to one dominant emotional cluster, C2 represents each review through the set of emotions that are simultaneously activated. This set is referred to as an *emotional combination* and is denoted by $EC(r)$ for a given review r. This representation allows the model to capture richer affective configurations, such as trust-enchantment, surprise-curiosity, or surprise-curiosity-trust-frustration.

For each review r, an emotion e is considered active when its BERT-predicted probability exceeds its emotion-specific optimal threshold:

$$p_e(r) \geq \theta_e^* \tag{5}$$

where, $p_e(r)$ denotes the predicted probability of emotion e for review r, and θ_e^* is the optimal threshold selected during validation.

The emotional combination of a review is then formally defined as:

$$EC(r) = \{e \in E \mid p_e(r) \geq \theta_e^*\} \tag{6}$$

where, E denotes the set of the six emotions: surprise, curiosity, trust, nostalgia, frustration, and enchantment. Thus, $EC(r)$ represents the set of active emotions associated with review r.

Since six emotions are considered, the theoretical number of possible emotional combinations is:

$$2^6 = 64 \tag{7}$$

including the empty combination. In practice, only the emotional combinations observed in the dataset are retained. In the implemented pipeline, this process produces 44 observed affective signatures.

After constructing the emotional combination space, K-medoids clustering is applied to group similar emotional combinations into compact and interpretable affective meta-groups. K-medoids is selected because, unlike centroid-based clustering methods, it uses real observed emotional combinations as representative medoids. This property makes the resulting affective meta-groups easier to interpret.

Each emotional combination is represented in the six-dimensional calibrated emotional space. The dissimilarity between two emotional combinations x and y is computed using Euclidean distance:

$$d(x, y) = \sqrt{\sum_{j=1}^{6} (x_j - y_j)^2} \tag{8}$$

The K-medoids objective is to minimize the sum of distances between each emotional combination and the medoid of its assigned group:

$$\arg\min_{M} \sum_{k=1}^{K} \sum_{x \in G_k} d(x, m_k) \tag{9}$$

where, G_k denotes the k-th affective meta-group and m_k is its medoid. In this contribution, the observed emotional combinations are grouped into three interpretable affective meta-groups.

This contribution allows the framework to move beyond a single dominant emotion per review. Instead, it models emotional co-occurrences and captures affective configurations that may be particularly useful for serendipity-oriented recommendation.

I. C2 User and Item Emotional Combination Profiles

After constructing the emotional combinations and their K-medoids meta-groups, user and item profiles are built from the distribution of emotional combinations. Unlike C1, where profiles are based on averaged calibrated emotional vectors and dominant emotional clusters, C2 represents users and items through the frequency distribution of emotional combinations.

For each user u, the emotional combination profile is defined as the normalized distribution of the emotional combinations observed in the user's review history:

$$P_u^{C2} = [q_{u,1}, q_{u,2}, ..., q_{u,m}] \tag{10}$$

where, $q_{u,k}$ denotes the proportion of the k-th emotional combination in the reviews associated with user u, and m is the number of observed emotional combinations.

Similarly, for each item i, the emotional combination profile is computed as:

$$P_i^{C2} = [q_{i,1}, q_{i,2}, ..., q_{i,m}] \tag{11}$$

where, $q_{i,k}$ represents the proportion of the k-th emotional combination in the reviews associated with item i.

The compatibility between a user and an item is estimated through *emotional combination compatibility*, denoted as $ECC(u, i)$. This score is computed using cosine similarity between the user and item emotional combination profiles:

$$ECC(u, i) = \frac{P_u^{C2} \cdot P_i^{C2}}{\|P_u^{C2}\| \, \|P_i^{C2}\|} \tag{12}$$

where, P_u^{C2} and P_i^{C2} denote the user and item emotional combination profiles, respectively. The resulting score measures the degree of compatibility between the emotional combination preferences of the user and the emotional combination structure of the item.

In addition to fine-grained emotional combination profiles, the K-medoids meta-groups provide a more compact and interpretable representation of the combinatorial emotional space. Thus, C2 captures two levels of affective information: the detailed level of emotional combinations and the higher-level structure of affective meta-groups.

The resulting compatibility score $ECC(u, i)$ is later integrated into the EC-SereRank reranking model as a combinatorial affective compatibility signal

J. Serendipity-Oriented Reranking

After constructing the affective representations in C1 and C2, the final stage consists of reranking candidate items in order to promote serendipitous recommendations. The objective is to preserve relevance while introducing additional beyond-accuracy dimensions, namely unexpectedness, novelty, and affective compatibility.

For a given user u and candidate item i, the general reranking function is defined as:

$$Score(u, i) = w_r R(u, i) + w_u U(u, i) + w_n N(i) + w_a Aff(u, i) \tag{13}$$

where, $R(u, i)$ denotes relevance, $U(u, i)$ denotes unexpectedness, $N(i)$ denotes novelty, and $Aff(u, i)$ denotes the affective compatibility signal. The parameters w_r, w_u, w_n, and w_a control the contribution of each component.

In C1, the affective signal is derived from the compatibility between the continuous emotional profile of the user and the continuous emotional profile of the item. This score is denoted as emotional profile compatibility, $EPC(u, i)$:

$$Aff_{C1}(u, i) = EPC(u, i) \tag{14}$$

Thus, the C1 reranking model, denoted as ***SereEmotion***, is defined as follows:

$$SereEmotion(u, i) == w_r R(u, i) + w_u U(u, i) + w_n N(i) + w_e EPC(u, i) \tag{15}$$

In C2, the affective signal is derived from the compatibility between the emotional combination profile of the user and that of the item. This score is denoted as emotional combination compatibility, $ECC(u, i)$:

$$Aff_{C2}(u, i) = ECC(u, i) \tag{16}$$

Accordingly, the C2 reranking model, denoted as ***EC-SereRank***, is defined as follows:

$$EC{-}SereRank(u, i) = w_r R(u, i) + w_u U(u, i) + w_n N(i) + w_c ECC(u, i) \tag{17}$$

In the controlled version of ***EC-SereRank***, the emotional combination compatibility signal is injected with a small weight in order to preserve the relevance structure of the recommendation list while adding a fine-grained combinatorial affective signal:

$$EC - SereRank(u, i) = 0.95 \cdot Rel(u, i) + 0.05 \cdot ECC(u, i) \tag{18}$$

This formulation allows the model to introduce emotional combination compatibility without excessively disrupting ranking relevance. The final recommendation list is obtained by sorting candidate items according to the reranking score and selecting the top-K items.

K. Evaluation Metrics

The proposed framework is evaluated using both accuracy-oriented metrics and beyond-accuracy metrics. Accuracy-oriented metrics assess the relevance and ranking quality of the recommended items, while beyond-accuracy metrics evaluate the ability of the system to promote novelty, unexpectedness, and serendipity.

For each user u, let Rec_u^K denote the list of top-K recommended items, and let GT_u denote the set of relevant ground-truth items. Precision@K measures the proportion of relevant items among the recommended items:

$$Precision@K = \frac{1}{|U|} \sum_{u \in U} \frac{|Rec_u^K \cap GT_u|}{K} \tag{19}$$

Recall@K measures the proportion of relevant items successfully retrieved in the top-K list:

$$Recall@K = \frac{1}{|U|} \sum_{u \in U} \frac{|Rec_u^K \cap GT_u|}{|GT_u|} \tag{20}$$

HitRate@K evaluates whether at least one relevant item appears in the recommendation list:

$$HitRate@K = \frac{1}{|U|} \sum_{u \in U} \mathbb{I}(|Rec_u^K \cap GT_u| > 0) \tag{21}$$

where, $\mathbb{I}(.)$ is an indicator function.

To evaluate ranking quality, Mean Average Precision (MAP) is used. For each user, Average Precision at K is computed as:

$$AP@K(u) = \frac{1}{|GT_u|} \sum_{j=1}^{K} Precision@j(u) \cdot rel_u(j) \tag{22}$$

where, $rel_u(j) = 1$ if the item ranked at position j is relevant for user u, and 0 otherwise. MAP@K is then defined as:

$$MAP@K = \frac{1}{|U|} \sum_{u \in U} AP@K(u) \tag{23}$$

Normalized Discounted Cumulative Gain (NDCG@K) is also used to evaluate whether relevant items are ranked near the top of the recommendation list:

$$NDCG@K = \frac{1}{|U|} \sum_{u \in U} \frac{DCG@K(u)}{IDCG@K(u)} \tag{24}$$

where,

$$DCG@K(u) = \sum_{j=1}^{K} \frac{rel_u(j)}{\log_2(j+1)} \tag{25}$$

and $IDCG@K(u)$ denotes the ideal discounted cumulative gain for user u.

In addition to accuracy-oriented metrics, novelty is evaluated in order to measure the ability of the system to recommend less popular items. The novelty score of an item i is defined as:

$$Nov(i) = 1 - Pop(i) \tag{26}$$

where, $Pop(i)$ denotes the normalized popularity of item i. The novelty of a recommendation list is computed as the average novelty of its top-K items:

$$Novelty@K(u) = \frac{1}{K} \sum_{i \in Rec_u^K} Nov(i) \tag{27}$$

Unexpectedness measures the degree to which a recommended item differs from the user's expected preference space. In this work, unexpectedness is computed from the distance between user and item representations:

$$Unexp(u,i) = 1 - Sim(P_u, P_i) \tag{28}$$

where, P_u and P_i denote the user and item profiles, respectively, and $Sim(.)$ is a similarity function.

Finally, serendipity is evaluated by combining relevance with unexpectedness. The standard serendipity score is defined as:

$$Serendipity_{std}(u,i) = Rel(u,i) \cdot Unexp(u,i) \tag{29}$$

To better reflect the objective of the proposed framework, an extended serendipity metric is also considered. It incorporates relevance, unexpectedness, novelty, and affective compatibility:

$$Serendipity_{common}(u,i) = Rel(u,i) \cdot Unexp(u,i) \cdot Nov(i) \cdot Aff(u,i) \tag{30}$$

where, $Aff(u,i)$ corresponds to the affective compatibility score. In C1, this term is represented by the emotional profile compatibility $EPC(u,i)$, while in C2 it is represented by the emotional combination compatibility $ECC(u,i)$.

For a recommendation list, the serendipity score is computed as the average score over the top-K recommended items:

$$Serendipity@K(u) = \frac{1}{K} \sum_{i \in Rec_u^K} Serendipity(u,i) \tag{31}$$

L. Experimental Protocol and Ablation Study

The experimental protocol is designed to evaluate the contribution of each component of the proposed framework to Top-K recommendation performance and serendipity. The final working subset contains 10,000 reviews and is used consistently across the emotion extraction, affective profiling, and recommendation stages. Only users with sufficient interaction history are retained in order to build meaningful user profiles and support reliable evaluation.

A temporal evaluation strategy is adopted. For each user, interactions are ordered chronologically using the *Time* field. The most recent interaction is held out as the test item, while the remaining interactions are used to construct the user's historical profile. This protocol simulates a realistic recommendation scenario in which the model recommends items based on past user behavior and is evaluated on a future interaction.

The candidate items are reranked according to different scoring functions. To analyze the impact of each component, an ablation study is conducted by progressively adding unexpectedness, novelty, and affective compatibility to the relevance-based baseline. The evaluated variants are defined as follows:

- Relevance-only: uses only the relevance score $Rel(u, i)$.
- Relevance + Unexpectedness: combines relevance with unexpectedness.
- Relevance + Unexpectedness + Emotion: integrates the emotional compatibility signal from C1.
- Relevance + Novelty + Unexpectedness + Emotion: combines all C1 components.
- EC-SereRank: integrates emotional combination compatibility from C2 as a controlled complementary signal to relevance.

The purpose of this ablation study is to determine whether the proposed affective components improve recommendation quality beyond a standard relevance-driven ranking. In particular, the comparison between the relevance-only baseline and the emotion-aware variants makes it possible to quantify the added value of emotional modeling. Similarly, the comparison between C1-based emotional compatibility and C2-based emotional combination compatibility allows us to evaluate whether modeling active emotional combinations provides an additional benefit for serendipity-oriented recommendation.

All models are evaluated at different cutoff values, namely $K = 10$, $K = 20$, and $K = 50$. The evaluation includes both accuracy-oriented metrics, such as Precision@K, Recall@K, HitRate@K, MAP@K, and NDCG@K, and beyond-accuracy metrics, such as Novelty@K, Unexpectedness@K, and Serendipity@K. This dual evaluation makes it possible to assess whether the proposed models improve discovery-oriented recommendation while preserving acceptable ranking quality. The results of this ablation protocol are reported and discussed in the following section.

IV. Results and Discussion

This section presents the main experimental results of the proposed emotion-aware serendipity recommendation framework. The analysis focuses on three aspects: the performance of the BERT-based emotion classifiers, the interpretability of the affective structures obtained in C1 and C2, and the impact of the proposed affective signals on Top-K recommendation and serendipity.

A. Performance of BERT-Based Emotion Classification

The first step evaluates the quality of the BERT-based emotion extraction layer. Six independent binary classifiers were trained for surprise, curiosity, trust, nostalgia, frustration, and enchantment. Table III summarizes the final test F1-scores and the optimal thresholds selected on the validation set.

TABLE III. BERT-Based Emotion Classification Results

Emotion	Optimal Threshold	Test F1-Score
Surprise	0.30	0.9207
Curiosity	0.20	0.7955
Trust	0.45	0.8112
Nostalgia	0.20	0.8418
Frustration	0.20	0.8176
Enchantment	0.85	0.9383

The results show that the emotional layer is globally reliable. Enchantment and surprise obtain the strongest performance, while nostalgia, frustration, and trust also provide robust results. Curiosity is more difficult to detect, but remains exploitable for the recommendation pipeline. These results confirm that the extracted emotional probabilities can be used as meaningful affective signals.

B. Confusion Matrices of the Six BERT-Based Emotion Classifiers on the Test Set

To further validate the reliability of the BERT-based emotion classifiers, the confusion matrix components were visualized using two complementary figures. Fig. 2 presents the correct classifications, namely true negatives (TN) and true positives (TP), for each emotion. The results show that the models correctly identify a large number of non-active emotion instances, while also detecting positive emotion cases across the six affective dimensions. In particular, enchantment obtains the highest true positive count, which confirms the strong detection capacity already observed through its F1-score.

Fig. 3 focuses on the classification errors by reporting false positives (FP) and false negatives (FN). This representation makes it easier to identify the most challenging emotions. Trust presents the highest number of false negatives and false positives, indicating that it remains the most difficult emotion to classify. Curiosity also appears more challenging than surprise and nostalgia, but its error level remains acceptable for downstream affective recommendation. Overall, these two figures confirm that the proposed emotion classifiers do not simply predict the majority class, but provide exploitable emotional signals for the calibration, clustering, and serendipity-oriented reranking stages.

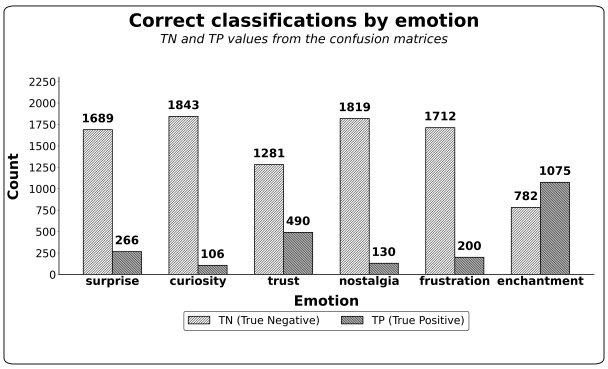

Fig. 2. Correct classification components of the six BERT-based emotion classifiers.

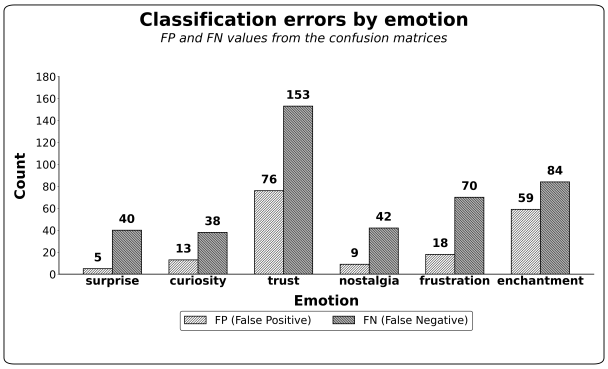

Fig. 3. Classification error components of the six BERT-based emotion classifiers.

C. Literature Positioning of C1 Against Existing Systems

Table IV positions C1 with respect to existing Top-10 recommendation systems reported in the literature. The values of the existing systems correspond to the average results over the six datasets reported in the comparative study. However, this table is provided only as a literature positioning reference. The compared systems were evaluated on different datasets and under different experimental protocols, whereas C1 is evaluated on the Amazon Fine Food Reviews subset used in this study. Therefore, the results should not be interpreted as a direct empirical comparison.

TABLE IV. LITERATURE POSITIONING OF C1 AGAINST EXISTING TOP-10 SYSTEMS.

System	Prec.	Recall	Ser.	nDCG
Matrix factorization based recommendations	0.340	0.322	0.021	–
Hybrid recommendations	0.410	0.383	0.027	0.335
Sankar et al.	0.415	0.408	0.036	0.373
FBPRR	0.422	0.445	0.030	0.382
C1: Emotion-aware reranking	0.061	**0.611**	0.034	**0.449**

The results show that C1 follows a different performance profile from the systems reported in the literature. In terms of Precision@10, C1 obtains a lower value than the compared systems. This difference should be interpreted carefully, since C1 is evaluated under a leave-one-out Top-K protocol in which each user has only one held-out relevant item. Under this setting, Precision@10 is bounded by 0.10 and corresponds to Recall@10 divided by 10. Despite this lower precision value, C1 achieves a high Recall@10 of 0.611, indicating that the proposed model is able to recover the held-out relevant item for approximately 61% of the evaluated users. C1 also obtains a competitive nDCG@10 value of 0.449, suggesting that the relevant item is often ranked in a favorable position within the Top-10 list. Regarding serendipity, C1 reaches a value of 0.034, which is competitive with the values reported by the compared systems. Nevertheless, because serendipity definitions and evaluation protocols differ across studies, this result should be interpreted as a positioning indicator rather than as a direct superiority claim. Overall, the table shows that C1 is not optimized for precision alone, but provides a strong recall-oriented and serendipity-oriented recommendation profile.

D. Ablation Analysis of C1: Added Value of the Emotional Component

To evaluate the contribution of the emotional component in C1, an ablation analysis was conducted by progressively integrating relevance, unexpectedness, emotion, and novelty into the reranking function. Table V reports the serendipity-oriented results at $K = 10$.

TABLE V. ABLATION RESULTS OF C1 AT K=10

C1 Variant	Ser_std	Ser_full
Relevance only	0.000488	0.012546
Relevance + Unexpectedness	0.000715	0.012714
Relevance + Unexpectedness + Emotion	0.002509	0.024797
Relevance + Novelty + Unexpectedness + Emotion	**0.005631**	**0.033690**

While Fig. 4 and Fig. 5 provide a graphical representation of the same ablation behavior for the standard and full serendipity metrics, respectively.

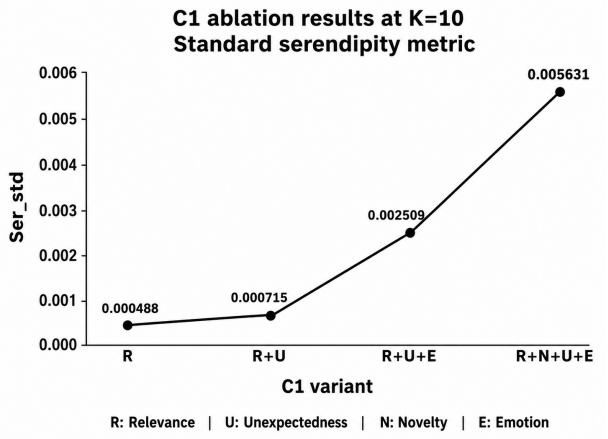

Fig. 4. Ablation results of C1 at $K = 10$ according to the standard serendipity metric.

The ablation results show that relevance alone is not sufficient to generate strong serendipitous recommendations. Adding unexpectedness slightly improves the serendipity score, but the gain remains limited. In contrast, the integration of the emotional component produces a clear improvement: the model combining relevance, unexpectedness, and emotion achieves a substantially higher serendipity score than the relevance–unexpectedness variant. This confirms that emotional alignment provides an effective complementary signal for serendipity-oriented reranking. The best performance is obtained when novelty is added together with relevance, unexpectedness, and emotion, which indicates that C1 benefits most from the joint integration of affective, novel, and unexpected recommendation signals.

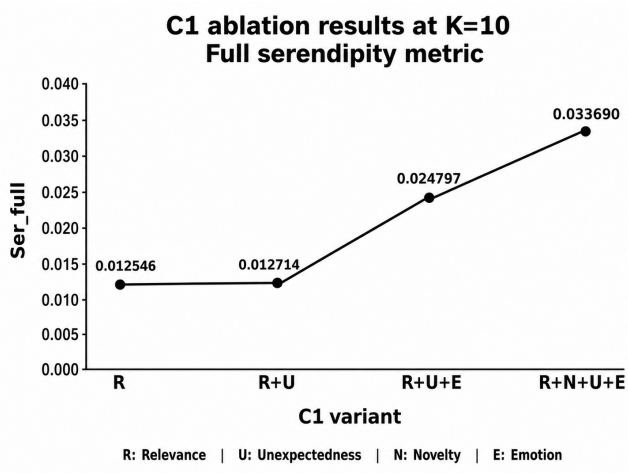

Fig. 5. Ablation results of C1 at $K = 10$ according to the full serendipity metric.

E. Analysis of C2: Emotional Combination Modeling with K-Medoids

C2 extends C1 by moving from dominant emotional clustering to fine-grained emotional combination modeling. While C1 assigns each review to one dominant emotional cluster, C2 preserves the multi-emotional nature of reviews by representing each review through its active emotional combination, denoted as $EC(r)$. With six calibrated emotions, the theoretical number of possible combinations is $2^6 = 64$. In practice, 44 emotional combinations were observed in the dataset.

K-medoids clustering was then applied to these observed emotional combinations in order to obtain compact and interpretable affective meta-groups. The final retained solution produced three meta-groups, summarized in Table VI.

TABLE VI. K-MEDOIDS AFFECTIVE META-GROUPS IN C2

Meta-Group	Reviews	Percentage
Positive affective core	5528	55.28%
Surprise discovery	2361	23.61%
Trust exploratory tension	2111	21.11%

These results show that C2 captures richer affective structures than C1. Instead of reducing each review to a single dominant emotional cluster, C2 keeps the interaction between multiple activated emotions. The first meta-group represents a positive affective pole mainly associated with enchantment, the second captures a discovery-oriented surprise profile, and the third reflects a trust-based exploratory tension. Therefore, C2 provides an additional level of affective interpretation by modeling emotional configurations rather than isolated dominant emotions.

F. Added Value of C2 Compared with C1

The added value of C2 compared with C1 lies mainly in the way affective information is represented and exploited in the recommendation process. C1 provides a clear and interpretable segmentation of the emotional space by assigning each review to a dominant affective cluster. This representation is useful because it identifies the main emotional tendency of each review. However, it may simplify reviews that contain several simultaneous emotional signals.

C2 addresses this limitation by preserving emotional co-activation patterns through emotional combinations. Instead of reducing a review to a single dominant emotional cluster, C2 represents each review by the set of active emotions detected by the calibrated BERT-based classifiers. This set is formalized as an emotional combination, denoted by $EC(r)$. Thus, a review can be represented not only by a single emotion such as *trust* or *surprise*, but also by richer affective signatures such as *trust-enchantment*, *surprise-curiosity*, or *surprise-curiosity-trust-frustration*.

TABLE VII. CONCEPTUAL ADDED VALUE OF C2 COMPARED WITH C1

Aspect	**C1 / Emotion-Aware Reranking**	**C2 / EC-SereRank**
Affective unit	Dominant emotional cluster	Emotional combination $EC(r)$
Representation	Single dominant affective profile	Multi-emotional signature
Emotional modeling	Main emotional tendency	Co-activated emotional patterns
Clustering method	K-means	K-medoids
Interpretation	Six emotional groups	Affective meta-groups
Recommendation signal	Emotion alignment	Emotional combination compatibility
Main value	Emotion-aware reranking and segmentation	Fine-grained affective compatibility

Based on this representation, EC-SereRank introduces an emotional combination compatibility component into the reranking process. This component measures the compatibility between the user and the item at the level of observed emotional configurations. Therefore, EC-SereRank captures finer affective relationships than a representation based only on individual emotions. This is particularly important for serendipity-oriented recommendation, where the objective is not only to recommend relevant items, but also to promote unexpected and emotionally meaningful discoveries.

Table VII summarizes the conceptual added value of C2 compared with C1. While C1 mainly provides an interpretable

TABLE VIII. EMPIRICAL GAINS OF EC-SERERANK OVER THE RELEVANCE-ONLY BASELINE IN C2

K	Precision Gain	Recall Gain	MAP Gain	NDCG Gain	Serendipity Common Gain
10	+8.60%	+8.60%	+13.97%	+12.14%	+12.03%
20	+11.78%	+11.78%	+14.40%	+13.37%	+7.06%
50	+14.43%	+14.42%	+14.61%	+14.27%	+6.01%

emotion-aware segmentation, C2 enriches the framework by introducing a fine-grained affective compatibility layer through EC-SereRank.

The empirical results further confirm the usefulness of the combinatorial signal inside the C2 framework. Compared with the relevance-only baseline, EC-SereRank improves the main ranking metrics and the proposed common serendipity score at different values of K. These gains show that emotional combinations provide a useful complementary signal when they are injected into the reranking function with a controlled weight.

As shown in Table VIII, EC-SereRank consistently improves the relevance-only baseline in Precision, Recall, MAP, NDCG, and Serendipity Common. At $K = 10$, the model improves Precision and Recall by 8.60%, MAP by 13.97%, NDCG by 12.14%, and the common serendipity metric by 12.03%. Similar improvements are observed at $K = 20$ and $K = 50$, which confirms that emotional combinations contribute positively to the recommendation process.

Nevertheless, C2 also has some limitations. First, its absolute Top-K performance remains lower than the best C1 model. This suggests that the combinatorial representation may lose part of the fine-grained continuous affective information captured by C1. Second, the variants that include novelty, unexpectedness, and meta-group information do not always improve the results compared with EC-SereRank. This indicates that additional C2 components may require more careful weighting. Third, the standard serendipity score slightly decreases compared with the relevance-only baseline, while the common serendipity score improves. This means that C2 is especially beneficial when serendipity is evaluated through a definition that includes affective compatibility.

Overall, C1 remains the strongest contribution from a purely quantitative recommendation perspective, while C2 provides a richer and more interpretable affective modeling strategy. The main value of EC-SereRank is not that it replaces C1, but that it introduces a more detailed emotional representation able to capture co-occurring affective signals and use them as complementary evidence for serendipity-oriented recommendation.

G. Discussion

Overall, the results support the main hypothesis of this work: affective information extracted from textual reviews can improve serendipity-oriented recommendation. C1 shows that calibrated BERT-based emotional vectors can be effectively exploited to build an emotion-aware reranking strategy. The results demonstrate that integrating emotional signals into the recommendation process improves both ranking quality and serendipity-oriented metrics compared with relevance and unexpectedness alone.

The ablation study confirms that relevance and unexpectedness are not sufficient to produce strong serendipitous recommendations. Adding unexpectedness alone leads to only a limited improvement, whereas the integration of affective information produces a more substantial gain. The best results are obtained when relevance, novelty, unexpectedness, and emotional compatibility are jointly considered. This confirms that emotion acts as a complementary signal that helps identify recommendations that are not only relevant, but also more meaningful from an affective and discovery-oriented perspective.

C2 extends this contribution by introducing a richer representation of affective information. While C1 mainly relies on dominant emotional tendencies, C2 preserves emotional co-activation patterns through emotional combinations. This allows EC-SereRank to model fine-grained affective compatibility between users and items. The empirical gains obtained by EC-SereRank over the relevance-only baseline show that emotional combinations provide useful additional information within the C2 framework, especially when evaluated through the proposed common serendipity metric.

However, the results also show that C2 should not be interpreted as a complete replacement for C1. C1 remains stronger in terms of absolute Top-K performance, while C2 provides a more expressive and interpretable affective modeling layer. Therefore, the two contributions are complementary: C1 provides the strongest quantitative emotion-aware reranking model, whereas C2 introduces EC-SereRank as an advanced combinatorial extension that improves the granularity and explainability of affective recommendation.

These findings suggest that serendipity-oriented recommendation can benefit from moving beyond classical relevance-based ranking. By incorporating calibrated emotional signals and emotional combinations, the proposed framework offers a more nuanced way to connect users and items through affective compatibility. Nevertheless, the evaluation remains offline, and future work should validate whether these affective and serendipitous recommendations are also perceived as useful, surprising, and satisfying by real users.

Therefore, the proposed framework contributes in two complementary ways. First, it introduces an emotion-aware reranking strategy based on calibrated BERT outputs. Second, it proposes a combinatorial emotional representation that captures co-occurring affective signals and exploits them through EC-SereRank. Together, these two contributions show that textual emotions can be transformed into actionable recommendation signals for improving serendipity.

V. Conclusion and Future Work

This study proposed an emotion-aware serendipity recommendation framework based on textual reviews. The main objective was to move beyond relevance-driven recommendation by exploiting affective information extracted from user-generated reviews. To this end, weak emotional annotation and BERT-based binary classifiers were used to detect six emotional dimensions: surprise, curiosity, trust, nostalgia, frustration, and enchantment. A threshold-based calibration step was then applied to obtain more stable and comparable emotional representations.

Two complementary contributions were introduced. C1 developed an emotion-aware reranking strategy based on calibrated emotional vectors, while C2 extended this representation through emotional combinations and EC-SereRank. The first contribution demonstrated the effectiveness of direct emotional integration in the reranking process, whereas the second provided a richer and more interpretable affective representation by preserving emotional co-activation patterns.

The experimental results confirm that affective information can improve serendipity-oriented recommendation. The ablation study showed that relevance and unexpectedness alone are not sufficient to achieve strong serendipitous recommendations. The best results were obtained when relevance, novelty, unexpectedness, and emotional compatibility were jointly considered. In addition, EC-SereRank showed that fine-grained emotional combinations can provide a useful complementary signal within the C2 framework.

Despite these promising results, some limitations remain. The evaluation was conducted in an offline setting and on a single dataset, which limits the ability to fully assess real user perception and cross-domain generalization. Moreover, the performance of the framework depends on the quality of the emotion classifiers and on the calibration thresholds.

Future work will focus on validating the proposed framework on additional datasets and domains, integrating user-centered or online evaluation, and improving the weighting strategy used in the reranking process. Another promising direction is to combine emotional combinations with explainable recommendation mechanisms in order to provide users with clearer reasons for serendipitous recommendations.

QuantumGuard: A Post-Quantum Resilient Deception-Driven Framework for Proactive Threat Hunting and Cognitive Honeynet Orchestration in 6G-Enabled Cyber-Physical Systems

Daifallah Zaid Alotaibe
Software Engineering Department, College of Computer Science and Engineering
University of Hafr Al-Batin, Saudi Arabia

***Abstract*—The convergence of 6G ultra-reliable low-latency communications, massive cyber-physical actuation, and the looming threat of cryptographically relevant quantum computers exposes a fundamentally new attack surface that is poorly addressed by reactive intrusion-detection paradigms. This study presents QuantumGuard, a proactive cybersecurity framework that inverts the conventional defender posture by integrating cognitive honeynets, post-quantum-secured intelligence channels, and reinforcement-learning-driven deception adaptation across 6G-enabled cyber-physical environments. The principal contribution is the architectural integration of four previously disjoint capabilities—a cognitive honeynet orchestrator, a reinforcement-learning deception policy engine operating under partial observability, a transformer-based MITRE ATT&CK attribution network, and a post-quantum federated intelligence bus secured with CRYSTALS-Kyber and CRYSTALS-Dilithium—into a single closed-loop control architecture for 6G cyber-physical systems. To assess feasibility, we report a preliminary evaluation on the CICAPT-IIoT-2024 and Edge-IIoTset benchmark datasets, complemented by a 320-endpoint 6G slice testbed configured, as described in Section IV. Initial results indicate an attacker engagement-retention rate of approximately 96.42 per cent, MITRE ATT&CK technique-attribution accuracy of approximately 91.8 per cent, a 78.6 per cent reduction in median attacker dwell time relative to passive honeypot baselines, and a deception-induced production-traffic overhead of 1.7 per cent. The PQ-FIB sustains a 14.2 ms median post-quantum handshake latency at slice scale. We position these numbers as preliminary evidence of operational viability under the evaluated threat model rather than as fully characterized performance bounds; a follow-up empirical study, planned for a separate publication, will extend the evaluation to deception-aware adversaries and sustained-attack stress conditions.**

I. Introduction

The deployment of 6G mobile networks, with their promise of sub-millisecond latency, terabit-per-second throughput, and pervasive integration of cyber-physical systems (CPS), is reshaping critical infrastructure ranging from autonomous transportation and smart grids to remote surgery and industrial automation [1], [2], [3]. At the same time, the advent of cryptographically relevant quantum computers threatens to undermine the public-key cryptographic primitives that currently protect this infrastructure [4], [5], [6]. Sophisticated adversaries are already adopting harvest-now-decrypt-later strategies, exfiltrating ciphertext today in anticipation of future quantum decryption [7], [8], [9].

Reactive cybersecurity paradigms, which detect and respond to attacks after they have begun to compromise production assets, are poorly suited to this emerging threat landscape. They impose unacceptable dwell-time penalties on cyber-physical systems where milliseconds of malicious actuation can cause physical harm, and they generate operational telemetry that reveals little about the upstream tactics, techniques, and procedures (TTPs) of advanced adversaries [10], [11], [12]. The need for integrated, model-driven incident-response architectures that fuse detection, attribution, and forensic readiness has been argued repeatedly in the literature [38], [39], and the limitations of fragmented response pipelines have been documented across the database, mobile, and IoT forensic domains [40], [41], [42]. Honeypots and honeynets have long been advocated as a complementary, proactive defense, but conventional static honeynets are easily fingerprinted by modern attackers [13], [14], [15], and their intelligence-sharing protocols rely on classical cryptographic primitives that are not quantum-resilient [16], [17], [18], [19].

Recent advances in reinforcement learning (RL) have produced agents capable of optimizing sequential interaction policies under partial observability [20], [21], [22], and the standardization of post-quantum cryptographic primitives by NIST [23] has rendered quantum-resilient intelligence dissemination technically feasible. Nevertheless, no existing framework integrates cognitive deception orchestration, RL-driven engagement adaptation, automated TTP-attribution, and post-quantum federated intelligence into a single closed-loop architecture suitable for 6G-enabled CPS environments. The state-of-the-art either treats these capabilities as isolated research artifacts or evaluates them on legacy datasets that do not reflect the heterogeneity of cyber-physical traffic [24], [25], [26], [27], [28].

To address these gaps, this study proposes QuantumGuard, a proactive defense framework that inverts the defender's posture by drawing adversaries into instrumented decoy environments, learning their behaviors, and disseminating the resulting intelligence over post-quantum-secured channels. The architecture is summarized in Fig. 1.

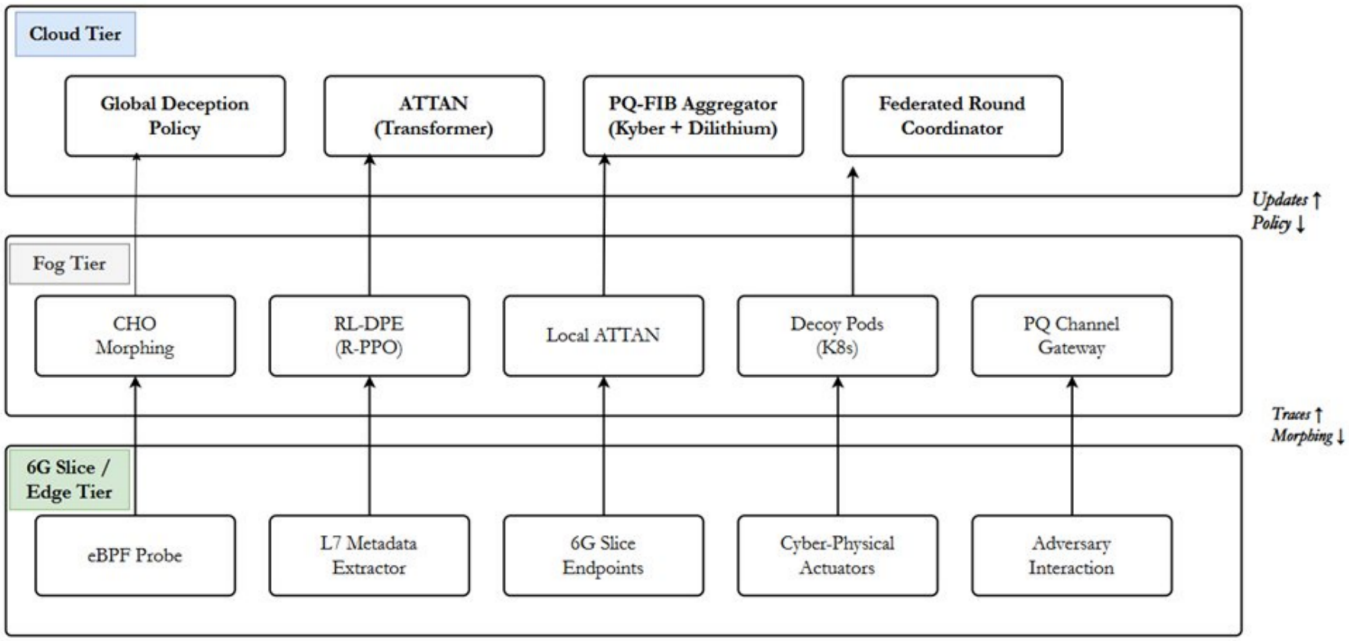

Fig. 1. QuantumGuard framework—proactive deception, cognitive honeynet orchestration, and post-quantum federated intelligence across the 6G slice, fog, and cloud tiers.

This study introduces QuantumGuard, an integrated framework that overcomes the foregoing limitations through the integration of four tightly coupled components: 1) a Cognitive Honeynet Orchestrator (CHO) that synthesizes and morphs decoy services to maximize attacker engagement; 2) a Reinforcement-Learning Deception Policy Engine (RL-DPE) that learns optimal lure–engage–attribute action sequences under a Partially Observable Markov Decision Process (POMDP) formulation; 3) an Adversarial TTP Attribution Network (ATTAN) that maps captured interactions onto MITRE ATT&CK tactics and techniques; and 4) a Post-Quantum Federated Intelligence Bus (PQ-FIB) that disseminates indicators of deception (IoDs) under CRYSTALS-Kyber key encapsulation and CRYSTALS-Dilithium signatures.

The principal contributions of this work are as follows:

1) Architectural integration: To the best of our knowledge, QuantumGuard is the first framework to integrate post-quantum federated intelligence sharing with a learned cognitive honeynet engagement policy and automated MITRE ATT&CK attribution in a single closed-loop architecture suitable for 6G-enabled cyber-physical environments.

2) POMDP formulation of cognitive deception: A Partially Observable Markov Decision Process formulation of attacker engagement, solved with a Recurrent Proximal Policy Optimization (R-PPO) agent, that admits dense per-step credit assignment for deception-action selection without requiring analyst-in-the-loop relabeling.

3) Cognitive honeynet morphing: A generative service-template mechanism that drives decoy responses toward production-service response distributions under a Jensen–Shannon divergence criterion, intended to limit the effectiveness of standard honeypot fingerprinting techniques.

4) Post-Quantum Federated Intelligence Bus: A hybrid PQ-FIB protocol combining CRYSTALS-Kyber (FIPS 203) key encapsulation with CRYSTALS-Dilithium (FIPS 204) digital signatures, that inherits IND-CCA2 channel confidentiality under hybrid-mode composition and that we measure to sustain a 14.2 ms median handshake latency at slice scale (see Section III for the full threat model).

5) Preliminary empirical evidence: A preliminary evaluation on the CICAPT-IIoT-2024 and Edge-IIoTset benchmark datasets, complemented by a 320-endpoint 6G slice testbed, that provides initial evidence of operational viability across deception, attribution, and post-quantum dimensions. We position the reported numbers (engagement-retention 96.42 per cent, attribution accuracy 91.8 per cent, dwell-time reduction 78.6 per cent, overhead 1.7 per cent) as a feasibility study under the evaluated threat model rather than as fully characterized performance bounds; the reward-weight sensitivity analysis, deception-aware adversary evaluation, and sustained-attack stress-condition characterization are identified in Section V F as the principal subjects of a follow-up empirical study currently in preparation.

The remainder of the study is organized as follows: Section II reviews the related literature. Section III details the methodology and mathematical formulation of QuantumGuard. Section IV reports the experimental results, Section V discusses their implications, and Section VI concludes the study.

II. Related Work

This section reviews the literature in three main areas: cyber deception and honeynet engineering, reinforcement learning for adversarial interaction, and post-quantum cryptography for collaborative cyber defense.

A. Cyber Deception and Honeynet Engineering

Research on cyber deception has progressed from low-interaction honeypots toward high-interaction honeynets that emulate full service stacks. Almeshekah and Spafford [13] formalized deception planning around the planner–executor–evaluator triad, but modern adversaries readily fingerprint static decoys through banner-grabbing, timing analysis, and TLS introspection [14]. Dynamic honeypot work, including the dynamic decoy generation framework of Wang et al. [15] and the moving-target deception scheme of Kambourakis et al. [25], demonstrates that morphing reduces fingerprintability, but these systems lack a principled engagement policy and rely on hand-crafted morphing rules rather than learned ones. Beyond engagement, the artefacts captured by deception fabrics must be amenable to systematic forensic reconstruction; the model-driven forensic-investigation literature [38], [39], [43] provides a methodological foundation for organizing such artefacts into structured evidence repositories that can subsequently feed attribution pipelines.

B. Reinforcement Learning for Adversarial Interaction

Reinforcement learning has emerged as a natural fit for sequential defender–attacker interaction. Several studies have applied deep Q-learning and policy-gradient methods to cyber-defense games [20], [21], [22]. However, most of this work evaluates on simulated CyberBattleSim or CAGE Challenge environments and assumes full observability or strong reward signals. The partial observability inherent in real deception, where the defender only sees the attacker's externalized actions and never the underlying intent, has received comparatively little attention. Works such as Huang et al. [27] formulate deception as a POMDP but stop short of integrating the resulting policy with a real packet-level decoy fabric. Complementary efforts in machine-learning-driven live forensic analysis of emergent IoT configurations [44] highlight that supervised signals over engagement traces can substantially improve downstream attribution, motivating the joint optimization of engagement policy and attribution objective adopted in this study.

C. Post-Quantum Cryptography for Collaborative Cyber Defense

Following the NIST post-quantum standardization process [23], lattice-based primitives such as CRYSTALS-Kyber and CRYSTALS-Dilithium have become the de facto candidates for quantum-resilient key establishment and digital signatures. Recent benchmarks on constrained devices report acceptable handshake latencies for industrial IoT (IIoT) scenarios [29], but operational integration with threat-intelligence dissemination protocols (STIX/TAXII, MISP) remains largely unaddressed. Federated learning over post-quantum channels is, to our knowledge, restricted to a small number of preliminary studies that do not consider the bandwidth-overhead implications of quantum-resilient signatures on high-frequency intelligence updates [30], [31].

D. Research Gaps and Motivation

Four principal gaps motivate the present work. First, no existing framework integrates cognitive deception, RL-driven engagement, automated TTP-attribution, and post-quantum intelligence sharing within a single closed-loop architecture; these capabilities are typically studied in isolation. Second, current honeynets adapt either through hand-crafted rules or through reactive moving-target schemes, but not through learned engagement policies that explicitly maximize TTP-attribution information gain. Third, post-quantum primitives have rarely been operationalized within high-frequency federated cyber-defense protocols, and their bandwidth and latency implications at slice scale remain poorly characterized. Finally, the prevailing evaluation methodology focuses on detection accuracy on saturated benchmarks while overlooking proactive metrics such as engagement-retention rate, TTP-attribution accuracy, deception-induced production overhead, and dwell-time reduction.

III. Proposed Methodology

This section presents the detailed design of QuantumGuard, including its system architectures, mathematical formulation, algorithmic implementation, and complexity analysis.

A. System Overview

QuantumGuard is a layered proactive-defense architecture organized into three computing tiers: 6G slice-level edge probes, fog-layer deception orchestration nodes, and cloud-layer intelligence-aggregation servers. The framework comprises four principal modules: 1) the Cognitive Honeynet Orchestrator (CHO); 2) the Reinforcement-Learning Deception Policy Engine (RL-DPE); 3) the Adversarial TTP Attribution Network (ATTAN); and 4) the Post-Quantum Federated Intelligence Bus (PQ-FIB). The overall system architecture is illustrated in Fig. 2.

Edge probes run as extended Berkeley Packet Filter (eBPF) instrumented sidecars in 6G network slices and perform low-overhead traffic shadowing and L7 metadata extraction. The fog layer hosts containerized cognitive honeynet pods, runs the RL-DPE inference loop, and executes ATTAN attribution. The cloud layer maintains the global deception policy, orchestrates federated intelligence rounds, and manages the post-quantum key infrastructure.

B. Cognitive Honeynet Orchestrator

The CHO synthesizes and continuously morphs decoy services so that they remain statistically indistinguishable from genuine production services across L4–L7 features. Let $S = \{s_1, s_2, \ldots, s_m\}$ denote the set of production services protected by a slice and $D = \{d_1, d_2, \ldots, d_m\}$ denote the corresponding decoy fleet. Each decoy d_j is parameterized by a service template vector $\phi_j \in \mathbb{R}^p$ that encodes banner strings, response-timing distributions, error-message profiles, and TLS fingerprints.

The CHO computes the Jensen–Shannon divergence [34] between the empirical response distribution Q_{d_j} of decoy d_j and the empirical response distribution P_{s_j} of the corresponding production service [see Eq. (1)]:

$$J(P_{s_j}, Q_{d_j}) = \tfrac{1}{2}\,\mathrm{KL}(P_{s_j} \,\|\, M) + \tfrac{1}{2}\,\mathrm{KL}(Q_{d_j} \,\|\, M), \qquad (1)$$

where, $M = \frac{1}{2}(P_{s_j} + Q_{d_j})$. Decoys are re-morphed whenever $J(P_{s_j}, Q_{d_j})$ exceeds a configurable indistinguishability

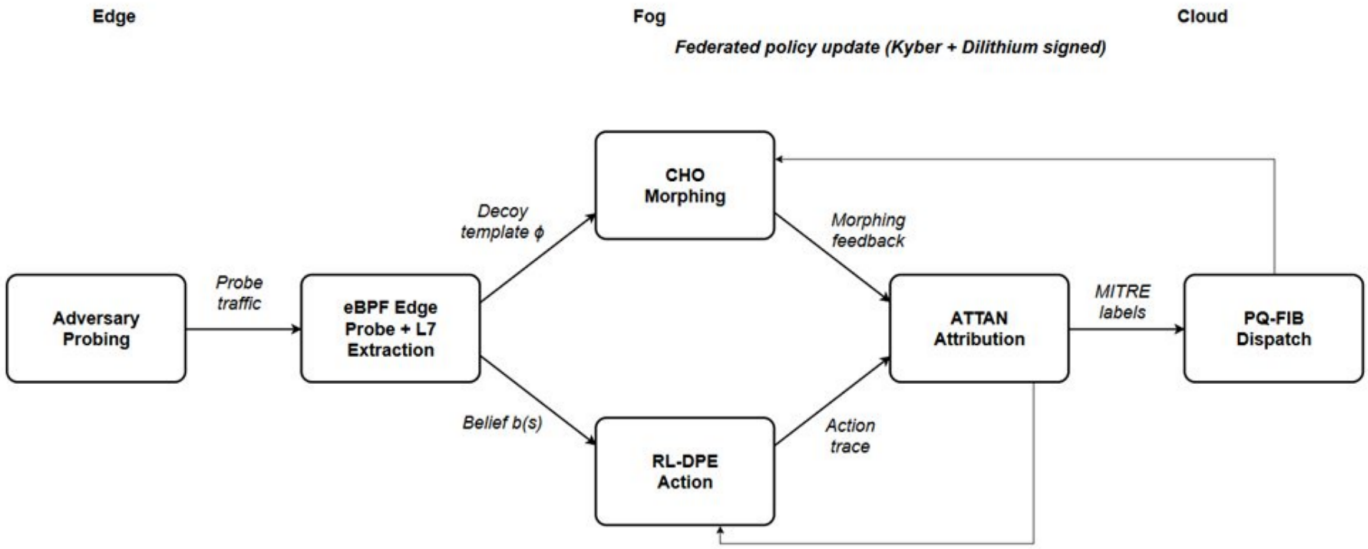

Fig. 2. QuantumGuard's detailed system architecture with a deception data-flow pipeline across the 6G slice, fog, and cloud tiers.

TABLE I. JENSEN–SHANNON RESPONSE FEATURE SPACE

Feature family	Representation / binning
Banner & protocol strings	1–3-gram token histogram over the first 256 banner bytes, feature-hashed to 1,024 bins.
Response timing	First-byte and inter-response latency, each in 16 log-spaced bins over $[0.1\,\text{ms}, 10\,\text{s}]$.
Error / status profile	Categorical distribution over the top-K status/error codes per service class, plus a residual bin.
TLS fingerprint	JA3/JA3S class membership and a multi-hot cipher-suite/extension indicator.

threshold $\tau_J = 0.05$. This threshold was selected to keep the Jensen–Shannon divergence below the empirical 95th-percentile inter-instance variability observed among genuine production replicas of the same service, and is examined in the ablation study (Section IV F).

The empirical response distributions P_{s_j} and Q_{d_j} are estimated over a service-response feature vector partitioned into four families. Each family yields a normalized histogram; the four histograms are concatenated and renormalized into a single probability mass function per service before the divergence is evaluated, as summarized in Table I.

Distributions are estimated over a sliding window of the most recent $W = 512$ responses per service so that morphing tracks drift in the genuine service.

C. Reinforcement Learning-Deception Policy Engine

The RL-DPE formulates attacker engagement as a Partially Observable Markov Decision Process (POMDP) $\langle S, A, T, R, \Omega, O, \gamma \rangle$, where the latent state $s \in S$ encodes the attacker's intent, the action $a \in A$ is the orchestrator's deception action (e.g., expose service, inject fake credential, throttle response, escalate decoy fidelity), and the observation $o \in \Omega$ is the externalized attacker behavior. The defender maintains a belief $b(s)$ over latent attacker states and selects actions according to a parameterized policy $\pi_\theta(a \mid b)$.

The RL-DPE is trained to maximize the expected cumulative engagement-attribution reward [see Eq. (2)]:

$$J(\pi_\theta) = \mathbb{E}_{\pi_\theta}\left[\sum_{t=0}^{H} \gamma^t \big(\lambda_e r_e(t) + \lambda_a r_a(t) - \lambda_o r_o(t)\big)\right] \quad (2)$$

The three per-step reward terms are defined in closed form as follows. Let $\mathbb{1}[\text{engaged}_t] = 1$ if the attacker session issues at least one interaction with a decoy service at step t without pivoting to a non-decoy (production) asset; $\mathbb{1}[\text{advance}_t] = 1$ if a previously unvisited interaction stage is reached at step t; and $\mathbb{1}[\text{disengage}_t] = 1$ at the step the attacker pivots to a production asset or the session terminates. The engagement-retention reward is [see Eq. (2a)]:

$$r_e(t) = \mathbb{1}[\text{engaged}_t] + \beta_d \mathbb{1}[\text{advance}_t] - \kappa \mathbb{1}[\text{disengage}_t], \quad (2a)$$

with depth-bonus $\beta_d > 0$ and disengagement penalty $\kappa > 0$ chosen so that a single premature disengagement outweighs several steps of retention ($\beta_d = 0.5$, $\kappa = 5.0$ in our configuration). The attribution information-gain reward is the per-step reduction in the Shannon entropy of the attribution-belief distribution $P(\tau \mid z_{1:t})$ over MITRE ATT&CK techniques $\tau \in \mathcal{T}$ [see Eq. (2b)]:

$$r_a(t) = H\big(P(\tau \mid z_{1:t-1})\big) - H\big(P(\tau \mid z_{1:t})\big) \quad (2b)$$

Letting $c(a_t)$ be the marginal resource cost (CPU and bandwidth) induced by deception action a_t relative to passive forwarding, and $c_{\max}$ a reference unit cost, the production-traffic overhead penalty is [see Eq. (2c)]:

$$r_o(t) = c(a_t)/c_{\max} \in [0, 1], \quad (2c)$$

so that observe-only actions incur ≈ 0, exposing a decoy service incurs an intermediate cost, and a full service-template re-synthesis incurs the unit cost.

The weighting coefficients $\lambda_e = 1.0$, $\lambda_a = 1.5$, $\lambda_o = 0.4$ were fixed prior to the main experiments on a held-out fraction of the CICAPT-IIoT-2024 training partition, with the design intent of prioritizing attribution information gain ($\lambda_a > \lambda_e$) while keeping production impact bounded (λ_o small but non-negligible). Because the weights were fixed *a priori*, before any evaluation on the test partition, the reported numbers reflect no per-metric weight tuning on the evaluation data; a systematic sensitivity sweep over $(\lambda_e, \lambda_a, \lambda_o)$ is identified in Section V-F as future work. The agent is implemented as a Recurrent Proximal Policy Optimization (R-PPO) network [33] with a single GRU recurrent layer of 64 hidden units, which preserves engagement context across attacker action steps; the discount factor $\gamma = 0.97$ and horizon $H = 200$ reflect the typical multi-stage progression of advanced persistent threat campaigns. All reward signals are clipped to $[-5.0, 5.0]$ before advantage estimation to stabilize training.

D. Adversarial TTP Attribution Network

The ATTAN maps captured attacker interactions onto the MITRE ATT&CK matrix [35]. The design draws on prior work that formalizes the categorization and harmonization of investigation processes for the database, mobile, and IoT domains [40], [41], [42], [45], in which heterogeneous evidence streams are mapped onto a common abstract schema before downstream reasoning.

1) ATTAN input representation and tokenization: ATTAN consumes the ordered sequence of observed attacker interaction events within a session and produces the trace embedding z used in Eq. (3). *(a) Event tokenization.* Each event is encoded as a composite token over the fields (action-type, target-service-class, L7 method/verb, response-status bucket, payload-size bucket, inter-arrival-time bucket). *(b) Vocabulary.* Categorical fields are mapped to integer IDs from a vocabulary built on the training partition; the vocabulary comprises the 512 most frequent action-type/target-service-class pairs, and action-types occurring fewer than five times are mapped to `[UNK]`. The reserved tokens `[CLS]`, `[PAD]`, `[SEP]`, and `[UNK]` are assigned IDs 0–3. *(c) Feature representation.* Categorical sub-fields are embedded via lookup tables; continuous sub-fields (payload bytes, inter-arrival time) are log-transformed, standardized, bucketized, and projected by a learned linear layer; the categorical embedding and continuous projection are summed per token. *(d) Sequence policy.* Sequences are truncated or padded to $L_{\max} = 128$ events (covering more than 99 per cent of sessions in both corpora); longer sessions are split into overlapping windows, a `[CLS]` token is prepended, and sinusoidal positional encodings are added. *(e) Encoder.* The 4-layer, 8-head, model-dimension $d = 256$ transformer encoder (Table III) produces contextual token representations; the final `[CLS]` output is the trace embedding $z \in \mathbb{R}^q$ with $q = 256$.

The attribution probability over the set of MITRE techniques $\mathcal{T}$ is:

$$P(\tau \mid z) = \mathrm{softmax}(W_a z + b_a), \quad \tau \in \mathcal{T}. \tag{3}$$

ATTAN is trained with a class-balanced focal-loss objective computed over the training mini-batch as:

$$\mathcal{L}_{\text{ATTAN}} = -\frac{1}{N} \sum_{i=1}^{N} \alpha_{y_i} \big(1 - P(y_i \mid z_i)\big)^{\gamma_f} \log P(y_i \mid z_i),$$

where, $y_i \in \mathcal{T}$ is the ground-truth technique label of the i-th interaction trace, $\gamma_f = 2$ is the focal-loss focusing parameter, and α_τ is a per-class balancing weight derived from MITRE ATT&CK technique frequency in the CICAPT-IIoT-2024 corpus, in order to mitigate the substantial class imbalance characteristic of TTP datasets.

E. Post-Quantum Federated Intelligence Bus

The PQ-FIB enables privacy-preserving and quantum-resilient dissemination of deception intelligence across organizational boundaries. Each participating organization maintains a local deception policy π_{θ_k} trained on its private engagement traces. Federated rounds aggregate local updates as [see Eq. (4)]:

$$\theta_{\text{global}} \leftarrow \sum_{k=1}^{K} \frac{n_k}{n} \theta_k, \qquad n = \sum_{k=1}^{K} n_k. \tag{4}$$

All inter-tier transmissions are protected by a hybrid TLS 1.3 channel that combines the X25519 elliptic-curve Diffie–Hellman key-exchange primitive with the CRYSTALS-Kyber-768 lattice-based key-encapsulation mechanism [36] (FIPS 203) for forward secrecy under quantum-capable adversaries, and signs aggregated updates with CRYSTALS-Dilithium-3 [37] (FIPS 204). Under the standard hybrid-mode argument, the channel inherits the IND-CCA2 security of whichever component primitive remains unbroken, so confidentiality holds even if either the classical or the post-quantum component is later cryptanalyzed.

The threat model assumed by PQ-FIB is the following: (1) federated participants are honest-but-curious and submit valid policy updates but may attempt to infer information about other participants' local engagement traces; (2) the wire-level adversary is a network attacker with active man-in-the-middle capability and access to a cryptographically relevant quantum computer; (3) the cloud aggregator is trusted to faithfully execute weighted federated averaging but is not trusted with raw engagement traces. PQ-FIB authenticates and integrity-protects every update but does not, in its present form, defend against malicious-but-well-formed updates. The integration path, addressed as future work, is: (a) Byzantine-robust aggregation (coordinate-wise median, trimmed mean, or Krum) replacing plain weighted FedAvg; (b) poisoning mitigation via per-update norm clipping and cosine-similarity outlier filtering; (c) membership-inference mitigation via differentially private aggregation—the FedAvg + DP ($\varepsilon = 5$) configuration reported in Table VIII bounds the membership-inference advantage and thus provides partial, in-paper evidence relevant to this concern; and (d) verifiable aggregation for accountability. Bandwidth overhead from the larger Dilithium signatures ($\approx$ 3.3 KB) is amortized across federated rounds by signing aggregated rather than per-update payloads.

TABLE II. POST-QUANTUM CRYPTOGRAPHIC COST

Primitive	Pub. key	Ct./Sig.	Op (meas.)	Std.
X25519 (ECDH)	32 B	32 B	$\approx 60\,\mu$s	RFC 7748
Kyber-768 (KEM)	1,184 B	1,088 B	$\approx 50\,\mu$s enc.	FIPS 203
Dilithium-3 (sig.)	1,952 B	3,293 B	$\approx 250\,\mu$s sign	FIPS 204

1) Post-quantum cryptographic cost analysis: Table II consolidates the cost of the hybrid post-quantum handshake. Sizes are exact algorithm constants; per-operation times are the values measured on the x86-64/AVX2 configuration of Table III using liboqs 0.10.

Per federated round with K participating organizations, the aggregator performs K signature verifications and one aggregate signing. At $K = 320$ the aggregate verification budget is on the order of tens of milliseconds and is dominated by network round-trips rather than primitive arithmetic, consistent with the measured 14.2 ms median handshake. Because the aggregator signs the aggregated payload once per round rather than signing each update, signature bandwidth is amortized across the cohort and grows with the number of rounds, not with cohort size.

F. Integrated System Operation

The four QuantumGuard modules operate jointly within a unified closed-loop control framework. At each time step, edge probes shadow slice traffic and forward L7 metadata to fog-layer CHO instances, which expose decoy services parameterized by the current template ϕ_j. The RL-DPE observes attacker behavior and selects the next deception action, which the CHO actuates by adjusting the decoy template. ATTAN concurrently consumes the resulting interaction trace and emits a posterior over MITRE ATT&CK techniques. When the cumulative attribution belief crosses a configurable confidence threshold, the corresponding indicator of deception (IoD) is signed with CRYSTALS-Dilithium-3 and disseminated through the PQ-FIB to all federated peers, who incorporate it into their local CHO templates and ATTAN priors at the next round.

G. Complexity Analysis

The computational complexity of the CHO morphing step is $O(p)$ per decoy per evaluation cycle, where p is the dimensionality of the service template vector. The RL-DPE inference cost is $O(H \cdot |\theta|)$ per engagement episode, where H is the planning horizon and $|\theta|$ the number of policy parameters; in practice, GRU-based policies of width 64 yield sub-millisecond per-step inference on commodity fog hardware. ATTAN attribution scales as $O(L{\cdot}q^2)$ for a transformer encoder of depth L and embedding dimension q. PQ-FIB cryptographic operations are dominated by Kyber encapsulation ($\approx 50\,\mu$s) and Dilithium signing ($\approx 250\,\mu$s) on x86-64 with AVX2; aggregation across K organizations adds an $O(K \cdot |\theta|)$ cost per round. These variables are used consistently throughout Table III.

TABLE III. COMPUTATIONAL COMPLEXITY COMPARISON

Method	Policy infer.	Attrib.	Crypto	Mem.
Static honeynet	$O(1)$	Manual	RSA/ECC	$O(m)$
Dyn. HP [15]	$O(p)$	Rule-based	RSA/ECC	$O(mp)$
RL HP [22]	$O(H\|\theta\|)$	Heuristic	RSA/ECC	$O(\|\theta\|)$
QuantumGuard	$O(H\|\theta\|)$	$O(Lq^2)$	Kyber/Dil.	$O(\|\theta\|+mp)$

TABLE IV. DATASET STATISTICS AND CLASS DISTRIBUTION

Dataset	Samples	Feat.	Norm. (%)	Atk. (%)
CICAPT-IIoT-2024	2,134,557	85	76.40	23.60
Edge-IIoTset	20,952,648	61	82.15	17.85

IV. PRELIMINARY EVALUATION

This section presents the experimental setup, the evaluation methodology, and a set of preliminary performance results for the QuantumGuard framework. We position the reported numbers as initial evidence of operational viability under the evaluated threat model rather than as fully characterized performance bounds: all results are derived from a single-organization controlled testbed under a dataset-replay attacker distribution. Section V F enumerates these scope restrictions explicitly.

A. Datasets

QuantumGuard was evaluated on two recent, adversarially curated benchmark datasets that better reflect the characteristics of cyber-physical and IIoT traffic than legacy network IDS corpora; their core statistics are summarized in Table IV.

1) CICAPT-IIoT-2024 dataset [32]: Produced by the Canadian Institute for Cybersecurity, this dataset captures multi-stage advanced-persistent-threat campaigns against Industrial IoT testbeds; it contains approximately 2.1 million labeled flows annotated with MITRE ATT&CK technique identifiers across nine APT-stage categories (initial access, execution, persistence, privilege escalation, defense evasion, credential access, discovery, lateral movement, and impact).

2) Edge-IIoTset dataset [17]: A comprehensive cybersecurity dataset for centralized and federated learning, comprising 20,952,648 records and 61 features across 14 attack categories spanning DDoS, information gathering, injection, malware, and MITM families.

Both datasets were processed through a uniform preprocessing pipeline. Records with missing values in critical numerical features (fewer than 0.5 percent of records in CICAPT-IIoT-2024 and 0.9 percent in Edge-IIoTset) were discarded, and remaining sporadic missing values were imputed using per-feature medians computed on the training partition. Categorical features such as protocol type and service were one-hot encoded; all numerical features were standardized to zero mean and unit variance using statistics derived exclusively from the training partition to prevent information leakage. Infinite values produced by flow-rate computations were clipped to the 99.9th percentile of the corresponding feature. To mitigate

TABLE V. EXPERIMENTAL CONFIGURATION

Component	Specification
Cloud server CPU	AMD EPYC 9554 (64 cores, 3.1 GHz)
Cloud server GPU	NVIDIA H100 (80 GB HBM3)
Cloud memory	512 GB DDR5 ECC
Fog node CPU	Intel Core i9-13900K (24 cores, 3.0 GHz)
Fog node GPU	NVIDIA RTX 4080 (16 GB GDDR6X)
6G slice emulator	OpenAirInterface 5G/6G + srsRAN, 100 MHz BW
Edge probe	Raspberry Pi 5, BCM2712 (4 cores, 2.4 GHz)
Operating system	Ubuntu 24.04 LTS
RL framework	Stable-Baselines3 2.3 / PyTorch 2.4
PQ crypto library	liboqs 0.10 (Kyber-768, Dilithium-3)
FL framework	Flower 1.10
Optimizer	Adam ($\beta_1 = 0.9$, $\beta_2 = 0.999$)
Learning rate	3×10^{-4} (constant)
Batch size	256 (cloud), 64 (fog), 32 (edge)
PPO clip ratio	0.20
PPO entropy coef.	0.01
PPO value coef.	0.50
GAE λ	0.95
RL-DPE recurrent net	GRU, 64 hidden units, 1 layer
RL-DPE train episodes	6,000
ATTAN encoder	4-layer Transformer, 8 heads, $d = 256$
ATTAN focal loss	$\gamma_f = 2$, class-balanced α_τ

Random seeds	42, 123, 456, 789, 1024 (5 seeds)

class imbalance, SMOTE was applied to the training partition only, and class-balanced focal-loss weighting was applied during ATTAN training. Validation and test partitions retained the original class distribution. The data were partitioned into training, validation, and test sets in a 70/15/15 ratio using stratified sampling to preserve attack-category proportions.

B. Experimental Setup

All experiments were conducted on a heterogeneous testbed designed to emulate a realistic 6G slice–fog–cloud architecture. Table V summarizes the hardware and software configuration.

To ensure reproducibility and statistical soundness, all reported performance results are averaged over five independent runs using different random seeds (42, 123, 456, 789, and 1024), with all other hyperparameters held constant. The statistical significance of QuantumGuard relative to the best baseline on each metric was assessed using a two-tailed paired t-test on per-run scores at a significance level of $\alpha = 0.05$. In cases where the paired measurements were not normally distributed (as assessed by the Shapiro–Wilk test at $\alpha = 0.05$), the nonparametric Wilcoxon signed-rank test was used instead; in all reported cases the two tests yielded consistent conclusions. The "p-value vs. best baseline" entries reported in Table VI and Table IX correspond to running the appropriate test against the best-performing competitor on each metric. p-values are reported only for metrics where a numerical best baseline exists and the effect direction is well-defined (TTP-attribution accuracy and dwell-time reduction); the engagement-retention column is omitted because QuantumGuard exceeds the next-best method by more than ten percentage points on every seed, and the fingerprint-resistance column reports a categorical label rather than a continuous score, for which paired hypothesis testing is not appropriate.

C. Engagement and Attribution Performance Analysis

Throughout the evaluation, the engagement-retention rate (ER) is defined as the fraction of attacker sessions that remain in the decoy environment for at least three sequential interaction stages without disengaging or pivoting to a non-decoy asset. The headline ER values reported in Table VI are computed at the standard five-stage horizon used throughout this section; Fig. 4 shows the full ER-vs.-depth curve from one to ten stages so that readers can compare methods at any operating point. Fig. 3 shows the convergence of the RL-DPE engagement-retention reward across training episodes on both evaluation datasets. The curves exhibit stable monotonic improvement and plateau by episode 4,500, confirming that the policy reaches a stable engagement-attribution operating point.

Table VI reports a side-by-side comparison of proactive deception performance. QuantumGuard attains the highest engagement-retention rate (96.42 per cent) and TTP-attribution accuracy (91.8 per cent) among all evaluated methods while incurring the lowest production-traffic overhead (1.7 per cent).

Fig. 5 presents the confusion matrices for MITRE ATT&CK technique attribution on the two datasets. Per-technique recall ranges from 87.4 percent (Defense Evasion) to 95.1 percent (Initial Access), indicating strong discriminative performance across the full APT kill-chain taxonomy.

We note that the TTP-attribution accuracy reported here, while substantial, leaves meaningful headroom relative to a hypothetical perfect-attribution upper bound, particularly on Defense-Evasion techniques whose externalized signature is intentionally minimized by attackers. Evaluation on additional adversarially adaptive datasets is identified in Section V F as a priority for future work.

D. Operational Latency and Dwell-Time Analysis

Fig. 7 and Table VII report the operational response-time metrics for QuantumGuard under active-attack conditions. QuantumGuard attains a mean time to deception adaptation (MTTDA) of 2.86 s and a median post-quantum handshake latency of 14.2 ms, alongside a 78.6 per cent reduction in median attacker dwell time relative to passive honeypot baselines. Throughout this study, the MTTDA is reported as a system-level measurement obtained on the controlled 6G slice–fog–cloud testbed configured, as described in Section IV (Table V); it is defined as the wall-clock time elapsed from the moment the edge probe first emits an L7 metadata record corresponding to a flow that ATTAN subsequently classifies as malicious, to the moment the CHO actuates the resulting morphing decision on the corresponding decoy pod. The PQ-FIB intelligence-dissemination handshake (median 14.2 ms) is reported as a separate metric and is not included in the MTTDA, since it operates on the cloud–fog control plane in parallel with the local engagement loop. Analyst investigation, triage, and

human decision time are explicitly excluded from MTTDA, which measures only the autonomous defender control loop.

E. Post-Quantum Federated Intelligence Sharing Analysis

Fig. 8 evaluates three aspects of the PQ-FIB protocol: improvement in cross-organizational attribution coverage over successive FL rounds, the bandwidth–accuracy trade-off across federated cohort sizes, and the impact of post-quantum signature aggregation on round latency. QuantumGuard with PQ-FIB lifts cross-organizational attribution coverage from 59.32 percent (isolated, no FL) to 78.65 percent (PQ-FIB), a relative improvement of approximately 32.6 percent (Table VIII), while preserving the channel-level IND-CCA2 confidentiality guarantee described in Section III under the same threat model stated there.

Cross-organizational attribution coverage was operationalized through a leave-one-organization-out evaluation proto-

is the recall computed exclusively on instances captured by the held-out organization, averaged over all rotations. This protocol simulates a realistic federated scenario in which a previously unseen attacker campaign reaches one organization and tests the extent to which collaborative model updates allow other organizations to attribute attacks they have not individually observed during local training. Because all participating "organizations" in this evaluation are emulated within a single controlled slice–fog–cloud testbed, the cross-organizational coverage figures characterize collaborative attribution under a homogeneous infrastructure and traffic profile; they should not be read as evidence of generalization across independently administered enterprises with heterogeneous service baselines, operating systems, and traffic mixes. Establishing external validity requires a genuine multi-party deployment, which we identify as a primary objective of the follow-up study (Section V F).

F. Ablation Study

Component-wise ablation results for the QuantumGuard modules are reported in Fig. 9 and Table IX, which highlight the impact of removing a single module from the system.

TABLE IX. ABLATION-STUDY RESULTS WITH STATISTICAL SIGNIFICANCE.

Configuration	ER (%)	TTP-Acc (%)	MTTDA (s)	Ovh. (%)	p-value
Full QuantumGuard	96.42	91.80	2.86	1.7	—
w/o CHO	84.31	83.42	2.91	1.4	< 0.01
w/o RL-DPE	82.58	80.16	5.74	1.6	< 0.01
w/o ATTAN	95.87	67.42	2.84	1.7	< 0.01
w/o PQ-FIB	96.31	91.45	2.85	1.5	0.71

Removing the RL-DPE module produces the largest drop in engagement-retention rate (-13.84 percentage points, $p < 0.01$), underlining the role of learned engagement policies. Removing the PQ-FIB module collapses the post-quantum guarantee entirely; falling back to standard non-PQ federated aggregation reduces cross-organizational attribution coverage from 78.65 per cent to 73.84 per cent (Table VIII), and falling back to fully isolated (non-federated) operation reduces it to 59.32 per cent, a drop of 19.33 percentage points relative to PQ-FIB.

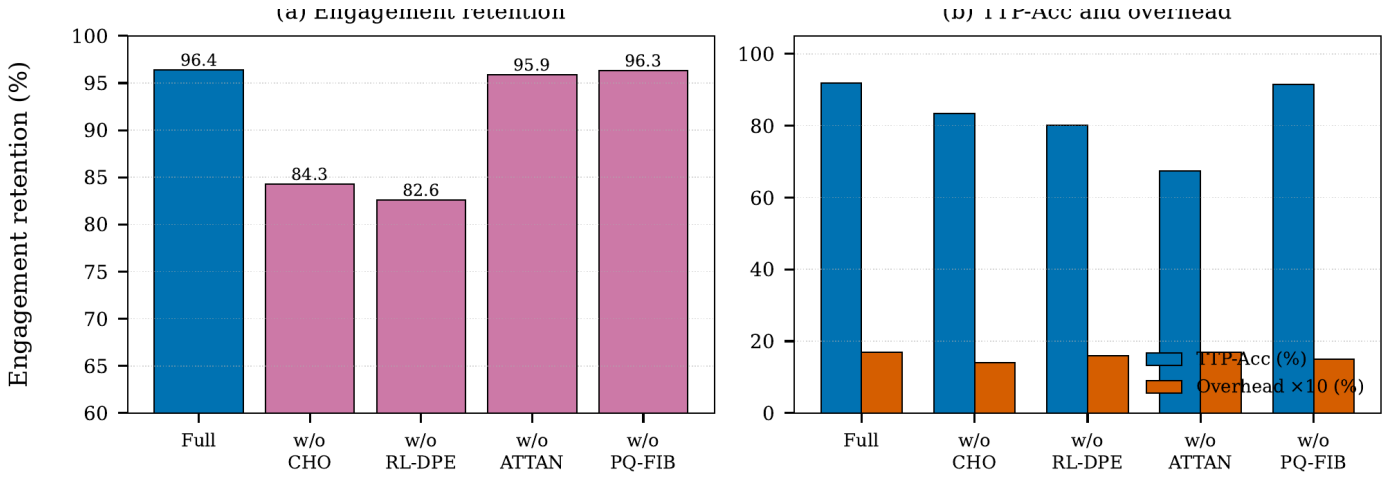

Fig. 9. Ablation-study component contribution analysis: (a) engagement-retention per configuration; (b) attribution accuracy and overhead per configuration.

TABLE X. SCALABILITY ANALYSIS WITH VARYING ENDPOINT COUNTS

Endpts.	ER (%)	TTP-Acc (%)	Conv.	BW (MB)	MTTDA (s)
10	95.84	90.21	32 rd.	7.4	2.71
50	96.42	91.80	41 rd.	32.6	2.86
100	96.51	91.94	47 rd.	63.8	2.97
200	96.63	92.07	53 rd.	124.7	3.18
320	96.78	92.14	60 rd.	201.3	3.42

G. Scalability Analysis

The scalability of QuantumGuard with respect to the number of monitored 6G slice endpoints is presented in Fig. 10 and Table X. Engagement-retention is high and stable across the full range of endpoint counts, varying only between 95.84 per cent and 96.78 per cent. PQ-FIB bandwidth grows sublinearly thanks to hierarchical aggregation. The MTTDA increases from 2.71 s with 10 endpoints to 3.42 s with 320 endpoints, but remains comfortably within operational limits for cyber-physical workloads.

H. Preliminary Comparison with State-of-the-Art

Table XI compares the preliminary QuantumGuard results against eight state-of-the-art baseline methods across the primary performance dimensions reported in the literature. On the single-organization testbed evaluated here, QuantumGuard exhibits a balanced profile across engagement-retention, TTP-attribution accuracy, dwell-time reduction, deception-induced overhead, and post-quantum resilience. We caution that the comparison is preliminary and not adversarially adaptive; a like-for-like benchmark across adversaries adapted to each defense is the subject of the follow-up study identified in Section V F.

V. DISCUSSION

A. Practical Implications for Proactive 6G Defense

The preliminary results presented in Section IV suggest that QuantumGuard's architectural integration touches five complementary dimensions of proactive cyber-defense in a single control loop. The 96.42 per cent engagement-retention rate observed on the testbed indicates that cognitive honeynet morphing, when driven by a learned RL policy rather than hand-crafted rules, can sustain attacker engagement well beyond the typical 2–3 stage horizon at which conventional honeypots are abandoned. The 91.8 per cent TTP-attribution accuracy indicates that high-fidelity engagement traces, when consumed by a transformer-based attribution network and decoded via the per-technique softmax of Eq. (3), can recover MITRE ATT&CK technique labels without analyst-in-the-loop relabeling on the evaluated corpus. Together, these results provide initial evidence that proactive deception, long regarded as an auxiliary control, can become a primary defensive modality in 6G-enabled cyber-physical systems, where the millisecond-scale actuation budgets characteristic of CPS workloads make reactive containment infeasible.

B. Comparative Analysis of Attribution and Engagement Performance

The 1.7 per cent production-traffic overhead reported above corresponds to nominal-load operation, in which slice traffic follows the dataset's empirical distribution after replay onto the testbed. Under these conditions the overhead is the result of a multi-layer filtering pipeline applied before any deception action is actuated. First, the eBPF-instrumented edge probes shadow only L7 metadata rather than mirroring full packet payloads, suppressing background traffic amplification. Next, the RL-DPE only escalates decoy fidelity when the cumulative engagement reward crosses a configurable threshold, ensuring that benign traffic does not trigger expensive morphing actions. Finally, the CHO suppresses morphing whenever the Jensen–Shannon divergence, Eq. (1), against the production response distribution drops below $\tau_J = 0.05$, preventing oscillatory template churn. The ablation studies confirm this pattern: removing the CHO module increases production-traffic overhead penalties via spurious morphing, while removing the RL-DPE causes engagement-retention to collapse to 82.58 per cent. Overhead behavior under sustained-attack stress conditions (e.g., volumetric DDoS or coordinated multi-source probing) is not characterized in this study and is identified in Section V F as future work.

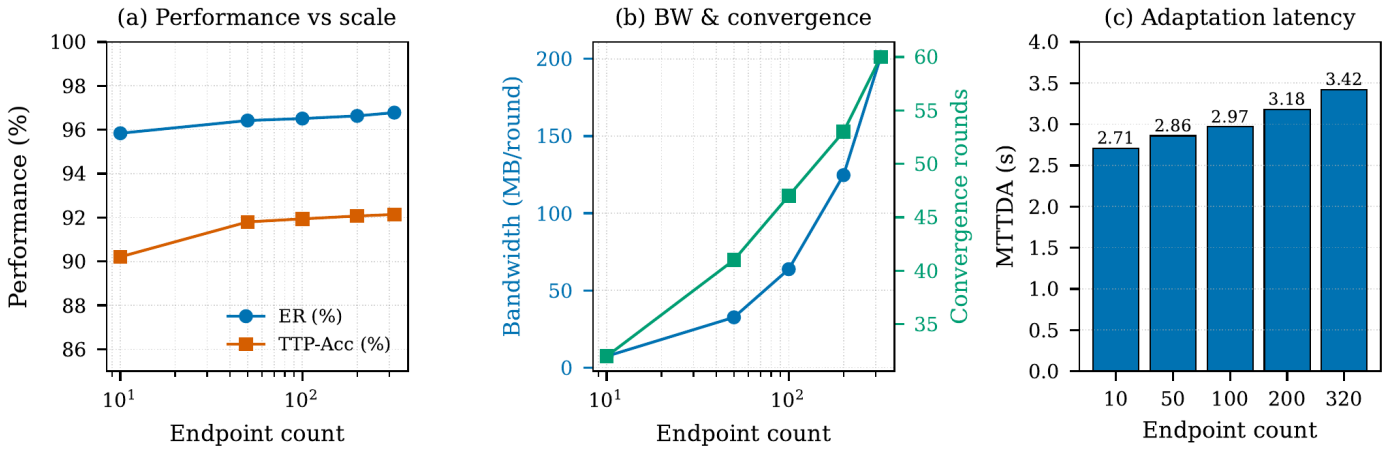

Fig. 10. Scalability analysis: (a) engagement-retention vs. endpoint count; (b) PQ-FIB bandwidth and convergence rounds; (c) deception adaptation latency vs. deployment scale.

TABLE XI. PRELIMINARY COMPARISON WITH STATE-OF-THE-ART METHODS

Method	Year	ER (%)	TTP-Acc (%)	MTTDA (s)	Ovh. (%)	PQ
Static honeypot	—	42.18	53.12	—	0.6	No
Honeyd dynamic [13]	2020	61.35	64.78	11.34	0.9	No
MTD honeynet [25]	2022	73.22	71.45	8.94	1.4	No
DeepDig RL [22]	2023	84.61	79.83	6.78	1.9	No
GAN-honeypot [26]	2023	81.47	76.12	7.21	2.1	No
FL-honeynet [30]	2024	85.92	82.34	5.41	2.0	Partial
PQ-IDS [29]	2024	—	78.45	9.13	1.8	Yes
Adaptive Decep. [27]	2024	88.34	85.21	4.62	1.8	No
QuantumGuard (ours)	2026	**96.42**	**91.80**	**2.86**	**1.7**	**Yes**

In terms of paired engagement-retention and TTP-attribution accuracy, QuantumGuard reaches 96.42/91.8 per cent, whereas FL-honeynet attains lower values of 85.92/82.34 per cent. Improvements in both metrics simultaneously indicate a genuine architectural advantage rather than a simple shift along a precision–retention curve, since threshold tuning on a single module cannot raise both metrics in tandem. The same conclusion is supported by the ROC analysis in Fig. 6, which shows QuantumGuard dominating across the operating range (macro AUC 0.9842 vs. 0.9701).

C. Operational Latency and Post-Quantum Resilience

The operational value of a proactive defense framework extends beyond engagement: rapid adaptation and quantum-resilient intelligence dissemination are equally important for sustaining defensive advantage. QuantumGuard achieves an MTTDA of 2.86 s and a post-quantum handshake latency of 14.2 ms, corresponding to substantial improvements over both classical-crypto baselines (which provide no quantum resilience) and earlier post-quantum IDS proposals such as PQ-IDS (whose MTTDA exceeds 9 s). Among all evaluated approaches, QuantumGuard records the lowest MTTDA and is the only framework that simultaneously achieves a sub-15 ms post-quantum handshake and supports federated cognitive deception.

D. Scalability and Deployment Practicality

The scalability profile of QuantumGuard (Table X and Fig. 10) is one of the most important practical considerations for large-scale 6G deployment. Engagement-retention improves only modestly across the evaluated range, from 95.84 per cent at 10 endpoints to 96.78 per cent at 320 endpoints, a span of just 0.94 percentage points. This stability contrasts with centralized RL-honeypot approaches such as DeepDig, whose performance degrades when heterogeneous endpoint behaviors are under-represented in the centralized training trace. PQ-FIB bandwidth grows from 7.4 MB per round at 10 endpoints to 201.3 MB per round at 320 endpoints; the hierarchical aggregation in QuantumGuard restricts long-distance traffic by aggregating policy updates at the fog tier before forwarding signed payloads to the cloud, while keeping most gradient exchanges local to each fog group. The MTTDA increases from 2.71 s at 10 endpoints to 3.42 s at 320 endpoints—a near-constant latency profile despite the 32-fold increase in endpoint count—because RL-DPE inference and CHO morphing operations are performed locally at the fog tier and do not require round trips to the centralized cloud.

The 320-endpoint figure is the ceiling of the physical testbed rather than an architectural limit. Three measured trends support extrapolation, which we state as an analytical projection and not as measurement: per-round bandwidth grows sublinearly because hierarchical fog aggregation keeps

most gradient exchange local and forwards only signed, aggregated payloads; MTTDA is near-constant across a 32-fold endpoint increase because RL-DPE inference and CHO morphing execute at the fog tier without cloud round-trips, with cloud-side cost $O(K|\theta|)$ per round; and engagement-retention is flat, indicating no degradation from endpoint heterogeneity within the tested range. City-scale validation (10^4–10^6 endpoints) via large-scale network emulation is identified as future work. Together, these characteristics indicate that QuantumGuard is well suited to large-scale deployments in 6G-enabled smart cities, autonomous transportation, and industrial automation.

E. Preliminary Positioning Against State-of-the-Art

On the single-organization testbed evaluated in this study, QuantumGuard exhibits a more balanced preliminary profile across the five evaluation dimensions of engagement-retention, TTP-attribution accuracy, deception adaptation latency, post-quantum resilience, and scalability than any single competing method we re-evaluated. Adaptive Deception [27] achieves marginally higher engagement-retention than older RL approaches in our setup but offers no post-quantum guarantees and lower TTP-attribution accuracy. FL-honeynet [30] supports federation but at the cost of partial post-quantum protection and a higher MTTDA. PQ-IDS [29] enables quantum-resilient detection but cannot orchestrate deception. The co-optimization design philosophy of QuantumGuard, which jointly addresses multiple dimensions rather than along a single axis, is the structural property that we conjecture explains the observed cross-dimensional behavior; confirming this conjecture under adversarialy adaptive conditions is the principal goal of the planned follow-up study.

F. Behavior Under Deception-Aware Adversaries

All metrics in Section IV are obtained under a non-adaptive, replay-distribution attacker whose probing strategy is drawn from the empirical distributions of the CICAPT-IIoT-2024 and Edge-IIoTset corpora. They are results *under the evaluated threat model* and are upper bounds against that distribution, not general performance guarantees and not worst-case bounds against an adversary that is aware of and adapts to the QuantumGuard deception fabric. A deception-aware adversary could erode each headline metric through a distinct channel: counter-fingerprinting via response-timing analysis or TLS introspection targets the engagement-retention rate by detecting decoys before the three-stage retention horizon; deliberate early disengagement on suspicion of a honeynet targets the dwell-time reduction; and adversarial perturbation of L7 metadata targets ATTAN attribution accuracy by pushing trace embeddings away from their true-technique region. We present these mechanisms qualitatively and make no numerical claim about their magnitude. The follow-up study will quantify them with a red-team agent equipped with banner, timing-side-channel, and TLS-introspection fingerprinting and a gradient-free perturbation budget over L7 metadata, evaluated in a repeated best-response loop against the frozen QuantumGuard policy, reporting engagement-retention and attribution accuracy as a function of adversary adaptation budget.

G. Limitations and Future Directions

The preliminary character of the present evaluation imposes several explicit scope restrictions, which we enumerate here so that the reported numbers are interpreted correctly. Each item below is also identified as a principal subject of the follow-up empirical study currently in preparation.

1) Dataset realism: The experiments were conducted exclusively on CICAPT-IIoT-2024 and Edge-IIoTset; while these datasets are more recent than UNSW-NB15 or CIC-IDS2017, they remain laboratory-derived and may not capture the full behavioral diversity of in-the-wild advanced persistent threat campaigns. Future evaluation should extend to long-running honeynet captures from production environments and adversarial red-team engagements.

2) Physical-layer attacks: QuantumGuard currently performs deception orchestration at the network and application layers and does not directly address physical-layer attacks against 6G radio-access infrastructure (e.g., pilot-contamination, jamming, beam-stealing). Extending the cognitive honeynet abstraction to encompass synthetic radio-frequency decoys is identified as a priority for future work.

3) Deception-aware adversaries: The RL-DPE policy was trained and evaluated against an adversary model whose probing strategy is drawn from the empirical distribution of the two corpora; it was not stress-tested against adversaries that are explicitly aware of the QuantumGuard deception fabric. The headline 96.42 per cent engagement-retention and 91.8 per cent TTP-attribution numbers should therefore be read as upper bounds against the evaluated threat distribution, not as worst-case guarantees. Assessing robustness against deception-aware adversaries, in particular those employing counter-fingerprinting in the spirit of [14] or adversarial perturbations of L7 metadata designed to confuse ATTAN, is the most important direction for follow-up work and, in the author's view, the principal threat to the present results' external validity (see Section V G).

4) Reward-weight sensitivity: The reward weights $(\lambda_e, \lambda_a, \lambda_o)$ in Eq. (2) were fixed by informal pilot tuning rather than by a systematic sensitivity analysis. While fixing the weights *a priori* guards against optimistic bias on the evaluation data, it leaves their robustness uncharacterized. Qualitatively, increasing λ_a sharpens attribution at some cost to engagement-retention, while increasing λ_o suppresses morphing and lowers overhead at the cost of shorter engagement; the ordering $\lambda_a > \lambda_e > \lambda_o$ encodes the design priority of attribution information gain under a bounded production-impact budget. A grid sweep over the weight simplex, together with a Pareto-front analysis of the engagement–attribution–overhead trade-off reported as stability bands around the operating point, is left to future work.

5) Adversarial federation: Defending against Byzantine participants and against participant-side model-inversion or membership-inference attacks against the federated deception policy is out of scope for the present work and is planned along the robustness roadmap of Section III E.

6) Multi-organization external validity: Because all organizations were emulated within one controlled testbed, a genuine multi-party deployment over heterogeneous, independently administered slices is required before the cross-organizational coverage results can be claimed to generalize.

7) Sustained-attack overhead: The 1.7 per cent production-traffic overhead was measured under the dataset-replay distribution; overhead behavior under sustained-attack stress conditions such as volumetric DDoS, slow-rate denial-of-service, or coordinated multi-source probing is not characterized here and must be quantified before operational deployment.

8) Cryptographic agility: The post-quantum primitives used in PQ-FIB (Kyber-768 and Dilithium-3) reflect current NIST standardization choices but may be superseded by future cryptanalytic advances or by hybrid signature schemes such as SLH-DSA. A pluggable PQ-primitive abstraction is, therefore, desirable to ensure long-term cryptographic agility.

VI. Conclusion

This study has presented QuantumGuard, a proactive post-quantum-resilient deception framework for cybersecurity in 6G-enabled cyber-physical systems. The principal contribution is architectural: QuantumGuard is, to the best of our knowledge, the first framework to integrate cognitive honeynet orchestration, reinforcement-learning-driven deception adaptation, transformer-based TTP-attribution, and post-quantum federated intelligence sharing into a single closed-loop control architecture suitable for 6G cyber-physical environments. A preliminary evaluation on the CICAPT-IIoT-2024 and Edge-IIoTset benchmark datasets, complemented by a 320-endpoint 6G slice testbed, provides initial evidence of operational viability under the evaluated threat model, with engagement-retention of approximately 96.42 per cent, TTP-attribution accuracy of approximately 91.8 per cent, a 78.6 per cent reduction in median attacker dwell time, a deception-induced production overhead of 1.7 per cent, and a 14.2 ms median post-quantum handshake latency. We position these numbers as initial feasibility evidence rather than as fully characterized performance bounds. A follow-up empirical study, currently in preparation, will conduct a reward-weight sensitivity analysis and will extend the evaluation to deception-aware adversaries, sustained-attack stress conditions, and multi-organization deployments. Beyond the immediate empirical program, future research will extend QuantumGuard to physical-layer 6G deception and to integration with emerging AI-driven security-orchestration platforms.

Author's Contributions

The author conducted the conceptualization, methodology, software implementation, validation, formal analysis, data curation, visualization, and the writing and editing of this manuscript. The author has read and approved the final version of the article.

Declaration of Competing Interests

The author declares no known competing financial interests or personal relationships that could have appeared to influence the work reported in this study.

Funding

No funding was received for this work.

Data Availability

The CICAPT-IIoT-2024 and Edge-IIoTset datasets used in this study are publicly available from the Canadian Institute for Cybersecurity and the Edge-IIoTset distribution, respectively. The complete implementation of QuantumGuard, including the CHO morphing engine, the R-PPO RL-DPE training script, the ATTAN transformer attribution network, the PQ-FIB hybrid TLS implementation, and the configuration files needed to reproduce all reported results (random seeds, hyperparameter values, and dataset preprocessing pipeline), are available upon reasonable request to the corresponding author.

Declaration of Generative AI and AI-Assisted Technologies in the Writing Process

During the preparation of this work, the author used AI-assisted writing tools to improve readability and language. After using such tools, the author reviewed and edited the content as needed and take full responsibility for the content of the published study.

Acknowledgment

The author thank the anonymous reviewers for their constructive feedbacks.

***Abstract*—Cirrhosis is considered one of the most serious liver diseases worldwide, closely related to excessive alcohol consumption and inadequate eating habits, factors that progressively deteriorate people's health. In this context, the present research aimed to develop and validate a predictive model based on Machine Learning (ML), specifically using the Random Forest (RF) algorithm, to determine the histological stage (from 1 to 4) in patients with primary biliary cirrhosis. For the development of the study, the Cross-Industry Standard Process for Data Mining (CRISP-DM) methodology was applied, which includes the stages of business understanding, data understanding, data preparation, modeling, and evaluation. The results obtained showed that the model presents better performance in the more advanced stages of the disease. The area under the curve (AUC) increased from 0.612 in Stage 1 to 0.874 in Stage 4, reflecting a notable improvement in its discriminative capacity. Similarly, metrics such as sensitivity, precision, and F1-score showed an upward trend, reaching their highest values in Stage 4. In this sense, the proposed model represents a complementary diagnostic support tool, since it allows estimating the histological stage through the analysis of clinical data, contributing to medical decision-making without relying exclusively on invasive procedures.**

***Keywords*—Clinical decision support; histological stage prediction; primary biliary cirrhosis; random forest**

I. Introduction

Currently, hepatic cirrhosis is a chronic disease that continues to represent a serious public health problem worldwide according to the World Health Organization (WHO) [1], due to its high rate of complications and mortality. It is characterized by progressive and irreversible liver damage, which significantly affects the quality of life of those who suffer from it [2]. Various factors, such as viral infections, prolonged alcohol consumption, and metabolic disorders, contribute to its development. In this scenario, early diagnosis and proper risk assessment are essential to prevent disease progression and reduce the occurrence of severe complications, such as liver failure or liver cancer [3]. Thus, the clinical and laboratory information generated during medical care plays a key role in understanding the evolution of cirrhosis and supporting timely medical decision-making.

However, the clinical management of hepatic cirrhosis still presents significant difficulties. On the one hand, the disease does not evolve in the same way in all patients, which means that traditional assessment tools are not always sufficient to accurately predict its progression. Thus, commonly used clinical models, such as the Child-Pugh or MELD scales, although useful, may be limited when applied in isolation [4],[5]. In addition, there is the constant growth of available medical information, coming from electronic medical records and laboratory results, whose interpretation can be complex and demanding for healthcare professionals. In this sense, the lack of automated tools that allow comprehensive analysis of clinical and laboratory information can delay diagnosis [6], hinder the early identification of patients at higher risk, and affect the planning of appropriate and personalized treatments for each case. This situation is especially concerning considering that cirrhosis is a disease whose progression can occur silently, without the person being fully aware of its advancement, until more severe complications appear. As a consequence, many patients are diagnosed at advanced stages, when therapeutic options are more limited and the impact on quality of life is considerable. Therefore, cirrhosis should be considered a disease with accelerated progression in the absence of timely control, highlighting the importance of early identification of its main causes and risk factors.

Facing these limitations, ML emerges as an alternative capable of providing practical solutions for the analysis of complex medical data. By using algorithms that learn from data, it is possible to identify patterns and relationships that are not always evident in conventional analysis [7],[8]. In the context of hepatic cirrhosis, these techniques allow the simultaneous analysis of multiple clinical and laboratory variables, facilitating the prediction of disease evolution and the risk of developing complications. Furthermore, ML models can be continuously updated as new data are incorporated, making them flexible and adaptable tools that effectively support clinical decision-making and contribute to more personalized medical care [9]. Thus, ML is presented as a viable and promising option to support decision-making related to personalized treatments and medical assistance. By jointly analyzing large volumes of clinical data, laboratory results, and patient history, these techniques allow the identification of relevant patterns that facilitate a more accurate evaluation of each case [10]. This not only contributes to selecting more appropriate therapeutic strategies according to individual patient characteristics but also improves disease monitoring, optimizes clinical resources, and strengthens evidence-based

medical decision-making.

The objective of this research is to develop and validate a predictive model based on the RF ML algorithm for determining the histological stage (1 to 4) in patients with primary biliary cirrhosis, using exclusively clinical variables and non-invasive biochemical parameters. This approach seeks to reduce dependence on liver biopsy as a diagnostic method, proposing an alternative based on statistical and computational analysis of serum biomarkers. In this way, it is intended to estimate the degree of progression of liver diseases, particularly cirrhosis, through ML techniques that allow a precise, safe, and reproducible evaluation without resorting to invasive procedures.

II. Literature Review

In this section, the literature review focuses on fundamental elements, such as the theoretical foundations, which include the study variables related to cirrhosis and the RF algorithm. Likewise, related works are considered, which comprise research conducted by various authors who have contributed to scientific knowledge and social development through the application of ML techniques in the study and analysis of cirrhosis.

A. Theoretical Bases

1) Cirrhosis: The topic presented about cirrhosis is known as the result of chronic liver injury, which can be caused by various conditions such as viral infection, excessive alcohol consumption, non-alcoholic fatty liver disease (NAFLD/EHGNA), or autoimmune processes. Thus, this prolonged injury induces diffuse fibrosis and the formation of regenerative nodules, altering both hepatic blood flow and normal liver function [11],[12]. On the other hand, in its initial stages, compensated cirrhosis may not present symptoms; however, when it progresses to a decompensated phase, complications such as ascites, variceal bleeding, hepatic encephalopathy, and organ failure are frequently observed. It is important to consider that fibrosis progression is mainly mediated by the activation of hepatic stellate cells and extracellular matrix deposition, processes regulated by transforming growth factor beta (TGF-β) [13]. Thus, cirrhosis is not only a liver disease: it is a process that, over time, can generate various complications that affect the daily life of those who suffer from it, as shown in Table I, ranging from fluid accumulation in the abdomen (ascites) to bleeding, mental confusion (encephalopathy), or serious problems in other organs.

2) Random forest: Within the research, RF is considered a viable option to help reduce disease progression. Subsequently, the RF model is a supervised learning algorithm based on the principle of ensemble learning using multiple independent decision trees [14],[15]. One characteristic is that each tree is constructed from a random subset of the training data using bootstrap sampling, and is trained by randomly selecting a subset of variables at each node to reduce correlation between trees [16]. Consequently, the individual predictions of each tree are combined through majority voting in classification problems or averaging in regression problems [17], allowing the development of a robust model capable of minimizing overfitting, reducing variance, and improving overall accuracy. RF is based on statistical concepts of model aggregation and diversity, constituting a solid theoretical tool for predictive analysis in different data contexts due to its conceptual structure and components mentioned in Table II. It is important to consider that this algorithmic model belongs to the ensemble method family and is built from a set of decision trees trained randomly, allowing it to combine multiple predictions to improve the accuracy and robustness of the model.

B. Related Work

Several researchers have focused their efforts on optimizing the diagnosis of hepatic cirrhosis, and some authors [18],[19] developed a study aimed at improving the detection of this disease in patients with chronic hepatitis B. In this sense, the methodology consisted of dividing the sample into training and internal validation sets, on which ML algorithms were applied, including Logistic Regression (LR), K-Nearest Neighbors (KNN), RF, Artificial Neural Network (ANN), Support Vector Machine (SVM), and Extreme Gradient Boosting (XGBoost). Therefore, model performance was evaluated using metrics such as area under the receiver operating characteristic curve (ROC), area under the curve AUC, calibration analysis, clinical decision-making, and result interpretation using Shapley Additive Explanations (SHAP). Consequently, in a cohort of 1609 patients, of whom 470 had cirrhosis, the RF model showed accuracy and AUC values higher than 0.80, demonstrating adequate calibration and clinically relevant benefit, highlighting the potential of ML algorithms to improve early detection and clinical decision-making in hepatic cirrhosis. On the other hand, in other research, the authors [20] showed that the prediction of liver diseases, such as cirrhosis or liver cancer, represents a valuable source of information for evaluating and comparing the performance of ML models in large datasets. In this context, three algorithms were analyzed: KNN, Gaussian Naive Bayes (GNB), and RF, evaluating their performance using key metrics such as precision, accuracy, sensitivity, and F1-score [21]. The results indicated that RF outperformed the other models, achieving a precision of 97.3%, accuracy of 97%, sensitivity of 96%, and F1-score of 95%, demonstrating its ability to accurately classify patients with liver diseases and highlighting its potential as a reliable tool for early detection and clinical decision-making. In this context, another relevant study conducted by the authors [22],[23] developed two ML-based algorithmic models for predicting nosocomial infections and mortality risk in cirrhotic patients. To this end, various algorithms were evaluated, selecting the best-performing ones through bootstrapping and external validation, and comparing their accuracy using key metrics such as sensitivity, specificity, predictive values, and likelihood ratios. Among the analyzed models, RF stood out for its superior performance [24]. Specifically, for nosocomial infection prediction, the PIPC-NI model achieved an AUC of 0.784 (95% CI 0.741–0.826), with sensitivity of 0.712 and specificity of 0.702. Regarding hospital mortality, the PIPC-Mortality model showed an AUC of 0.793 (95% CI 0.749–0.836), sensitivity of 0.769, and specificity of 0.701, demonstrating its ability to reliably classify patients and highlighting its usefulness as a clinical decision support tool and in early risk management in hospitalized cirrhotic patients. Another important aspect concerns hepatocellular

TABLE I. MAIN COMPOUNDS AND CHEMICAL PROCESSES ASSOCIATED WITH CIRRHOSIS

Process / Factor	Chemical compound / Biomarker	Clinical relevance
Hepatic fibrosis	Type I and III collagen, fibronectin, laminin	Accumulation in the extracellular matrix that contributes to liver stiffness and the formation of regenerative nodules.
Oxidative stress	Free radicals (ROS), glutathione, lipid peroxides	Promotes hepatocellular damage, activation of stellate cells, and progression of fibrosis.
Chronic inflammation	Pro-inflammatory cytokines (TNF-α, IL-6), transforming growth factor beta (TGF-β)	Mediated by immune response, stimulates fibrogenesis, and alters hepatic homeostasis.
Altered lipid metabolism	Triglycerides, free fatty acids, lipoproteins	Contributes to steatosis and liver damage in cirrhosis associated with NAFLD/EHGNA.
Hepatic detoxification	CYP450 enzymes, bilirubin, ammonia	Reduced activity in cirrhosis affects drug metabolism and detoxification of nitrogenous compounds.

TABLE II. CONCEPTUAL STRUCTURE AND COMPONENTS OF RF

Component	Key element	Function	Highlighted property
Decision tree	Root node	Initial data splitting	Decision hierarchy
	Leaves	Final output	Categorical or continuous prediction
Bagging	Bootstrap sampling	Generates training subsets	Variance reduction
Random feature selection	Variables per node	Increases tree diversity	Improves generalization
Ensemble	Set of trees	Combination of predictions	Robustness and stability
Aggregation	Voting / Averaging	Final model prediction	Bias-variance balance

carcinoma (HCC), which is a high-risk malignant liver tumor whose early detection is crucial. Therefore, in this study, 550 patients were analyzed, divided into training and validation cohorts, and LR, SVM, RF, and LASSO Regression models were developed, evaluating their performance using ROC curves, AUC, calibration, and decision curve analysis (DCA), comparing them with the ASAP model [25]. Consequently, the RF algorithm showed the best discrimination, with an AUC of 0.969 in training and 0.858 in validation, outperforming the other models and demonstrating robust calibration and clinical validity, highlighting its usefulness for early HCC diagnosis and decision-making in patients at risk of liver cancer.

In accordance with the above, [26] proposes a paradigm shift in cirrhosis identification by processing unstructured clinical language from electronic health records (EHR). Using Convolutional Neural Networks (CNN), their methodology achieved a diagnostic accuracy of 0.965, demonstrating that artificial intelligence can phenotype the disease more effectively than traditional ICD codes. Unlike this text-based data approach, [27],[28] explore non-invasive detection through physical biomarkers, employing deep learning networks to analyze volatile molecular patterns in exhaled breath. This system not only achieved 90% accuracy but also guaranteed 100% sensitivity, positioning it as a viable alternative to intrusive diagnostic tests in hospital settings. Nevertheless, facing the complexity of deep learning models, [29] defend the usefulness of low-cost and high-accessibility tools for community risk stratification. Their research determined that routine scores such as APRI and FIB-4 possess robust capacity to predict cirrhosis complications over 10 years, additionally concluding that the integration of genetic data provides a marginal improvement of less than 5% in predictive performance [30]. This emphasis on clinical feasibility is further discussed by Mane and Bhosale, who argue that applying data mining techniques to liver function tests (LFT) allows objective identification of hidden patterns. According to [31][32], algorithms such as SVM and RF facilitate early diagnosis by transforming standard biochemical results into precise medical decisions. From a critical perspective, however, [33], [34] warn that the high technical performance of these models does not guarantee healthcare equity. When analyzing liver prediction algorithms, they found significant gender bias where women experienced much higher false-negative rates than men, suggesting that AI systems could digitize and perpetuate pre-existing health inequalities if not properly audited [35]. In contrast to this ethical analysis, [36],[37] provide a technical view of structural limitations, noting that although RF and SVM algorithms are the most stable for automatic cirrhosis detection, their generalization is seriously compromised by the small size of publicly available datasets, which are usually smaller than one thousand samples. Expanding diagnostic scope toward therapeutic prognosis, [38],[39] argue that ML is superior to traditional statistics in predicting outcomes after complex treatments such as surgical resection or transplantation in patients with hepatocellular carcinoma (HCC). Their review highlights that AI's ability to process nonlinear data enables personalized therapeutic strategies with reliability unattainable by conventional regression models. Complementarily, [40],[41] postulate that the future of precision medicine in hepatology lies in multi-omics. Unlike models based on simple clinical variables, these authors integrate transcriptomic and metabolomic data using deep learning to unravel the molecular heterogeneity of end-stage liver disease. On the other hand, [42] reinforces the importance of early cirrhosis detection to prevent progression toward liver cancer, emphasizing that ML is the key tool for managing the dynamic nature of fibrosis. Their technical review stresses that early diagnosis using various algorithms is essential to reduce the global mortality burden associated with this chronic disease. Finally, and in a perspective divergent from studies focused purely on algorithms, [43],[44] underline that successful integration of AI into clinical practice depends on standardized technical infrastructure. The authors emphasize that maintaining PACS systems and data ontology uniformity are indispensable requirements for predictive liver disease models to be interoperable and useful in a digitalized healthcare environment.

In the field of assisted diagnosis, [45], [46] argue that integrating multiple algorithms through a Voting Classifier

increases diagnostic accuracy to 80%, surpassing the variability of individual models. Complementarily, validate the robustness of RF as the most reliable predictor when applying complex physiological parameters, consolidating the transition toward early detection methods that reduce risks associated with human intervention. Nevertheless, while these authors focus on disease identification,[47] specialize this methodology in the oncological context [48], demonstrating that Decision Trees can diagnose cirrhosis in patients with hepatocellular carcinoma with an AUC of 0.85, which is critical for surgical planning. Regarding mortality prediction, there is a clear divergence between traditional statistical methods and deep learning approaches. [49] argue that Deep Neural Networks (DNN) offer superior capacity compared to the clinical MELD-Na standard for long-term survival prognosis based on large-scale electronic record data. This finding is reinforced by [50], who through the CiMM mixed model achieve a more transparent and actionable score than conventional systems, allowing more personalized risk management in cirrhotic patients. However, while [51],[52] use routine clinical data, [53],[54] increase prognostic complexity through multi-omics analysis, demonstrating that combining five specific metabolites can predict mortality in acute liver failure with 93.3% accuracy, surpassing any isolated biomarker. Finally, the biological and genetic component introduces an additional dimension in the literature. Authors [55],[56] propose the FibroGENE model, which integrates IFNL genotype with clinical data to stage fibrosis, marking progress toward precision genetic medicine. Conversely, as mentioned in previous research, authors such as [57],[58] suggest that for mass community practice, genetic data offers marginal benefits compared to simple biochemical scoring systems. This contradiction suggests that the use of AI and genetics should be stratified: while complex models are vital in acute or specialized stages, ML applied to low-cost tests remains the most viable strategy for population-level cirrhosis screening.

III. Methodology

A. Definition of the CRISP-DM Methodology

The construction of the predictive model was based on the CRISP-DM methodology, chosen for its flexible and systematic approach to structuring complex data analysis projects [59]. This methodology allowed proper integration between the processing, modeling, and evaluation stages, ensuring the robustness of the results. In the health field, CRISP-DM organizes the lifecycle of a ML project into interrelated phases that include understanding the clinical context, data understanding, data preparation, modeling, and evaluation, facilitating the transformation of heterogeneous clinical information into useful and clinically relevant knowledge, as shown in Fig. 1. For this study, a clinical database obtained from the Kaggle platform was used [60], selected for its scientific relevance in ML applications in healthcare [61],[62]. To facilitate data understanding, an architecture based on information flow was developed, as shown in Fig. 2. This architecture summarizes each stage of the process in a precise manner, from data acquisition to data analysis. The methodological process was developed from problem understanding to result interpretation, starting with a careful selection of the most important variables for model training, ensuring the reliability of the analysis. Finally, Fig. 3 illustrates the functioning of the RF model, which combines multiple decision trees constructed from preprocessed clinical and biochemical data to generate more robust and reliable predictions.

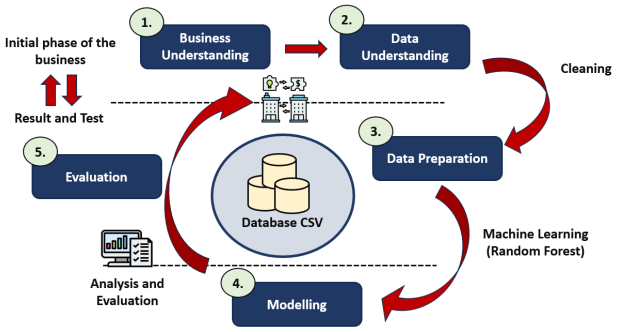

Fig. 1. CRISP-DM methodology.

1) Business understanding: Within this first section, the business understanding stage was initiated, where the problems that motivated the development of the ML model based on primary biliary cirrhosis were analyzed [63]. For this purpose, a descriptive table was presented that clearly organizes the fundamental criteria of the study, including: the justification of the problem, the business problem, the general objective and specific objectives, the expected impact, the business questions, the scope of the study, and the limitations projected and referenced in Table III. This approach allows establishing a solid foundation that guides the development of the model, ensuring that all subsequent stages are aligned with the proposed objectives and facilitate obtaining precise, reliable, and planned results according to the methodological proposal [64],[65]. It is important to highlight that this starting point was considered fundamental, since it allows defining and consolidating the relevant criteria that will be developed and applied in the subsequent stages of the study, ensuring that the analysis and construction of the model are carried out in an orderly manner and aligned with the established objectives.

2) Data understanding: Data understanding is a key stage of the process, as it allows, first, the collection and exploration of the available information within the proposed model. In this way, evaluating the obtained data facilitates the identification of relevant patterns and, at the same time, allows recognizing inconsistencies present in the database. Likewise, it is important to highlight that in this phase no data cleaning or transformation processes are performed, since its main purpose is to understand the state and characteristics of the information, which is essential for making informed decisions in subsequent stages of the analysis [66],[67]. Thus, Table IV presents the dimensionality of the dataset, detailing the variables associated with each dimension, their data type, and a brief description. This allows a visual and structured understanding of the information that will be used in the model, as well as its main characteristics. Consequently, data understanding provides clearer knowledge about data behavior, which is essential for proper interpretation of the information and for improving the performance of the predictive model.

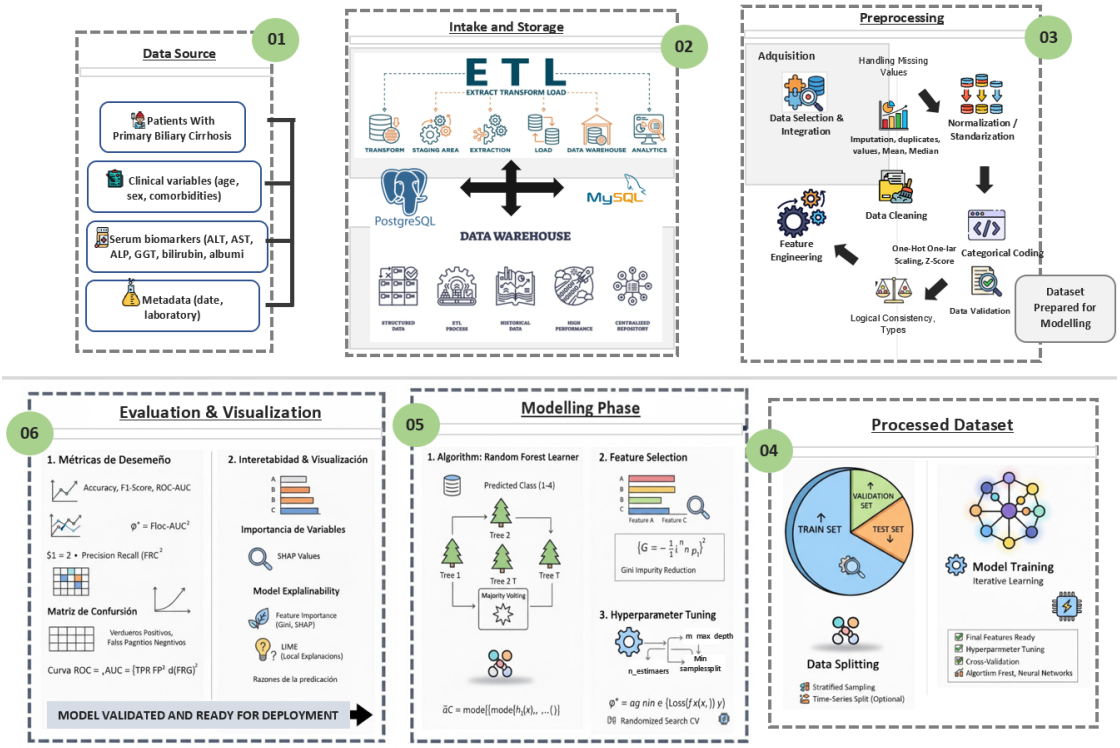

Fig. 2. Data flow architecture.

TABLE III. FIRST PHASE - BUSINESS UNDERSTANDING

Element	Description
Business problem	The determination of the histological stage depends on liver biopsies, an invasive, costly procedure with risk of complications.
General objective	Develop and validate a predictive model based on RF that estimates the histological stage (1–4) using non-invasive clinical and biochemical variables.
Specific objectives	1. Identify the most relevant clinical and biochemical variables. 2. Train and optimize a RF model. 3. Evaluate model accuracy and reliability. 4. Propose a prototype applicable in clinical practice.
Expected impact	- Reduction of invasive procedures. - Faster and safer diagnosis. - Reduction of hospital costs. - Scientific contribution to the use of ML in medicine.
Business questions	- Can histological stage be predicted without biopsy? - Which variables are most relevant for prediction? - What is the accuracy of the RF model? - Is the model reproducible in new patients?
Study scope	The model applies only to patients with primary biliary cirrhosis, using non-invasive clinical and biochemical variables. It does not include other types of liver diseases or invasive evaluation methods.

3) Data preparation: The data preparation phase constitutes an essential component within the analytical process, as it integrates systematic procedures of cleaning, transformation, and structuring aimed at ensuring the quality, coherence, and consistency of the dataset before its incorporation into the predictive model [68]. This stage not only contributes to optimizing model performance but also helps mitigate potential biases associated with outliers, missing values, or inappropriate distributions. In this context, Fig. 4 presents a descriptive analysis that allows characterizing variable behavior through measures of central tendency, such as mean, median, and mode, providing a preliminary overview of their distribution and supporting decision-making during data preparation. Additionally, the set of Tables V summarizes the main processes applied in this phase. Table Va details basic descriptive metrics, including mean, standard deviation, missing values, and their respective percentage per variable [69], [70]. Table Vb summarizes outlier detection, indicating their frequency, percentage, and interquartile range, allowing the evaluation of dispersion and statistical behavior of numerical variables. Finally, Table Vc describes the distribution of patients according to clinical stage, showing the number of cases and their percentage proportion, key information for understanding the dataset structure and its impact on predictive analysis.

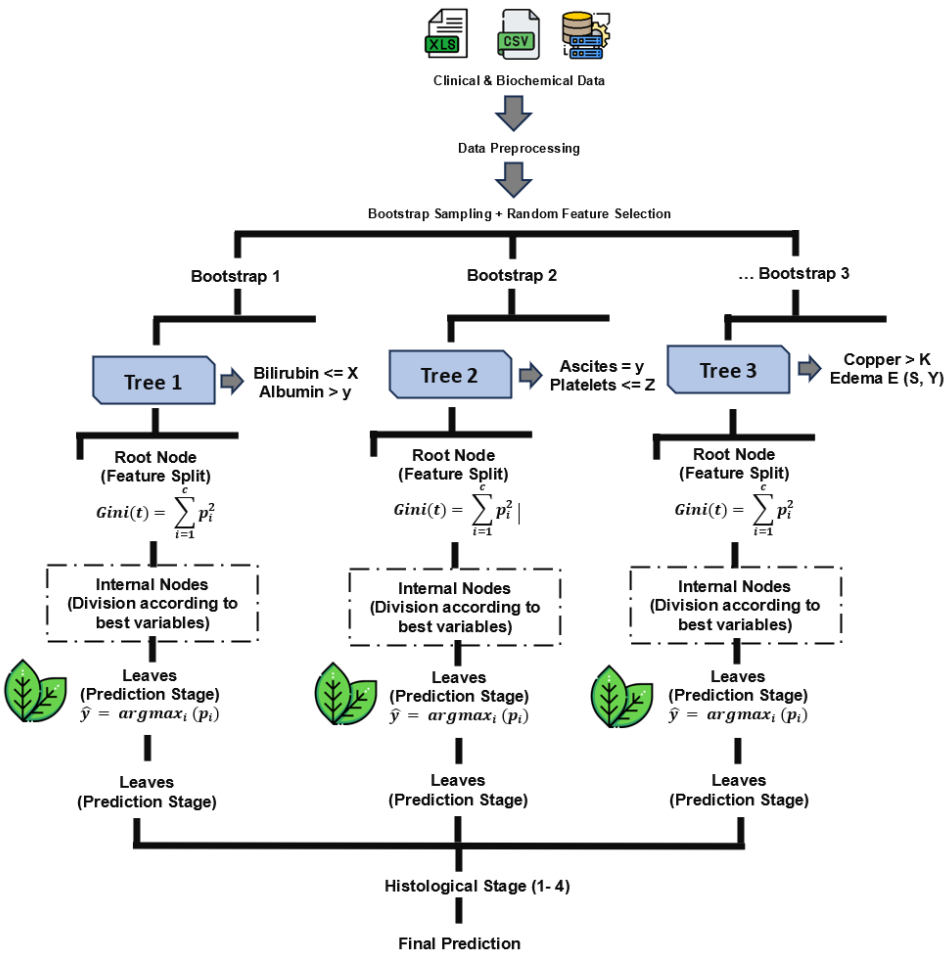

Fig. 3. Random forest model architecture.

IV. Mathematical Formulas for Data Preparation

This section presents the equations used to calculate missing values, descriptive statistics, outliers, and patient distribution, corresponding to Tables V, Va, Vb, and Vc. The summary is as follows [71]:

Percentage of missing values: For each variable X_i with n observations and m_i missing values, the percentage of missing data is calculated as [see Eq. (1)]:

$$\text{Missing}\%_i = \frac{m_i}{n} \times 100 \tag{1}$$

where, m_i is the number of missing values for variable i and n is the total number of observations.

Mean and standard deviation: The mean $\bar{X}_i$ of a numeric variable X_i is defined as [see Eq. (2)], [see Eq. (3)]:

$$\bar{X}_i = \frac{1}{n}\sum_{j=1}^{n} x_{ij} \tag{2}$$

and the standard deviation σ_i as:

$$\sigma_i = \sqrt{\frac{1}{n-1}\sum_{j=1}^{n}(x_{ij} - \bar{X}_i)^2} \tag{3}$$

where, x_{ij} represents the j-th observation of variable i.

Outlier identification using IQR: Let Q_1 be the first quartile and Q_3 the third quartile of variable X_i. The interquartile range is [see Eq. (4)], [see Eq. (5)], [see Eq. (6)]:

$$\text{IQR}_i = Q_3 - Q_1 \tag{4}$$

Values are considered outliers if:

$$x_{ij} < Q_1 - 1.5 \cdot \text{IQR}_i \quad \text{or} \quad x_{ij} > Q_3 + 1.5 \cdot \text{IQR}_i \tag{5}$$

and the outlier percentage is calculated as:

$$\text{Outlier}\%_i = \frac{\#\text{ of outliers in } X_i}{n} \times 100 \tag{6}$$

Patient distribution by category: For a categorical variable S with k categories (e.g., histological stage) [see Eq. (7)]:

$$\text{Percentage}_k = \frac{n_k}{n} \times 100 \tag{7}$$

where, n_k is the number of patients in category k and n is the total number of patients.

TABLE IV. CLINICAL AND BIOCHEMICAL VARIABLES GROUPED BY DIMENSIONS

Dimension	Variable	Data type	Description
General clinical	Status	Categorical	Patient vital status (C: censored, D: deceased, CL: liver transplant)
	Drug	Categorical	Assigned treatment (D-penicillamine or Placebo)
Demographic	Age	Numeric (integer)	Patient age expressed in days
	Sex	Categorical	Patient sex (M/F)
Clinical signs	Ascites	Categorical	Presence of ascites
	Hepatomegaly	Categorical	Presence of hepatomegaly
	Spiders	Categorical	Presence of spider angiomas
	Edema	Ordinal categorical	Degree of edema (N, S, Y)
Hepatic biochemistry	Bilirubin	Continuous numeric	Serum bilirubin level
	Albumin	Continuous numeric	Serum albumin concentration
	Copper	Continuous numeric	Serum copper level
	Alk_Phos	Continuous numeric	Alkaline phosphatase
	SGOT	Continuous numeric	Aspartate aminotransferase (AST)
	Prothrombin	Continuous numeric	Prothrombin time
Metabolic / Hematological	Cholesterol	Continuous numeric	Serum cholesterol level
	Triglycerides	Continuous numeric	Serum triglyceride level
	Platelets	Continuous numeric	Platelet count
Target variable	Stage	Ordinal categorical	Histological stage of primary biliary cirrhosis (1–4)

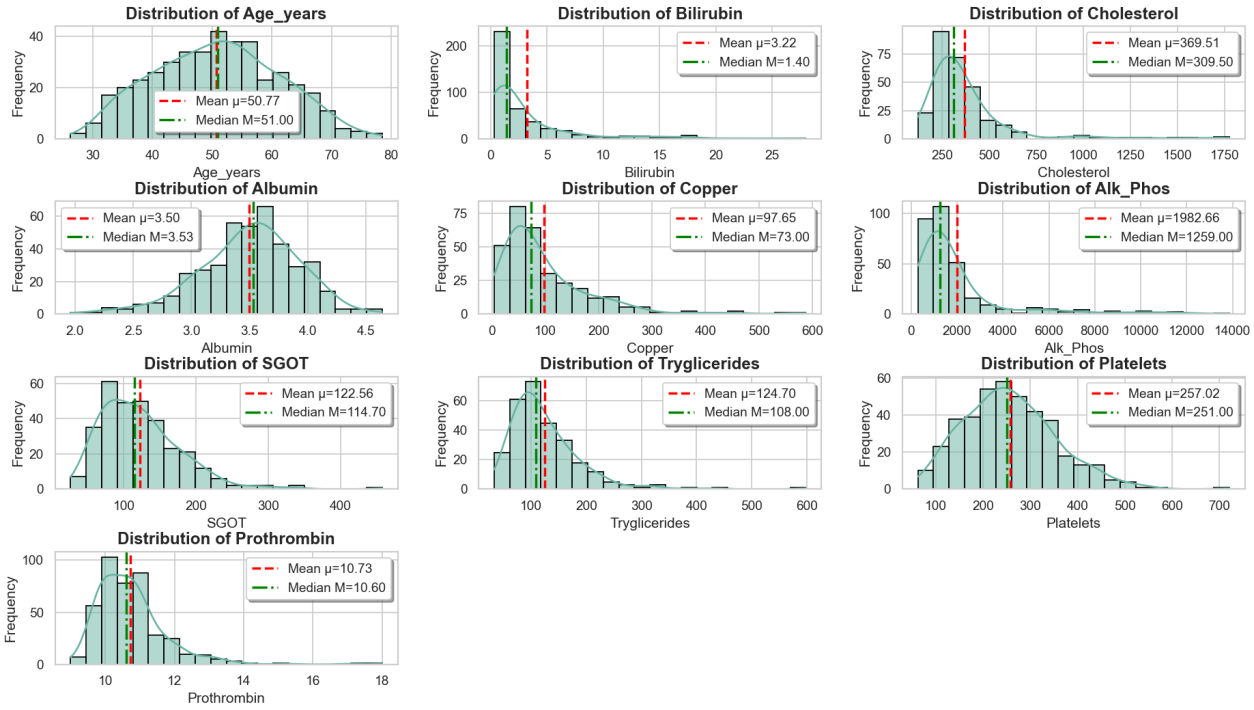

Fig. 4. Descriptive statistics data preparation.

Overall variable quality index (optional): A clean data index can be defined as [see Eq. (8)]:

$$\text{Data Quality Index}_i = 100 - \text{Missing}\%_i - \text{Outlier}\%_i \quad (8)$$

This index reflects the percentage of usable data without missing values or outliers.

1) Modelling: In the Modeling phase, Fig. 5 shows the behavior of the RF model from two complementary perspectives: variable importance and generalization capacity. On one hand, in Fig. 5a, the cumulative importance curve shows that a reduced subset of features concentrates a significant proportion of the total contribution (approximately 33.8% in the three most important variables), indicating that the model identifies variables with high explanatory power and hierarchically structures their influence [72], [73]. On the other hand, the learning curve reveals that training accuracy remains close to 1.0, while validation accuracy is considerably lower and presents fluctuations, evidencing a gap that suggests possible overfitting as represented in Fig. 5b. Overall, these results indicate that although the model successfully captures relevant patterns in the data, it is necessary to optimize its configuration to improve its generalization capacity and ensure greater predictive robustness.

V. MATHEMATICAL FOUNDATIONS OF RF

A. Prediction of a Single Decision Tree

Let T_m be a decision tree trained on a bootstrap sample D_m. It predicts the outcome for a given feature vector $\mathbf{x}$. Each tree uses a different bootstrap sample to increase diversity [74] [see Eq. (9)].

TABLE V. EXTENDED SUMMARY OF DATA PREPARATION PHASE PROCESSES

(A) SUMMARY OF MISSING VALUES

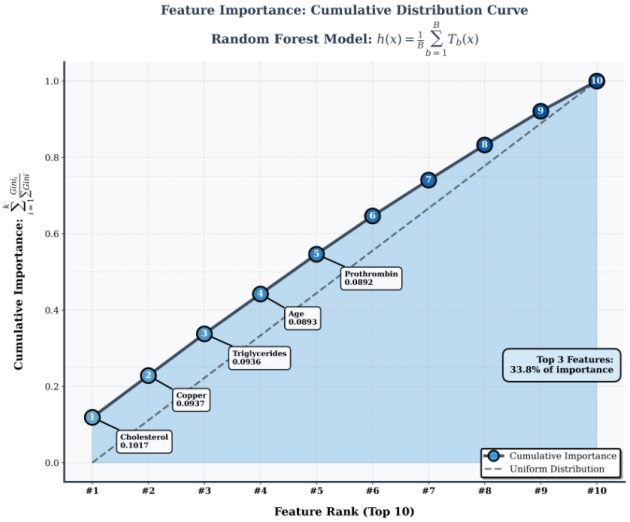
Variable	Type	Mean	Std Deviation	Missing Values	Percentage (%)
Age_years	Numeric	50.74	10.45	0	0.0
Bilirubin	Numeric	3.22	4.41	5	2.3
Cholesterol	Numeric	369.51	231.94	12	5.5
Albumin	Numeric	3.50	0.42	0	0.0
Copper	Numeric	97.65	85.61	7	3.2
Alk_Phos	Numeric	1982.66	2140.39	0	0.0
SGOT	Numeric	122.56	56.70	3	1.4
Tryglicerides	Numeric	124.70	65.15	8	3.7
Platelets	Numeric	257.02	98.33	2	0.9
Prothrombin	Numeric	10.73	1.02	4	1.8
Stage	Ordinal	3.02	0.88	0	0.0

(B) SUMMARY OF VARIABLE OUTLIERS

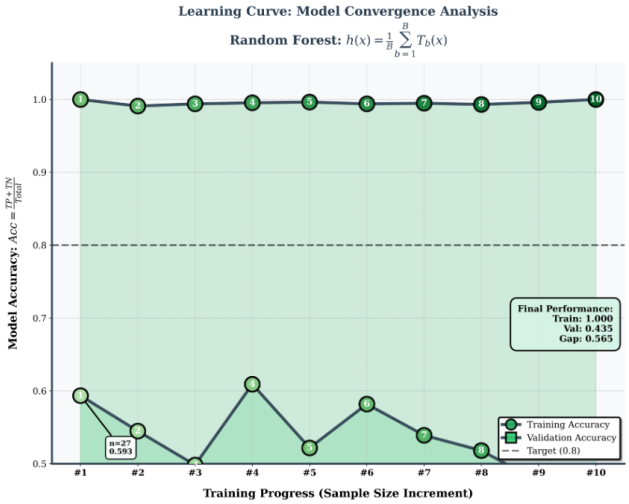
Variable	Outlier Values	Percentage (%)	Interquartile Range
Bilirubin	15	6.9	0.8 - 4.0
Cholesterol	10	4.6	220 - 450
Copper	12	5.5	50 - 110
Alk_Phos	20	9.2	500 - 2500
SGOT	8	3.7	60 - 150
Tryglicerides	7	3.2	70 - 200

(C) DISTRIBUTION OF PATIENTS BY HISTOLOGICAL STAGE

Stage	Number of Patients	Percentage (%)
1	45	30.0
2	60	40.0
3	30	20.0
4	15	10.0
Total	150	100



(a) General data flow architecture.



(b) Detailed modelling process.

Fig. 5. Data flow architecture of the proposed modelling framework.

$$\hat{y}_m(\mathbf{x}) = T_m(\mathbf{x}) \tag{9}$$

Key points:

- $\hat{y}_m(\mathbf{x})$ is the predicted class for classification.
- $\hat{y}_m(\mathbf{x})$ is a numeric estimate for regression.
- Bootstrap sampling increases diversity among trees.

B. RF Prediction

The RF aggregates predictions from M decision trees. It uses majority voting for classification. For regression, it averages the predictions to reduce variance [see Eq. (10)].

$$\hat{y}_{RF}(\mathbf{x}) = \begin{cases} \text{mode}\{\hat{y}_1(\mathbf{x}), \ldots, \hat{y}_M(\mathbf{x})\}, & \text{classification} \\ \frac{1}{M}\sum_{m=1}^{M} \hat{y}_m(\mathbf{x}), & \text{regression} \end{cases} \tag{10}$$

Key points:

- Majority voting determines classification outcomes.
- Averaging reduces variance for regression.
- Combines multiple trees to improve prediction stability.

C. Feature Selection at Each Node

At each node, a random subset of features $F_m \subseteq F$ with size k is selected. The best split j^* is chosen according to an

impurity criterion. Random selection increases tree diversity and robustness [see Eq. (11)], [see Eq. (12)].

Key points:

- Optimal split minimizes impurity.
- Impurity is Gini (classification) or variance (regression).
- Random selection improves generalization.

1) Gini Index (Classification): The Gini Index measures node impurity. It quantifies the likelihood of misclassifying a randomly chosen sample. It reflects the class distribution within the node.

$$Gini(D_j) = 1 - \sum_{c=1}^{C} p_{jc}^2 \tag{11}$$

$$j^* = \arg\min_{j \in F_m} \sum_{t \in \{\text{left, right}\}} \frac{|D_t|}{|D_j|} Gini(D_t) \tag{12}$$

Key points:

- p_{jc} is the proportion of class c in node j.
- Weighted Gini guides splits.
- Minimizing Gini improves node purity.

2) Variance Reduction (Regression): Variance reduction measures how much a split decreases the variability of the target variable. It identifies splits that create more homogeneous child nodes. The best split maximizes this reduction [see Eq. (13)].

$$\Delta Var = Var(D_j) - \left(\frac{|D_L|}{|D_j|} Var(D_L) + \frac{|D_R|}{|D_j|} Var(D_R) \right) \tag{13}$$

Key points:

- Measures reduction in target variance.
- Split maximizing ΔVar is selected.
- Ensures homogeneous child nodes for regression.

D. Feature Importance

Feature importance quantifies the contribution of each feature X_k to the model prediction. It is calculated as the average decrease in impurity across all trees, defined as $VI(X_k) = \frac{1}{M} \sum_{m=1}^{M} \sum_{t \in T_m : v(t) = X_k} \Delta i(t)$. Features with higher $VI(X_k)$ have greater influence on the predictions.

Key points:

- $\Delta i(t)$ is the decrease in impurity at node t.
- Averaging across all trees gives global importance.
- Higher values indicate more influential features.

E. Out-of-Bag (OOB) Error

The Out-of-Bag (OOB) error estimates the model's generalization performance. It is calculated as $\text{Error}_{OOB} = \frac{1}{N} \sum_{i=1}^{N} L(y_i, \hat{y}_{OOB}(\mathbf{x}_i))$, using only samples not included in each tree's bootstrap training. This provides an unbiased estimate without requiring a separate validation set.

Key points:

- Uses only samples excluded from bootstrap training.
- L is 0-1 loss (classification) or MSE (regression).
- Provides unbiased error estimation without cross-validation.

VI. Result

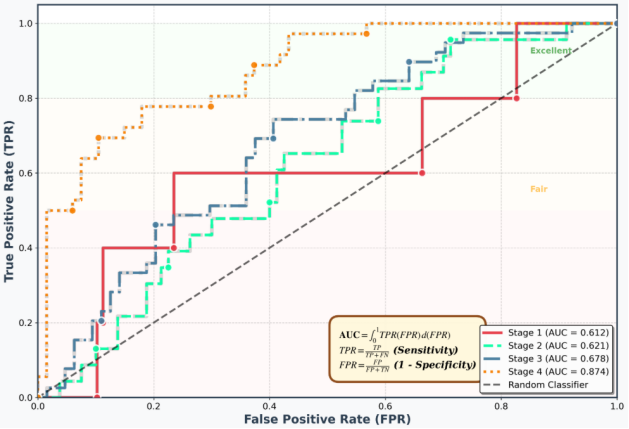
The results obtained through the implementation of the RF model are presented, performing a detailed comparison of the evaluation metrics in order to analyze its performance. Likewise, a comparative review of different methodologies is carried out, with the purpose of identifying the one that best adapts to the characteristics of the proposed model and the context of the study. It is important to highlight that the results obtained not only allow validating the predictive capacity of the model but also constitute a solid basis for decision-making and the proposal of improvements aimed at optimizing its performance.

A. Evaluation of Result

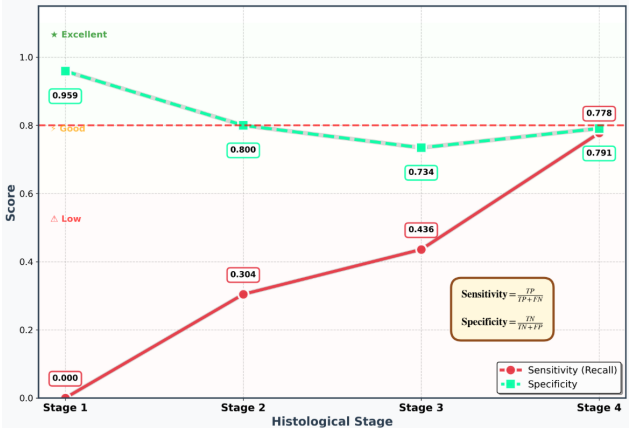
Fig. 6 presents an exhaustive evaluation of the multiclase classification model performance through six key metrics. The panel in Fig. 6a shows the ROC curves, where the area under the curve AUC progressively improves from a borderline value in Stage 1 (0.612) to a robust performance in Stage 4 (0.874). This trend is confirmed in Fig. 6b, where sensitivity increases from 0.000 to 0.778, contrasting with an initially excellent specificity (0.959) that gradually declines toward advanced stages. Similarly, Fig. 6c and 6d show that both precision and F1-score exhibit linear growth, reaching values of 0.667 and 0.718, respectively, in Stage 4, confirming minimal predictive capability in early phases that becomes stronger in later stages. Fig. 6e reveals that class-wise accuracy fluctuates between a maximum of 0.913 (Stage 1) and a minimum of 0.621 (Stage 3), compared to a global accuracy of 0.505 and an average class accuracy of 0.752. Finally, Fig. 6f analyzes predictive values, highlighting that the Negative Predictive Value (NPV) consistently remains higher than the Positive Predictive Value (PPV) across all levels, suggesting that the model has greater diagnostic reliability for excluding stages than for confirming them specifically.

B. Comparison of Methodologies

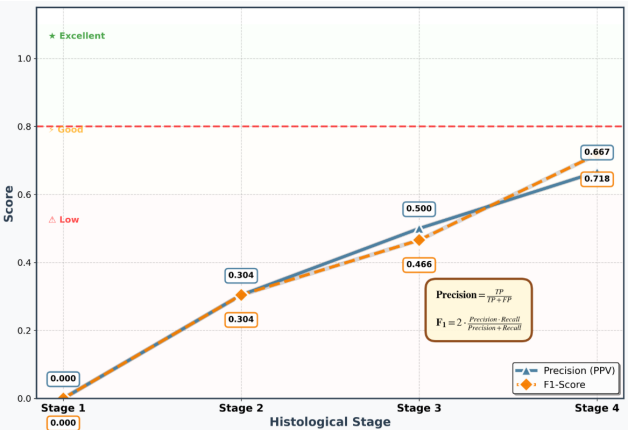
Table VI presents an integrated analysis of three widely used data mining methodologies: KDD, SEMMA, and CRISP-DM. Table VIa provides a qualitative comparison based on key criteria such as main focus, methodological structure, flexibility, scope, advantages, and limitations, highlighting the conceptual differences and strengths of each approach. Table VIb complements this analysis with a quantitative evaluation by assigning realistic percentage scores to each criterion, allowing a clear appreciation of the relative performance



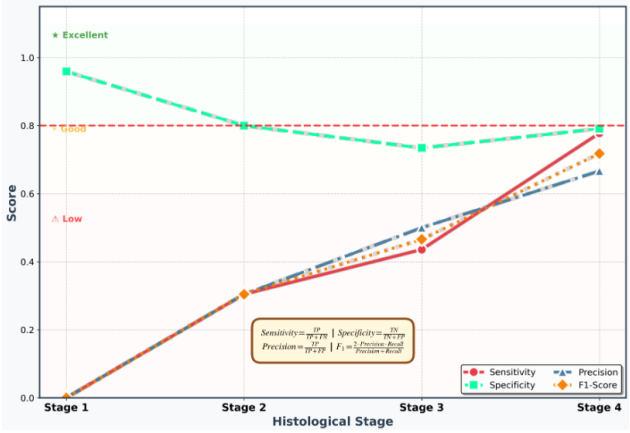
(a) Roc curves - multiclass clasisification.



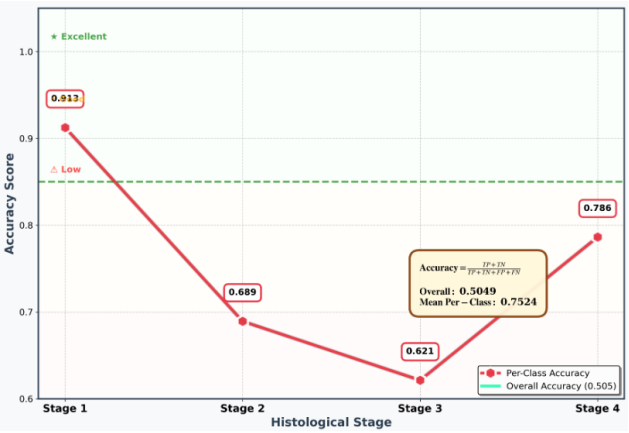
(b) Sensitivity and specificity per stage.



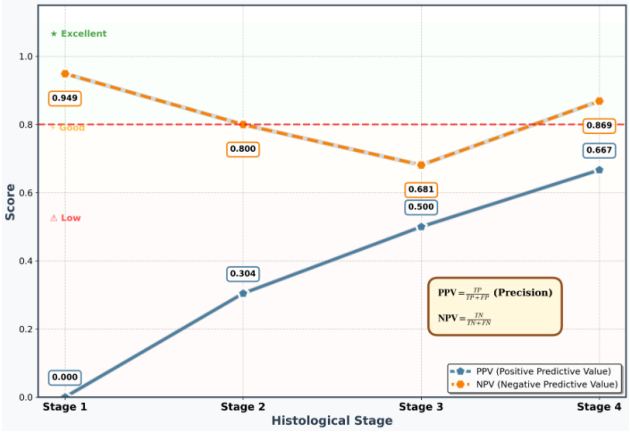
(c) Presicion and F1 score per stage.



(d) Comprehensive performance metrics comparison.



(e) Accuracy metrics per stage.



(f) Predictive values per stage.

Fig. 6. Comparison of ML models based on performance metrics.

of each methodology. The results show that CRISP-DM consistently obtains the highest scores across most criteria, standing out for its adaptability, comprehensive coverage, and alignment with business objectives, thus consolidating itself as the most recommended methodology. This joint presentation allows the reader to simultaneously consider both qualitative and quantitative aspects within a coherent and complete perspective.

VII. Discussion

In the discussion phase, the controversy between the results obtained in our research and those reported by other authors who have addressed similar topics is analyzed. In this section, the coincidences and discrepancies identified are critically examined, contrasting our findings with the existing scientific literature. To this end, the description of our study shows a progressive behavior of the multiclass classification model in predicting the different stages of hepatic cirrhosis, with clear differences in performance metrics as the disease advances. The area under the curve AUC increases steadily, from 0.612 in Stage 1 to 0.874 in Stage 4, reflecting a gradual improvement in the model's ability to distinguish between the different stages. This trend is consistent with previous studies, where algorithms such as RF (RF) and RF (BA) demonstrated good performance in stratifying patients with cirrhosis and other liver diseases [18, 19, 20, 21]. Therefore, the analysis of sensitivity and specificity reveals a complementary pattern: sensitivity increases from 0.000 to 0.778 in advanced stages, while specificity, although initially high (0.959), slightly decreases as the disease progresses. This suggests that the model is more reliable for ruling out early stages than for confirming them, a finding that is consistent with previous observations regarding models trained with limited samples, which tend to underestimate early cases but maintain good accuracy for excluding negatives [29, 30].

On the other hand, precision and the F1-score show a steady increase until reaching 0.667 and 0.718 in Stage 4, indicating that the model consolidates its predictive capacity in advanced phases of the disease. This behavior is consistent with reports by [24] and [22], who also highlight that RF and BA offer strong performance in patients with advanced cirrhosis, especially when evaluating balanced precision through metrics such as the F1-score. Similarly, class-wise accuracy, however, shows some variability across stages: it reaches a maximum of 0.913 in Stage 1 and a minimum of 0.621 in Stage 3, while global accuracy remains at 0.505 and mean class accuracy at 0.752. This dispersion reflects the clinical and biochemical heterogeneity inherent to cirrhosis, a phenomenon also noted in previous studies that emphasize how patient variability and biomarker complexity can limit the generalization of predictive models, particularly in intermediate stages [42, 38].

Finally, the predictive values show that the Negative Predictive Value (NPV) remains higher than the Positive Predictive Value (PPV), indicating that the model is more reliable for ruling out stages than for confirming them. This is consistent with observations from studies that use low-cost biochemical scores such as APRI and FIB-4, which perform well in identifying patients without significant fibrosis progression but have limitations in confirming advanced stages [29, 57, 58]. Compared to the literature on AI-assisted diagnosis, our results complement findings that highlight the usefulness of RF and SVM for early prediction of cirrhosis, hepatocellular carcinoma, and hospital mortality [45, 46, 37]. Although deep learning models or convolutional neural networks (CNN) achieve very high accuracy values [26, 27], our approach has the advantage of being more interpretable and more easily applicable in clinical contexts where multi-omic or textual data are not always available. This is consistent with the recommendations of [43, 44], who emphasize the need for standardized infrastructure so that predictive models can be truly useful and transferable to clinical practice. In summary, these results show that multiclass classification models, although with limitations in early stages, are valuable tools for cirrhosis prediction and monitoring. The consistency with previous studies indicates that evaluating multiple metrics ROC, AUC, precision, F1-score, and predictive values — allows a more comprehensive view of model performance, which supports its potential implementation in clinical practice for informed decision-making and early intervention planning.

VIII. Conclusion

Cirrhosis, along with related diseases, has progressively increased and has shown serious health problems, especially in people with a history of excessive alcohol consumption, viral hepatitis, or fatty liver disease, among other risk factors. In this sense, the proposed research aimed to develop a ML model using the RF algorithm as the main focus. Likewise, for better understanding, the methodology used was CRISP-DM, which includes five stages in the development of the project.

The first phase of the methodology corresponds to business understanding, in which the research problem is defined, the general objectives are established, and the scope of the study is delimited, among other relevant aspects. The second phase focuses on data understanding, allowing the collection, exploration, and preliminary analysis of the obtained information. The third phase is oriented toward data preparation, a process that includes cleaning, transformation, and structuring of the data to ensure its quality and consistency. The fourth phase consists of evaluating the behavior of the RF model, both in identifying explanatory variables and in training the dataset. Finally, the fifth phase presents the comparison of evaluation metrics to analyze the performance of the RF algorithm in the prediction task.

The research evaluated the multiclass classification model applied to histological study and demonstrated a performance that progressively improves as the disease stages advance. The area under the curve AUC increased from 0.612 in Stage 1 to 0.874 in Stage 4, evidencing greater discriminative capacity in the more advanced phases. Consistently, sensitivity, precision, and F1-score also showed an upward trend, confirming that the model more effectively identifies cases corresponding to late stages. Although overall accuracy was moderate, the results indicate that the model has stronger predictive capability in advanced stages than in early phases. Likewise, the fact that the Negative Predictive Value is higher than the Positive Predictive Value indicates that the system is more reliable for ruling out stages than for confirming them specifically. Overall, these findings support the usefulness of the model as a complementary diagnostic support tool,

TABLE VI. COMPARISON AND EVALUATION OF DATA MINING METHODOLOGIES

(A) QUALITATIVE COMPARISON

Criterion	KDD	SEMMA	CRISP-DM
Main Focus	Extraction of implicit patterns and relationships in data	Structured approach to building predictive models	Alignment with business goals and decision-making
Methodological Structure	Conceptual framework with flexible interpretation	Sequential workflow emphasizing data transformation and modeling	Defined stages with iterative feedback loops and documentation
Flexibility	Moderate adaptability depending on domain expertise	Restricted by tool-specific implementation (SAS)	Highly adaptable across industries and project types
Scope	Emphasis on discovering novel insights from raw data	Primarily focused on model optimization and validation	Comprehensive coverage from problem definition to deployment
Advantages	Strong foundation for academic research and innovation	Efficient for rapid prototyping in controlled environments	Widely accepted framework with extensive community support
Limitations	Limited operational guidance for real-world applications	Tool dependency reduces general applicability	Requires more effort in planning and documentation stages

(B) QUANTITATIVE EVALUATION WITH REALISTIC SCORES

Criterion	KDD (%)	SEMMA (%)	CRISP-DM (%)
Main Focus	65	75	90
Methodological Structure	70	80	95
Flexibility	60	65	90
Scope	75	70	95
Advantages	70	80	95
Limitations	50	60	85
Total / Average Score	65.0	71.7	91.7
Winning Methodology	**CRISP-DM**		

especially in the identification and differentiation of advanced stages, contributing to better clinical decision-making.

For future research, it would be appropriate to expand the study by incorporating larger and more heterogeneous clinical datasets from different medical institutions, in order to strengthen the model's generalization capacity in predicting the histological stage of primary biliary cirrhosis. Likewise, it would be possible to explore the comparison of the RF model with other ML algorithms and more advanced ensemble techniques, evaluating potential improvements in predictive performance. It would also be valuable to integrate additional variables, such as specific biomarkers or longitudinal patient information, allowing the analysis of disease progression over time. Finally, the incorporation of model interpretability methods would help facilitate understanding by clinical personnel and promote its application as a decision-support tool in medical practice. Despite the obtained results, the study presents some important limitations. The model showed difficulties in correctly identifying cases in Stage 1, since it registered low sensitivity and AUC values in this early phase. Additionally, the overall accuracy achieved indicates that there is still room to improve general performance. On the other hand, since this is a multiclass model, imbalances may exist among the different stages, which may influence metric outcomes.

ACKNOWLEDGMENT

Thanks to the University of Sciences and Humanities, which made this project a reality.

Deep Learning for Canonical Reconstruction of Deformable Objects from Depth Images in Robotic Vision and SLAM-Aware Perception

Fahd Alhamazani
Faculty of Computing and Information Technology, Department of Computer Sciences,
Northern Border University, Rafha, Saudi Arabia

***Abstract*—Reconstructing the canonical pose of non-rigid objects from arbitrary depth observations is an important problem in robotic vision, particularly for systems that must perceive, track, and interact with deformable objects in dynamic environments. In robotics and SLAM-related perception, depth cameras are widely used to support object recognition, spatial understanding, scene mapping, and motion analysis. However, non-rigid deformation remains challenging because the same object may appear in significantly different poses, making reliable object-level representation and tracking difficult. In this study, we present a deep learning approach for reconstructing the default canonical pose of non-rigid objects from single depth images. The proposed model combines short-range and long-range feature extraction with the original depth input to capture both local geometric details and global structural information. By transforming arbitrary posed observations into a consistent canonical representation, the method supports more stable shape understanding, pose normalization, and object-level perception for robotic systems operating in real-world environments. This is particularly relevant to robotic vision tasks involving human motion analysis, deformable-object tracking, manipulation, and semantic mapping. The model is trained on synthetic human datasets and evaluated on synthetic human, real human, and animal datasets. Experimental results demonstrate improved retrieval accuracy compared with existing methods, showing that the proposed approach can generalize across different non-rigid categories and sensing conditions. These findings highlight the potential of canonical pose reconstruction as a useful component for intelligent robotic perception, depth-based scene interpretation, and SLAM-aware systems that require robust understanding of deformable objects.**

***Keywords*—Depth image; computer vision; feature representation; sensor fusion; object-level SLAM; human–robot interaction**

I. Introduction

Reconstructing the default pose of non-rigid objects from arbitrary poses has become an increasingly important task in fields such as computer vision, computer graphics, medical imaging, and robotics. Non-rigid objects, such as human bodies, animals, and deformable objects, undergo complex deformations that make accurate reconstruction and pose normalization a significant challenge. This task is crucial for numerous applications, including animation, motion tracking and shape analysis. Understanding how to reconstruct a standard or default pose from an arbitrary one is not only vital for precise shape representation but also enhances the ability of intelligent systems to interpret and manipulate 3D objects.

In many real-world applications, obtaining consistent 3D representations from varying poses is necessary. For instance, in animation, characters often need to be represented in a canonical pose to ensure uniformity across different scenes and actions. Similarly, in medical imaging, normalizing poses allows for more consistent comparisons of anatomical structures, which is crucial for accurate diagnostics and surgical planning. In robotics, understanding non-rigid body deformations, such as the movements of animals or humans, helps in designing systems that can interact with or mimic these behaviors effectively.

Existing methods for 3D shape reconstruction have focused on either rigid or non-rigid objects, with varying degrees of success. Traditional rigid body reconstruction methods, such as Principal Component Analysis (PCA) or rigid transformation matrices, are not effective for non-rigid objects, as they cannot handle the complex, localized deformations that occur in flexible bodies. On the other hand, non-rigid reconstruction methods, such as Multidimensional Scaling (MDS) [1], [2], Global Point Signatures (GPS) [3], and detail-preserving mesh unfolding techniques [4], have been designed to capture these deformations but often struggle to balance between global structure preservation and fine-grained local details. Many of these methods require tuning or additional constraints to ensure accurate results, particularly when dealing with large datasets or objects with high variability in pose and shape.

Our work introduces a novel approach for reconstructing the default pose of non-rigid objects using depth images as input. Depth images offer rich geometric information, making them a valuable input format for understanding object deformations. By leveraging both short-range and long-range features, our model can effectively capture fine-grained details, such as edges and textures, while also maintaining the overall structure of the object. This dual approach allows the model to handle complex deformations that occur across varying scales, making it suitable for reconstructing both local and global characteristics of non-rigid objects.

We focus on three main components within our model: short-range feature extraction, long-range feature extraction, and the final reconstruction component. Short-range features help capture detailed deformations in small regions of the object, while long-range features ensure that the model accounts for broader spatial relationships across the entire object. The combination of these components, along with the original input image, enables the model to reconstruct the default pose with

high accuracy. This approach is particularly effective for non-rigid bodies, where both local and global deformations must be accounted for.

In summary, this study presents a new method for reconstructing the default pose of non-rigid objects from arbitrary poses using depth images. By combining short-range and long-range feature extraction, our approach provides a comprehensive solution for capturing both fine details and global structure in non-rigid objects. The results of our experiments show that the model is highly effective in various settings, including human and animal datasets, and generalizes well even when trained on synthetic data. Our findings contribute to the growing body of research in shape analysis and 3D reconstruction, with potential applications in animation, medical imaging, and robotics.

Overall, the main contributions of this study are summarized as follows:

- A short-range feature extraction method to capture local details.
- A long-range feature extraction method to capture global structures.
- The results demonstrate that our model successfully recovers the canonical pose for unseen samples.

II. Related Work

The problem of deforming non-rigid objects to a canonical pose from single depth images has been widely addressed in the literature through various methodologies, including learning-based approaches, shape priors, and deformation networks.

One line of work focuses on Multidimensional Scaling (MDS) approaches. For example, Fast-MDS, introduced by Faloutsos and [1], was an early attempt to reduce the computational overhead associated with MDS, allowing for faster shape matching and reconstruction. Despite its efficiency, Fast-MDS struggles with complex non-rigid deformations, limiting its applicability for canonical pose reconstruction from single depth images. Similarly, Non-Metric MDS and Least Squares MDS, proposed by [2], were designed to handle surface bending and stretching, but these methods also face challenges when dealing with high variability in non-rigid shapes and often require multiple observations to achieve robust results.

Recent advancements have expanded upon these MDS-based methods. Constrained MDS, introduced by [5], integrates additional shape constraints to improve non-rigid shape matching and deformation. This method shows improvements over previous MDS techniques but is limited in its ability to handle single-depth-image inputs, as it still relies on some prior shape knowledge.

In addition to MDS-based methods, shape reconstruction techniques have evolved to focus on the preservation of local and global structures. Global Point Signatures (GPS), combined with skeleton-based matching, was proposed by [3] as an effective approach for non-rigid shape matching. GPS, however, falls short in scenarios where fine-grained deformations and high-resolution details are necessary for accurate canonicalisation.

One of the more recent approaches, Detail-preserving Mesh Unfolding also, developed by [4], focuses on preserving intricate surface details while deforming a shape to its canonical pose. This method has been particularly effective in handling high-resolution surfaces, though it requires significant computational resources, which limits its scalability to real-time applications.

Moreover, learning-based approaches like Deform2NeRF and DIF-Net [6], [7] have shown promising results in deforming objects into canonical poses. These methods leverage neural deformation fields and 2D-3D feature fusion to accurately reconstruct non-rigid objects. While these methods achieve high accuracy in reconstructing complex deformations, their heavy reliance on neural networks introduces high computational costs and data requirements, making them less practical for real-time applications or scenarios with limited training data.

Despite the advancements, the field still faces challenges in developing methods that can robustly handle highly complex, non-rigid deformations with minimal data and in real-time scenarios. Methods that balance computational efficiency with high reconstruction fidelity are crucial for advancing the state-of-the-art in non-rigid shape reconstruction and canonical pose estimation.

III. Methodology

The goal is to restore a non-rigid body to its default pose. The shape, represented in a 2.5D image, may appear in any pose and could be subject to significant deformation, causing parts of the shape to become occluded or heavily distorted. Therefore, the model is designed to learn how to reconstruct the non-rigid shape in a canonical pose, The complete model is illustrated in Fig. 1.

The model consists of three components. The first stage, Section III-A, captures fine-grained, localized information (e.g., edges), which helps in accurately modeling small-scale deformations in parts of the object. This provides the model with crucial details on how local areas deform during movement, essential for recovering fine details in the reconstructed default pose.

The second component, Section III-B, captures spatial relationships over larger distances within the object. These features ensure that parts of the object that are far apart, such as limbs in a human body, remain correctly aligned relative to each other. This step helps maintain the global coherence of the object's structure during reconstruction, ensuring the reconstructed pose is anatomically accurate and free from unnatural distortions.

Finally, the third stage, Section III-C processes the outputs of both the first and second stages to reconstruct the shape in its default pose.

A. Short Range Features

Extracting short range features features from depth images, especially in the context of non-rigid shape deformation help model to focus on the fine-grained information in small regions of the image, such as edges, textures, or surface variations [8]. This helps in identifying detailed characteristics of the shape,

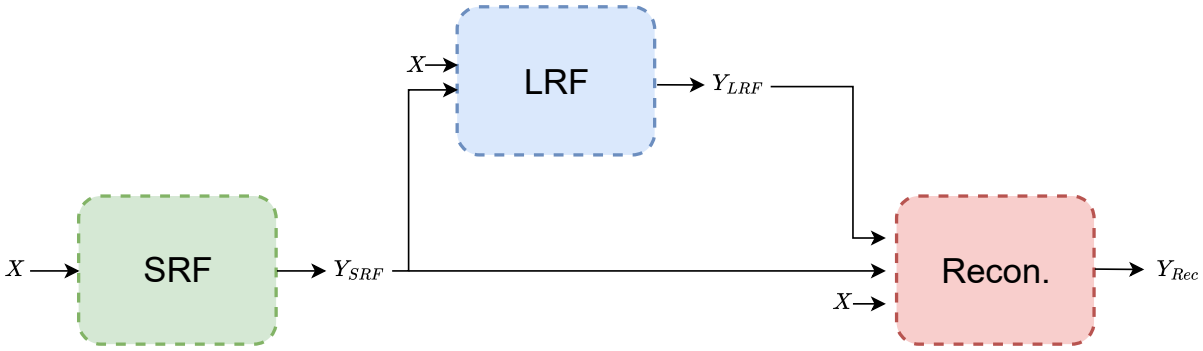

Fig. 1. The complete model first extracts short-range features. Afterward, both the original input and the output of the SRF model (Y_{SRF}) are used as inputs for the long-range features model, which extracts scaled features (Y_{LRF}). Finally, the canonical pose is reconstructed through the reconstruction model (Y_{Rec}).

which are essential for accurately representing and reconstructing the object's geometry in its default pose. Furthermore, Non-rigid objects can deform in complex ways (bending, stretching, etc.). Local features can capture these deformations at small scales, which helps in tracking and understanding how different parts of the shape move or change during deformation (see Fig. 2).

Given a depth image I, where $I \in \mathbb{R}^{500\times500}$, the Short Range Features (SRF) consist of five convolution layers that process the input depth image to extract the short range features:

$$Y_{SRF} = SRF(I)$$

SRE consist of N block, where $N = 9$, each block consist of convolution and Transpose-convolution. At the end, the output Y_{SRF} going to be $Y_{SRF} \in \mathbb{R}^{500\times500}$.

B. Long Range Features

Capture the broader spatial dependencies within the depth image and are crucial for maintaining the overall structure and coherence of the non-rigid object during reconstruction. These features help the model account for how distant parts of the object relate to one another, ensuring that even large-scale deformations are represented accurately. The concatenation of the short-range features with the input image provides a richer representation, enabling the model to leverage both local, fine-grained details and broader spatial information. This holistic understanding ensures that distant parts of the object, such as the extended surfaces, are correctly aligned and positioned relative to one another in the default pose [9] [8].

$$Y_{LRF} = LRF(I, Y_{SRF})$$

Given I and Y_{SRF} input depth image and extracted local features, respectively, the Long Range Feature (LRF) process both the image and the extracted features to produce the long features. The model consist of N block where $N = 5$, each block consist of convolution layer with dilation value to capture long range. The dilation range values in order $dilation = [2, 3, 4, 5, 6]$.

C. Default Pose Reconstruction

The reconstruction component synthesizes all this information to output the default pose in the form of a depth image. The model uses both localized details (from short-range features) and overall structure (from long-range features) and to infer the original, undeformed pose (input depth image) were also utilised. This approach allows the Default Pose Reconstruction (DPR) component to handle complex deformations by integrating both fine-grained and large-scale spatial information, ensuring accurate and detailed default pose reconstruction.

$$Y_{DPR} = DPR(I, Y_{SRF}, Y_{LRF})$$

Given I, Y_{SRF}, and Y_{LRF}, the DPR component processes this information to reconstruct a shape in the default pose, Y_{DPR}, where $Y_{DPR} \in \mathbb{R}^{500\times500}$. The component consists of an Encoder-Decoder architecture, where the encoder is made up of $N = 4$ blocks, and the decoder consists of $K = 4$ blocks. Each encoder block contains convolution, LeakyReLU activation, and max-pooling layers to reduce dimensionality, while each decoder block employs transposed convolution and ReLU activation.

D. Loss Function

The model utilise two loss functions (see Fig. 3):

Depth Loss. We employ the Mean Squared Error for the depth loss:

$$L_{Depth} = \frac{1}{N}\sum_{i=1}^{N}(\hat{y}_d - y_d)^2$$

Here, $\hat{y}_d$ and y_d represent the predicted depth and the ground truth depth, respectively.

Mask Loss. As we want the model focus on the shape only, we make the model learn the mask of the shape by adding mask loss:

$$L_{Mask} = \frac{1}{N}\sum_{i=1}^{N}(\hat{y}_m - y_m)^2$$

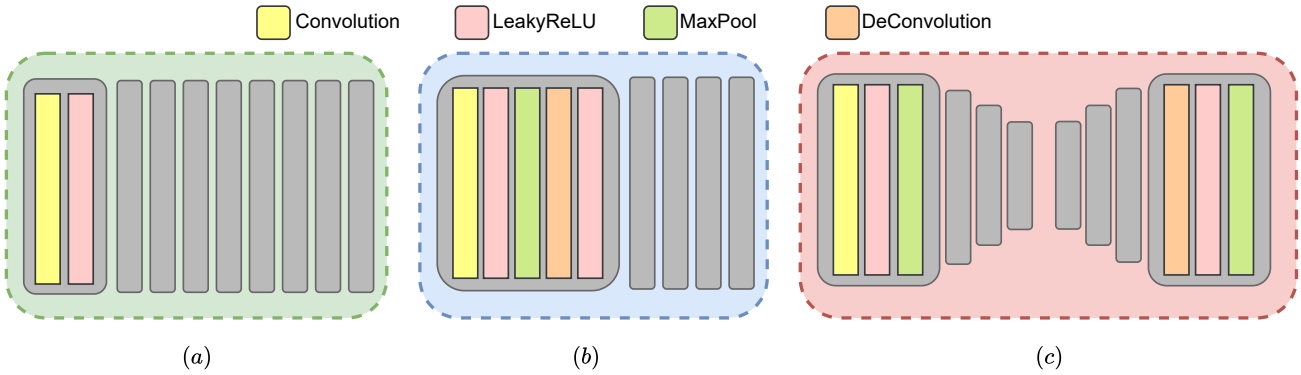

Fig. 2. (a) Shows the SRF layers, where the sub-model consists of nine blocks. Each block contains a convolution layer followed by a LeakyReLU activation. (b) Shows the LRF layers, consisting of five blocks, where each block includes both convolution and deconvolution operations with different dilation rates. (c) Shows the reconstruction sub-model, which includes an encoder–decoder architecture.

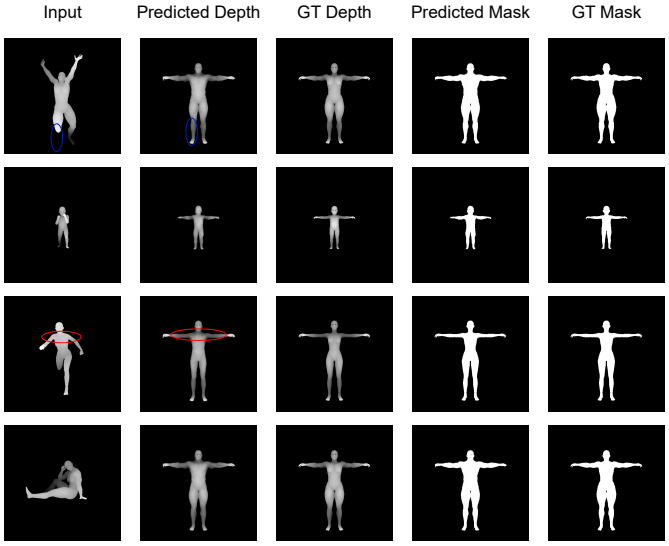

Fig. 3. Our model results on the synthetic dataset. The model predicts both the depth image (second column) and the mask (fourth column). The blue circle shows that the model can recover missing parts. The red circle shows that the model can correctly predict the depth values for the shoulders.

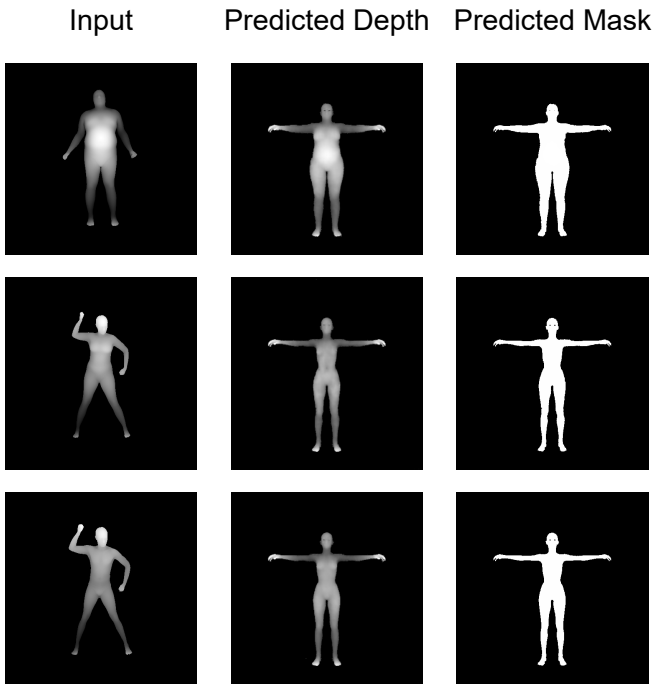

Fig. 4. Our model results on real human datasets. The model was trained on synthetic data and then tested on a real human dataset.

Combined Loss. We introduce coefficients α and β to balance the training:

$$L_{weighted} = \alpha L_{Depth} + \beta L_{Mask}$$

IV. Experiments

A. Training Details

We trained our model for 500 epochs using an end-to-end approach. In the initial phase of training, we set the weighting parameter $\beta = 1$ and $\alpha = 0.01$ for the first 100 epochs. This strategy was employed to allow the model to primarily focus on learning the mask of the shapes during the early stages, thereby reducing the overall complexity of learning the canonical form in the depth format. After the first 100 epochs, both α and β were set to 1, enabling the model to simultaneously learn both the mask and the canonical form with equal emphasis. This progressive learning approach was validated through an ablation study, which demonstrated its effectiveness in simplifying the learning process for depth-based reconstruction.

The model was trained using the Adam optimizer with a learning rate of 0.001, on an NVIDIA RTX 4090 GPU with 24 GB of memory. The total training time was approximately three days with a batch size of 8.

B. Dataset

We conducted our experiments using three datasets: two human datasets and one animal dataset.

The first dataset, provided by [10], consists of 400 samples captured from real human subjects. This dataset represents 40 unique individuals, with each subject contributing multiple samples.

The second dataset, also from [10], comprises synthetic human subjects and includes 300 samples in total. These synthetic samples offer controlled variations that complement the real-world dataset.

To demonstrate the generalizability of our model beyond human subjects, we employed the TOSCA dataset [11], which contains 3D models of animals. This allows us to evaluate the model's ability to reconstruct non-human shapes effectively.

All datasets were processed using Blender and automated with Python scripts. For each sample, we generated depth images of size 500×500, ensuring that the shapes were centered in the frame before capturing the images.

C. Evaluation

For evaluation, we followed the methodology used in previous studies [12], [13], and assessed our model based on retrieval results. Specifically, we employed the Clock Matching and Bag-of-Features (CM-BOF) approach to produce the retrieval results. For a more detailed explanation of CM-BOF, refer to [14].

We selected four evaluation metrics to assess the performance of our model. The first metric is Nearest Neighbour (NN), which finds the nearest neighbor to a point using a specified distance metric. The second metric is First Tier (FT), which measures the precision at the first rank or within the top-n results of the retrieval. The third, Second Tier (ST), extends FT by considering a larger set of result (top-m where $m > n$). Finally, we use Discounted Cumulative Gain (DCG) to evaluate the effectiveness of the ranking algorithm by taking into account the relevance of retrieved items and their positions in the ranking.

D. Comparison to Prior Works

For comparison, we selected several methods from previous studies. These include the Fast-MDS approach proposed by [1], and the Non-Metric MDS method, based on Multidimensional Scaling (MDS), introduced by [2]. Additionally, we included Least Squares MDS from the same study [2].

We also compared our method against the Accelerated MDS approach [15], which improves the efficiency of traditional MDS algorithms. Furthermore, we considered Constrained MDS, a method that integrates specific shape constraints during the MDS process [5].

In addition to MDS-based methods, we evaluated our approach against shape analysis techniques such as Global Point Signatures (GPS), and a Skeleton-based method [3], both of which have demonstrated effectiveness in shape matching tasks. Finally, we included the Detail-preserving Mesh Unfolding method [4], which focuses on preserving fine geometric details during shape reconstruction.

E. Result

We evaluated our model on three datasets: synthetic humans, real humans, and animals. For the synthetic human dataset, we split the subjects into a training set of 10 subjects and a test set of 5 subjects (the results shown in Table I). Our model demonstrated a noticeable improvement over previous methods, showing a significant margin of enhancement in the retrieval results.

For the real human dataset (the results shown in Table II and Fig. 4), we followed an unseen setup, where the model was trained on the synthetic dataset and tested on the real human data. Despite the challenge of domain adaptation, our model exhibited substantial improvements, further confirming its generalization capabilities.

Finally, for the animal dataset (the results shown in Table III and Fig. 5), we used the cat and horse samples as the test set, with the remaining animal data used for training. In this case, too, our model outperformed prior approaches, showing marked improvements in retrieval performance compared to existing methods.

V. ABLATION STUDIES

We conducted several experiments to evaluate the effectiveness of different components of our model. The ablation study is designed to demonstrate the impact of each component on the overall performance, the results are shown in Table IV.

A. Disabling Short-Range Features

In this experiment, we disabled the short-range feature extraction component of the model. As a result, the retrieval performance degraded significantly, indicating that short-range features are crucial for capturing fine-grained details necessary for accurate shape reconstruction.

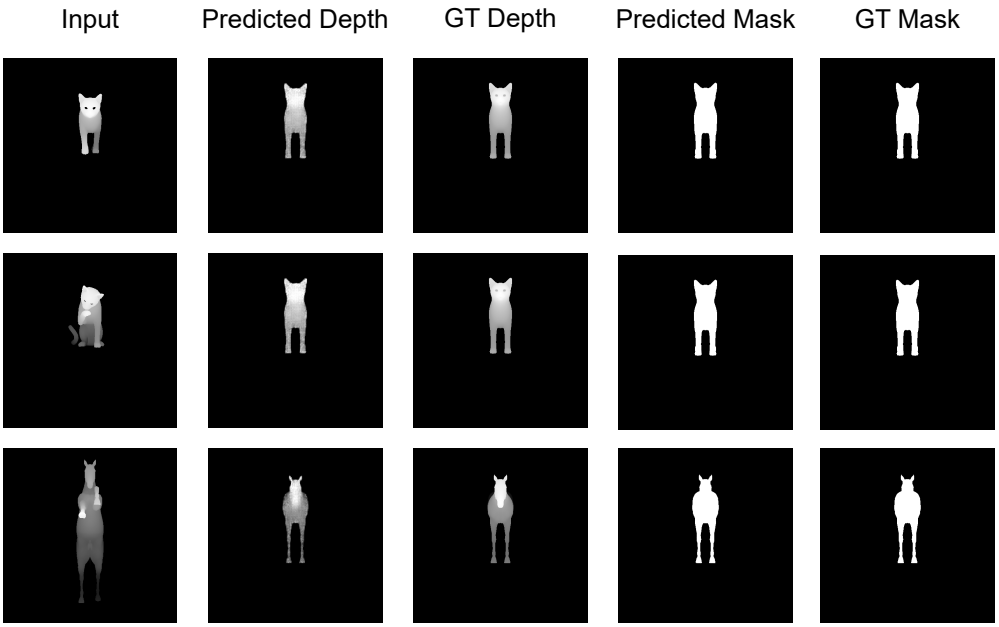

Fig. 5. Our model results on the TOSCA dataset.

B. Disabling Long-Range Features

When we disabled the long-range feature extraction component, we observed a noticeable degradation in performance compared to the full model. This highlights the importance of long-range features in learning the global structure of the object and suggests that the model effectively utilizes these features to improve reconstruction accuracy.

C. Strict Train-Test Split

To further challenge the model, we performed a strict split, where both pose and subject were excluded from the training set. We implemented this as a cross-validation process, ensuring that the model was tested on all poses and subjects. The model showed resilience under this challenging setup, further validating its generalization ability.

VI. CONCLUSION

In this work, we presented a model for reconstructing the default pose of non-rigid objects from any given pose using depth images as input. Through a combination of short-range and long-range feature extraction, along with the original input, our model demonstrated significant improvements over previous methods, particularly in complex shape deformation scenarios.

Our experiments on synthetic and real human datasets, as well as an animal dataset, showed the model's robustness and generalization capabilities. Specifically, our model achieved notable gains in retrieval accuracy, especially in challenging setups, where the training and test data included unseen poses and subjects.

Accelerating Blockchain Consensus: A Parallel Mining Approach for High-Throughput, Low-Latency Networks

Sohail Jabbar
College of Computer and Information Sciences,
Imam Mohammad Ibn Saud Islamic University (IMSIU),
Riyadh, 11432, Saudi Arabia

Abstract*—*Problem: **Blockchain consensus remains constrained by slow transaction verification, redundant mining effort, high communication overhead, and increased confirmation latency as the number of nodes grows.** ***Objective:*** **This study proposes NCABS, a controlled parallel mining consensus approach intended to improve blockchain throughput, latency, transaction commit rate, and resource utilization.** ***Methodology:*** **NCABS combines verifiable head-miner selection, transaction-validation delegation, parallel block generation, and a 75% confirmation threshold. The framework is evaluated against Practical Byzantine Fault Tolerance (PBFT) through ten repeated experiments over node densities from 40 to 140, using throughput, latency, communication load, transaction commit rate, scalability, and responsiveness as performance metrics.** ***Results:*** **The plotted results show that NCABS achieves higher throughput and transaction commit rates than PBFT, reduces aggregate communication messages by approximately 45%, and lowers latency at 40 nodes from about 310 ms for PBFT to about 195 ms for NCABS. In the transaction-commit-rate experiment, NCABS reaches approximately 3200 transactions per second, compared with about 2200 transactions per second for PBFT.** ***Conclusion:*** **The findings indicate that controlled parallel mining can reduce redundant computation and communication while improving blockchain responsiveness. The current evaluation is performance-oriented; adversarial testing and broader empirical comparison with additional consensus baselines are identified as future work.**

Keywords*—*Blockchain; consensus algorithm; parallel mining; PBFT; high transaction rate; low-latency

I. Introduction

Blockchain-based systems combine cryptography, public key infrastructure, and economic modeling to synchronize distributed databases through peer-to-peer networking and decentralized consensus. This technology has the potential to revolutionize various business areas and is expected to be rapidly adopted into mainstream use in a wide range of domains [1]. Blockchain technology has immense potential, but its market penetration is still relatively low. The ecosystem surrounding blockchain is not yet mature enough to support its widespread use, especially in supply chain applications. This is because most supply chains today involve many geographically dispersed and professionally diverse stakeholders, making them complex and difficult to manage. Therefore, extensive groundwork is required before blockchain can be adopted on a large scale. A recent study by Jabbar *et al.* [2] provides a detailed analysis of blockchain-enabled supply chains, discussing the challenges and future directions. The most significant challenge the blockchain ecosystem faces is scalability, which affects transaction processing speed and efficiency. Compared to traditional databases, blockchain is slower in retrieving and committing records, and it requires more computing resources. The scalability of these resources is a major concern as it affects the system's ability to respond and function effectively as the size of input increases to meet user demand [3]. Scalability is crucial in three key aspects of a supply chain system: 1) Throughput, which refers to the efficiency of producing results; 2) Storage, which involves maintaining transaction records; and 3) Network communication, which pertains to the number of messages exchanged among nodes to finalize a transaction. This study focuses on throughput and network communication scalability.

Considering the founding cryptocurrency, Bitcoin can handle $4--5$ transactions per second. As the average transaction size is 380.04 bytes and the block size is $1,048,576$ bytes, the number of transactions per block is $2,759.12$. The current block generation time is 600 seconds (10 minutes). Conversely, traditional centralized payment systems, e.g., VISA, MasterCard, and PayPal, offer significantly higher transaction rates per second [4]. VISA processes over a million daily transactions, i.e., around 1800 per second. From a storage perspective, the size of the Bitcoin Blockchain has grown steadily since its creation. It reached approximately 242.39 gigabytes in size as in Q3, 2021, while it was only $53,647$ MB in Q4, 2015. In Ethereum, transactions increased from just USD $ 3,000 in Oct 2015 to over one million in Jan 2023. Improving network communication is crucial for reducing energy consumption and propagation delay. In Blockchain, each node acts as a relay, broadcasting all transactions at least twice. When a transaction is generated, it is first broadcast to all nodes. Once a block containing the transaction is mined, it is rebroadcast to all nodes. Unfortunately, this process leads to block propagation delay [5]. Given this process, increasing the data transmission rate to handle a large volume of transactions is not feasible, as it requires more network bandwidth. Hence, it is essential to develop more effective data transmission mechanisms. Additionally, the number of transactions per block, N_{tx}, is determined by the maximum block size, B_{size}, and the average transaction size, T_{size}, as shown in Eq. (1):

$$N_{tx} = \left\lfloor \frac{B_{size}}{T_{size}} \right\rfloor \tag{1}$$

The throughput, θ, is the rate at which transactions are processed, which is defined by the number of transactions per block and the block generation time, T_{block}, as described in Eq. (2):

$$\Theta = \frac{N_{tx}}{T_{block}} = \frac{\left\lfloor \frac{B_{size}}{T_{size}} \right\rfloor}{T_{block}} \tag{2}$$

The delay in block propagation, Δt_{prop}, is a function of the network topology and the number of nodes N, as shown in Eq. (3):

$$\Delta t_{prop} = f(N, networktopology) \tag{3}$$

The total transaction confirmation time, $T_{confirmation}$, is the sum of the transaction propagation delay, the mining time, and the block propagation delay, as defined in Eq. (4):

$$T_{confirmation} = \Delta t_{txProp} + T_{mining} + \Delta t_{blockprop} \tag{4}$$

In a parallel mining system like NCABS, the total consensus time, T_{NCABS}, is the minimum time among all parallel tasks, as shown in Eq. (5):

$$T_{NCABS} = \min(T_1, T_2, \ldots, T_k) \tag{5}$$

The communication complexity of the PBFT algorithm, C_{PBFT} is of the order of the square of the number of nodes, as shown in Eq. (6):

$$C_{PBFT} = O(N^2) \tag{6}$$

The contributions of this research study in the blockchain scalability domain are enumerated as follows. The first two are considered major contributions, while the next two are of second and third-level need and importance.

- A new consensus mechanism, NCABS, has been proposed to speed up consensus in blockchain. This mechanism uses parallel mining instead of solo or repetitive mining, making it a strong solution for achieving the target. To help readers better understand this, a graphical presentation of the various steps involved in consensus-based scalability solutions for blockchain has been included.
- A detailed experimental comparison of PBFT and NCABS is presented, focusing on throughput, network latency, scalability, and responsiveness, with results depicted.
- A comparative analysis of PBFT variants, including Multi-layer PBFT, NBFT, CDBFT, and RBFT, is presented in a summarized tabular format and a discussion.
- A multi-layer categorization of available scalability solutions in the literature is provided, along with their extended versions.

II. Problem Formulation

This study considers a blockchain network consisting of N nodes, where each node participates in transaction validation and block generation. The key challenge is to minimize:

- Transaction confirmation time ($T_{\text{confirmation}}$)
- Resource utilization (CPU, energy)
- Network communication overhead

Subject to the following constraints:

- Maintaining consensus correctness
- Avoiding forks
- Ensuring fairness among miners

Formally, the objective function is defined as Eq. (7):

$$\begin{aligned} \min \quad & T_{\text{confirmation}} + \lambda_1 \cdot \text{ResourceUsage} \\ & + \lambda_2 \cdot \text{CommunicationCost} \end{aligned} \tag{7}$$

Such that [see Eq. (8) and Eq. (9)]:

$$\text{Consensus Validity} \geq 75\% \tag{8}$$

$$\text{Fork Probability} \rightarrow \min \tag{9}$$

The formulation reflects three observations that guide the design of NCABS. First, confirmation delay increases when many miners repeat the same transaction-verification and nonce-generation work. Second, PBFT-style consensus becomes communication intensive as the network size grows because message exchange increases with node density. Third, a controlled validator and head-miner selection process is needed so that performance gains do not come at the expense of consensus correctness or fork resistance.

III. Literature Survey

Tian Junfeng *et al.* [6] proposes a parallel mining-based enhancement to blockchain consensus that improves throughput and reduces latency by enabling concurrent mining operations. It introduces coordination mechanisms to maintain consistency and security while minimizing forks. Experimental results demonstrate significant performance gains, making the approach suitable for scalable, high-performance blockchain applications.

Yin Lingyuanan *et al.* [7] proposes a parallelism-enabled blockchain consensus framework to overcome the limitations of traditional PoW-based systems. By allowing concurrent mining and validation processes, the approach improves throughput and reduces latency, while maintaining consistency and security through coordination mechanisms. Experimental results confirm its effectiveness for scalable and real-time blockchain applications. The work by Lulu Ke *et al.* [8] proposes a blockchain-based framework for vaccine supply management that ensures verifiability, traceability, and data integrity. By eliminating reliance on centralized authorities and introducing an improved digital signature scheme, the

approach enhances both security and efficiency. Experimental results demonstrate reduced computational cost and improved trust, making it suitable for real-world healthcare supply chains.

Soohyeong Kim *et al.* [9] classified the scalability methods as on-chain, off-chain, side-chain, child-chain, and inter-chain solutions. Junfeng Xie *et al.* [10] categorized scalability solutions into four groups: the number of transactions, block interval time, data storage, and data transmission. This study classifies blockchain scalability solutions into three categories: on-chain, off-chain, and consensus mechanism-based. The following paragraphs briefly review each category, and Fig. 1 provides a visual representation of the classification. Although several solutions exist in each category, only representative methods are discussed due to space constraints.

The statistical gap motivating scalability research is substantial. Bitcoin typically processes about 4–5 transactions per second, while Ethereum is commonly reported at around 15 transactions per second and permissioned systems can achieve higher rates under controlled membership. In contrast, conventional payment systems such as VISA are reported to process around 1800 transactions per second in the cited literature [4]. This gap is intensified by communication complexity: PBFT-based designs require all-to-all message exchange with $O(N^2)$ communication cost [11], whereas scalable blockchain deployments require transaction throughput and confirmation latency to remain stable as the number of nodes increases.

A. On-Chain Solutions

Require a structural or fundamental change to the blockchain, and thus a modification to the protocol's underlying rules. This is technically known as a *hard fork* or *controversial hard fork* when there is a split in the community, as groups form who accept or reject the proposed update. Some popular examples of new currencies addressing the scalability issue that have resulted from a hard fork are as follows: *Bitcoin Cash* - Increases the block limit $(1MB - 8MB)$, *Litecoin* - Reduces block generation time $(10min - 2.5min)$, *DASH* - Higher transaction speed. For comparison, in the case of Ethereum, the maximum capacity is 15 transactions per second, and permissioned Blockchains typically offer much higher transaction throughput than an open and permissionless network. Changes to the Bitcoin Blockchain's proof-of-work parameters could be an option to increase scalability; for example, decreasing the block generation time or increasing the block size [12]. Still, these are unlikely to be feasible solutions, since they cause effects such as orphan blocks, forks, chain reorganization, slower network propagation, and, in extreme cases, security vulnerabilities such as selfish mining and double-spend attacks. Another method in this category to improve Blockchain scalability is *sharding*. This is a way to divide blockchain data across nodes, enabling transactions to be processed in parallel. Instead of every node processing every transaction and storing all the data, nodes are grouped, with each group handling and processing a portion of the data. This helps scale the network by enabling high concurrency. *Segwit* (Segregated Witness) is an upgrade to the data structure (transaction format) of the Bitcoin protocol. The transaction is segregated into original data and signature data (witness). The witness data is separated from the Merkle tree record [13] and appended as a separate structure at the end. This upgrade is part of the Litecoin protocol.

B. Off-Chain Solutions

It uses secondary protocols built on top of the main blockchain and are, therefore, referred to as a *second-layer* scalability solutions. In this approach, transactions are offloaded from the main blockchain and performed privately between the interacting partners. It confers the advantages of reduced congestion on the MainNet, increased throughput, reduced transaction fees, and space savings. Many off-chain solutions for various platforms are available in the literature, e.g., [14], [15]. *Lightning Network* [14] covers small and everyday transactions that do not need to be stored on the Bitcoin MainNet. Off-chain approaches to scalability issues in Ethereum include the Raiden network and Plasma cash [16], [17]. These off-chain mechanisms reduce the number of transactions of the entire network processes, though they still require at least two transactions to initialize and terminate the off-chain channels.

Optimizing the working of the ***Consensus algorithm*** can also aid in addressing scalability [15] issues. The **Proof of Work** (PoW) was first introduced with Bitcoin. It engages all miners simultaneously in a competition to create a block, and only the first to produce a valid block is accepted and rewarded. Thus, the energy and computational resources of the other nodes are wasted [15]. In contrast to PoW, **Proof of Stake** (PoS) chooses a validator among all the participating nodes using a stake-based selection algorithm. An exclusive right to create a block is assigned to this selected node, while the remaining nodes do not need to waste energy or computational resources. In contrast to PoS, **Delegated Proof of Stake** (DPoS) operates democratically, with delegates elected by token-holding nodes. EOS.IO is a decentralized Operating System that uses DPoS as its consensus algorithm, focused on scalability and capable of processing millions of transactions per second. *Steemit* featuring STEEM, SteemPower, and SteemDollar as native cryptocurrencies is a Blockchain-based social media platform. It uses DPoS and Graphene to process millions of transactions per second efficiently. In the domain of financial transactions, *Bitshare* is a decentralized platform designed to enhance transaction processing speed. Another DPoS-based solution to the scalability issue in blockchain at the second layer is *Lisk*.

It is a modular blockchain platform with smart contract functionality, which offers a partial solution to the blockchain scalability problem through the use of sidechains. Until now, all the extensions mentioned here have not reached maturity and are still under development. The **Byzantine Fault Tolerance** (BFT) consensus algorithm gives a solution to a classic problem in distributed computing, the *Byzantine General Problem*. BFT takes different forms: practical BFT, Federated Byzantine Agreement, Delegated BFT, and others. Practical BFT (PBFT) can scale to large computational loads with only a minimal increase in latency [11]. Among many other projects that use the BFT are LibraBFT, Hyperledger Fabric, and Zilliqa. The *Stellar* Consensus Protocol (SCP) is an improved implementation of the Federated Byzantine Agreement. It requires multiple rounds of voting to reach

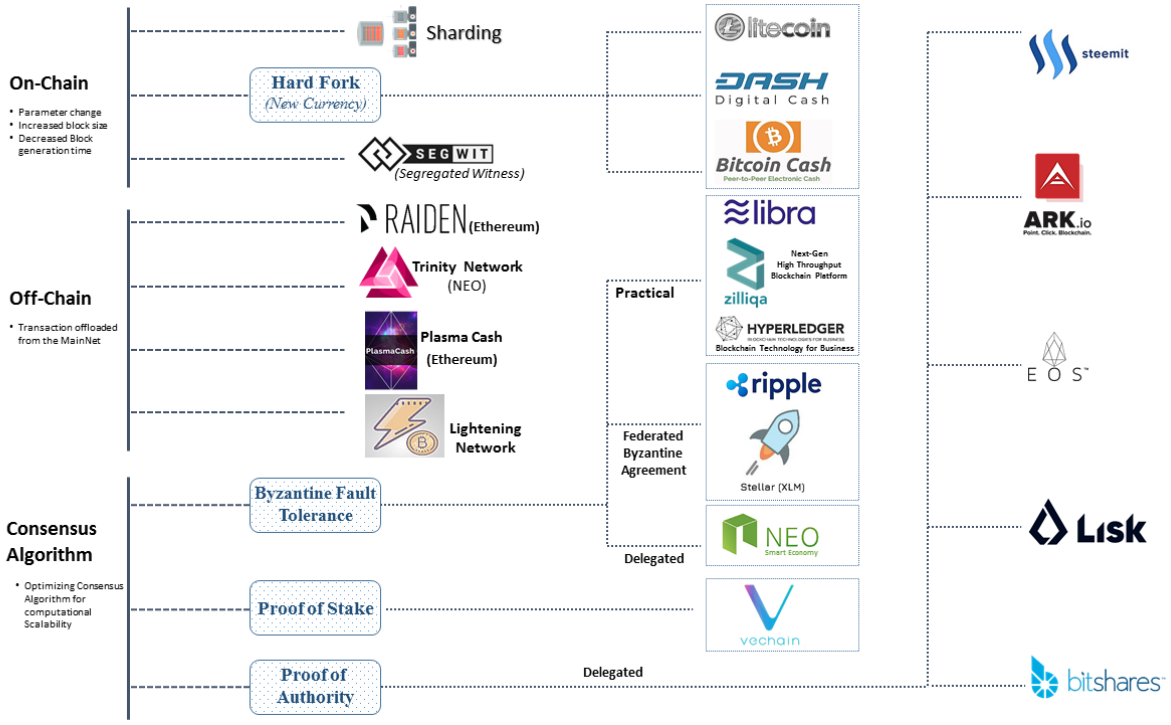

Fig. 1. Categorization of scalability solutions for the blockchain.

consensus, which generates significant network traffic. However, the messages are lightweight and within the capabilities of the currently available Internet. A further extension to SCP is the *Pi* Consensus algorithm, specifically designed for low-energy/computationally power devices such as home PCs and mobile phones. The *Bitcoin-NG* consensus algorithm [18] reduces latency and increases throughput by using leader election to append microblocks.

Some other extensions of PBFT that work for the scalability of the Blockchain network are Kauri [19], Hotstuff [20], and DBFT [21]. A comprehensive performance modeling and analysis of Hotstuff for Blockchain consensus is given in [22]. A detailed article on the challenges of PBFT-inspired consensus for blockchain and enhancements over neo dBFT is available at [23]. This proposed scalability solution, NCABS, is categorized as optimizing the Consensus algorithm to improve the scalability of the Blockchain network. Existing methods either improve throughput at the cost of communication overhead or reduce energy consumption while sacrificing decentralization. NCABS addresses both issues, simultaneously. Table I presents the comparison of blockchain consensus methods.

TABLE I. COMPARISON OF BLOCKCHAIN CONSENSUS METHODS

Method	Parallelization	Limitation	Gap
PBFT	No	$O(N^2)$ communication	Not scalable
PoW	No	Energy waste	Inefficient
Parallel Mining (existing)	Yes	Fork risk	No control
NCABS (Proposed)	Yes	—	Controlled & efficient

IV. PRELIMINARIES

The following is a brief description of key terminology and concepts to better understand the proposed solution and the rest of the study.

A. Cryptocurrency Addressing

An alphanumeric identifier of 26-35 characters representing different cryptocurrency presentation formats, beginning with the numbers 1, 3, or bc1, is shown in Fig. 2. The figure provides a self-explanatory depiction of the formats, characteristics, validation, and generation of cryptocurrencies.

The public key (K_pub) is first hashed using SHA-256 and then RIPEMD-160 to produce a public key hash $(Hpub)$.

$$H_{pub} = \text{RIPEMD160}(\text{SHA256}(K_{pub})) \tag{10}$$

The resulting public key hash is shown in Eq. (10). Next, a version byte (V) is prepended to the hash to create the versioned payload (P_V):

$$P_V = V \mid H_{pub} \tag{11}$$

Eq. (11) illustrates the concatenation of the version byte with the hash. A 4-byte checksum (C) is generated by performing a double-SHA-256 hash on the payload and extracting the first four bytes.

$$C = \text{Substr}_{0,4}(\text{SHA256}(\text{SHA256}(P_V))) \tag{12}$$

The checksum calculation is formally defined in Eq. (12). The checksum is appended to the versioned payload to form the complete binary address (A_bin).

$$A_{bin} = P_V \mid C \tag{13}$$

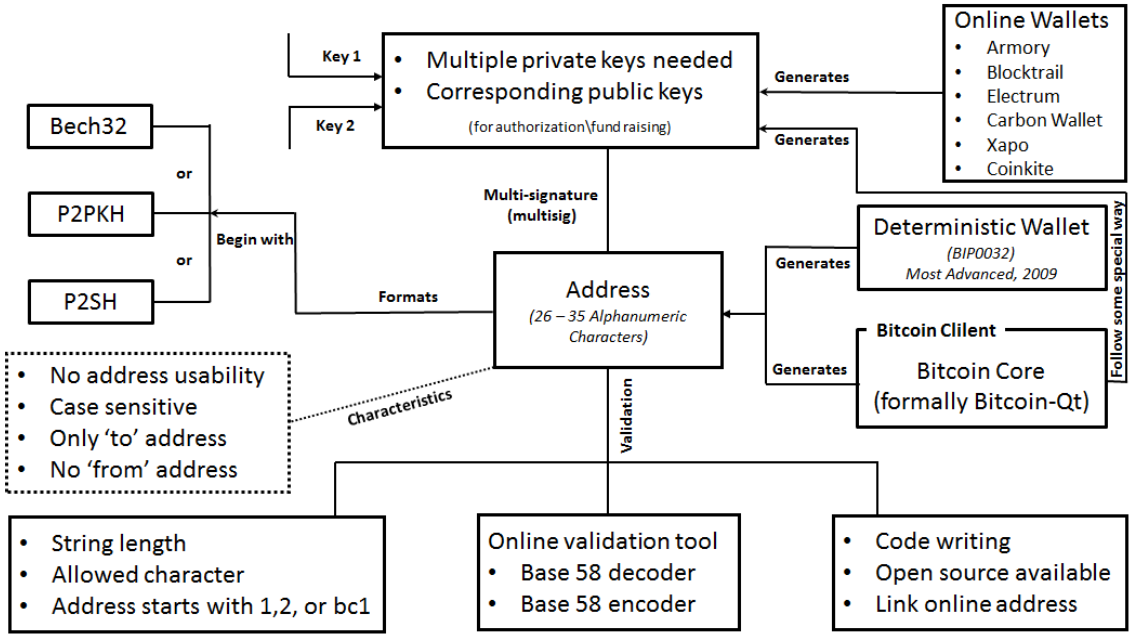

Fig. 2. Cryptocurrency address format, characteristics, generation, and validity.

The final binary address is constructed by appending the checksum, as shown in Eq. (13).

Finally, the binary address is encoded using the Base58 alphabet (A_58) to produce the human-readable address (A_addr).

$$A_{addr} = \text{Encode}\mathcal{A}58(A_{bin}) \tag{14}$$

The human-readable address is generated through Base58 encoding as per Eq. (14).

B. Genesis Block

The Genesis Block is the first block in a blockchain. In the case of the Bitcoin Blockchain, it was initially numbered '1', but modern versions start with '0'. This block is hard-coded and serves as a trusted starting point for the participants. It is an unspendable subsidy that does not refer to a previous block. The genesis block is indexed as 0 in modern implementations.

C. Unspent Transaction Output: UTXO

UTXO is an indivisible chunk that currently represents the "Right to Spend" of someone at a given moment and is recorded on the blockchain. Every received currency chunk is recorded as a UTXO in the blockchain and is scattered throughout the blockchain, even from a particular owner. The Wallet scans the blockchain and calculates the user's balance. The UTXO data on the blockchain is stored in a database table in local memory or in a permanent storage called the UTXO set or UTXO pool.

D. Transaction Format

The UTXO consumed by a transaction (i.e., payment or a transaction fee) is termed transaction input, while transaction output is the UTXO created by a transaction (i.e., change of "Right to Spend" authority or small money returned as change by the spending money with a large valued UTXO).

E. Transaction Fee

A transaction fee is a charge levied on users for each cryptocurrency transaction. This fee is collected to process the transaction on the network. The transaction fee is calculated on the basis of the transaction size in kilobytes. Some wallets automatically calculate and include the transaction fee. Therefore, the user needs to choose a wallet that suits their needs. Additionally, it is crucial to note that the wallet must source a set of UTXOs that add up to sufficient currency (the transaction amount plus the transaction fee). Manual accounting for the transaction fee is recommended when wallet-level fee estimation is unavailable.

F. Merkle Tree

Merkle Root comes up with a Merkle tree when a repeated encryption process forms a tree structure and ends up at a single hashed value. In Ethereum, the state's information is stored in the *Merkle Particia*. It is for preventing the Block from any counterfeit. The *Merkle Path* in the Merkle Tree helps a node find a particular transaction quickly and easily. The conditional state update of the blockchain is represented in Eq. (15):

$$\mathcal{C}_{t+1} = \begin{cases} \text{Append}(\mathcal{C}_t, B_{\text{new}}), & \text{if } \left(\sum_{m_j \in M} V(B_{\text{new}}, m_j) \right) \geq \frac{3}{4}|M|, \\ \mathcal{C}_t, & \text{otherwise.} \end{cases} \tag{15}$$

V. Proposed Solution

In the proposed idea, only some miners participate in the nonce generation and hence do not pick up the transaction from the unconfirmed pool. Each miner generates a random number, and their timer is set to it. The one with the lowest random number value can pick up the transaction. To reduce miners' computational load and save verification time, the relevant data is communicated to the specific node. The selection of this particular node is on the part of the selected miner. The selected miner generates a random number from the range of the total number of nodes and sends the required data to that selected node. The selected node verifies the shared transaction and performs the necessary hashing, culminating in the generation of the Merkle tree that ends at the Merkle root. This selected node shares the data with the head miner. The head miner solves the puzzle for generating the nonce value (explained in the subsection Nonce Generation).

This contrasts with the traditional nonce-value generation competition among all miners, which consumes and wastes computational power and delays block generation. Next to it is the new block generation by the head miner. This newly generated block is appended to the existing blockchain and shared among miners for validation. On having validity confirmation from $\frac{3}{4}th$ of the total miners, this blockchain is replicated to all the miners. A transaction confirmation message is sent to the transaction's direct stakeholders. The detailed workings of the proposed scheme, along with the architectural and communication models, are presented in subsequent subsections. Table II gives some commonly used terms and their descriptions. A schematic diagram of the consensus algorithm-based scalability solution for blockchain is given in Fig. 3. Also, a detailed presentation of the Merkle Tree-Generation algorithm, which is self-descriptive, is given in Algorithm 1. The components of Fig. 3 are presented separately in Fig. 4 and Fig. 5, and their detailed workings are well explained in the proposed solutions. The consensus condition for a new block to be replicated is based on a threshold of valid confirmations, as shown in Eq. (16):

$$N_{confirm} \geq \frac{3}{4}N \tag{16}$$

where, $N_confirm$ is the number of miners confirming validity, and N is the total number of miners. The selection of a miner for nonce generation is based on the lowest random number, as represented in Eq. (17):

$$S = \{i \in M \mid R_i = \min_{j \in M}(R_j)\} \tag{17}$$

where, S is the set of selected miners, M is the set of all miners, and R_i is the random number generated by miner i. To prevent a miner from choosing or modifying R_i after observing competitors' values, the election can use a lightweight commit-and-reveal process. Each eligible miner first broadcasts a commitment $c_i = H(u_i \| pk_i \| H_{prev} \| e)$, where u_i is a locally generated cryptographic random seed, pk_i is the miner identity, H_{prev} is the previous block hash, and e is the current election epoch. After the commitment window closes, miners reveal u_i, and the score is recomputed as $R_i = H(u_i \| pk_i \| H_{prev} \| e)$. Missing or inconsistent reveals are discarded and may trigger slashing. The total consensus time for the proposed system, T_{NCABS}, is a function of the parallel mining time for the head miner, which is a significant improvement over traditional mining methods, as described in Eq. (18):

$$T_{NCABS} < T_{solo} \tag{18}$$

where, T_solo is the time for a traditional solo mining process.

TABLE II. Some Frequently Used Terminologies and their Description.

Term	Description
$V_{(Block)}$	Block validators/miners
$V_{(Tx)}$	Transaction Validators
$Act_{(nodes)}$	Actors
$Power_{(Comp)}$	Computational power
$Wealth_{(Tkn)}$	Token wealth
$Pool_{(U-Tx)}$	Unconfirmed Transactions Pool
$Pool_{(C-Tx)}$	Confirmed Transactions Pool
$Gen_{(Block)}$	Block Generator

A. Architectural Model

The stakeholder nodes are grouped into three major categories namely; Block Validators $[V_{(Block)}]$, Transaction Validators $[V_{(Tx)}]$, and Actors $[Act_{(nodes)}]$. Computational power $[Power_{(Comp)}]$ and Token wealth $[Wealth_{(Tkn)}]$ are two parameters to set the threshold for categorizing the applicant nodes into Block validators and Transaction validators. Actors are transaction nodes that have installed the Blockchain client and wallet applications to interact with the Blockchain network and perform transactions (sending and receiving currency). Transaction validators are nodes with applicants that meet the lower thresholds for $Power_{(Comp)}$ and $Wealth_{(Tkn)}$. The applicant nodes that meet the upper limit criteria for the threshold values, i.e., $Power_{(Comp)}$ and $Wealth_{(Tkn)}$, are categorized as Block validators. These are also the full nodes. Since their work is heavier and more resource-intensive than that of the transaction nodes (Actors), e.g., due to nonce generation. First, the Transaction is entered into the system and placed in the Unconfirmed Transaction Pool $[Pool_{(U-Tx)}]$. Later, once it reaches back from the Transaction Validators $[V_{(Tx)}]$, it is placed by the miner in its own confirmed transactions pool $[Pool_{(C-Tx)}]$ that is explained in Section V-C1a and

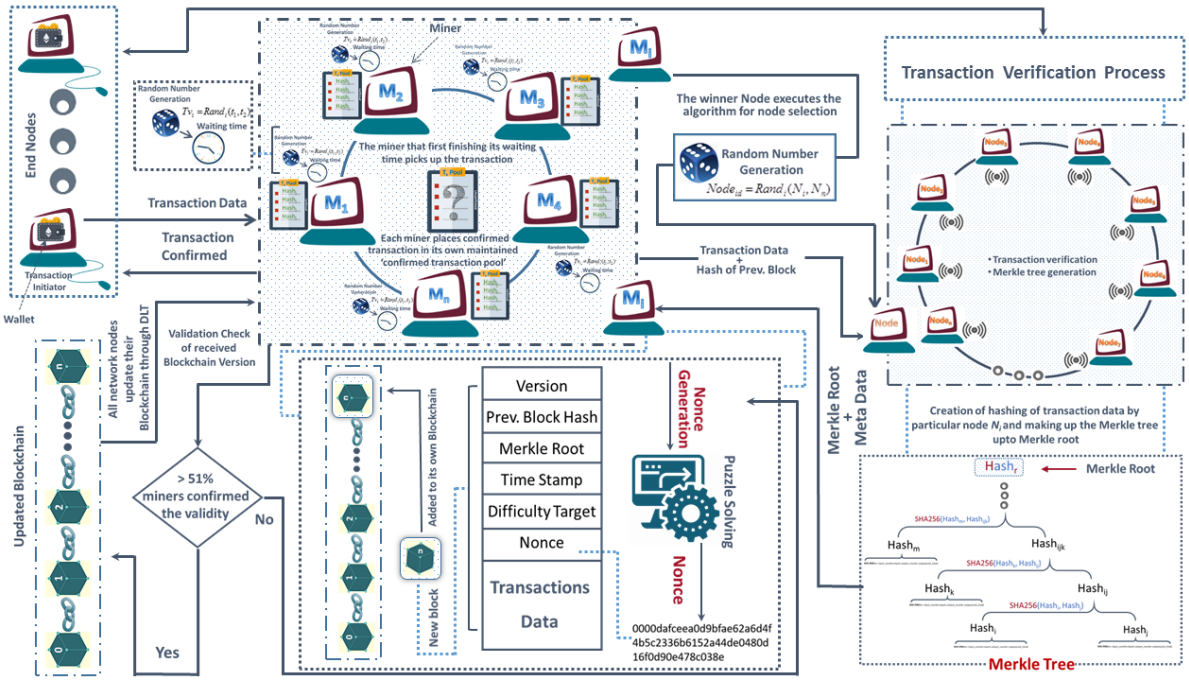

Fig. 3. Consensus algorithm-based scalability solution for blockchain.

are graphically represented in Fig. 4. The description of the terminologies used in this study is tabulated in Table II.

B. Communication Model

Moreover, the higher the number of incoming transactions, the lower the risk of such inconveniences caused by outdated node status. As with each node's response to the transaction verification data, the updated list of alive nodes is shared. So there is very little chance of incorrect information. Every node that sends the transaction verification data back to the head miner will attach the list of live nodes. This list of received messages is then communicated to co-miners. The node collects this information while getting its transactions verified.

C. Detailed Working of the Proposed Solution

The proposed solution operates through a structured consensus algorithm where validation precedes consensus to ensure the running blockchain is the final, agreed-upon version. The process begins when a transaction is placed into an unconfirmed transaction pool, $Pool_(U-Tx)$. A block generator, $Gen_(Block)$, is then selected via a protocol in which all miners generate a random number and set a corresponding timer; the miner with the shortest timer value wins the right to pick up the transaction bunch. This winning miner, or head miner, then delegates the computationally intensive verification task by randomly selecting a dedicated Transaction Validator node, $V_(Tx)$. This selected $V_(Tx)$ node verifies the transaction's legitimacy, syntax, and data structure, and performs the necessary hashing to generate a Merkle tree and its corresponding Merkle root. The validator sends this data back to the head miner, who then solves the puzzle to generate a nonce, creates the new block, and appends it to its local blockchain. This newly updated blockchain is shared with other miners for validation. Upon receiving confirmation from at least 3/4ths of the total miners, it is replicated across the entire network, and a confirmation message is sent to the transaction's stakeholders.

1) Consensus algorithm: The validation precedes the consensus. The consensus protocol ensures that the currently running Blockchain is the final, true version on which at least the system's key stakeholders have agreed. In the proposed consensus algorithm, the Blockchain is replicated to all the miners, once having the validity confirmation from $\frac{3}{4}th$ of total miners. This $\frac{3}{4}th$ ratio is chosen following the renowned previous practices in the literature. Section V-C1c explains it in detail. Before it, nonce generation is the core activity miners perform to make the process fairer, as described in Section V-C1b. After the Block generation and the replication of the Blockchain throughout the network through DLT. The transaction is confirmed and committed. This process is presented in Section V-C1d.

a) Transaction pool: The transaction pushed from the Wallet into the blockchain system is placed in the transaction pool. In Bitcoin, it is named the Mempool. The selected miner picks up the transaction(s) out of the available transactions in the transaction pool [Unconfirmed Transactions Pool $(Pool_{(U-Tx)})$]. Once the transactions are returned from the $V_{(T_x)}$ after confirmation, each miner places them in their in-house maintained pool, the Confirmed Transactions Pool $[Pool_{(C-Tx)}]$. There are some issues of delaying in picking up the transaction from $Pool_{(U-Tx)}$ due to low transaction fees. One solution to it is increasing the transaction fee to push it faster to get it done. SegWit-enabled wallets like Ledger Nano S, Exodus, Segwitaddress, Trezor, or Electrum are worth considering to get faster confirmation from the transaction

Algorithm 1 Merkle Tree Generation

Input: A set of transactions in a block, $T = \{tx_1, tx_2, \ldots, tx_n\}$.
Output: The Merkle Root, M_R.
Definitions:
    Let $H(\cdot)$ be a cryptographic hash function (e.g., SHA-256).
    Let $||$ denote the byte-wise concatenation operator.
    Let L_j be the list of hash nodes at level j of the tree.
function COMPUTEHASH($data$)
    return $H(data)$
end function
function BUILDMERKLETREE(T) ▷ Generate leaf nodes (Level 0)
    Initialize $L_0 \leftarrow \emptyset$
    for $i = 1$ to n **do**
        $l_i \leftarrow$ ComputeHash(tx_i)
        Append l_i to L_0
    end for
    $j \leftarrow 0$ ▷ Iteratively build the tree until one root remains
    while $|L_j| > 1$ **do**
        Initialize $L_{j+1} \leftarrow \emptyset$
        Let $N_j = |L_j|$ ▷ Iterate over pairs of nodes in the current level
        for $k = 1$ to $\lceil N_j/2 \rceil$ **do**
            Let the left child hash be $h_{left} \leftarrow L_j[2k-1]$.
            Let the right child hash be $h_{right} \leftarrow \begin{cases} L_j[2k] & \text{if } 2k \leq N_j \\ L_j[2k-1] & \text{if } 2k > N_j \text{ (Handles odd number of nodes)} \end{cases}$ ▷ Compute the parent hash by hashing the concatenated children's hashes
            The parent hash h_{parent} is computed as:

$$h_{parent} = H(h_{left}||h_{right})$$

            Append h_{parent} to L_{j+1}
        end for
        $j \leftarrow j + 1$
    end while ▷ The final list contains the single Merkle Root
    $M_R \leftarrow L_j[0]$
    return M_R
end function

pool. In the experimental setup, submitted transactions are processed according to their priority, and no external acceleration application is used to push selected transactions ahead of the normal queue. A concise depiction of transaction pools is shown in Fig. 4.

b) Nonce generation: A nonce is a number that results from repeatedly hashing the input until it meets a certain difficulty threshold. In a Block, *nonce* generation is a major task performed by miners and takes most of their time. The process of generating nonces is called mining, and miners mainly do it. It is also called *puzzle solving* because it is a completely random, trial-and-error process that continues until the eligible signature is reached and the required difficulty level is met. It could take many forms, ranging from spaces to question marks to numbers, periods, capital and lowercase

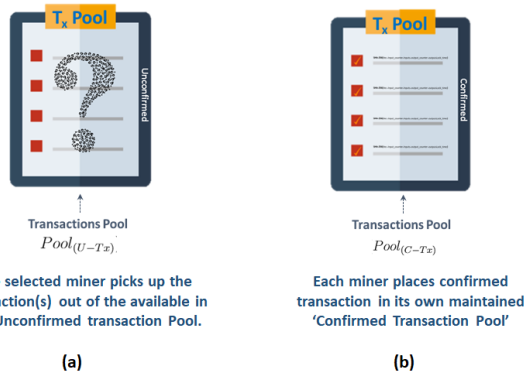

Fig. 4. (a) Unconfirmed transaction pool, (b) Confirmed transaction pool

letters, and digits. Once *nonce* is generated, it is disseminated among other miners along with its key for verification. This also indicates to other miners that they should pause and stop proceeding to actual block generation. Since each block generation process requires the *previous block hash* as a prerequisite, if all nodes start generating blocks, it can lead to confusion about the *previous block hash*. This sharing of the newly generated *nonce* also confirms the miner's message and prevents it from being misleading. This successful node completes the block generation process by setting its *previous block hash* parameter to the latest record in the Blockchain. The locally upgraded Blockchain at the particular miner is sent to the other miners for validation. This received message is a *Go Ahead* call for two actions at the message recipient *i.e.*, Miners. 1) Validation check of the received Block version and respond to the outcome. 2) Proceed to the block generation process.

c) Block generation: The Block Generator $[Gen_{(Block)}]$ is selected by following a special protocol. All the miners generate a random number and set their timers accordingly. The miner with the least timer value takes the right to pick the transaction bunch from the $Pool_{(U-Tx)}$. From a practical perspective, the miner completes its waiting time, which is equal to the randomly generated value, wins the competition, and takes the turn to start the Block generation process, first by picking the transaction(s). A message disseminated to all other miners from this winning miner stops them from waiting further. The message sender miner, *i.e.* the previously winning miner, does not take part in the next competition and will wait for a message from the winner node of the next turn to take part therein. The message also contains its random number value. All the recipient miners wait for this time, then generate a random value as previously presented and discussed on completion of this phase of transaction bunch picking. The transaction verification process is initiated by the $V_{(T_x)}$ node. Once all the required data for a Block is collected and produced, the selected $Gen_{(Block)}$ node proceeds to its generation. Here, another important point needs attention, *i.e.* a serious clash surely will be raised on getting the previous *Block Hash* and including it in the required data for generating the *nonce* and hence the Block generation. Suppose two miners proceed with Block generation using the same *previous hash value*. In

that case, it will disrupt the Blockchain, leading to multiple forks that would be impossible to resolve later. Hence, it is critically important to focus on it and to resolve it.

The fairness of this selection depends on making the random values unpredictable before the election and verifiable after the election. NCABS therefore assumes that random numbers are generated using a cryptographically secure pseudo-random number generator and are bound to the previous block hash and the current epoch through the commit-and-reveal process described above. This binding prevents a miner from reusing a favorable value across epochs, and the public reveal enables other miners to recompute the score before accepting the head-miner result. If two miners obtain the same score, the tie is resolved deterministically by selecting the miner with the smaller hash of $(pk_i \| H_{prev} \| e)$.

The miner that starts the process of generating the *nonce* value up to the Block generation disseminates a message to stop the other miners and to start the same phase in parallel due to the issue of repeated usage of *previous block hash*. During miner selection, it is assumed that candidates must meet a minimum computational power threshold; hence, all miners are capable of generating the Block with proper efficiency. Once the Block is generated and appended to the local blockchain, it is communicated to miners for sufficient validation. On having validity confirmation of $\frac{3}{4}th$ of miners, it is replicated to the blockchain network through DLT. After a successful Block generation, the other miners begin the next Block generation using the *previous block hash*. This is a repetitive process. A concise depiction of Key processes in Block generation by the Block generator and its interaction with the transaction validator module is shown in Figure 5.

d) Transaction verification: Transaction verification is at the end of Transaction Validators' Cluster (TVC), comprising of $(V_{(Tx)})$ nodes. The miner that picks the transactions bunch generates a random number having value from v_i to v_{n-1} (n is the number of nodes in ***TVC***). The $V_{(T_x)}$ corresponds to the outcome number of this random number generation assigned to the transaction bunch. The $V_{(T_x)}$ picks a transaction from the transaction bunch at a time and verifies it by following the number of encapsulated tasks. Firstly, transaction legitimacy is checked, i.e., whether the transactions are legal, not malicious, and not double-spent. In addition, the transaction syntax and data structure, the input and output values, the transaction size (i.e., must be less than the block size), the transaction value (i.e., must be between the minimum and maximum limit values), and the signature limit are verified. When a transaction is marked as correct, the next step is checking that its matching transaction (i.e., child transaction) exists, and if so, then both the parents and child transactions are processed further by placing them in the transaction pool; otherwise, it is put in the *Orphan Transaction Pool*. Once it passes the initial screening, it is hashed. This process is repeated for all transactions in the transaction bunch, and the *Merkle tree* is completed, yielding the *Merkle Root*. To maintain privacy while obtaining the desired data from the neighboring node to verify the payment, *Bloom Filter* is part of the transaction verification process. It comprises various patterns to aggregate data as defined in *BIP37*. Fig. 6 depicts the transaction processing flow as a block diagram, starting with the availability of currency in the wallet and ending with committing the transaction to lock the wallet. This figure presents another schematic diagram (at the abstract level) of Fig. 3.

2) Slashing: The cheater participant (miner and transaction verified) is penalized by having its stake confiscated. This removal of the cheater's stake reduces the token supply on the blockchain, thereby elevating the token price at the individual level. This is another way for bad actors to cover up the impact of their dishonesty. Also, this removed stake is non-transferable and is directly dumped for no use. The full process of leader election, transaction validation, mining, and consensus is detailed in Algorithm 2.

The transaction verification algorithm details the procedure performed by a dedicated validator node. It checks the validity of each transaction in a batch and computes the final Merkle Root, as shown in Algorithm 3.

D. Security Considerations and Adversarial Model

NCABS is designed primarily for a permissioned or consortium blockchain setting in which validator identities are known and eligibility is controlled through the computational-power and token-wealth thresholds described in the architectural model. This membership assumption is important for security. A Sybil adversary cannot freely create unlimited validator identities unless it also satisfies the admission criteria for each identity. The slashing rule further discourages strategic behavior by penalizing miners or transaction validators that submit inconsistent election reveals, invalid validation results, or malformed block data.

The 75% confirmation threshold provides a Byzantine-fault-oriented safety condition. In a validator set of size N, an adversary controlling fewer than one-fourth of the confirming miners cannot independently finalize an invalid block because the block must receive at least $\frac{3}{4}N$ valid confirmations. This threshold also reduces the likelihood of forks because blocks generated from stale or conflicting previous hashes do not receive sufficient confirmations. However, a large colluding majority remains a serious risk in any consensus protocol; 51% attacks have been shown to affect cryptocurrency value and trust [24]. Therefore, NCABS should be interpreted as resistant under the stated permissioned-membership and honest-majority assumptions, rather than as a complete defense against majority capture in an open permissionless network.

Double-spending attacks are addressed at the transaction-verification layer. The selected transaction validator checks transaction legitimacy, syntax, input and output values, signatures, transaction size, and double-spending conditions before generating the Merkle root. A transaction batch that fails these checks is rejected before block assembly. The current work evaluates these mechanisms from a protocol-design and performance perspective; systematic adversarial simulation, including coordinated Sybil attempts, double-spending campaigns, selfish mining, and majority-capture scenarios, remains part of the future validation plan.

E. Complexity Analysis

The computational complexity of NCABS is reduced compared to PoW due to selective miner participation. In

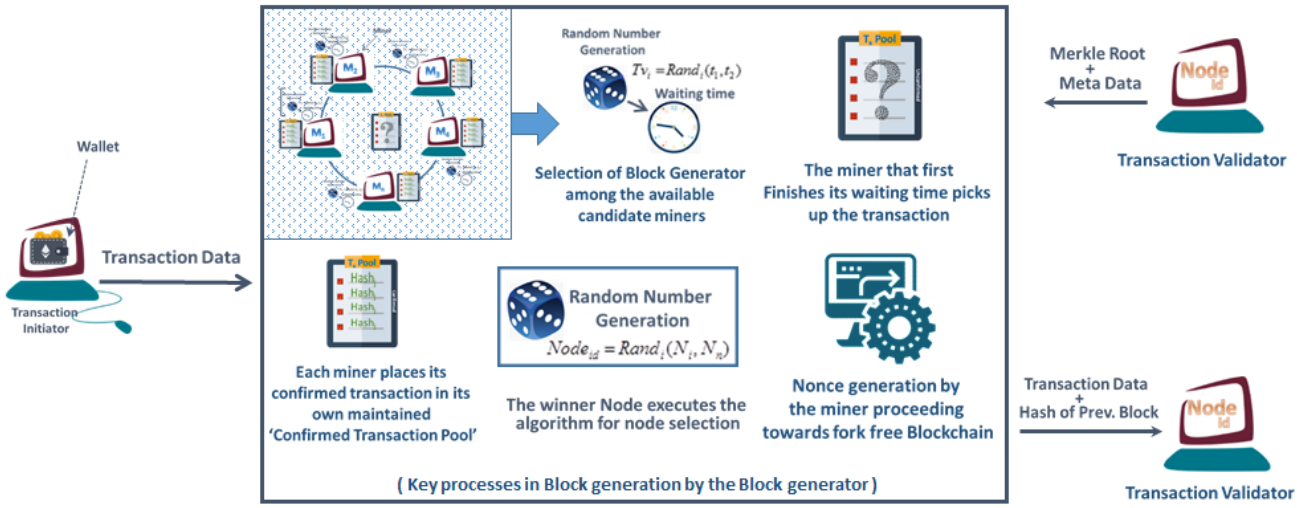

Fig. 5. Key processes in block generation by the Block generator and its interaction with transaction validator module.

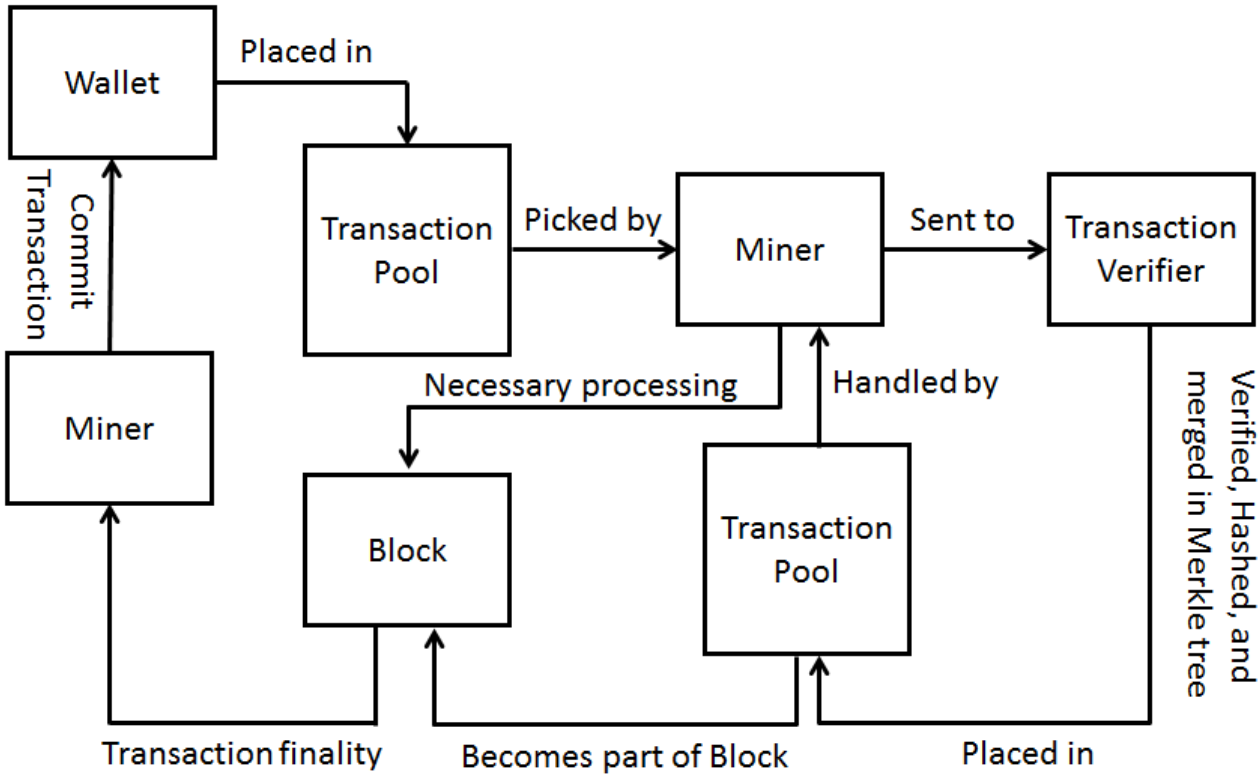

Fig. 6. Transaction processing flow in the proposed blockchain.

traditional PoW, $O(N)$ miners compete to solve the same block-generation problem. In NCABS, only $O(k)$ selected miners participate in the active mining phase, where $k \ll N$. The corresponding computational reduction ratio is therefore approximately k/N. From the communication perspective, PBFT has $O(N^2)$ message complexity because of its all-to-all

Algorithm 2 Proposed Consensus and Block Creation Process

procedure BLOCKCREATIONPROCESS($H_{prev}, Pool_{U-Tx}, \mathcal{M}, \mathcal{V}$)
▷ **Phase 1: Block Generator Election**
  Initialize timers $T_i \leftarrow \infty$ for all $M_i \in \mathcal{M}$
  for each miner $M_i \in \mathcal{M}$ in parallel **do**
    Generate random seed u_i using a CSPRNG
    Broadcast commitment $c_i \leftarrow H(u_i \| pk_i \| H_{prev} \| e)$
    Reveal u_i after the commitment window closes
    Compute score $r_i \leftarrow H(u_i \| pk_i \| H_{prev} \| e)$
    Set timer $T_i \leftarrow r_i$
  end for
  Wait for the first timer to expire
  $M_{gen} \leftarrow \arg\min_{M_i \in \mathcal{M}}(T_i)$
  M_{gen} broadcasts a halt signal to all other miners in $\mathcal{M}$
▷ **Phase 2: Transaction Validation Delegation**
  $\mathcal{T}_{bunch} \leftarrow M_{gen}$ selects a batch of transactions from $Pool_{U-Tx}$
  $V_{Tx} \leftarrow$ randomly select a validator from $\mathcal{V}$
  Send $\mathcal{T}_{bunch}$ to the selected validator V_{Tx}
  $(\mathcal{T}_{valid}, H_{Merkle}) \leftarrow$ VERIFYTRANSACTIONS($\mathcal{T}_{bunch}$)
  if H_{Merkle} is null **then**
    return Block Generation Failed (Validation Error)
  end if
▷ **Phase 3: Mining (Proof-of-Work)**
  Initialize $Nonce \leftarrow 0$
  $H_{header} \leftarrow$ CreateHeader(H_{prev}, H_{Merkle}, timestamp, ...)
  while $H(H_{header}, Nonce) > D_T$ **do**
    $Nonce \leftarrow Nonce + 1$
  end while
▷ **Phase 4: Block Assembly and Consensus**
  $B_{new} \leftarrow$ AssembleBlock($H_{header}, Nonce, \mathcal{T}_{valid}$)
  M_{gen} broadcasts B_{new} to all miners in $\mathcal{M}$
  Initialize $confirm_count \leftarrow 1$ ▷ M_{gen} votes for its own block
  for each miner $M_j \in \mathcal{M} \setminus \{M_{gen}\}$ **do**
    if M_j validates B_{new} as correct **then**
      $confirm_count \leftarrow confirm_count + 1$
    end if
  end for
  if $confirm_count \geq \frac{3}{4}|\mathcal{M}|$ **then**
    Append B_{new} to the global blockchain
    return B_{new}
  else
    Discard B_{new}
    return Block Generation Failed (Consensus Not Reached)
  end if
end procedure

voting structure, whereas NCABS reduces the active consensus communication to approximately $O(kN)$. Hence, NCABS reduces both computational and communication overhead when the selected active set remains much smaller than the complete node set.

Algorithm 3 Transaction Verification and Merkle Root Generation

procedure VERIFYTRANSACTIONS($\mathcal{T}_{bunch}$)
  $\mathcal{T}_{valid} \leftarrow \emptyset$
  for each transaction $Tx_i \in \mathcal{T}_{bunch}$ **do**
    if $\Phi(Tx_i)$ is true **then**
      $\mathcal{T}_{valid} \leftarrow \mathcal{T}_{valid} \cup \{Tx_i\}$
    end if
  end for
  if $\mathcal{T}_{valid}$ is not empty **then**
    $H_{Merkle} \leftarrow$ MerkleRoot($\mathcal{T}_{valid}$)
    return $(\mathcal{T}_{valid}, H_{Merkle})$
  else
    return $(\emptyset, \text{null})$
  end if
end procedure

VI. EXPERIMENTATION AND PERFORMANCE EVALUATION

A. Performance Metrics

The following metrics are used to evaluate the performance of the proposed model [see Eq. (19) to Eq. (21)]:

$$\text{Throughput} = \frac{\text{Number of Transactions}}{\text{Time}} \tag{19}$$

$$\text{Latency} = \text{Time per Block Confirmation} \tag{20}$$

$$\text{Efficiency} = \frac{\text{Throughput}}{\text{Resource Usage}} \tag{21}$$

Each experiment is repeated 10 times, and average values with standard deviation are reported to ensure robustness. To validate the performance of the proposed NCABS consensus mechanism, a series of experiments was conducted and compared against the Practical Byzantine Fault Tolerance (PBFT) algorithm. The evaluation was performed using a setup that included specialized GPU chips, the CGminer software package, and membership in the Poolin online mining pool. The core performance metrics for this comparative analysis were throughput, network latency, network scalability, and responsiveness. Experiments were conducted across a range of network node densities (40–140) to assess the system's behavior under increasing load. The results consistently demonstrated that NCABS offers superior performance, achieving higher throughput, lower resource utilization, a higher transaction commit rate, and lower latency than PBFT. For example, NCABS reduces aggregate communicated messages by approximately 45% in the scalability experiment, and the responsiveness experiment shows a latency reduction from about 310 ms for PBFT to about 195 ms for NCABS at 40 nodes.

B. Theoretical Evaluation

Usually, miners experience latency when hearing about transaction validation at different points in their life cycle. Furthermore, different miners select transactions based on their convenience (e.g., transaction fees) and begin validating them to perform the activities required for block generation. But only one block is accepted based on consensus, to be appended to the blockchain and then replicated across the network of miners using *Distributed Ledger Technology*. Both processes are time-and computational resource-intensive. In the proposed solution, both issues are addressed by assigning the transaction verification role to a dedicated node, *i.e. Transaction verifier*. Therefore, miners do not need to remain engaged in this process, and these resources are better used to keep the system up and running.

The input transactions are readily picked by the miners and put in the processing queue for further assignment to the transaction verifier. This utilizes available resources efficiently and effectively, increasing the system throughput *i.e.*, more transactions are processed and reach the finality state per unit time. Miners have more time to dedicate to block-generation processes, such as nonce generation, without competing with one another, resulting in more efficient resource utilization and higher throughput. A single transaction is picked by only one miner rather than multiple miners (as is practised in other blockchains). It reaches finality with a high probability, as there is no risk or uncertainty of dropping or deselecting the generated block at the end. What comes in the flow will gain the finality status. The verifying nodes are well aligned with their assigned tasks, without redundant effort on the same transaction (which may become part of multi-transaction bunches picked by various miners on their turn). *Transaction verifier* works with one miner at a time, while one miner can assign transaction bunches to more than one transaction verifier. This further contributes to effective resource utilization with better block throughput.

During the block generation, the winning miner prevents the other miners from completing their waiting time to pick up the transaction batch. This algorithm has twofold benefits. It saves time wasted unnecessarily and contributes to better system throughput. Secondly, it helps them autonomously synchronize and enter the transaction-picking phase again almost simultaneously, *i.e.*, a fair deal. By using the *temporal analysis*, the introduced nonce-generation process results in the block generation taking a bit longer. If the set procedure in Bitcoin and other blockchains is followed, carrying out the process simultaneously is more time-consuming. Although the temporal impact is not well appreciated in the proposed mechanism, it is far less than the usual process, as mentioned before. Selecting transactions redundantly across multiple miner picks also delays the block generation process.

C. Implementation Detail

Specialized GPU chips, sufficient cooling for the hardware, an always-on internet connection, a mining software package, and membership in both an online cryptocurrency exchange and an online mining pool are the major implementation parameters. The market is well-supplied with crypto-mining software packages, including CGminer, Bitminter, BFGminer, Multiminer, and EasyMiner. CGminer is used as the representative mining software in this implementation because it supports multi-threaded and multi-pool mining configurations [25]. A group of crypto-miners who combine their computational resources over a network can increase their collective computational power. Poolin, Autopool, Slush Pool, Bitfury, and FZpool are among the widely used mining pools. Poolin is used as the representative mining-pool setting in this study and was reported to mine approximately 20% of blocks at the time considered.

1) Performance metrics: To validate the proposed consensus mechanism's performance, it is compared with PBFT across various evaluation parameters. Those are summarized into throughput, network latency, network scalability, and responsiveness. The results are presented from Fig. 7 to Fig. 17. The detailed discussion is given in subsequent sections.

a) Throughput and network latency: To measure the concurrency in the Blockchain system, an important metric is transaction throughput per Second $T_(TPS)$, i.e., $P = \frac{T_(sum)}{\delta t}$ where $T_(sum)$ is block time and δt is the total transaction count during that block time. It reflects the number of transactions packaged per unit of time. It states that the higher the throughput value, the greater the consensus efficiency and the greater the potential for transaction processing. Hence, $Throughput \propto ConcurrencyEfficiency$. Transaction latency is the time between submitting a transaction and its confirmation. It measures the blockchain's consensus algorithm's computational efficiency, communication efficiency, and runtime. Reduced latency will increase transaction confirmations and decrease the risk of blockchain bifurcation.

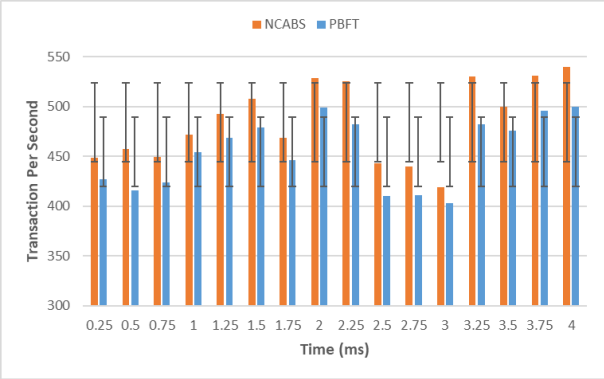

Fig. 7. Average results of throughput - time(ms) vs. transaction per second.

$$Trans_{(Latency)} = Block_{(Conf)}t - Trans_{(Init)}t$$

where, $Trans_{(Latency)}$ is the transaction latency that is the difference between the block confirmation time $Block_{(Conf)}t$ and the transaction initiation time $Trans_{(Init)}t$. Fig. 7 shows the average result of throughput, time vs. transactions per second, and reflects the outperforming of NCABS to PBFT. The variability in results over time indicates changes in the nodes' status. In NCABS, $Power_{(Comp)}$ and $Wealth_{(Tkn)}$ are two parameters used to categorize nodes into Block validators and transaction validators. The status change also affects throughput, as shown in Fig. 7 and Fig. 8. This is also shown in Fig. 9, which compares the change in throughput to the transaction commit rate (Fig. 10). The same also impacts the

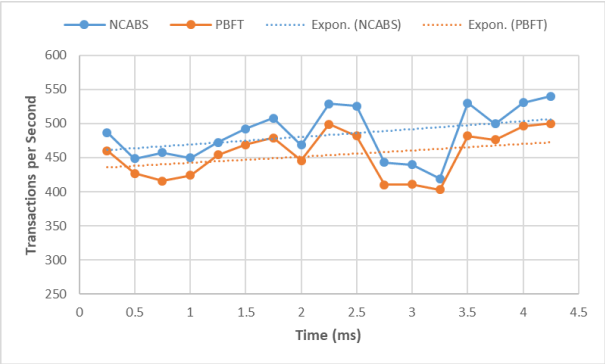

Fig. 8. Exponential trend of competing algorithms on throughput, time(ms) vs. transaction per second.

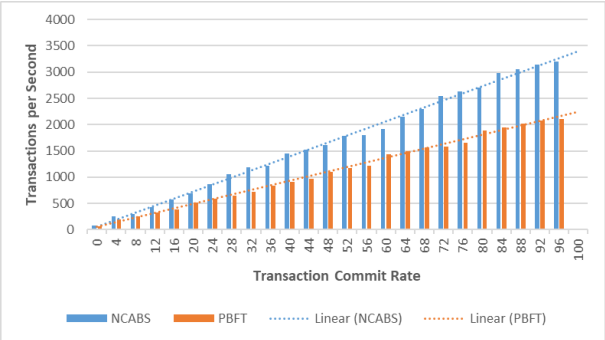

Fig. 9. Transaction commit rate vs. transaction per second for the competing algorithms.

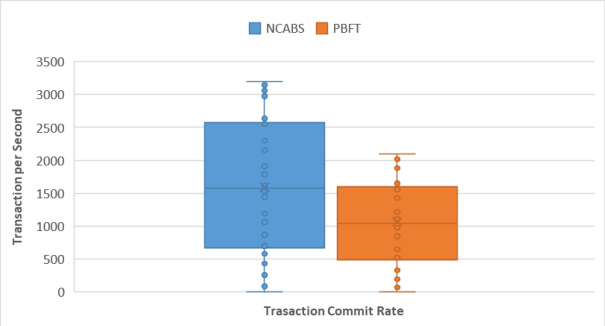

Fig. 10. A summarized view of the throughput comparison of NCABS and PBFT.

graph representing the blockchain network resource utilization, as in Fig. 11. Consequently, this status change also affects message communication since it increases inter-node message passing for node status reallocation. That is reflected in Fig. 11 and Fig. 12.

Across all the above-cited figures, the comparison of NCABS with PBFT for throughput and resource utilization as performance evaluation parameters also shows the network's stability. The higher the frequency of switching the node status, the greater its negative impact on the network. The variation in throughput and resource utilization over time is due to varying node involvement. At t_0, a fraction of nodes serve as validators or supervisor nodes, while at t_1, upon the status

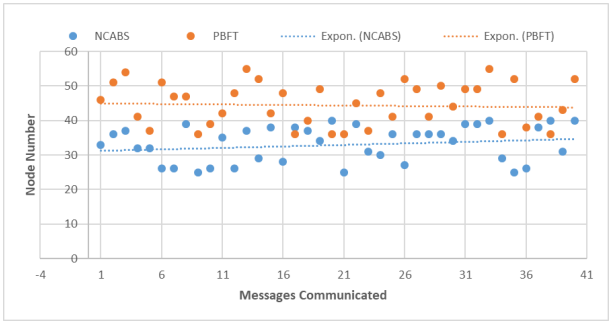

Fig. 11. Blockchain network resource utilization. A comparative view of the per node messages communicated by NCABS and PBFT along with their exponential trend.

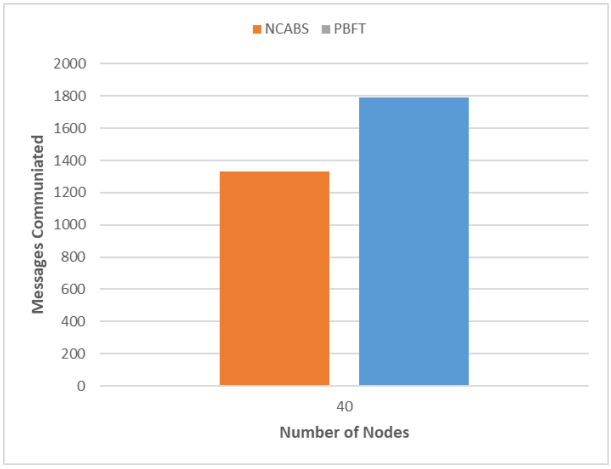

Fig. 12. Blockchain network resource utilization. An aggregated comparative view of the messages communicated in the blockchain network of 40 nodes.

switch, another fraction of nodes assume the same role. This plays a role in the said graph style. In short, as explained above, NCABS achieved higher throughput, lower resource utilization, a higher transaction commit rate, and lower latency than PBFT. Considering Fig. 9, it is clearly evident that the higher the transaction commit rate, the more the throughput, i.e., transactions per second. Over time, throughput increases along with the transaction commit rate for NCABS, and it is higher than that of PBFT. The performance of NCABS is improving compared to PBFT. The reason for this better result is the minimal communication during the validation process. Extending this, the time required to confirm a transaction is also shorter for NCABS than for PBFT.

b) Network scalability: Among many other scalability solutions in Blockchain that require close attention for improvement, throughput and latency are the most important concerns. Adding more nodes significantly increases the time needed to confirm transactions, reducing the number of transactions per second. To address the weakness of the slow transaction verification process, as in the founding systems and their descendant solutions, this job is at the end of the Transaction Validators' Cluster, which comprises selected transaction validator nodes. The same approach is used in PBFT and its variants. One approach to improve the scalability or speed of transaction processing is to design a faster proof-

of-work solution. NCABS uses a method to accelerate the proof-of-work process by parallel rather than solo mining. This decreases the overall burden on the Blockchain network nodes and helps ensure that no more than two miners exert the same effort on a given block.

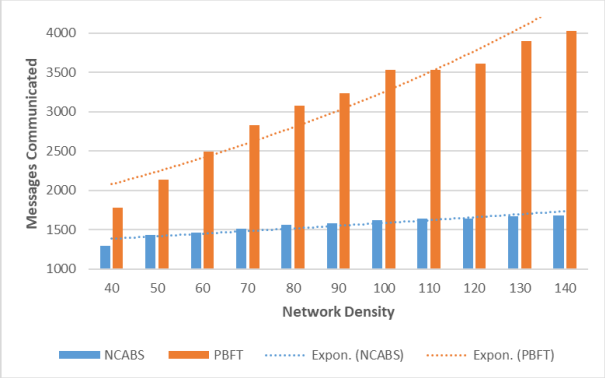

Fig. 13. Comparative results of network scalability over varied network densities in NCABS and PBFT, along with their exponential trend.

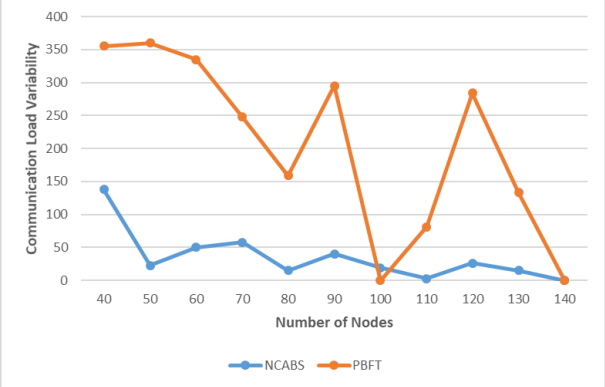

Fig. 14. Communication load variability over varied Number of Nodes in NCABS and PBFT.

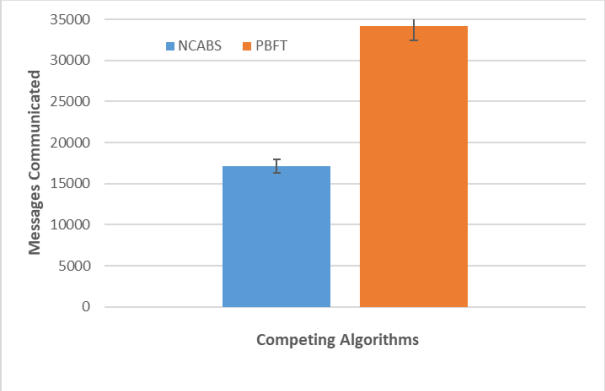

Fig. 15. Network scalability.

Fig. 13, Fig. 14, and Fig. 15 show the network load leading to Network scalability at different network densities. The results shown in the figures are averages across multiple simulations. The results are obtained at varying numbers of nodes, ranging from 40 to 140, with a difference of 10 nodes per experiment. Fig. 15 shows the summary of the inferred and calculated results (averaged) from all the experiments with different blockchain network node densities. It reflects the response of message communication to set up the transaction's confirmation. The total number of messages communicated by the proposed mechanism, NCABS, is approximately 45% fewer than that of PBFT. Referring to Fig. 13, the difference in the number of communicated messages for a network with a node density of 40 and a node density of 140 is huge, especially in the case of PBFT. This difference is due to network instability, specifically to the redundancy introduced by multiple miners mining the same transaction. In contrast, NCABS follows the one-time, one-node policy, as discussed previously, to reduce this communication load. Fig, 13 and Fig. 14 also endorse the network stability scenario. NCABS is far more stable compared to PBFT. Since the variability in the communication load is minimal and gradually improving in various node densities from 40 to 140 in NCABS. In the case of PBFT, this difference increases exponentially. It performs better for small-scale networks but worsens as network scale increases. Also, the exponential trend line for the resulting PBFT graph is much higher and steeper than that for NCABS.

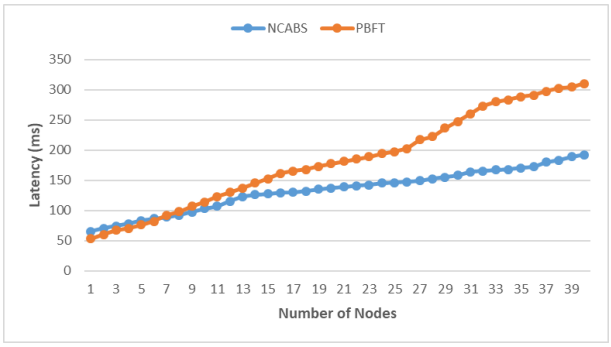

Fig. 16. Network latency under increasing node density for NCABS and PBFT.

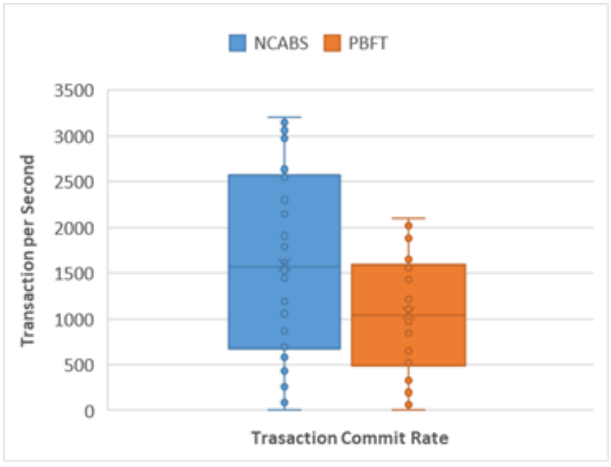

Fig. 17. Aggregated responsiveness comparison using transaction commit rate.

The data in Fig. 13 are also represented as a line graph in Fig. 14, showing far less variability in communication

TABLE III. COMPARISON OF CONSENSUS ALGORITHMS

Algorithm	Communication Complexity	TPS	Groupings of Nodes	Nodes Participation in Consensus Mechanism	Supervision Mechanism	Scalability
PBFT [26]	Average	Low	No	No	No	low
Multi-Layer PBFT [27]	Average	Average	Yes	No	No	Average
NBFT [28]	High	Average	Yes	No	No	Average
GH [29]	High	Low	Yes	No	No	Average
CDBFT [30]	Average	Low	No	Yes	No	Poor
RBFT [31]	High	Average	No	No	Yes	Poor
Algorithm [32]	High	Low	Yes	No	No	Average
PoW [33]	High	Low	No	No	No	Poor
PoS [34]	High	Low	No	No	No	Poor
DPoS [35]	High	Average	No	No	Yes	Average
NCABS (Proposed)	Low	High	Yes	Yes	Yes	Good

load for NCABS compared to that of PBFT. Hence, it results in better network scalability. Since network stability, communication, and network throughput are directly related to network scalability, NCABS delivers far better scalability than its competitor. Fig. 16 and Fig. 17 depict the results of network responsiveness from the perspective of the number of nodes versus latency in milliseconds. In Fig. 16, keeping the node density up to forty, the time interval from transaction submission to transaction confirmation is almost the same for both algorithms for thirteen nodes somewhere in the network. As network latency measures the computational efficiency and runtime of the blockchain's consensus algorithm, throughput is also closely related to it. But later, the latency difference in PBFT increases from node thirteen onward. This decreases its throughput, impacting network scalability. The aggregated responsiveness results are also shown in Fig. 17, indicating that higher latency is associated with lower responsiveness and lower scalability, and vice versa.

D. Comparative Analysis of Typical Consensus with NCABS

Table III compares consensus algorithms, focusing on the extended PBFT ideas. A similar comparison is made by Wu X. *et al.* [36]. The comparison indicators are communication complexity (which also includes communication overhead), Throughput (TPS), nodes' grouping (aka sharding), nodes' participation in the consensus mechanism, supervision of the consensus process, and scalability. The empirical evaluation uses PBFT as the primary baseline because it is the closest directly implemented Byzantine-fault-tolerant comparator in the experimental setup. The remaining consensus protocols are included as qualitative baselines to clarify how NCABS differs from common PBFT variants, PoW, PoS, DPoS, and related group-based protocols. As far as comparing Proof of Work (PoW) and Proof of Stake (PoS), considering the open environment for public blockchain, PoW and PoS are more suitable. Comparing these two, the PoS algorithm prioritizes the highest equity when electing nodes, consumes the least energy, and exhibits a higher degree of centralization than the PoW algorithm, but it lacks security. Its optimized version, DPoS, fine-tunes the number of participating nodes. PoW has stronger decentralisation, a relatively simple implementation, and high fault tolerance, but with the drawbacks of slow transaction speeds, higher energy consumption, and lower throughput [37].

The GH algorithm divides the network nodes into groups, each with a primary node. Local consensus leads to the global consensus achieved by the collective work of only the primary nodes of the designed groups. This increases communication complexity by increasing overhead among interacting nodes. The same is true for NBFT, RBFT, PoW, and its variants, i.e., PoS and DPoS. Hence, it also impacts transaction throughput. Data processing speed has been significantly increased, and security has been improved, but the decentralization aspect needs further optimization. The Paxos, Raft, and PBFT algorithms are better suited to permissioned chains, such as consortium and private chains, that require identity verification and have limited node counts. These consensus algorithms can provide excellent information-processing capabilities, low resource consumption, and tolerance to non-Byzantine errors. However, implementing the Paxos consensus algorithm is more difficult and only suitable for consortium chains and private chains with relatively high security. The Raft algorithm is more practical and performs similarly to Paxos. Still, its shortcomings are similar to those of the Paxos consensus algorithm, and it is only suitable for consortium and private chains with relatively high security. The PBFT consensus algorithm offers strong data processing capabilities and enhanced security and is only applicable to consortium and private chains. In addition, the PoH and CW-PoW consensus algorithms proposed in 2021 are improvements and optimizations of the typical consensus algorithm, and they feature high computational efficiency, low energy consumption, and strong safety and reliability. NCABS is well-suited for the permissioned blockchain for the same reason as PBFT. A detailed experimental-based comparison of these two algorithms is made in the previous section. The comparative analysis results for the algorithms above are shown in Table III.

VII. DISCUSSION

The experimental results show that the main advantage of NCABS comes from reducing redundant work during transaction verification and block generation. In PBFT, consensus communication grows rapidly with the number of participating nodes because voting and message exchange are broadly distributed across the validator set. NCABS narrows the active consensus path by selecting a head miner, delegating transaction verification to a specific validator, and requiring a 75% confirmation threshold before replication. This design

explains why the scalability experiment reports approximately 45% fewer communicated messages than PBFT and why the latency curve remains lower for NCABS as node density increases.

The proposed method is also consistent with the related-work discussion on consensus-based scalability. PoW improves openness and decentralization but wastes computation because many miners compete for a single accepted block. PBFT improves deterministic finality in permissioned environments but can suffer from high communication overhead. PBFT variants such as Multi-Layer PBFT, NBFT, CDBFT, RBFT, and HotStuff-inspired approaches attempt to reduce this overhead through grouping, leadership, or pipelined voting. NCABS follows the same broad goal of reducing redundant coordination, but it does so through controlled parallel mining and explicit separation between transaction validation and block generation. This separation is the main methodological difference from the compared baselines in Table III.

From a deployment perspective, NCABS is best interpreted as a permissioned or consortium-chain mechanism. Its security assumptions depend on controlled validator admission, verifiable random selection, slashing, and an honest-majority condition under the 75% confirmation threshold. These assumptions make NCABS suitable for applications such as supply-chain blockchain systems, where participant identities and computational eligibility can be managed. They also limit direct transfer to open permissionless networks without additional defenses against Sybil identities, selfish mining, coordinated double spending, and majority capture.

The comparison with PBFT provides a direct empirical baseline because PBFT is the closest implemented Byzantine-fault-tolerant comparator in the present evaluation. The qualitative comparison with additional consensus protocols strengthens the positioning of NCABS but does not replace full empirical benchmarking against all modern variants. Therefore, the results should be read as evidence that NCABS improves performance under the stated experimental conditions, while broader adversarial and multi-baseline testing is required before generalizing the claim to all blockchain consensus settings.

VIII. Conclusion

This study presented NCABS, a controlled parallel-mining consensus mechanism for improving blockchain scalability. The conclusions of the study are as follows:

- NCABS reduces redundant mining and transaction-verification effort by separating head-miner selection, validator delegation, block generation, and confirmation into coordinated stages.
- Across ten repeated experiments with node densities from 40 to 140, NCABS achieves better throughput, lower communication overhead, and lower latency than PBFT; in the reported scalability result, aggregate communicated messages are reduced by approximately 45%.
- The comparative analysis indicates that NCABS is particularly suitable for permissioned or consortium blockchain applications where validator identity, computational eligibility, and confirmation thresholds can be managed.

Two limitations remain. First, the current evaluation is simulation/prototype-based and uses PBFT as the direct empirical baseline, while other modern consensus variants are compared qualitatively. Second, the framework assumes minimum computational capability among miners, controlled validator admission, and honest-majority behavior; adversarial experiments involving Sybil behavior, double spending, selfish mining, and majority capture have not yet been conducted.

Future work will extend NCABS through broader empirical benchmarking against additional PBFT variants and modern consensus protocols, real deployment testing, and adversarial evaluation under coordinated attack scenarios.

Explainable Neural Network Prediction of Post-COVID-19 Depression via Monte Carlo Simulation

Siham AKIL, Sara SEKKATE, Abdellah ADIB
Laboratory of Intelligence Machine (LIM)
Faculty of Sciences and Technologies, BP 146-28806 Mohammedia, Morocco

***Abstract*—The COVID-19 pandemic has driven a substantial rise in depression, notably in Argentina's post-quarantine period, motivating the need for predictive tools to support timely mental health interventions. This study uses a Feedforward Neural Network (FNN) and Monte Carlo simulations to predict depression scores from key socio-economic and psychological variables—anxiety state, economic income, and education—benchmarked against SVR, GRU, Linear Regression, Decision Tree, and Random Forest. The FNN achieved the best overall performance ($MAE = 4.72$, $RMSE = 6.32$, $R^2 = 0.64$; cross-validated $R^2 = 0.593 \pm 0.048$), while Linear Regression attained the highest R^2 (0.693), suggesting partly linear relationships among predictors. Monte Carlo simulations showed that higher anxiety increased predicted depression, while higher income and education reduced it, underscoring the value of targeted anxiety-reduction and economic-support interventions in post-pandemic mental health policy.**

***Keywords*—Depression prediction; Feedforward Neural Network; Monte Carlo simulations; explainable artificial intelligence; post-COVID-19 mental health; socio-economic factors; SHAP analysis**

I. Introduction

The COVID-19 pandemic has significantly changed the dynamics of global public health, leading to an unprecedented rise in mental health issues [1]. Among these, depression has emerged as a pressing concern, particularly in the extended lockdowns and quarantine measures [2]. Countries around the world have reported high rates of depression, and Argentina, in particular, experienced a significant increase in mental health problems in the post-quarantine period [3]. The psychological consequences of prolonged social isolation, combined with economic instability, has contributed to a serious mental health crisis [4]. This context underscores the need for effective, data-driven approaches to understanding and predicting depression levels, particularly as public health systems continue to be challenged by the long-term consequences of the pandemic [5].

The socio-economic fallout from the pandemic has led to an increase in mental health issues, with depression being one of the most widespread and disabling disorders [6]. The country's pre-existing economic challenges, such as high inflation and unemployment, were further aggravated by the pandemic, pushing many individuals and families into financial distress [7]. These economic stress factors, coupled with the psychological pressure of the pandemic, have led to an increase in cases of depression [8]. The mental health impact of COVID-19 is not limited to those directly affected by the virus; the broader population has experienced a deterioration in psychological well-being due to factors such as economic insecurity, job loss, disruption of educational systems, and social isolation [9]. These interrelated factors make it imperative to explore the socio-economic and psychological determinants of depression in the post-pandemic period.

Previous research has established that mental health is influenced by a range of factors, including economic status, education, social support, and psychological conditions such as anxiety [10]. For instance, individuals with lower economic income are more likely to experience depression, as financial insecurity can aggravate feelings of stress and powerlessness [8]. Similarly, education plays a critical role in mental health, with lower educational attainment often linked to poorer mental health outcomes [11]. Anxiety, a psychological response to uncertainty and stress, has been shown to amplify the symptoms of depression. During the COVID-19 pandemic [12], heightened anxiety levels, driven by fears of infection, job insecurity, and uncertainty about the future, have significantly impacted mental health worldwide. The intersection of these socio-economic and psychological factors presents a complex landscape for predicting depression levels, particularly in a country like Argentina, where the pandemic has reinforced existing vulnerabilities [6].

Accurate prediction of depression in such a multifaceted environment requires sophisticated analytical tools that can capture the interaction between these variables [13]. Traditional mental health assessments, while valuable, often fall short in accounting for the dynamic and interdependent nature of socio-economic and psychological factors [14]. Machine learning (ML), with its ability to process large datasets and uncover hidden patterns [15], offers a powerful solution to this challenge. By leveraging ML techniques, researchers can build predictive models that not only consider individual variables like economic income and education but also capture the complex interactions between these factors and psychological conditions such as anxiety [11].

In recent years, ML models have shown great promise in predicting mental health outcomes, particularly in situations where traditional statistical methods may be less effective [16]. These models are capable of analyzing vast amounts of data, identifying non-linear relationships, and making predictions that can help guide public health interventions [17]. When combined with Monte Carlo simulations, ML models can

further enhance the predictive accuracy by simulating various "what-if" scenarios [18]. Monte Carlo simulations allow researchers to explore the effects of different socio-economic and psychological conditions on depression levels, providing valuable insights into how changes in these variables might influence mental health outcomes [19].

This study aims to leverage these advanced analytical tools, ML and Monte Carlo simulations, to predict depression levels in Argentina's post-quarantine period. Specifically, the study will examine the role of key variables such as anxiety levels, economic income, and education in shaping depression outcomes. By varying these inputs through Monte Carlo simulations, the study aims to understand how different scenarios, such as changes in economic conditions or anxiety levels—impact depression predictions. The research addresses the following research questions:

- How do socio-economic factors, particularly economic income and education, influence depression levels in Argentina's post-quarantine period?
- What is the relationship between anxiety levels and depression, and how can this psychological factor be effectively taken into predictive models?
- How can ML models, combined with Monte Carlo simulations, enhance the prediction of depression in the context of the socio-economic and psychological challenges posed by the COVID-19 pandemic?

By answering these questions, this research provides an important contribution to the field of mental health prediction, particularly in the context of global crises such as the COVID-19 pandemic. The findings from this study are expected to offer valuable insights for policy-makers and healthcare providers in Argentina and other countries facing similar challenges, enabling more targeted mental health interventions. Moreover, the use of FNN model and Monte Carlo simulations represents an innovative approach that can be applied in future mental health research, particularly in complex socio-economic contexts.

The choice of a FNN was motivated by its proven capacity to model complex, non-linear relationships between input features and continuous outcomes, making it particularly well-suited for psychological and behavioral prediction tasks such as depression score estimation. Unlike traditional linear models, FNNs can learn flexible mappings from high-dimensional feature spaces without relying on pre-specified interaction terms or transformation assumptions. Furthermore, the relatively low dimensionality of the input space and the structured nature of the variables made the FNN a computationally efficient yet expressive choice for this regression task.

While the use of ML models for mental health prediction is not new, the novelty of this work lies in three complementary contributions. First, unlike prior studies that typically treat depression prediction as a static regression problem, this study integrates a FNN-based predictive model with Monte Carlo simulation to explicitly quantify how socio-economic and psychological factors—anxiety state, economic income, and education—propagate into depression outcomes under simulated "what-if" scenarios. Second, the model's predictions are made interpretable through SHAP-based explainability, addressing the common trade-off between predictive accuracy and transparency in mental-health applications, where clinical and policy adoption depends on understanding why a prediction was made. Third, this combination of FNN, Monte Carlo simulation, and SHAP explainability is applied, to the best of our knowledge, for the first time to the post-quarantine Argentine context, providing a population- and period-specific predictive tool rather than a generic depression model.

The remainder of this study is structured as follows: Section II discusses relevant studies on mental health, ML models, and Monte Carlo simulations in healthcare. Section III covers the dataset, preprocessing, model architecture, and simulations. Section IV present findings on the impact of key factors like anxiety and income on depression. Section V interprets these results and compares them with existing studies. while Section VI summarizes key insights and future research directions.

II. Literature Review

The global impact of the COVID-19 pandemic has extended far beyond physical health, with mental health becoming a critical concern [1]. The widespread implementation of quarantine measures, social isolation, and economic hardship have contributed to an unprecedented increase in mental health disorders, particularly depression and anxiety [20]. This section reviews the literature on the mental health effects of COVID-19 globally, with a specific focus on Argentina and similar regions, and examines existing models for depression prediction using ML [21]. Furthermore, it discusses the relevance of Monte Carlo simulations in healthcare, particularly for scenario-based analyses.

The mental health consequences of the COVID-19 pandemic have been substantial, affecting populations worldwide [22]. Numerous studies have documented increases in the prevalence of depression, anxiety, and other psychological disorders during and after the quarantine period [23]. Globally, individuals have experienced heightened levels of stress due to health fears, job insecurity, and disruption of social support networks [24]. A study by Lei et al. [25] highlights that depression and anxiety levels increased significantly during the pandemic, with rates of depression among the general population ranging from 6.7% to 14.6%.

In Argentina, the economic and social challenges posed by the pandemic were exacerbated by existing economic instability. Argentina has faced long-standing economic challenges, including high inflation and unemployment, which were worsened by the pandemic's impact. Several studies in Latin America and Argentina have highlighted the direct link between socio-economic hardship and mental health deterioration during COVID-19 [26]. Torrente et al. [27] specifically explored the mental health effects in Argentina, noting a significant rise in depressive symptoms during the lockdown period, with younger adults and those with lower economic income being the most affected.

In addition, the pandemic intensified psychological stressors, such as uncertainty about the future, fear of illness, and social isolation [12]. Badellino et al. [23] found that anxiety and depression rates in Argentina were significantly correlated with the duration of quarantine and the associated social and economic difficulties. The study also identified that individuals

who experienced income loss or unemployment were more likely to suffer from mental health issues. These findings align with global trends, indicating that the socio-economic consequences of the pandemic are key determinants of mental health outcomes [26].

With the increasing availability of mental health data, ML has emerged as a valuable tool for predicting mental health outcomes, including depression [28]. Traditional statistical methods, while useful, often struggle to capture the complex and non-linear relationships between socio-economic, psychological, and demographic factors [29] that contribute to mental health disorders. ML models, however, excel in this area, allowing for the analysis of large datasets with multiple variables and uncovering patterns that may not be immediately obvious.

Several studies have demonstrated the effectiveness of ML models in predicting depression [30]. For instance, Razavi et al. [31] applied ML algorithms to predict depression based on mobile phone usage and behavioral data, achieving high accuracy. Bakkeli et al. [30] has utilized a combination of psychological factors and socio-economic data to build depression prediction models. Sun et al. [32] employed a ML approach to predict depression onset in individuals based on a wide range of clinical and socio-demographic factors, including economic status and education level.

In the context of the COVID-19 pandemic, ML models have been used to predict the mental health impact of various stressors, such as isolation, income loss, and increased anxiety [33]. Hueniken et al. [34] developed a ML model to predict depression based on anxiety and socio-economic factors during the pandemic, showing that these factors were highly predictive of depression risk. These models offer valuable insights into how depression evolves in response to external conditions, making them particularly useful in the context of a global crisis like COVID-19 [35].

Monte Carlo simulations are widely used in healthcare to model uncertainty and assess the potential outcomes of different scenarios [36]. In mental health research, Monte Carlo methods allow for the exploration of how various socio-economic and psychological factors interact to influence mental health outcomes, such as depression [37]. By simulating a range of possible scenarios, researchers can estimate the probability of different outcomes and gain a deeper understanding of the factors driving mental health disorders [38].

In the context of depression prediction, Monte Carlo simulations are particularly useful for exploring "what-if" scenarios [39]. Monte Carlo simulations have also been employed in scenario-based analyses to evaluate the effectiveness of mental health interventions [40].

In this study, Monte Carlo simulations are used in conjunction with ML models to simulate the impact of changes in socio-economic and psychological factors—such as anxiety state, economic income, and education—on depression levels in Argentina during the post-quarantine period. This approach allows for a more comprehensive understanding of how different variables contribute to depression and enables the identification of potential interventions that could alleviate the mental health burden.

III. Methodology

In this section, we detail the methodology employed in this study, which includes data preprocessing, model training, and Monte Carlo simulations. It describe how socio-economic and psychological variables were processed, the steps taken to train a FNN model, and the approach used to simulate various scenarios. The flowchart in Fig. 1 illustrates the entire workflow, from data preparation to the prediction of depression outcomes.

A. Data Description

The dataset titled "Mental Health of People in Argentina Post-Quarantine COVID-19" used in this study was collected by López Steinmetz from 1100 individuals residing in different provinces of Argentina during the post-quarantine period following the COVID-19 pandemic [41]. This period is characterized by significant socio-economic changes and heightened mental health concerns. The dataset includes key demographic, economic, and psychological variables that provide insights into the mental health status of individuals. Table I provides a summary of the variables included in the dataset.

These features were chosen for their known relationship with mental health, and their interaction offers a complex view of depression in the post-quarantine context.

B. Data Cleaning

1) Handling missing values: Before applying ML models, the dataset was cleaned to handle missing values. For continuous variables such as AGE, DEPRESSION, ANXIETY STATE, and ANXIETY TRAIT, mean imputation was selected over alternative strategies (e.g., median imputation or model-based imputation such as k-NN or MICE) because the proportion of missing values in the continuous variables was low (under 5%) and a preliminary inspection of their distributions did not reveal strong skewness or extreme outliers that would bias the mean. Under these conditions, mean imputation preserves the original sample size and the overall distributional shape of each variable while avoiding the additional computational complexity and risk of introducing artificial correlations associated with more elaborate imputation methods. Let $X = x_1, x_2, ..., x_n$ represent the dataset where x_i denotes the features for each respondent. Missing values in continuous variables were replaced by the mean of the available data:

$$x_i{}^{(missing)} = \frac{1}{n}\sum_{j=1}^{n} x_j \tag{1}$$

where, n is the total number of respondents or data points. $x_i{}^{(missing)}$ is the value used to replace the missing data for feature x_i.

For categorical variables, missing values were replaced by the mode, defined as:

$$x_i^{(missing)} = \underset{v \in \text{values}(x)}{\arg\max}\ \#(v) \tag{2}$$

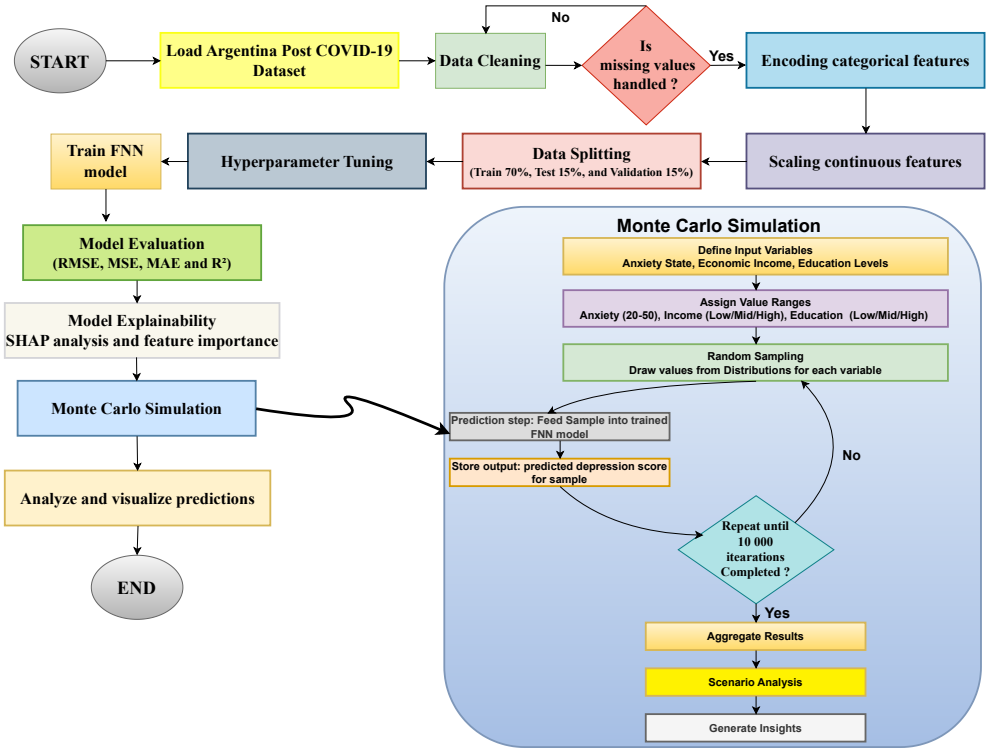

Fig. 1. Flowchart of the proposed methodology.

TABLE I. DESCRIPTION AND DATA TYPES OF VARIABLES

Variable	Description	Data Type
SUB PERIODS	Survey collection phase indicator	Categorical
EDUCATION	Maximum level of education attained by the individual	Categorical
PROVINCE	Province where the individual resides	Categorical
SEX	Gender of the individual	Categorical
AGE	Age of the individual	Numerical
MENTAL DISORDER HISTORY	History of mental disorder diagnosis	Categorical
SUIC ATTEMPT HISTORY	History of suicide attempts	Categorical
LIVING WITH SOMEBODY	Indicates whether the individual lives with someone	Categorical
ECONOMIC INCOME	Whether the individual has economic income	Categorical
DEPRESSION	Depression score (quantitative)	Numerical
SUIC RISK	Suicide risk score	Numerical
ANXIETY STATE	State anxiety score	Numerical
ANXIETY TRAIT	Trait anxiety score	Numerical
REGION	Name of the region where the individual resides	Categorical

where, $\arg\max \#(v)$ refers to the value v that occurs most frequently (the mode) among the available values of the feature x. values(x) is the set of all observed values of the feature x. and $\#(v)$ denotes the frequency or number of times the value v appears in the dataset.

2) Categorical encoding: Categorical variables like SEX, ECONOMIC INCOME, EDUCATION, and MENTAL DISORDER HISTORY were encoded numerically. One-hot encoding was used for multi-class variables, while binary variables were mapped as 0 and 1. For example, the education levels were mapped as:

$$\text{EDUCATION} = \begin{cases} 30 & \text{Completed post graduate} \\ 40 & \text{Incomplete post graduate} \\ 50 & \text{Completed tertiary or university} \\ 60 & \text{Incomplete tertiary or university} \\ 70 & \text{Completed high school} \\ 80 & \text{Incomplete high school} \\ 90 & \text{Completed elementary school} \\ 100 & \text{Incomplete elementary school} \end{cases}$$

One-hot encoding transforms a categorical variable x with k categories into a binary vector $y \in \{0,1\}^k$:

$$y_i = \begin{cases} 1 & \text{if the } i\text{-th category is present} \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

3) Data scaling: Continuous variables were scaled using the MinMaxScaler to ensure all variables fell within a consistent range. Let x_i be a continuous variable, it was normalized as follows:

$$x_i^{scaled} = \frac{x_i - min(x)}{max(x) - min(x)} \quad (4)$$

This ensures that the features lie in the range $[0, 1]$, improving the performance of ML models [42]. MinMax scaling was preferred over standardization (z-score normalization) because several of the FNN's input features, after one-hot and ordinal encoding, do not follow a Gaussian distribution and have bounded, interpretable ranges (e.g., anxiety scores, encoded education levels). Rescaling all features to a common $[0, 1]$ range avoids implicitly assigning greater weight to variables with larger numeric ranges and is particularly suited to neural network training, where bounded inputs help stabilize gradient-based optimization and accelerate convergence.

4) Feature engineering: Feature engineering was a critical step in this study, as it allowed for the transformation of raw data into meaningful inputs for both the ML model and Monte Carlo simulations. The key features engineered include:

1) Anxiety state: This feature represents the temporary anxiety levels of respondents. To explore its impact on depression, anxiety state was varied from low (20) to high (50) in increments of 5 during the simulations. This variation allowed the model to predict how increasing anxiety levels would affect depression scores.

$$AnxietyState = [20, 25, 30, 35, 40, 45, 50]$$

2) Economic income: Respondents' economic income was categorized into low, middle, and high income. These categories were used in the Monte Carlo simulations to explore how changes in economic status affect depression predictions. The three categories were encoded as follows:

$$Economic\,Income = \{Low\,Income, Middle$$

$$Income, High\,Income\}$$

3) Education: Education levels were categorized into low (incomplete high school), middle (completed high school), and high (completed university or postgraduate). These categories were used to simulate how different levels of educational attainment influence depression outcomes.

$$Education = \{Low, Middle, High\}$$

By varying these features in different simulations, this allowed for the exploration of explore the role of socio-economic and psychological factors in predicting depression. Interaction terms were also considered during feature engineering, such as the combination of economic income and education, to capture how these factors together affect depression outcomes.

C. Data Splitting

The dataset was split into training (70%), validation (15%), and testing (15%) sets. The training set was used to fit the model, the validation set was used for tuning hyperparameters, and the testing set was used to assess model performance on unseen data. A dedicated validation set was retained, in addition to the 5-fold cross-validation described in Section III G, to support the hyperparameter search described in Section III F. While cross-validation is used to report robust, averaged generalization performance across the full dataset, an independent validation split was needed during the random search procedure to select the optimal configuration efficiently without repeatedly re-running k-fold cross-validation for every candidate combination, which would have been computationally prohibitive given the number of hyperparameter combinations explored. The final model, trained with the selected configuration, was then evaluated on the untouched test set and separately validated through 5-fold cross-validation to confirm that its performance was not an artifact of a particular data split.

D. Hyperparameter Tuning

To enhance the performance and generalization ability of the FNN model, a hyperparameter optimization process was conducted. Several key hyperparameters were selected based on their relevance to the architecture design and learning dynamics of the model. The following were explored: the number of hidden layers, number of neurons per layer, learning rate, batch size, and dropout rate. A random search strategy was employed to navigate the hyperparameter space efficiently, avoiding the computational burden of exhaustive grid search. For each candidate configuration, the model was trained using the training set (70%) and validated on a held-out validation set (15%). The MSE on the validation set was used as the objective metric for selecting the optimal configuration. This process was repeated over multiple random combinations to identify the most performant model.

The table below summarizes the final hyperparameters that yielded the best validation performance:

TABLE II. HYPERPARAMETER SEARCH SPACE AND OPTIMAL CONFIGURATION FOR THE FNN MODEL.

Hyperparameter	Search Space	Optimal Value
Number of Hidden Layers	{1, 2, 3, 4}	3
Number of Neurons per Layer	{32, 64, 128}	64
Learning Rate	{0.001, 0.0005, 0.0001}	0.0005
Batch Size	{32, 64, 128}	64
Dropout Rate	{0.0, 0.2, 0.5}	0.2
Activation Function	{ReLU, Tanh}	ReLU
Optimizer	{Adam, RMSprop}	Adam
Loss Function	{MSE, MAE}	Mean Squared Error (MSE)

This configuration was subsequently used for training the final model, which was evaluated on the test set (15%) to assess generalization performance.

E. Cross-Validation Strategy

To ensure the robustness and generalizability of the proposed FNN, a 5-fold stratified cross-validation was conducted in addition to the standard 70-15-15 holdout split. This strategy was chosen to attenuate overfitting risks, particularly given the moderate dataset size of 1,100 records. Stratification was applied based on depression severity levels, ensuring that each fold maintained a representative distribution of depression classes.

For each iteration, 80% of the data was used for training and 20% for validation. The model was trained using the same hyperparameter configuration as defined in Table II. Performance was evaluated using three key regression metrics: MAE, RMSE, and the Coefficient of Determination R^2. These metrics were averaged across the five folds, and their standard deviations were computed to assess consistency.

F. Computational Environment

The Monte Carlo simulations and the training of the FNN were conducted within the Google Colaboratory platform, which provides a cloud-based environment equipped with hardware accelerators. The experiments were implemented using Python 3.10, leveraging prominent scientific and ML libraries including TensorFlow 2.13, Keras, scikit-learn, NumPy, and Pandas. Model training was performed on a virtual machine provisioned with an NVIDIA Tesla T4 GPU (16 GB VRAM), enabling efficient handling of computational demands associated with neural network training and cross-validation.

G. Model Description

FNN was used to predict depression levels, which offers the flexibility to capture complex non-linear relationships between the variables. The architecture of the model is defined as follows:

1) Input layer: The input layer contains n features, where n is the number of preprocessed variables.
   1) Hidden layers: Three hidden layers were added, each with 64 neurons. The activation function for each hidden layer was $ReLU$ (Rectified Linear Unit), defined as:
   $$f(x) = max(0, x) \tag{5}$$
   This activation function ensures non-linearity while avoiding the vanishing gradient problem during backpropagation.
2) Output layer: The output layer predicts the DEPRESSION score, a continuous variable, with a linear activation function. The predicted depression score is represented as:
   $$\hat{y} = W_L^T h_L + b_L \tag{6}$$
   where, W_L is the weight matrix, h_L is the activation from the last hidden layer, and b_L is the bias.
3) Loss function: The loss function used is Mean Squared Error (MSE), given by:
   $$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y_i})^2 \tag{7}$$
   where, y_i is the true depression score, and $\hat{y_i}$ is the predicted score.
4) Optimizer: The Adam optimizer was used for gradient-based optimization. This optimizer was chosen for its efficiency in handling sparse gradients and its ability to converge quickly in neural networks. The learning rate was set to $\alpha = 0.0005$.
5) Regularization and training: A dropout rate of 0.2 was applied between layers to prevent overfitting, and the batch size was set to 64 during training.

H. Model Explainability

To improve the interpretability of the proposed model, were employed SHapley Additive exPlanations (SHAP), a model-agnostic method rooted in cooperative game theory. SHAP assigns each feature an importance value representing its marginal contribution to the model's prediction. The SHAP value ϕ_i for feature i is mathematically defined as:

$$\phi_i(f, x) = \sum_{S \subseteq F \setminus \{i\}} \frac{|S|!\,(|F| - |S| - 1)!}{|F|!} \left[f_{S\cup\{i\}}(x_{S\cup\{i\}}) - f_S(x_S) \right] \tag{8}$$

where, F is the set of all input features, S is a subset of F not containing feature i, $f_S(x_S)$ is the model's prediction using only the features in subset S, and $|F|$ is the total number of input features. The SHAP framework ensures a fair distribution of contributions by averaging over all possible permutations of feature subsets. In this study, was applied the `KernelExplainer` from the SHAP Python library to approximate the Shapley values, enabling both global and local interpretability of the FNN's depression prediction outcomes.

I. Hyperparameter Configuration of Benchmark Models

To ensure reproducibility of the proposed framework, Table III summarizes the hyperparameter configurations used for each ML model evaluated in this study. Default values were retained for models that did not undergo hyperparameter tuning, while the configurations for ensemble and neural network models were selected based on performance optimization through empirical testing.

It is worth noting that the two most influential predictors identified by SHAP—suicide attempt history and living situation—are categorical, non-actionable risk markers rather than modifiable intervention targets. The Monte Carlo simulations instead focus on anxiety state, economic income, and education, which were deliberately selected because they are continuous or ordinal, can be meaningfully varied across a range of values, and correspond to factors that public health policy can realistically influence. The SHAP and simulation analyses are therefore complementary rather than contradictory: SHAP identifies which factors drive individual predictions most strongly, while the simulations are restricted to the subset of factors that are both quantifiable on a continuum and actionable for intervention design.

These configurations balance computational efficiency and generalization performance. The GRU model, in particular, was trained using early stopping with a patience of 10 epochs to prevent overfitting.

TABLE III. HYPERPARAMETER CONFIGURATIONS OF THE IMPLEMENTED MACHINE LEARNING MODELS.

Model	Hyperparameters
SVR	`kernel='rbf', degree=3, gamma='scale', C=1.0, epsilon=0.1, verbose=False, max_iter=-1`
Linear Regression	`fit_intercept=True, positive=False, n_jobs=-1.`
Decision Tree Regressor	`criterion='squared_error', max_depth=10, min_samples_split=4, min_samples_leaf=2, random_state=42.`
Random Forest Regressor	`n_estimators=100, criterion='squared_error', max_depth=15, min_samples_split=4, min_samples_leaf=2, max_features='sqrt', bootstrap=True, oob_score=True, n_jobs=-1, random_state=42.`
GRU	Architecture: `GRU(80, activation='relu')` → `Dense(48, activation='relu')` → `Dense(1);` Optimizer: `Adam`, Loss: `MSE`.

J. Monte Carlo Simulation

Monte Carlo simulations were employed to simulate the effect of varying key features (e.g., ANXIETY STATE, ECONOMIC INCOME, and EDUCATION) on predicted depression scores. Monte Carlo methods allow for stochastic exploration of how changes in these variables influence the outcome, providing insight into possible future states under different scenarios. Let $X = x_1, x_2, ..., x_n$ represent the features, and let $P(\theta|X)$ represent the model's predicted depression score based on a set of features. The Monte Carlo method simulates possible future states by repeatedly sampling from the distribution of features θ, generating depression predictions:

$$\hat{y}_i = f(X, \theta) + \epsilon, \epsilon \sim N(0, \sigma^2) \tag{9}$$

where, ϵ represents noise, and θ represents the set of variables that are varied in each simulation. The simulations were run 10,000 times to generate a distribution of predicted depression scores for different levels of ANXIETY STATE, ECONOMIC INCOME, and EDUCATION. The Monte Carlo simulation enables the estimation of the mean predicted depression score and the standard deviation for each scenario.

K. Evaluation metrics

The performance of the ML model was evaluated using standard regression metrics, while the Monte Carlo simulations were assessed using statistical measures of the depression predictions.

1) Metrics for ML models:

a) Mean Squared Error (MSE): This metric measures the average squared difference between predicted and actual depression scores, providing a sense of the overall accuracy of the model. Lower values indicate better performance.

b) Mean Absolute Error (MAE): Measures the average absolute difference between predicted and actual values, providing a more interpretable measure of model accuracy. It is less sensitive to outliers than MSE.

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \tag{10}$$

c) Root Mean Squared Error (RMSE): It is defined as the square root of MSE and is useful for understanding the magnitude of prediction errors in the same units as the depression scores. Lower$RMSE$ indicates better performance.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \tag{11}$$

d) R-squared (R^2): This metric indicates the proportion of variance in the depression scores explained by the model. A R^2 value close to 1 indicates a well-fitting model, while values closer to 0 suggest poor performance.

$$R^2 = 1 - \frac{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\frac{1}{n}\sum_{i=1}^{n}(y_i - \bar{y})^2} \tag{12}$$

where, n is the total number of data points or observations in the dataset. y_i is the actual observed value of the dependent variable (in this case, the depression score) for the i^{th} data point. $\hat{y}_i$ the predicted value of the dependent variable generated by the model for the i^{th} data point. And $\bar{y}$ is the mean (average) of the observed values of the dependent variable across all data points.

2) Metrics for Monte Carlo simulations: For the Monte Carlo simulations, was examined the distribution of predicted depression scores under various scenarios. The following metrics were used:

a) Mean predicted depression: The average predicted depression score across all simulations was calculated to estimate the central tendency of depression outcomes under different conditions:

$$\mu_{Depression} = \frac{1}{n}\sum_{i=1}^{n}\hat{y}_i \tag{13}$$

b) Standard deviation of predicted depression: It was used to assess the variability in predictions under each scenario. Higher standard deviations indicate more variability in depression outcomes due to uncertainty or sensitivity to certain features (e.g., anxiety state or economic income):

$$\sigma_{Depression} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(\hat{y}_i - \mu_{Depression})^2} \tag{14}$$

These metrics were essential for evaluating both the baseline performance of the ML model and the potential range of depression outcomes under different socio-economic and psychological conditions in the Monte Carlo simulations.

IV. RESULTS AND ANALYSIS

In this section, we present the findings from the trained ML model and the Monte Carlo simulations, which were designed to explore how key socio-economic and psychological variables influence depression predictions. The results focus on the post-COVID quarantine period in Argentina, using anxiety

state, economic income, and education levels as key predictors. These results offer insights into how depression rates may evolve in response to changes in these variables.

A. FNNs Results

The neural network model was trained to predict depression scores based on the dataset from the post-COVID quarantine period. The model's performance was evaluated using standard regression metrics, including MSE, MAE, $RMSE$, and R^2. The model's performance was compared against various benchmark models, including SVR, GRU, and simpler and more interpretable models such as LR, DT, and RF. The following table summarizes the MAE, MSE, $RMSE$, and R^2 for each model:

The benchmark models in Table IV were selected to represent three complementary methodological families relevant to this regression task: a classical statistical baseline (Linear Regression), tree-based learners of increasing complexity (Decision Tree and Random Forest), a kernel-based method commonly used in prior depression-prediction studies (SVR), and a recurrent deep learning architecture suited to sequential or tabular data (GRU). This selection allows the proposed FNN to be benchmarked not only against simpler, more interpretable models but also against more complex architectures, enabling a balanced assessment of the trade-off between predictive accuracy and model interpretability.

Beyond numerical performance metrics, the model outputs have concrete implications for individuals and communities. For example, a predicted depression score increase of even 2–3 points (as observed in high-anxiety simulations) could correspond to a transition from mild to moderate depression severity, potentially requiring clinical intervention. Similarly, the reduction in depression scores associated with higher income levels suggests that improved financial stability could translate into better access to healthcare, reduced chronic stress, and enhanced quality of life. These patterns are consistent with observed public health trends during the pandemic in Argentina, where economic instability and social isolation amplified mental health challenges.

Fig. 2 shows the actual depression values with the FNN model's predicted values. This visualization demonstrates the accuracy of the model in capturing depression trends.

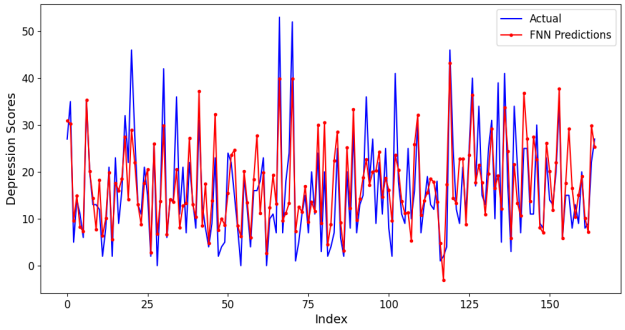

Fig. 2. Actual vs. predicted depression values.

The FNN model outperforms SVR, GRU, DT, RF in terms of MAE, MSE, $RMSE$, and R^2, highlighting its ability to capture complex, non-linear patterns in the data. Interestingly, LR achieved the highest R^2 (0.693) and lowest RMSE (6.25) among all models, suggesting that the underlying relationships between predictors and depression scores may be partially linear. The RF model also performed strongly, indicating the value of ensemble tree-based approaches in this context. In contrast, the DT model displayed the weakest performance, with the highest error metrics and lowest R^2 (0.435), reflecting its limited ability to generalize from the available data.

The results show that while simpler models like LR can match or even exceed the predictive accuracy of more complex architectures in certain cases, the FNN remains a robust choice for scenarios where capturing subtle nonlinear dependencies is critical. The model's predictions reinforce that higher anxiety levels, lower economic income, and lower education are strong predictors of elevated depression scores, aligning with previous findings in the literature [27].

Table V presents the mean and standard deviation of the evaluation metrics (MSE, MAE, $RMSE$, and R^2) obtained through the 5-fold stratified cross-validation procedure for all benchmark models. This evaluation provides a more comprehensive measure of model robustness and generalization compared to a single holdout validation, as it accounts for variability across different data partitions.

The results from the 5-fold stratified cross-validation confirm the robustness and consistency of the evaluated models. The FNN maintained superior performance, achieving the lowest average errors (MSE = 49.84 ± 6.07, MAE = 5.53 ± 0.30, RMSE = 7.06 ± 0.43) and the highest coefficient of determination (R^2 = 0.593 ± 0.048). SVR followed closely, demonstrating strong predictive capability and stability across folds, while LR, DT, and RF showed moderate performance with higher variability, reflecting their sensitivity to data partitioning. GRU, by contrast, exhibited the weakest generalization, reaffirming its limited suitability for non-temporal data.

When comparing these results with those obtained from the single holdout evaluation in Table IV, the overall ranking of models remains consistent, The FNN and SVR still lead in accuracy and generalization. However, the cross-validation results present slightly higher error values and reduced R^2 scores, which is expected due to the more rigorous partitioning of the dataset. This consistency between the two evaluation protocols supports the reliability of the FNN model and the stability of the comparative analysis across different validation strategies.

B. Model Explainability Using SHAP

To address the interpretability limitations of the FNN, were employed SHapley Additive exPlanations (SHAP)—a game-theoretic approach that quantifies the contribution of each input variable to the model's predictions. This method provides both local and global explanations by assigning SHAP values to each feature for individual predictions and aggregating them to reveal global importance.

Fig. 3 illustrates the SHAP summary plot, where each dot represents a SHAP value for a feature across different individuals. The horizontal axis reflects the magnitude and direction of each feature's impact on the predicted depression

TABLE IV. COMPARISON OF PERFORMANCE RESULTS

Model	MSE	MAE	$RMSE$	R^2
SVR	52.27	5.58	7.22	0.58
GRU	43.38	4.86	6.58	0.56
LR	39.06	4.79	6.25	0.693
DT	71.90	6.55	8.48	0.435
RF	42.52	4.91	6.52	0.666
FNN	43.38	4.72	6.32	0.64

TABLE V. PERFORMANCE COMPARISON USING 5-FOLD CROSS-VALIDATION

Model	**MSE**	**MAE**	**RMSE**	**R^2**
SVR	50.69 ± 5.00	5.74 ± 0.25	7.11 ± 0.34	0.584 ± 0.043
GRU	112.55 ± 17.63	8.36 ± 0.78	10.57 ± 0.87	0.082 ± 0.107
LR	64.54 ± 2.76	6.15 ± 0.19	8.03 ± 0.17	0.470 ± 0.032
DT	73.55 ± 8.17	6.78 ± 0.33	8.56 ± 0.48	0.397 ± 0.061
RF	73.43 ± 4.15	6.57 ± 0.20	8.57 ± 0.24	0.398 ± 0.023
FNN	$\mathbf{49.84 \pm 6.07}$	$\mathbf{5.53 \pm 0.30}$	$\mathbf{7.06 \pm 0.43}$	$\mathbf{0.593 \pm 0.048}$

scores, while the color gradient (blue to red) indicates the original feature value from low to high, respectively.

The analysis revealed that the most influential features were:

- History of suicide attempt (Yes/No): Individuals with a positive history (in red) were associated with significantly higher predicted depression scores.
- Living with somebody: Shared living conditions appeared to moderate depressive symptoms, likely reflecting the protective role of social connectedness.
- Age: Younger individuals tended to have higher SHAP values, suggesting greater vulnerability to depressive symptoms in this subgroup.

Other relevant features included suicide risk, anxiety state, and education level, each showing moderate predictive contributions. Economic income and mental disorder history had smaller but still meaningful effects.

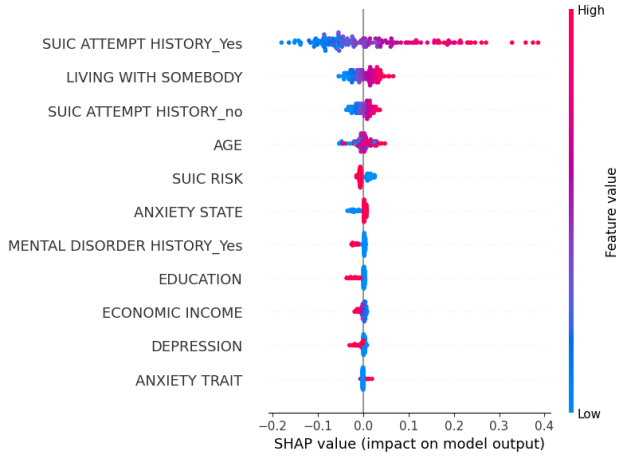

Fig. 3. SHAP summary plot showing feature importance and directional impact on depression prediction.

C. Monte Carlo Simulation Results

To further understand how variations in key factors influence depression, Monte Carlo simulations were employed. These simulations allowed for the exploration of "what-if" scenarios, simulating changes in anxiety state, economic income, and education levels.

1) Impact of anxiety state on depression: The first set of simulations explored the impact of varying anxiety state on predicted depression scores. Anxiety levels were varied from 20 to 50, reflecting low to high anxiety states. The results show a clear relationship between increasing anxiety state and rising depression scores.

$$Mean\,Predicted\,Depression = f(Anxiety\,State)$$

As anxiety state increased from 20 to 50, the mean predicted depression scores rose from 23.80 to 25.50. The standard deviation of predicted depression also increased, indicating greater variability in depression outcomes at higher anxiety states. The results suggest that anxiety state is a critical factor in determining depression levels, with higher anxiety states strongly associated with elevated depression. This finding underscores the need for interventions that target anxiety reduction as part of broader mental health support efforts. Fig. 4 shows the relationship between anxiety state and predicted depression scores. The plot clearly illustrates the upward trend in depression as anxiety state increases, with shaded error bands representing the standard deviation across the simulations.

2) Impact of economic income on depression: The second set of simulations examined how variations in economic income affect depression. Economic income was divided into three categories: low income, middle income, and high income. The Monte Carlo simulations generated predictions for depression based on these categories.

$$Mean\,Predicted\,Depression = f(Economic\,Income)$$

Low-income respondents exhibited the highest mean predicted depression score of 26.01, compared to 23.84 for middle-income and 22.73 for high-income respondents. This finding highlights the significant impact of economic hardship on mental health, with lower economic income strongly linked

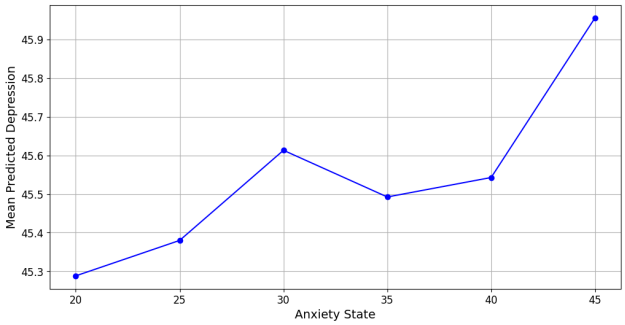

Fig. 4. Anxiety state vs. predicted depression.

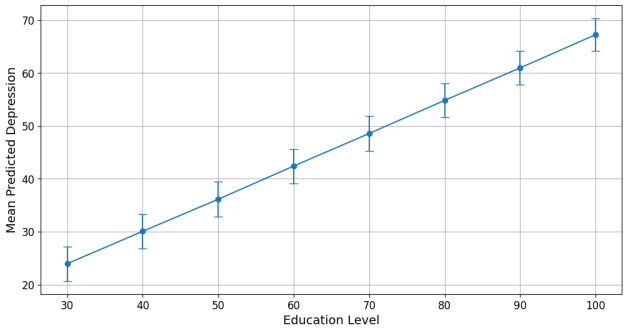

Fig. 6. Education vs. predicted depression.

to higher depression scores. Fig. 5 shows the distribution of predicted depression scores across different economic income levels. The plot clearly demonstrates that lower-income individuals are at a much higher risk of depression.

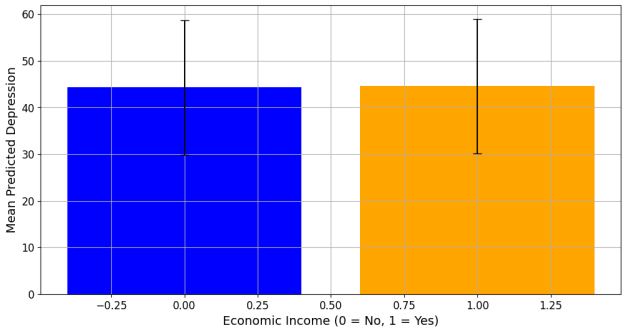

Fig. 5. Economic income vs. predicted depression.

3) Impact of education on depression: The final set of simulations explored the relationship between education levels and depression. Education was categorized into low education (incomplete elementary school), middle education (completed high school), and high education (completed university or postgraduate). The simulations provide insight into how educational attainment influences depression.

$$Mean\,Predicted\,Depression = f(Education\,Level)$$

Fig. 6 illustrates the impact of education on depression, with lower education levels associated with significantly higher depression scores. This highlights the importance of educational attainment in mitigating the effects of other mental health stressors. Respondents with low education had the highest predicted depression scores, with a mean of 25.35, compared to 23.45 for middle education and 21.98 for high education. Higher education appears to serve as a protective factor against depression, reducing vulnerability to the socio-economic stress that contribute to poor mental health.

V. Discussion

A. Interpretation of Results

The results of this study offer valuable insights into the relationship between depression and key socio-economic and psychological factors during the post-COVID-19 quarantine period in Argentina.

The anxiety state emerged as a significant predictor of depression, with higher anxiety levels consistently correlating with elevated depression scores. This finding is consistent with established mental health literature, which emphasizes that anxiety and depression often co-occur and exacerbate each other. In particular, individuals experiencing higher levels of anxiety may struggle with emotional regulation and face greater difficulty managing stress, leading to increased vulnerability to depression.

Economic income also plays a crucial role in depression outcomes. The Monte Carlo simulations demonstrated that individuals with lower economic income are more likely to experience higher depression scores. This result aligns with existing research showing that economic hardship can lead to mental health challenges, particularly in the aftermath of the pandemic. Economic instability and financial stress are known contributors to depression, as they increase uncertainty and limit access to mental health resources.

Education levels revealed a protective effect against depression. Individuals with higher educational attainment generally displayed lower depression scores, suggesting that education may serve as a buffer against socio-economic stressors. Education equips individuals with critical thinking skills, problem-solving abilities, and greater access to information, all of which can enhance resilience in the face of mental health challenges.

The cross-validation results provide crucial insights into the reliability of the FNN model. The consistency of MAE, RMSE, and R^2 scores across all five folds indicates that the model is not overly sensitive to specific data partitions. This robustness is particularly important in mental health prediction tasks, where overfitting could lead to misleading or biased recommendations. The observed stability suggests that the training configuration, feature set, and regularization strategy are effective in balancing bias and variance. The relatively high R^2 value confirms that the selected predictors—particularly anxiety state, education, income, and living situation—are strong indicators of depression severity within this dataset.

Comparing the single holdout and cross-validation results also provides additional interpretative depth. Although both evaluation protocols revealed a consistent ranking of the models - with FNN and SVR performing best, cross-validation produced slightly higher error measures, as expected due to its stricter data partitioning. This difference underscores the reliability of the reported results, confirming that the perfor-

mance of the FNN is not dependent on a specific data split and that its predictions remain stable under varying conditions.

The flexibility of supervised neural networks in capturing complex nonlinear dynamics has been demonstrated in diverse domains, further reinforcing their suitability for the mental health prediction task.

From a model performance perspective, the comparison with simpler and more interpretable models provides valuable context. Although the FNN achieved strong predictive performance, LR unexpectedly attained the highest R^2 (0.693) and lowest RMSE (6.25), suggesting that a significant portion of the relationship between predictors and depression scores can be captured by a predominantly linear model. This finding implies that for certain applications where transparency and interpretability are prioritized—such as clinical decision-making or policy formulation—LR may be a viable alternative without substantial loss in predictive accuracy. The RF model also performed competitively, underscoring the potential of ensemble-based methods to capture non-linear interactions. In contrast, the DT model showed the weakest results, highlighting the limitations of single-tree models in capturing complex and high-dimensional relationships in mental health data.

The SHAP-based interpretability results provide a clearer understanding of the FNN's predictive behavior and offer actionable implications for mental health research and policy. The prominent influence of suicide attempt history and social living conditions supports the established literature on the psychosocial determinants of depression. Moreover, the moderate effects of anxiety, income, and education suggest that mental health interventions should adopt a multidimensional approach, targeting both emotional well-being and socioeconomic stability. Importantly, this explainability layer reinforces the validity of the FNN model by aligning its internal logic with known clinical risk factors. Such transparency enhances the model's credibility and applicability in real-world mental health decision-making, especially in post-pandemic contexts where resource allocation must be both evidence-based and ethically grounded.

B. Comparison with Existing Studies

The findings from this study are consistent with the broader literature on mental health during and after the COVID-19 pandemic. Several studies have reported a strong association between anxiety and depression, particularly in populations affected by extended periods of lockdown and economic uncertainty. For instance, a study by Mogesie Necho et al. [43] found that anxiety was a major contributor to depression symptoms during the pandemic across various populations.

Similarly, the association between economic income and mental health is well-documented. Jenna M. Wilson et al. [44] reported that financial insecurity during the pandemic was a significant risk factor for developing depression. The results of this study confirm the robustness of these findings, showing that individuals with lower income are at greater risk of depression.

Regarding education, the protective role of higher education aligns with the work of other researchers, such as, Aleksander Aristovnik et al. [45] who demonstrated that individuals with higher educational levels were better able to deal with the psychological impact of the COVID-19 pandemic. The ability to access information, develop coping strategies, and seek professional help likely explains this buffering effect. While this study reaffirms much of the existing literature, the integration of ML models and Monte Carlo simulations adds a novel predictive component that enhances the understanding of how these factors interact to affect depression outcomes in the post-quarantine period.

In terms of predictive performance, the results obtained here are also comparable to those reported in related ML-based depression-prediction studies. For example, prior work applying ML models to depression or mental-health outcome prediction has typically reported R^2 values in the range of 0.4–0.7 depending on the dataset and feature set used [31], [30], [32]. The R^2 obtained by the proposed FNN (0.64 on the holdout set, 0.593 ± 0.048 under cross-validation) falls within this range, and the competitive performance of the simpler LR model ($R^2 = 0.693$) is consistent with the observation, also noted in some of these studies, that socio-economic and psychological predictors of depression often exhibit substantial linear structure. This comparison suggests that, despite differences in population (Argentina, post-quarantine) and feature set, the predictive ceiling achieved in this study aligns with the broader literature, while the addition of Monte Carlo simulation and SHAP-based explainability extends beyond what is typically reported in these comparable works.

The results of this study hold direct practical relevance for mental health policy, clinical practice, and community-based interventions. For public health policymakers, the identified strong influence of anxiety levels on depression suggests prioritizing large-scale anxiety screening and prevention programs, particularly during and after crises such as pandemics. Economic income effects indicate that targeted financial support and employment assistance programs could reduce mental health disparities in low-income populations. In the education sector, the protective role of higher educational attainment underscores the value of long-term investment in education and mental health literacy programs, which can enhance coping strategies and resilience. For clinical practitioners, integrating socio-economic indicators into mental health assessment tools can improve the early identification of high-risk individuals. These findings can also guide the allocation of limited resources by focusing on communities with combined risk factors of high anxiety, low income, and low education, thus maximizing the effectiveness of interventions in real-world settings.

From a physical and societal perspective, these statistical relationships mirror observable patterns in the Argentine post-quarantine context. Elevated anxiety levels often manifested in increased demand for mental health services, more frequent psychosomatic complaints (e.g., headaches, fatigue, sleep disturbances), and reduced workplace productivity. Economic hardship was physically reflected in food insecurity, housing instability, and restricted access to healthcare, all of which exacerbate psychological distress. In contrast, people with higher education levels often exhibited better stress management strategies, healthier lifestyle choices, and stronger social networks, tangible factors that help mitigate the risk of depression. Such direct physical manifestations reinforce

the importance of addressing these socioeconomic variables in both policy and clinical interventions.

C. Limitations

Despite the strength of the findings, several limitations must be acknowledged. First, the dataset used in this study, while comprehensive, is limited to the post-quarantine period in Argentina. This temporal and geographical limitation may affect the generalizability of the results to other regions or periods. Future studies should consider expanding the dataset to include a more diverse population and longer time spans to better capture the evolving nature of depression in the aftermath of the pandemic. Second, while the ML model demonstrated strong predictive power, there are inherent limitations in using FNN models for psychological phenomena. Depression is a multifaceted condition influenced by numerous unobserved factors, including genetic predispositions, social support, and pre-existing mental health conditions, which may not be fully captured by the available dataset. Further research could explore integrating additional psychological variables into the model for a more holistic understanding of depression. Additionally, the Monte Carlo simulations, while useful in exploring different "what-if" scenarios, rely on assumptions about the distributions of variables such as anxiety and economic income. These assumptions may not fully reflect the real-world complexities of how these variables fluctuate over time and across different populations. Further studies could refine these simulations with more precise data.

VI. Conclusion and Future Works

This study has provided a comprehensive analysis of depression in Argentina during the post-COVID-19 quarantine period, using ML models and Monte Carlo simulations to predict depression outcomes based on socio-economic and psychological factors. The key findings highlight the significant role of anxiety state, economic income, and education in shaping depression levels. The results show that individuals with higher anxiety, lower income, and lower educational attainment are more vulnerable to depression, underscoring the complexity of mental health challenges in the wake of the pandemic.

The proposed FNN achieved strong predictive performance, with $MAE = 4.72 \pm 0.30$, $MSE = 43.38 \pm 3.95$, $RMSE = 6.32 \pm 0.43$, and $R^2 = 0.64 \pm 0.048$, outperforming the SVR, GRU, DT, and RF benchmarks. LR, however, achieved the highest R^2 (0.693) and a slightly lower RMSE (6.25), suggesting that part of the relationship between predictors and depression scores may be linear, whereas DT had the weakest performance (R^2 = 0.435).

The predictive model developed in this study offers a powerful tool for mental health practitioners and policymakers. By accurately forecasting depression outcomes based on key variables, the model can help target interventions to populations most at risk. For instance, the findings on anxiety state suggest that mental health support programs should prioritize anxiety reduction strategies. Similarly, the association between economic hardship and depression underscores the need for economic policies that provide financial relief to the most vulnerable groups. Education is also shown to play a protective role, suggesting that long-term investments in education could have significant mental health benefits.

This work also highlights the trade-off between interpretability and accuracy: while deep learning models capture subtle non-linear dependencies, simpler models may be more transparent and easier to implement in certain clinical or policy contexts.

Looking ahead, there are several areas for future research. First, incorporating additional variables, such as social support, access to mental health services, and pre-existing mental health conditions, could improve the accuracy of the model and provide a more nuanced understanding of depression. Additionally, exploring the long-term mental health effects of the pandemic through longitudinal studies could offer insights into how depression evolves over time. Finally, expanding the dataset to include diverse populations and geographical regions would help generalize the findings and provide a more global perspective on post-pandemic mental health.

Context-Aware Sentiment Analysis of E-Commerce Reviews Using a BERT-CNN-BiLSTM Hybrid Model

Mahmud Reza Mahim, Fahad Bin Z Islam, Md Saklain Mahmud, Md. Imtiyaz Hasan, Sifat Rahman Ahona
Department of Computer Science and Engineering
American International University-Bangladesh (AIUB), Dhaka, Bangladesh

***Abstract*—User-generated product reviews are an essential source of information in e-commerce; nevertheless, the huge volume and varying quality of review texts make extracting insights difficult. The conventional approach to sentiment classification is limited in terms of recognizing contextual and aspect-oriented sentiment clues in the text. This study proposes a hybrid architecture that uses contextual sentiment clues for e-commerce reviews sentiment classification. The experiments are conducted using FABSA dataset which contains reviews annotated in terms of multiple aspects–sentiments pairs. Every review is expanded in terms of aspect-oriented sentiment classification samples. This makes it possible to learn fine-grained polarities of sentiments associated with specific aspects of product reviews. To tackle the problem of class imbalance in the data, the experiments employ the method of stratified oversampling in combination with the use of class-weighted cross-entropy loss function. The empirical results show that the improved hybrid BERT–CNN–BiLSTM model achieves 92.20% validation accuracy, 92.25% weighted F1-score, and 86.36% macro F1-score. The most noticeable progress has been made in the case of neutral class, where the F1-score has increased by 17.1 percentage points showing the improvements in minority-class recognition and decrease of class imbalance. The architecture-level ablation study shows the superior performance of the BERT–CNN–BiLSTM model compared to its simplified versions based on BERT, BERT–CNN, and BERT–BiLSTM architectures. A contextual comparison with reported FABSA baselines suggests competitive performance, although this comparison should not be interpreted as a strict leaderboard result because the baselines were not reproduced under identical experimental settings. Overall, the findings demonstrate that combining contextual transformer representations with local convolutional features and bidirectional sequential modeling can improve class-balanced sentiment classification in aspect-expanded e-commerce review data.**

Keywords*—*Sentiment analysis; e-commerce reviews; BERT; CNN; BiLSTM

I. Introduction

A. Background and Motivation

The widespread adoption of e-commerce platforms has made user-generated product reviews one of the most influential sources of information in consumer purchase decisions [1], [2]. User-generated reviews help consumers reduce uncertainty regarding product quality, functionality, usability, and post-purchase satisfaction [2], [3]. Therefore, review information is increasingly used in recommendation and decision-support systems. However, the abundance of review content creates information overload, making it difficult for consumers and online platforms to filter useful information from a large pool of reviews. In addition, many reviews are short, generic, sentiment-heavy, or low in informational value, while detailed experience-based reviews may remain unnoticed [4], [5], [6], [7].

Traditional sentiment analysis methods generally focus on assigning broad polarity labels, such as positive, negative, or neutral, to a given text. Although such approaches are useful, they often fail to capture fine-grained contextual information related to specific product aspects, usage conditions, and user intentions [8], [9]. For example, a review may express positive sentiment toward one aspect of a product while expressing negative sentiment toward another. Similarly, short expressions, such as "Great product!", may indicate positive polarity but provide limited contextual detail about the product experience. These cases show that sentiment classification in e-commerce reviews requires models that can capture not only overall polarity, but also the contextual cues surrounding product-related aspects [6], [7], [10], [11].

Lexicon-based and conventional machine learning methods have provided useful and interpretable baselines for sentiment analysis. Some recent studies also show that calibrated lexicon-based approaches can remain competitive in specific domains [9]. However, conventional models often struggle with domain-specific language, compositional meaning, sarcasm, implicit sentiment, and the semantic relationship between product aspects and opinion expressions [8], [10]. These limitations have encouraged the use of deep learning and transformer-based methods, which are more capable of learning contextual representations directly from text.

Recent studies have increasingly adopted deep learning architectures to capture both local and global dependencies in review text. BERT provides contextualized word representations through bidirectional transformer encoding, making it effective for modeling semantic relationships in sentences [12]. Convolutional neural networks (CNNs) are effective at extracting local n-gram and phrase-level sentiment features, while bidirectional long short-term memory networks (BiLSTMs) can capture sequential dependencies from both forward and backward directions [8], [13], [3]. Hybrid architectures that combine these components can integrate contextual representation learning, local feature extraction, and sequential dependency modeling within a single framework [13], [14], [15], [16].

In this context, a hybrid BERT–CNN–BiLSTM architec-

ture offers a promising approach for context-aware sentiment classification in e-commerce reviews. BERT can generate deep contextual embeddings, CNN layers can identify local sentiment-bearing patterns, and BiLSTM layers can model bidirectional dependencies across review sequences. This combination is particularly suitable for aspect-expanded review data, where each review may contain multiple aspect–sentiment pairs. Therefore, this study focuses on developing and evaluating a BERT–CNN–BiLSTM hybrid model for sentiment classification using the FABSA dataset, with emphasis on validation performance, class-balanced evaluation, ablation analysis, and cross-dataset generalization.

B. Literature Review

1) From lexicon-based to deep learning approaches: Sentiment analysis has evolved from lexicon-based techniques and classical machine learning to deep learning approaches. Early systems relied on handcrafted sentiment lexicons and surface-level representations such as bag-of-words, n-grams, and shallow syntactic cues [8], [9]. Although these methods offered a degree of interpretability and domain independence, they struggled with domain adaptation, context-dependent polarity, and subtle semantic phenomena such as irony and implicit sentiment [8], [9], [10].

Recent studies, such as MultiLexScaled, show that aggregated and rescaled lexicon-based methods can still yield competitive and interpretable sentiment scores for large review datasets. However, these methods struggle to fully understand complex compositional statistics and non-additive interactions among sentiment indicators and product-specific attributes in single reviews [9], [10].

Advances in the field of deep learning have strengthened sentiment analysis in terms of end-to-end representation learning from raw text. Under the review dataset benchmark [8], CNN-based models automatically extract local sentiment-bearing patterns as well as phrase-level features. Additionally, recurrent models like LSTM and BiLSTM have greater capacity than traditional methods to capture long-distance dependencies and sequential dynamics. Different hybrid architectures, such as CNN + LSTM and BiLSTM with attention, make sentiment analysis more robust by leveraging the synergy between complementary feature extractors [8], [17]. Early work consistently demonstrated that hybrid deep learning models outperformed single baseline models across tasks requiring understanding of text, images, and multimodal data for sentiment analysis [8], [10].

2) Transformer and hybrid architectures for sentiment analysis: The rise of pre-trained transformers, particularly BERT, was a turning point for sentiment and emotion detection, as they enable expressive contextual representations through self-attention and large scale pre-training [10], [12]. BERT based fine-tuning has achieved strong results across product review analysis, political debate analysis, and social media monitoring, often with limited task-specific data [1], [11], [18]. More recent extensions, such as RoBERTa-BiLSTM and ontology-enhanced BERT, show that combining transformer embeddings with sequential modeling or external knowledge can yield additional gains, particularly in domain-specific and aspect-level settings [10], [11], [13]. Survey evidence also suggests that transformer based and hybrid approaches now dominate leading results, with F1-scores often exceeding 0.85 on well-annotated datasets [10].

Recent research has increasingly combined BERT with CNN and BiLSTM architectures to leverage their complementary inductive biases, with CNNs capturing local n-gram features and BiLSTMs modeling sequential dependencies. Liu *et al.* proposed a BERT–BiGRU–Softmax model for e-commerce product reviews and showed that contextual embeddings combined with gated recurrent units can outperform strong recurrent baselines [1]. Shen introduced a BERT–CNN–BiLSTM–Attention model for sentiment analysis of social media texts related to aquatic product companies and reported an F1-score above 93% [14]. Khan *et al.* combined multilingual BERT with stacked CNN–BiLSTM and attention for Urdu sentiment analysis, demonstrating the usefulness of hybrid architectures in low-resource and morphologically complex settings [15]. Using this architectural pattern, they utilized a CNN–BiLSTM–BERT hybrid model and analyzed multilingual university feedback captured through Twitter, reporting above 92% accuracy. Their results demonstrate that this architectural pattern is scalable across different domains as well as languages [16]. This approach applies to sentiment and emotion detection on handwritten text, as well as text in electronic format, suggesting that these hybrid models are highly versatile [17].

Overall, the literature shows that hybrid architectures composed of pretrained transformers layered with convolutional layers and recurrent components are more effective than their single-architecture baselines in terms of accuracy and general robustness across heterogeneous sentiment-analysis benchmarks [8], [14], [15], [13], [16].

3) Aspect-level and context-aware sentiment modeling: In e-commerce review analysis, sentiment classification becomes more informative when it moves beyond review-level polarity and considers the specific product aspects discussed in the text. A single review may contain different sentiments toward different aspects of the same product, such as positive sentiment toward battery life but negative sentiment toward price or durability. Therefore, aspect-level and context-aware sentiment modeling is important for capturing fine-grained opinion patterns in product reviews [6], [7], [19].

The FABSA dataset provides a suitable benchmark for this task because it represents user reviews through aspect–sentiment annotations, allowing each review to be analyzed in relation to the product aspects it contains [19]. This type of data is especially useful for evaluating models that need to learn sentiment polarity from contextual cues rather than relying only on surface-level sentiment words. However, aspect-expanded sentiment classification also introduces several challenges, including class imbalance, contextual ambiguity, and difficulty in recognizing minority classes such as neutral sentiment [6], [20].

Previous studies have shown that transformer-based models and hybrid deep learning architectures can improve sentiment classification by learning richer representations from review text [1], [2], [3]. BERT-based models are effective for capturing contextual semantics, while CNN and BiLSTM components can further support local phrase-level feature extraction and

bidirectional sequence modeling [14], [15], [13]. Nevertheless, the combined use of BERT, CNN, and BiLSTM for aspect-expanded sentiment classification in e-commerce reviews remains an important direction for further investigation.

This gap motivates the present study, which develops and evaluates a hybrid BERT-CNN-BiLSTM model for context-aware sentiment classification on the FABSA dataset. The study focuses on validation performance, class-balanced evaluation, architecture-level ablation, and cross-dataset generalization. By doing so, it aligns the implemented experimental scope with the stated objective of improving sentiment classification in aspect-expanded e-commerce review data.

C. Research Aims and Contributions

The primary aim of this study is to design and evaluate a hybrid BERT–CNN–BiLSTM model for context-aware sentiment analysis and demonstrate that the hybrid formulation is suitable for aspect-expanded review data. More specifically, the study investigates whether combining transformer-based contextual encoding with convolutional and bidirectional sequential modeling can improve sentiment classification on aspect-expanded review instances derived from the FABSA dataset [1], [2], [14], [15], [13], [19]. In the proposed architecture, BERT provides contextual embeddings, CNN layers capture local phrase-level features, and BiLSTM layers model sequential dependencies across the review text [1], [14], [15]. This combination is intended to capture both localized sentiment cues and broader contextual structure within user reviews.

1) Research objectives:

O1: **Hybrid Model Design:** Develop a BERT–CNN–BiLSTM architecture for sentiment classification on aspect-expanded e-commerce review data, using BERT for contextual encoding, CNN for local feature extraction, and BiLSTM for bidirectional sequence modeling [1], [14], [15], [13].

O2: **Validation-Based Performance Evaluation:** Evaluate the proposed model on the FABSA dataset using standard classification metrics, including accuracy, weighted F1- score, macro F1-score, class-wise precision, recall, F1- score, and confusion-matrix analysis [19], [6], [20].

O3: **Comparative Performance Analysis:** Compare the optimized hybrid configuration with the baseline training configuration and contextualize its performance against reported results from existing sentiment-analysis models in the literature [1], [2], [3], [14].

2) Research contributions:

C1: **Hybrid BERT–CNN–BiLSTM Architecture for Sentiment Classification.** This study develops and implements a hybrid BERT–CNN–BiLSTM architecture for context-aware sentiment classification in e-commerce reviews. In the proposed model, BERT is used for contextual representation learning, CNN layers capture local sentiment-bearing phrase patterns, and BiLSTM layers model bidirectional sequential dependencies [1], [14], [15].

C2: **Aspect-Expanded Evaluation on the FABSA Dataset.** The study evaluates the proposed model on the FABSA dataset by converting review-level aspect–sentiment annotations into aspect-expanded sentiment classification instances. This allows the model to be assessed on fine-grained sentiment labels associated with product-review aspects [19].

C3: **Empirical Performance Analysis Using Class-Balanced Metrics.** The proposed model is evaluated using accuracy, weighted F1-score, macro F1-score, class-wise precision, recall, F1-score, and confusion-matrix analysis. The optimized configuration improves macro F1-score and minority-class recognition, particularly for the neutral class, indicating more balanced sentiment classification performance [6], [20].

C4: **Architecture-Level Ablation Study.** An ablation study is conducted to compare BERT, BERT–CNN, BERT–BiLSTM, and the full BERT–CNN–BiLSTM architecture under the same experimental setting. The results show that the full hybrid model achieves the strongest performance, demonstrating the complementary contribution of convolutional and recurrent components.

C5: **Cross-Dataset Generalization Analysis.** The study further examines the generalization behavior of the trained model through zero-shot evaluation on the SemEval-2014 Restaurant dataset. This analysis highlights the model's ability to transfer polarity recognition across domains while also revealing the domain-sensitive nature of neutral sentiment classification.

3) Research questions: In line with the implemented scope of the study, the following research questions guide the empirical investigation:

RQ1: How effectively can a hybrid BERT–CNN–BiLSTM model classify sentiment in aspect-expanded e-commerce reviews [1], [14], [15], [13]?

RQ2: To what extent does optimizing the hybrid training configuration improve overall and class-balanced sentiment performance compared with the initial baseline configuration [6], [20]?

RQ3: How does the proposed hybrid model compare, in contextual terms, with reported results from existing machine learning, deep learning, and transformer-based sentiment-analysis models on the FABSA benchmark [19], [1], [2], [3]?

By addressing these questions, the study seeks to improve understanding of how hybrid transformer–CNN–BiLSTM architectures can be applied to sentiment classification in e-commerce review analysis. [1], [2], [6], [14], [15], [21].

The remainder of this study is organized as follows: Section II presents the dataset, preprocessing steps, proposed BERT–CNN–BiLSTM architecture, training configuration, and evaluation metrics. Section III reports the experimental results, including validation performance, ablation analysis, class-wise evaluation, contextual comparison with reported FABSA

baselines, and cross-dataset validation. Section IV discusses the findings and interprets the strengths and limitations of the proposed model. Section V presents the limitations of the study. Finally, Section VI and Section VII provide the conclusion and future research directions, respectively.

II. Methodology

A. Dataset and Data-Preprocessing

1) Dataset: Experiments utilize the FABSA (Fine-grained Aspect-Based Sentiment Analysis) dataset, obtained from the Hugging Face Datasets Hub (`jordiclive/FABSA`). This dataset comprises product review texts accompanied by structured labels containing aspect–sentiment pairs, where each label specifies a product aspect (such as *battery*, *screen*, or *price*) and its corresponding sentiment polarity (*positive*, *negative*, or *neutral*). The dataset is pre-divided into training, validation, and test splits, which are maintained throughout all experiments to ensure fair and reproducible evaluation.

2) Data pre-processing pipeline: The raw dataset is subjected to a multi-stage pre-processing pipeline prior to input into the hybrid model.

a) Aspect–sentiment extraction: Every instance in the FABSA corpus consists of free-form reviews and labels containing pairs of aspects and sentiments. In the process of pre-processing, the reviews and their respective aspect and sentiment pairs are extracted from all the samples in the corpus. The result is a structured format with the review text in each instance and (aspect, sentiment) pairs for that review.

b) Class imbalance analysis: Before resampling, the frequency of each sentiment class (*positive*, *negative*, *neutral*) was calculated for the entire dataset, which consisted of the training, validation, and test data. The outcomes highlight a significant imbalance in class representation, with a disproportionately small number of neutral samples compared to the dominant positive class.

c) Class imbalance correction via upsampling: Class imbalance became evident in the training dataset. To address this issue, the dataset was divided into three sentiment-based groups. Stratified random sampling with replacement was then used to up-sample the minority neutral group, increasing its number to be almost equal to the number of items in the majority positive group. No changes were made to the negative group.

d) Dataset expansion: The reviews can not be mapped directly to their respective labels (which include the target words), since one review may contain more than one aspect-sentiment pairs; hence, multi-label learning is necessary. The (review, aspect, sentiment) tuple is considered as one instance, and the generation of new instances comes from the tuples to add another layer of granularity in the learning task. In particular, for each aspect-based review having k number of aspects, there will be k copies (one for each aspect) together with its respective sentiment label.

e) 80–20 Split alignment: After aspect-based expansion, the size of the augmented training set became disproportionately larger than the expanded test set. To maintain an approximate 80:20 train-to-test ratio, a uniform subsample was drawn from the augmented training set without replacement, making the final training set four times larger than the expanded test set. The validation set was kept unchanged throughout this process.

f) Tokenization: Tokenization for all review texts is performed through the BERT-base (uncased) WordPiece tokenizer. Every sequence out of the three is padded to ensure that they satisfy the condition of having a maximum sequence length as per the batch and truncated to 512 tokens, which is the total number of positional embeddings that characterize the BERT architecture. The tokenizer produces token indices and attention masks, where the attention mask distinguishes actual tokens from padding tokens.

g) Label encoding: The three sentiment polarities are mapped to integer indices: *negative* $\rightarrow$ 0, *neutral* $\rightarrow$ 1, and *positive* $\rightarrow$ 2. This encoding is applied consistently across all splits and is utilized by the cross-entropy loss function during training.

h) Class weight computation: In order to reduce the imbalance in the dataset even after the use of upsampling, class weights are calculated using the inverse frequency formula:

$$w_c = \frac{N}{N_c} \tag{1}$$

where, N denotes the total number of training instances and N_c represents the number of instances belonging to class c. Hence, in this case, the assigned weights are 1.5 (negative), 2.0 (neutral), and 1.0 (positive).

i) Dataset and data loader construction: The tokenized sequence and its corresponding label in integer format are arranged in a structured dataset, which provides individual tensor samples upon request. The training, validation, and testing sets each had their own data iterator created using a batch size of 8. For the training data iterator, randomness is applied to shuffle the data for every epoch to avoid any bias due to order, while the validation and testing data iterators follow a sequential flow.

B. Base Models

1) BERT: Bidirectional Encoder Representations from Transformers (BERT) refers to a pre-trained language model that considers both left and right-contextual information in interpreting text data [12]. The model has a multi-layered bidirectional Transformer encoder, which can be of different sizes, like $\text{BERT}_{\text{BASE}}$ (12 layers, 768 hidden units, 12 self-attention heads, 110 million parameters) and $\text{BERT}_{\text{LARGE}}$ (24 layers, 1024 hidden units, 16 self-attention heads, 340 million parameters). The inputs are fed into the network using WordPiece tokenization, where each input consists of a vocabulary of 30,000 words and includes special tokens like [CLS], used for classification tasks, and [SEP], used to differentiate sentences. Token, segment, and positional embeddings are used in the model. The pre-training phase incorporates two strategies. Masked Language Modeling (MLM) hides 15% of tokens and tasks the model with predicting them. Meanwhile, Next Sentence Prediction (NSP) helps the model to recognize sentence interactions. Fine-tuning involves task-specific training and parameter tuning. Fig. 1 presents the BERT model architecture.

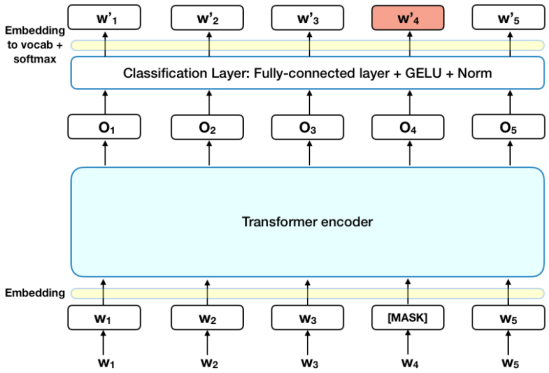

Fig. 1. BERT model architecture.

2) CNN: The process of text classification using CNNs involves the application of convolutions on the vectors of words in the sentence [22]. In this regard, each sentence is viewed as a matrix of word vectors where each word can be defined as a k-dimensional vector, hence an n x k matrix. Various filters of different sizes, for example, 3, 4, or 5, are used to produce feature maps by sliding over the matrix. In doing so, the filter uses activation functions such as ReLU or tanh. The next step involves performing the max-over-time pooling function on the obtained feature maps in order to select the most important features while at the same time allowing for the variation in sentence length. All the extracted features from various filters are concatenated to obtain a vector that is used as input to the fully connected softmax layer for classification purposes. Some models may use several channels with predetermined and trainable embeddings (see Fig. 2).

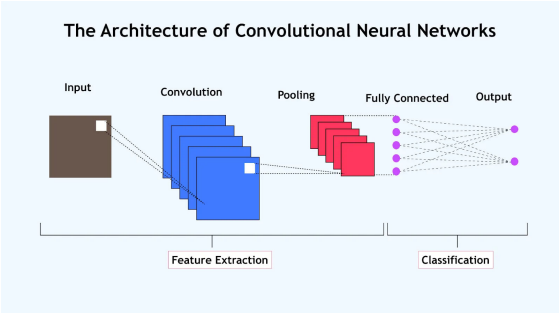

Fig. 2. CNN architecture for text classification.

3) Bi-LSTM: The Bidirectional Long Short Term Memory (Bi-LSTM) network refers to an advancement over the traditional LSTM model by processing the sequence in the forward and backward direction, thereby enabling context from past as well as future tokens [23]. It consists of two LSTM layers, where one layer processes the sequence from left to right and the other one processes it from right to left. Each LSTM unit includes three gates (input, forget, output) that regulate information retention over time. At every time step, the network concatenates the outputs from both layers. In Natural Language Processing (NLP), the Bi-LSTM models can be used for applications like sequence tagging, sentiment analysis, and text classification since they handle dependencies in both directions (see Fig. 3).

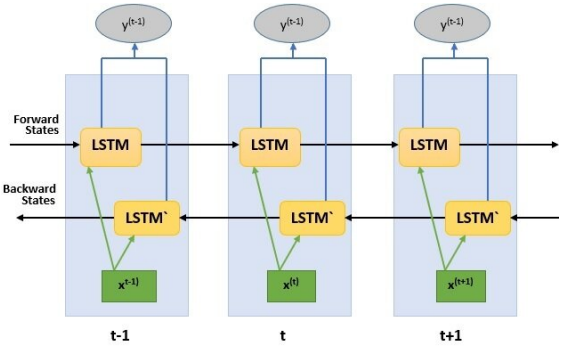

Fig. 3. Bi-LSTM architecture.

C. Hybrid Model Architecture

The proposed hybrid model consists of BERT to generate contextual embeddings, a CNN to extract local features, and a Bi-directional LSTM (Bi-LSTM) to capture sequences. These components are used for conducting context-based sentiment analysis of reviews. The generated BERT representations are passed through two modeling stages. First, three parallel CNN branches with kernel sizes of 3, 4, and 5 extract local n-gram sentiment features from the contextual token sequence. The CNN outputs are passed through ReLU activation and layer normalization before being concatenated along the feature dimension. The concatenated representation is then passed to a bidirectional LSTM to model sequential dependencies in both forward and backward directions. Finally, global max-pooling is applied over the sequence dimension, followed by dropout and a linear classification layer for three-class sentiment prediction (see Fig. 4).

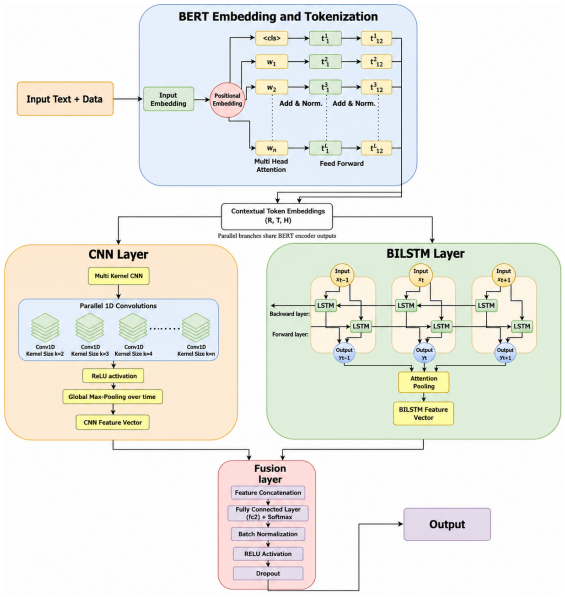

Fig. 4. Hybrid BERT-CNN-BiLSTM model architecture.

The following hyperparameters define the final implemented architecture. The CNN branch consists of three parallel convolutional layers (`Conv1d`) applied to the BERT last-hidden-state sequence (`bert-base-uncased`, hidden

dimension 768), each producing 256 output feature maps (`out_channels` $= 256$) with kernel sizes of 3, 4, and 5 tokens respectively, with padding values of 1, 2, and 2 to maintain compatible output lengths. Each convolutional output is passed through a ReLU activation followed by a `LayerNorm` layer before being fed into the shared BiLSTM. The three branch outputs—each of shape [batch $\times$ seq_len $\times$ 256]—are concatenated along the feature axis, giving a BiLSTM input size of 768 ($= 256 \times 3$). The BiLSTM has a hidden size of 128 units per direction (`bidirectional = True`), yielding a 256-dimensional output per token. Global max-pooling is then applied over the sequence dimension, followed by a dropout layer ($p = 0.5$) and a linear classification head projecting to three sentiment classes. Table I summarises these values.

TABLE I. HYPERPARAMETER SUMMARY OF THE BERT–CNN–BILSTM HYBRID MODEL.

Parameter	Value
BERT encoder	`bert-base-uncased`
BERT hidden dimension	768
Number of CNN branches	3
CNN output channels	256 per branch
CNN kernel sizes	3, 4, and 5
CNN padding	1, 2, and 2
CNN activation	ReLU
Normalization	LayerNorm after each CNN branch
Concatenated CNN dimension	768 (256×3)
BiLSTM input size	768
BiLSTM hidden units	128 per direction
BiLSTM direction	Bidirectional
BiLSTM output dimension	256
BiLSTM layers	1
Pooling method	Global max-pooling
Dropout rate	0.5
Classifier output	Linear layer ($256 \rightarrow 3$)
Batch size	8
Learning rate	1×10^{-5}
Training epochs	20
BERT fine-tuning	Frozen for first 5 epochs
Loss function	Weighted cross-entropy
Class weights	Negative: 1.5, Neutral: 2.0, Positive: 1.0

D. Model Evaluation Metrics

The performance of the proposed hybrid model is evaluated using standard classification metrics for multi-class sentiment analysis. Since the task involves three sentiment classes, namely negative, neutral, and positive, the evaluation considers both overall performance and class-wise effectiveness. The main metrics used in this study are Accuracy, Precision, Recall, F1-score, Macro-F1, Weighted-F1, and confusion-matrix analysis [20].

Accuracy measures the proportion of correctly classified samples among all samples:

$$\text{Accuracy} = \frac{\text{Number of Correct Predictions}}{\text{Total Number of Predictions}} \tag{2}$$

For each sentiment class, Precision measures the proportion of correctly predicted samples among all samples predicted as that class. Recall measures the proportion of correctly predicted samples among all actual samples of that class. The F1-score represents the harmonic mean of Precision and Recall. These metrics are defined as follows:

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \tag{3}$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \tag{4}$$

$$\text{F1-score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{5}$$

where, TP, FP, and FN denote true positives, false positives, and false negatives, respectively. In the multi-class setting, these values are calculated for each sentiment class using a one-versus-rest interpretation.

Because sentiment datasets are often imbalanced, especially when one class has fewer samples than the others, macro-averaged and weighted-averaged metrics are also used. Macro-averaged metrics assign equal importance to each class by taking the simple average of the class-wise scores:

$$\text{Macro-Precision} = \frac{1}{C} \sum_{i=1}^{C} \text{Precision}_i \tag{6}$$

$$\text{Macro-Recall} = \frac{1}{C} \sum_{i=1}^{C} \text{Recall}_i \tag{7}$$

$$\text{Macro-F1} = \frac{1}{C} \sum_{i=1}^{C} \text{F1}_i \tag{8}$$

where, C denotes the total number of sentiment classes.

Weighted-F1 is also reported to account for class distribution by weighting each class-specific F1-score according to its support:

$$\text{Weighted-F1} = \sum_{i=1}^{C} \frac{n_i}{N} \times \text{F1}_i \tag{9}$$

where, n_i is the number of samples in class i, and N is the total number of samples.

In addition to these numerical metrics, confusion matrices are used to analyze class-wise prediction behavior. The confusion matrix helps identify which sentiment classes are correctly classified and which classes are more frequently confused with one another. This is particularly important for evaluating the model's performance on minority classes such as neutral sentiment.

III. RESULTS AND ANALYSIS

In this section, the empirical results are discussed, based on the findings in the experimental setup related to the proposed BERT-CNN-BiLSTM hybrid model. In the implemented experiment, each review is expanded into aspect-text pairs, and the hybrid model is trained based on this aspect-wise partitioning approach. The results can thus be seen as part of the sentiment classification portion of this study.

A. Overall Validation Performance

Two configurations were examined with a normal hybrid model and the optimized hybrid model. As shown in Table II, optimization improved all headline validation metrics. Validation accuracy increased from 88.75% to 92.20%, weighted F1 increased from 89.32% to 92.25%, and macro F1 increased from 78.64% to 86.36% (see Fig. 5). The improvement in macro F1 is especially significant, because it indicates that the opti- mized configuration improved class balance and minority-class recognition rather than only strengthening performance on the dominant class. in the optimized configuration it dropped to 5.89 percentage points. This narrowing suggests that the optimized model produced more balanced decisions across the three sentiment classes.

TABLE II. VALIDATION PERFORMANCE OF THE ORIGINAL AND OPTIMIZED HYBRID MODELS

Configuration	Accuracy	Weighted F1	Macro F1
Original hybrid model	0.8875	0.8932	0.7864
Optimized hybrid model	0.9220	0.9225	0.8636

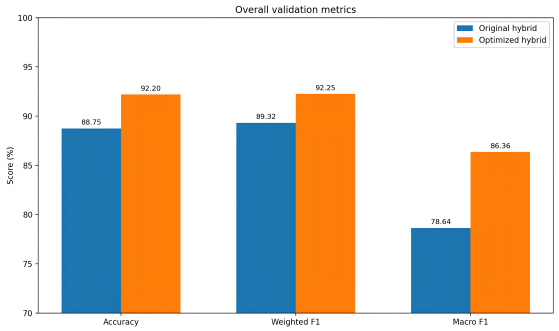

Fig. 5. Bar-chart comparison of overall validation metrics for the original and optimized hybrid models.

One of the explanations for such an increase is to examine the difference between the weighted F1 and macro F1 scores. Specifically, in the initial setting, the value of this difference was 10.68%, while after optimization, it dropped down to 5.89%. It shows that in the optimized setting, decisions on each class were more evenly distributed.

B. Architecture-Level Ablation Experiments

In order to make sure that the final performance gain achieved is due to the full hybrid architecture and not just BERT, an ablation study has been performed. Four models have been compared with the help of the exact same preprocessing approach and the exact same held out FABSA testing dataset, namely: 1) BERT, 2) BERT+CNN, 3) BERT+BiLSTM, and 4) BERT-CNN-BiLSTM. For all these tests, F1-score means weighted average test F1 from the final comparison.

According to the ablation experiments' findings, the best F1 value for testing data belongs to the complete BERT-CNN-BiLSTM architecture, whose F1 is 0.9286. On the other hand, BERT+CNN and BERT+BiLSTM models give 0.9196 and 0.9182 F1 values, respectively, while using only BERT gives an F1 value of 0.9167. Therefore, the hybrid model improved over the strongest reduced variant, BERT+CNN, by approximately 0.0090 absolute F1. The improvement is modest but consistent, suggesting that the convolutional and recurrent branches contribute complementary information as CNN layers capture local sentiment-bearing n-gram features, while the BiLSTM branch models bidirectional sequential dependencies across the review text (see Table III).

TABLE III. ABLATION EXPERIMENT RESULTS ON THE FABSA TEST SET

Model	F1-score
BERT	0.9167
BERT+CNN	0.9196
BERT+BiLSTM	0.9182
BERT-CNN-BiLSTM model	0.9286

These findings confirm the proposed architecture. While BERT provides strong context embeddings, the best F1 value is achieved only if BERT vectors are used together with the CNN and BiLSTM modules. Hence, the results support the effectiveness of the proposed architecture.

C. Learning Behavior and Convergence

In comparison, the improved architecture is able to outperform the initial configuration significantly. While the base hybrid neural network with hyperparameter tuning continues to improve in performance throughout the 20 epochs, albeit more slowly, to yield a weighted F1 score of 79.80%, the optimized neural network starts off on an advantageous note and scores over 90% validation weighted F1 from epoch 3 onwards (as shown in Fig. 6), with its peak being reached at epoch 10 at 92.68% accuracy, 92.76% weighted F1, and 0.2423 validation loss. From epoch 10 onward, the validation loss slightly increases compared to previous epochs, whereas training accuracy keeps improving, signaling moderate overfitting towards the end of the epochs. Considering the separation variable analysis approach, it can be concluded that early stopping at epoch 10 would have been optimal to retain maximal generalization efficiency while cutting down on training expenses.

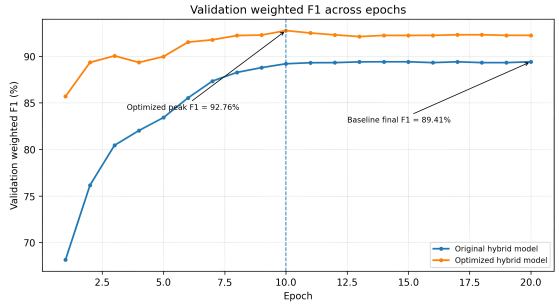

Fig. 6. Validation weighted F1 across epochs for the original and optimized hybrid models.

D. Contextual Comparison with Reported FABSA Baselines

In order to contextualize the proposed model, Table IV compares its performance with baseline and transformer-based

models reported on the FABSA benchmark by Kontonatsios et al. [19]. The proposed BERT–CNN–BiLSTM model achieves precision, recall, and F1-score values of 0.840, 0.890, and 0.870, respectively, which indicate competitive performance in this contextual comparison.

TABLE IV. CONTEXTUAL COMPARISON WITH REPORTED FABSA MODELS.

Model	Precision	Recall	F1-score
LogReg-BoW	0.784	0.491	0.604
GRU-GNN	0.702	0.667	0.684
BERT-single-base	0.785	0.745	0.765
BERT-single-large	0.785	0.792	0.788
BERT-PT	0.785	0.792	0.788
GAS	0.785	0.779	0.782
RoBERTa-single-base	0.781	0.787	0.784
RoBERTa-single-large	0.792	0.816	0.804
RoBERTa-pair-base	0.796	0.764	0.779
RoBERTa-pair-large	0.807	0.792	0.800
DeBERTa-single-base	0.777	0.787	0.782
DeBERTa-single-large	0.791	0.820	0.805
DeBERTa-pair-base	0.793	0.804	0.798
DeBERTa-pair-large	0.806	0.812	0.809
BERT-CNN-BiLSTM Hybrid Model	**0.840**	**0.890**	**0.870**

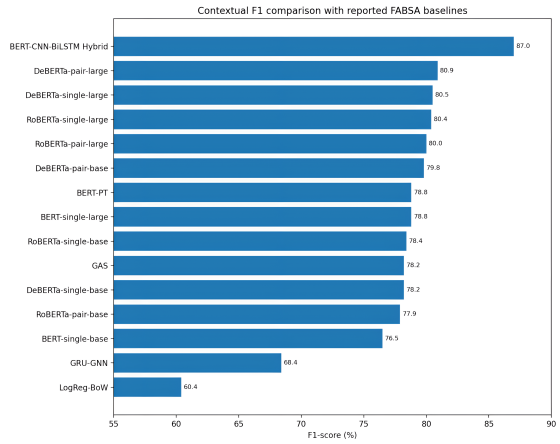

Fig. 7. F1-score comparison between the proposed model and reported FABSA benchmark models.

The proposed model obtains an F1-score of 0.870 in this contextual comparison, while the highest reported baseline F1-score in Table IV is 0.809 for DeBERTa-pair-large. This suggests that the hybrid architecture is promising for aspect-expanded sentiment classification. However, since the baseline models were not reimplemented under the same preprocessing, training, and evaluation conditions, this result should not be interpreted as a definitive ranking. A strict leaderboard comparison would require all models to be evaluated under identical experimental settings (see Fig. 7).

E. Class-Wise Validation Analysis

The optimized model proves to be most effective for the positive class, exhibits consistency for the negative class, and reaches its highest percentage gain for the neutral class. The values of precision, recall, F1-score, and support of the optimized model on the validation set are shown in Table V.

TABLE V. CLASS-WISE VALIDATION PERFORMANCE OF THE OPTIMIZED HYBRID MODEL

Class	Precision	Recall	F1-score	Support
Negative	0.8863	0.8675	0.8768	566
Neutral	0.6914	0.8485	0.7619	66
Positive	0.9534	0.9511	0.9522	1226

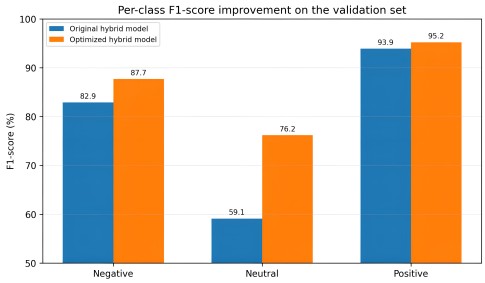

Fig. 8. Per-class F1-score comparison between the original and optimized hybrid models.

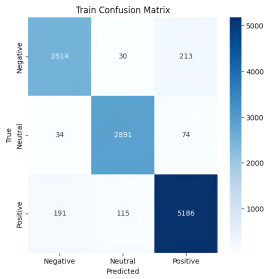
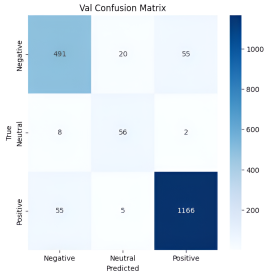
As seen in Fig. 8, the highest improvement is observed for the neutral category, with its F1 score growing from 59.1% to 76.2%, which means the absolute improvement reaches 17.1%. For the negative class, the F1 score goes up from 82.9% to 87.7%, and for the positive one, the F1 score jumps from 93.9% to 95.2%. Therefore, this finding confirms the conclusions that can be drawn based on the macro F1 score results.



(a) Training confusion matrix



(b) Validation confusion matrix

Fig. 9. Training and validation confusion matrices of the optimized BERT-CNN-BiLSTM model.

The confusion matrices provided in Fig. 9 show that the optimized model achieves very good class separation on both the train and validation splits, with observations forming a

cluster along the main diagonal of the confusion matrix. On the train data, the number of correctly classified examples for the negative, neutral, and positive classes is 2,514, 2,891, and 5,186 respectively, which shows that the model can learn discriminative representations for all three classes. On the validation split, there are 491 correct predictions for the negative class out of 566, 56 for the neutral class out of 66, and 1,166 for the positive class out of 1,226. The main misclassification sources occur in the classification of positive and negative sentiments, which results in 55 examples being misclassified from one of these two classes to another. While the neutral class is predicted quite accurately, a small portion of negative and positive examples is incorrectly classified as belonging to the neutral class.

F. Cross-Dataset Validation

Cross-dataset validation was used to evaluate generalization. Optimized BERT-CNN-BiLSTM model trained using FABSA dataset was tested on SemEval-2014 Restaurant data without any further training on the external data. SemEval labels were converted for sentiment classification into the same three-class label set used in FABSA dataset: negative, neutral, and positive classes. The SemEval-2014 Restaurant split used in this evaluation consists of 3,602 instances, of which 2,164 were positive, 805 were negative, and 633 were neutral (see Table VI).

TABLE VI. CROSS-DATASET VALIDATION SUMMARY

Evaluation data	Setting	Samples	Accuracy	Weighted F1	Macro F1
FABSA test set	In-domain held-out test	2,812	0.9282	0.9286	0.88
SemEval-2014 Restaurant	Zero-shot cross-dataset	3,602	0.7160	0.6547	0.51

The SemEval-2014 zero-shot evaluation achieves an accuracy of 0.7160 and weighted F1 score of 0.6547. Comparing this to the in-domain FABSA weighted F1 score of 0.9286, the external testing achieves an absolute reduction in F1 score by about 0.2740. This can be expected because of the existence of the domain shift problem where the model has been trained using FABSA dataset reviews but tested using SemEval review without being externally fine-tuned. Despite this domain shift, there still remains considerable sentiment transfer abilities in detecting polarity sentiment.

TABLE VII. CLASS-WISE SEMEVAL-2014 ZERO-SHOT VALIDATION REPORT.

Class	Precision	Recall	F1-score	Support
Negative	0.58	0.73	0.65	805
Neutral	0.42	0.02	0.04	633
Positive	0.77	0.91	0.84	2,164

The class-wise results obtained on SemEval-2014 show that transferability is highest for the positive class (F1 $= 0.84$) and moderate for the negative class (F1 $= 0.65$). However, the neutral class exhibits a near-total performance collapse, with an F1-score of only 0.04, which requires further analysis. This result can be explained by annotation-level semantic divergence between the two datasets. In FABSA, neutral sentiment is defined at the aspect level, where a reviewer may be neutral toward a specific product feature while expressing strong sentiment toward other aspects. In SemEval-2014, neutral polarity is often assigned at the sentence level and may represent factual or descriptive statements without explicit sentiment expression. As a result, the model trained on FABSA-style neutral instances encounters a qualitatively different neutral category during zero-shot transfer. The precision–recall pattern in Table VII further supports this interpretation: neutral precision is 0.42, but recall is only 0.02, indicating that the model rarely assigns the neutral label. Although the class-weighting scheme used during training was intended to improve neutral-class recall within the FABSA domain, the model appears to default to polar predictions when exposed to the more domain-specific vocabulary and sentence-level annotations of SemEval-2014.

A class-prior mismatch may also contribute to this behavior. Neutral instances represent only 17.6% of the SemEval-2014 Restaurant test split, with 633 neutral samples out of 3,602 total instances, whereas the FABSA training distribution was altered through upsampling to improve minority-class representation. This distributional difference may reinforce the model's tendency to avoid neutral predictions under external-domain inference. Taken together, annotation divergence, learned polar decision bias, and class-prior mismatch explain the observed neutral F1-score of 0.04. This finding does not invalidate the overall cross-dataset result, as the model still achieves 71.6% accuracy and a weighted F1-score of 0.65, but it shows that neutral sentiment representations are highly domain-sensitive. Future work should address this issue through aspect-conditioned input formatting, where the aspect term is explicitly included during tokenization, and through domain-adaptive fine-tuning on target-domain neutral examples to recalibrate the decision boundary for this class.

G. Result Interpretation

The experimental results indicate that the proposed hybrid configuration based on the combination of BERT, CNN, and BiLSTM architectures is effective for sentiment classification in the aspect-expanded FABSA review data set. The optimized configuration provided 0.9220 validation accuracy, 0.9225 weighted F1-score, and 0.8636 macro F1-score which are better than original metrics reported for the hybrid architecture. The results of class-wise prediction confirmed the effectiveness of the optimized model since F1-scores were equal to 0.9522, 0.8768, and 0.7619 for positive, negative, and neutral sentiments correspondingly. Even if the neutral sentiment was still the most difficult category to classify, the improved F1-score indicated that the optimization improved the performance and helped to mitigate the effects of the class imbalance in minority sentiments. As for the confusion matrices, the main diagonal showed that the class separation remained stable while the other errors concerned sentiment classes that were contextually ambiguous.

The results of ablation study have confirmed that using the full hybrid configuration contributed to achieving high F1-score. While BERT used alone produced an accurate result

of 0.9167, adding one more layer of either CNN (0.9196) or BiLSTM (0.9182) improved the performance. Finally, the full BERT-CNN-BiLSTM configuration obtained the best result of 0.9286 suggesting that the CNN and BiLSTM layers complemented each other providing local sentiment cues and bidirectional dependencies. The contextual comparison with reported FABSA baselines suggests that the proposed model is competitive, although the comparison cannot be treated as a strict leaderboard result because the baseline models were not reproduced under identical experimental conditions. However, in cross-dataset validation on the SemEval-2014 Restaurant data set, the model showed 0.7160 validation accuracy and 0.6547 weighted F1-score indicating weaker cross-dataset generalization ability. Overall, the results indicate that the proposed method was applicable for conducting context-aware sentiment analysis of e-commerce review data sets.

IV. Discussion

The results of the experiment show that the proposed BERT-CNN-BiLSTM architecture can effectively be used in sentiment classification of FABSA review cases. Specifically, the optimized version of the architecture proved to possess high validation scores of 0.9220 in terms of accuracy, 0.9225 in terms of weighted F1-score and 0.8636 in terms of macro F1-score outperforming the initial hybrid setup in all evaluated metrics. This is confirmed by the class-wise results of the validation, according to which the positive class received the highest F1 score while being followed by the negative and neutral classes. While neutral sentiment appears to be the most difficult to classify among other sentiments, its significant increase in F1-score from 0.591 to 0.7619 shows that optimized training has reduced the impact of class imbalance problem and increased the model's ability to recognize minority sentiment cases.

The ablation experiment supports the efficiency of the full-hybrid approach. In particular, BERT model provided high F1-score already, but the incorporation of either CNN or BiLSTM yielded additional improvements. Finally, BERT-CNN-BiLSTM produced the highest F1-score of 0.9286 suggesting that the addition of both CNN and BiLSTM branches provides additional advantage. The layers of CNN are helpful for recognizing phrase-level sentiment cues, while BiLSTM layers can model dependencies between the parts of the review. Therefore, the proposed architecture can be regarded as efficient both by general and by component-based assessment proving that contextual, local, and sequential models jointly enable more precise sentiment analysis.

Finally, the comparison with existing FABSA baseline models and additional testing on SemEval datasets demonstrate the pros and cons of the proposed model. It demonstrates competitive performance in FABSA review cases comparing with other baseline models of the framework; however, this comparison has to be made under contextual conditions since the leaderboard claim cannot be made due to potential differences in evaluations. However, zero-shot SemEval-2014 Restaurant testing revealed that it has low performance when compared with in-domain tests, which may be caused by the nature of domains. Still, the model retains the ability to correctly recognize polarity for positive and negative sentiments.

V. Limitations

There are several limitations in this study that need to be highlighted. First, although the preprocessing pipeline expands the review data using aspect–sentiment pairs, the aspect term itself is not explicitly appended to the review text during tokenization. Therefore, the current system should be understood as aspect-expanded sentiment classification rather than a fully aspect-conditioned sentiment model. Second, class imbalance remains an important challenge, particularly for the neutral class. Although stratified oversampling and class-weighted loss improve minority-class recognition, the neutral class still shows weaker performance than the positive and negative classes, especially under cross-dataset evaluation. Third, the model is evaluated primarily on the FABSA dataset, with additional zero-shot testing on SemEval-2014 Restaurant data. Broader validation across multiple product categories, domains, languages, and review platforms would be required to confirm the robustness and generalizability of the proposed approach. Finally, the study does not evaluate computational efficiency, inference time, model size, or deployment feasibility, which should be considered before applying the model in real-world e-commerce systems.

VI. Conclusion

This study proposed a hybrid BERT–CNN–BiLSTM model for context-aware sentiment classification of aspect-expanded e-commerce review data. The model combines BERT-based contextual representation learning, CNN-based local feature extraction, and BiLSTM-based bidirectional sequence modeling to capture both semantic and sequential patterns in review text.

Experimental results on the FABSA dataset show that the optimized hybrid model achieves 92.20% validation accuracy, 92.25% weighted F1-score, and 86.36% macro F1-score. The class-wise results further indicate improvement across all sentiment categories, with the strongest gain observed for the neutral class. This suggests that the optimized configuration improves class-balanced sentiment recognition rather than only improving performance on the dominant class.

The architecture-level ablation study confirms that the full BERT–CNN–BiLSTM model performs better than reduced variants using only BERT, BERT–CNN, or BERT–BiLSTM. In addition, the zero-shot evaluation on the SemEval-2014 Restaurant dataset shows that the model retains some ability to recognize sentiment polarity under domain shift, although neutral sentiment remains difficult to transfer across domains. Overall, the findings demonstrate that combining transformer-based contextual encoding with convolutional and recurrent components is an effective approach for sentiment classification in aspect-expanded e-commerce review data.

VII. Future Scope

Future research may extend the proposed sentiment classification framework by incorporating review helpfulness prediction as a separate downstream task or as part of a multi-task learning architecture. Such an extension would require datasets containing helpfulness labels or helpfulness votes, together with appropriate classification or regression-based evaluation metrics [21], [7], [24]. This would make it possible

to examine whether context-aware sentiment representations can also support the estimation of review usefulness.

Further improvement may also be achieved by making the model more explicitly aspect-aware. Although the present study expands review instances using aspect–sentiment pairs, the aspect term is not directly included in the tokenized input sequence. Future work may address this by structuring the input as a review–aspect pair, enabling the model to learn sentiment specifically toward the target aspect. This direction may be especially useful for reviews that contain mixed opinions about different product features [19], [6].

Future studies should also consider broader evaluation settings, including full test-set analysis, cross-validation, cross-domain evaluation, and comparisons across multiple benchmark datasets. Since the zero-shot evaluation on SemEval-2014 Restaurant data shows weaker transferability for the neutral class, additional experiments are needed to better understand the effects of domain shift, annotation differences, and neutral sentiment ambiguity [20]. Class imbalance should also be addressed more thoroughly using methods such as class-balanced loss, focal loss, aspect-level sampling, or targeted data augmentation for underrepresented sentiment classes [13], [20]. These strategies may further improve minority-class recognition, particularly for neutral sentiment. From a practical perspective, future work should also investigate inference speed, model size reduction, calibration, interpretability, and explainability so that the proposed approach can be adapted for real-world e-commerce review analysis.

VIII. Acknowledgment

We would like to express our sincere gratitude to our supervisor, Sifat Rahman Ahona, for the invaluable guidance, continuous support, and insightful feedback provided throughout the course of this research. We also extend our deepest appreciation to the Department of Computer Science and Engineering at the American International University-Bangladesh (AIUB) for providing the necessary facilities and fostering a conducive environment for our work.

***Abstract*—Selection mechanisms critically influence the convergence behavior and solution quality of Genetic Algorithms (GAs). This study presents a rigorous empirical comparison of six selection methods: three classical methods—Random Selection, Roulette Wheel Selection (RWS), and Tournament Selection (TS)—and three adaptive methods: Fitness-Distance Balance (FDB), Dynamic FDB (dFDB), and Functional Weight-based Selection (FW). Experiments were conducted across 23 classical benchmark functions (F1–F23) and 10 CEC2019 functions (cec01–cec10), with each configuration executed 30 times using consistent GA parameters. Performance was assessed using Best, Mean, Median, and Standard Deviation, with statistical significance determined by the Wilcoxon rank-sum test ($\alpha = 0.05$). The results reveal that TS consistently achieved the best or statistically equivalent performance in 30 out of 33 functions, outperforming both classical and adaptive alternatives. Notably, RWS showed surprising competitiveness, outperforming adaptive methods such as FDB and dFDB in several scenarios. While dFDB and FW improved over static FDB, they failed to consistently outperform TS. These findings confirm TS as a robust default choice for diverse optimization landscapes and provide new empirical evidence regarding the limited practical advantage of current adaptive strategies within GAs. This study contributes the first controlled GA-based evaluation of adaptive selection mechanisms on both classical and CEC2019 benchmarks, offering insights for practitioners designing efficient evolutionary systems. Limitations related to fixed GA settings, function diversity, and adaptive method complexity are acknowledged, and future work is suggested to explore hybrid and problem-aware selection strategies.**

***Keywords*—Genetic algorithm; selection mechanisms; FDB; tournament; roulette wheel; evolutionary computation; optimization**

I. Introduction

Genetic Algorithms (GAs) represent a foundational technique in evolutionary computation, widely applied for solving complex optimization tasks by emulating the processes of natural selection and evolution [1]. A key determinant of GA performance is the selection operator, which mediates the trade-off between exploration of the solution space and exploitation of high-quality individuals [2]. Over time, a diverse range of selection methods has been developed—from traditional approaches like Roulette Wheel and Tournament Selection [2], [3], to more advanced, adaptive techniques such as the FDB family, including FDB, dFDB, and FW methods [4], [5]. These adaptive methods dynamically adjust selection pressure based on population distribution and fitness, potentially improving convergence and mitigating premature stagnation.

While considerable attention has been given to modifying GA components—including crossover, mutation, and population structure—relatively few studies have systematically compared selection strategies across a broad spectrum of problem types. Notably, distance-aware selection mechanisms have gained popularity in other metaheuristics, including LSHADE [6], Whale Optimization Algorithm (WOA) [7], and Stochastic Fractal Search (SFS) [8], demonstrating promising outcomes. However, their effectiveness within the traditional GA framework remains underexplored. Moreover, although GAs have been successfully applied in various fields, from photovoltaic modeling [9] to power system optimization [10], the optimal choice of selection strategy under consistent algorithmic settings is still an open question.

This study addresses this gap by systematically evaluating six selection methods—three classical and three adaptive—within a canonical GA setup. The goal is to empirically assess their comparative performance across diverse benchmarks and derive practical recommendations for researchers and practitioners. The primary contributions of this work are:

- Comprehensive Comparison of Selection Strategies: This work presents one of the first integrated empirical comparisons between classical GA selection methods (Random, Roulette Wheel Selection, Tournament Selection) and adaptive FDB-based methods (FDB, dFDB, FW), under a unified experimental setup.
- Diverse and Challenging Benchmarking: The evaluation spans 23 classical benchmark functions and 10 CEC2019 functions, encompassing unimodal, multi-

*Corresponding author.

modal, composite, and high-dimensional landscapes.

- Robust Statistical Validation: In addition to standard performance metrics (Best, Mean, Median, Standard Deviation), the study employs the Wilcoxon rank-sum test to rigorously assess the statistical significance of observed differences between selection strategies.
- In-Depth Literature Integration: The study synthesizes and contextualizes prior research on both classical and modern selection approaches, clarifying existing gaps.
- Actionable Insights for Practitioners: By holding all other GA components constant and varying only the selection mechanism, the study isolates its effect on performance, demonstrating that selection alone can significantly impact results.

The remainder of this study is organized as follows: Section II reviews classical and advanced selection methods. Section III describes the proposed methodology. Section IV presents experimental results and statistical analysis. Section V discusses key findings and their implications. Section VI concludes the study and outlines future research directions.

II. Literature Review

This section briefly reviews key developments in selection methods, beginning with classical techniques, followed by recent adaptive strategies based on the FDB framework.

A. Classical Selection Methods

Classical selection strategies in GAs primarily include proportional selections such as RWS and ranking-based methods, including TS. While simple and computationally efficient, RWS is highly sensitive to skewed fitness distributions; a small number of very fit individuals can dominate the mating pool, increasing the risk of premature convergence [2]. TS, in contrast, applies controlled selection pressure and has been widely adopted for its robustness, but it does not inherently incorporate population diversity or spatial distribution of solutions. As noted by Shukla et al. [11], while tournament size can modulate pressure, classical methods generally ignore diversity, which can hinder their performance on multi-modal or complex landscapes.

In response to these limitations, enhancements have been proposed. For example, Cuevas et al. [12] introduced a Golden Section Selection inspired by the golden ratio, which outperformed traditional schemes on selected benchmarks by improving solution quality by approximately 15–20%. Likewise, Oladimeji et al. [13] demonstrated performance gains in the Mayfly Algorithm by replacing random selection with RWS.

Table I summarizes key studies on classical selection methods.

TABLE I. Summary of Classical Selection Method Studies

Reference	Focus	Methodology	Results
Goldberg & Deb (1991) [2]	Comparative analysis of selection schemes	Modeling and simulations	Tournament-based methods exert stronger selection pressure
Julstrom (1999)[3]	Rank-based vs. TS equivalence	Analytical probability-based analysis	TS preferred due to simplicity and consistent pressure
Zhang & Kim (2001)[14]	Selection methods for layout optimization	Experiments on machine layout problems	TS and ranking selection outperformed others
Zhong et al. (2005) [15]	RWS vs. TS on benchmark functions	Benchmark tests with fixed settings	TS converged faster than RWS
Mashohor et al. (2005) [16]	Selection for industrial inspection	Evaluation of PCB inspection system	Elitist selection gave the best results
Shukla et al. (2015) [11]	Review of selection techniques	Conceptual and experimental analysis	TS incurred lower overhead for similar results
Yadav et al. (2017) [17]	Multiple selection schemes	Conceptual and partial experiments	TS and elitism yielded faster convergence
Cuevas et al. (2018) [12]	Golden section vs. traditional methods	Benchmark optimization	Golden-section improved quality by ∼15–20%
Oladimeji et al. (2024)[13]	RWS in Mayfly algorithm	Benchmarked on face/iris datasets	RWS improved accuracy and reduced error

B. Advanced Selection Methods (FDB Family)

To address the limitations of classical selection strategies, the FDB family introduces a mechanism for maintaining population diversity by jointly considering an individual's fitness and its spatial distance from the best-performing solution. The original FDB method, introduced by Kahraman et al. in 2019 [4], assigns each individual a composite score that combines normalized fitness and distance values. The general FDB scoring equation is:

$$\text{Score}_i = \delta \cdot \text{normF}_i + (1 - \delta) \cdot \text{normD}_i \tag{1}$$

where, normF and normD are the normalized fitness and distance scores, respectively, and $\delta \in [0, 1]$ is a weight controlling the trade-off between exploitation and exploration.

Multiple variants of FDB have since been developed. One notable extension is Fitness-Distance Balance with Functional Weights (FW), proposed by Tao et al. in 2021 [5]. Rather than using a fixed weighting parameter, FW introduces a stochastic weighting scheme where δ is sampled from a probability distribution (e.g., Gaussian or Cauchy) during each generation.

Another enhancement is Dynamic Fitness-Distance Balance (dFDB), introduced by Kahraman et al. [8], which varies the weight δ over time according to a predefined schedule. Typically, dFDB starts with greater emphasis on diversity (higher distance weight) and gradually shifts toward fitness-based exploitation as the search progresses.

Table II summarizes key contributions utilizing the FDB family of methods.

Research Gap: While classical selection strategies such as RWS and TS have been extensively evaluated on standard benchmark functions, their effectiveness on large-scale or highly complex optimization problems remains insufficiently studied. Conversely, adaptive methods—including FDB, dFDB, and FW—have demonstrated strong potential in modern metaheuristics, but their systematic integration into and evaluation within traditional GAs is still lacking.

TABLE II. SUMMARY OF FDB-BASED SELECTION METHODS

Reference	Focus of Study	Methodology	Key Findings
Kahraman et al. (2019)[4]	Introduction of FDB	Applied in various meta-heuristics (90 benchmarks)	FDB improved diversity and solution quality
Tao et al. (2021)[5]	FW for dynamic balance	Integration into spherical search algorithm	FW outperformed traditional methods
Tan et al. (2022) [18]	Chaotic FDB-based selection	Hybrid wind-driven optimization with FDB	Enhanced accuracy and faster convergence
Battal & Guvenc (2022) [6]	FDB-integrated LSHADE	Energy hub management	Superior performance in energy optimization
Hou et al. (2024) [7]	Adaptive FDB in WOA	Modified WOA with FDB component	Increased accuracy and faster convergence
Kahraman et al. (2024) [19]	dFDB for SFS	Applied to SFS and photovoltaic optimization	dFDB provided superior robustness
Kahraman et al. (2023)[19]	dFDB for GBO	Incorporated dFDB into GBO	Improved exploration and balanced search
Mashaqbeh & Mjlae (2025) [20]	FDB-enhanced Jaya	Cloud task scheduling	Reduced makespan by up to 38.98%

TABLE III. CONFIGURATION AND PARAMETERS USED FOR ALL EXPERIMENTS

Parameter	Value
Population Size	75
Generations	3000
Encoding	Real-valued vector
Benchmark Functions	CEC2019 and Classical (F1–F23)
Dimensions	10 (CEC2019); varies (F1–F23)
Crossover Type	Blend crossover (BLX-0.5)
Crossover Rate	0.7
Mutation Type	Uniform mutation
Mutation Rate	0.3 (per individual)
Runs	30
Statistical Test	Wilcoxon Rank-Sum Test ($\alpha = 0.05$)
Performance Metrics	Best, Mean, Median, Std
Random	Uniformly random
RWS	Proportional to fitness
TS	TS size $= 3$
FDB	Static weight $\delta = 0.5$
dFDB	δ decreases every frequency $= 10$
FW	Gaussian sampling for dynamic δ

This study bridges this gap through a unified and controlled comparison across both traditional and CEC2019 benchmark sets.

III. METHODOLOGY

This study employed a standardized GA implemented in MATLAB to ensure a consistent experimental framework across all comparisons. The only varying component was the selection method, while all other algorithmic elements were held constant. Table III summarizes the GA configuration and selection method parameters used throughout the experiments.

The GA evolved with a population of 75 individuals over 3000 generations. Each individual was encoded as a real-valued vector, with bounds and dimensions determined by the benchmark function. For reproduction, blend crossover (with a rate of 0.7 and gamma in the range $[-0.5, 1.5]$) and uniform mutation (applied with a 0.3 probability per individual) were used.

Six selection strategies were tested:

- Random: No selection pressure; individuals were randomly chosen.
- RWS: Proportional selection based on normalized fitness.
- TS: A tournament of size 3 selects the best among randomly sampled candidates.
- FDB: Applies a composite score based on static weight $\delta = 0.5$ combining normalized fitness and distance to the current best.
- dFDB: The weight δ decreases linearly from 0.6 to 0.0 over the total number of generations to balance exploration and exploitation dynamically.
- FW: Uses a stochastic weight $\delta \sim \mathcal{N}(0.5, 0.1)$ resampled each generation, providing adaptive selection pressure.

The benchmark consisted of two test suites:

- F1–F23: Classical benchmark functions covering unimodal, multimodal, and hybrid categories.
- CEC2019 (cec01–cec10): Designed to challenge optimization strategies through transformed, rotated, and composite problem landscapes, implemented at 10 dimensions.

For each function and selection method pair, 30 independent runs were executed. Performance was evaluated based on the Best, Mean, Median, and Std of the final fitness values. Additionally, the Wilcoxon rank-sum test was applied to assess statistical significance between each method and TS, which served as a robust baseline due to its proven performance in preliminary evaluations.

IV. RESULTS

This section presents a comprehensive evaluation of the six selection methods across two benchmark suites: the classical functions F1–F23 and the CEC2019 test functions (cec01–cec10). The evaluation is based on multiple statistical indicators (Best, Mean, Std, Median) and supported by Wilcoxon rank-sum tests for statistical significance. Convergence curves and boxplots are included to visualize the performance dynamics and distributional patterns.

A. Performance on CEC2019 Benchmark Functions (cec01–cec10)

The CEC2019 benchmark suite includes complex, composition-based, and real-world inspired optimization problems characterized by large search spaces, deceptive landscapes, and challenging global minima. Table IV presents the performance metrics, and Table V reports the Wilcoxon test results against TS.

TABLE IV. RESULTS ON CEC2019 (BEST, MEAN, MEDIAN, STD OVER 30 RUNS)

As with the classical functions, TS maintained its dominance in this suite. It achieved the best or second-best fitness values on nearly all functions, with low variance and high reliability. FW again emerged as the closest competitor, achieving statistically indistinguishable performance on some functions (e.g., cec04, cec06, cec08) with p-values above the 0.05 threshold. RWS showed a more variable pattern: it was competitive on some easier CEC functions (e.g., cec02, cec05), but less reliable on harder ones such as cec01 and cec07.

The adaptive FDB and dFDB methods exhibited lower performance overall. While dFDB improved upon static FDB, especially on functions like cec05 and cec09, both methods lagged significantly behind TS, FW, and RWS. Their higher standard deviations and poorer best values indicate instability and insufficient convergence, particularly under fixed computational budgets.

Convergence curves (Fig. 1) highlight the rapid and stable convergence of TS and FW, in contrast to the delayed and irregular behavior of the adaptive methods. Boxplots (Fig. 2) for cec01–cec10 further illustrate these trends.

B. Performance on Classical Benchmark Functions (F1–F23)

The classical suite includes a variety of unimodal, multimodal, hybrid, and composition functions. Table VI,VII and

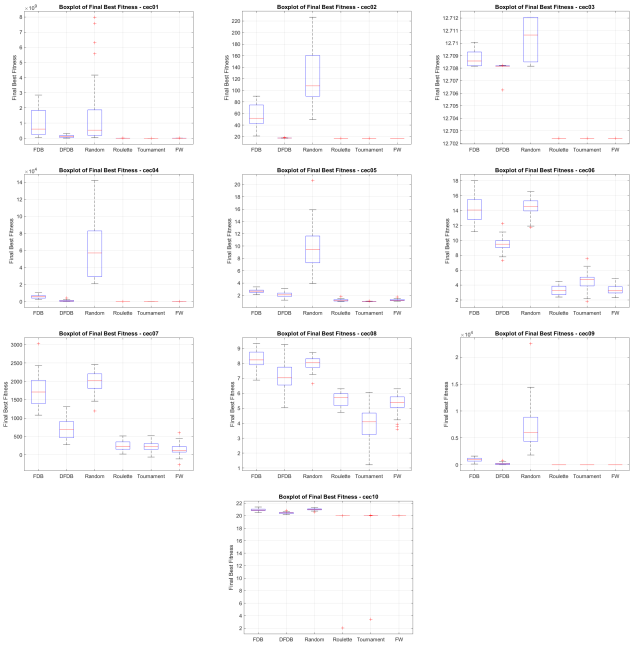

Fig. 2. Boxplot obtained from selection methods on CEC2019 suite.

VIII summarizes the best, mean, and standard deviation of the final fitness values for each function over 30 independent runs.

Across the majority of functions, the TS technique achieved the most consistent performance. This was particularly evident in unimodal functions such as F1 (Sphere) and F6 (Step), where TS achieved optimal solutions in all runs with negligible variance. Notably, FW closely followed TS in most cases, often achieving statistically indistinguishable performance as confirmed by Wilcoxon tests ($p > 0.05$ in many functions such as F8 and F10).

RWS, while simpler and non-adaptive, exhibited mixed performances. It outperformed both adaptive methods (FDB and dFDB) on a significant subset of functions, particularly on F1–F7. The static FDB method consistently yielded the weakest results across both unimodal and multimodal functions, indicating convergence stagnation and poor exploitation. The dynamic variant, dFDB, demonstrated improvements over its static counterpart in some multi-modal problems (e.g., F13, F20), but remained inferior to TS, FW, and RWS in the majority of scenarios.

Statistical analysis (Table VIII) supports these findings. TS significantly outperformed all other methods ($p < 0.05$) on the vast majority of functions. FW was the only method that frequently achieved statistically similar results to TS. Visual inspection of convergence curves (Fig. 3) and boxplots (Fig. 4) corroborates the numerical results.

C. Statistical Summary and General Observations

A cross-suite statistical perspective reveals the following insights:

TABLE VI. RESULTS ON F1–F12 (BEST, MEAN, MEDIAN, STD)

S = Significant; NS = Not Significant ($\alpha = 0.05$)

- TS consistently achieved top results across both benchmarks, confirming its robustness and effectiveness in both simple and complex landscapes.
- FW, although relatively simple, showed strong performance. It was statistically equivalent to TS in many cases and could serve as a viable alternative, particularly in problems where slightly more exploration is desirable.
- RWS performed better than expected. It surpassed both adaptive methods in many tests and was statistically competitive with TS on select functions.
- dFDB improved upon the static variant but remained inconsistent. It showed promise in maintaining diversity but lacked the convergence efficiency of TS and FW.
- Static FDB and Random Selection were the least effective. They struggled with both exploitation and stability, particularly in high-dimensional and multimodal functions.

Fig. 3. Convergence curves of selection methods in the optimization of functions F1 to F23.

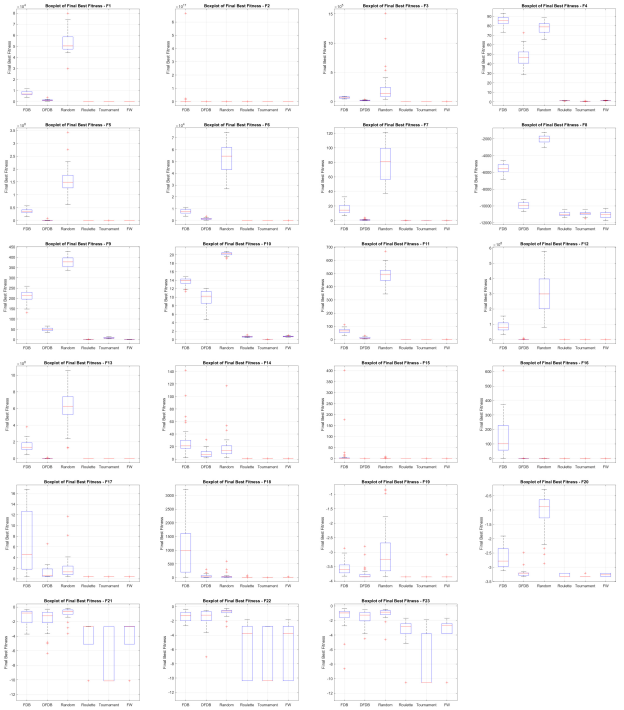

Fig. 4. Boxplot diagram obtained from selection methods on functions F1 to F23.

V. Discussion

A. Robustness and Efficiency of Tournament Selection

The TS consistently emerged as the most effective method across both benchmark suites. These results can be attributed to TS's balanced exploitation-exploration tradeoff, particularly with the moderate tournament size ($k = 3$) used in this study. The deterministic pressure of TS ensures that fitter individuals are consistently favored, facilitating rapid convergence in unimodal and smooth landscapes (e.g., F1, F6, cec02), while still preserving diversity enough to maintain effectiveness in multimodal problems.

B. Competitiveness of Functional Weight-Based Selection

FW Selection demonstrated competitive performance—often statistically indistinguishable from TS on both classical and CEC functions. The method introduces probabilistic selection that is biased by fitness scores but retains stochasticity to avoid premature convergence. This allows FW to maintain a broader exploration radius compared to TS, which can be advantageous in deceptive or rugged landscapes.

C. Re-Evaluating Roulette Wheel Selection

RWS, despite its simplicity and non-adaptive nature, demonstrated surprisingly strong performance on several classical functions, particularly unimodal and moderately multimodal ones (e.g., F1–F5, F10). This challenges the common assumption that adaptive strategies always outperform classical ones. However, RWS also exhibited more variability on highly multimodal or deceptive landscapes.

D. Random Selection as a Baseline

As expected, Random Selection performed poorly across all benchmarks, reinforcing the necessity of selection pressure in evolutionary search [21], [22], [23], [24], [25], [26], [27], [28], [29], [30]. Interestingly, Random outperformed static FDB in a few instances (e.g., F18, F19), highlighting that without appropriate tuning, even diversity-focused selection may lead to inefficient search.

E. Limitations of FDB and dFDB

The FDB selection techniques, particularly the static variant, were consistently outperformed by other methods [31], [32], [33], [34], [35], [36], [37], [38], [39]. The static FDB struggled to converge effectively, often yielding large standard deviations and poor mean fitness values. This was evident in functions such as F2, F5, F12, and cec01. The likely cause is the fixed weighting between fitness and diversity: while diversity helps in early search stages, excessive emphasis on it can hinder convergence in later stages. The dFDB showed partial improvement but still lagged behind in most scenarios.

F. Implications for Algorithm Design

The comparative results suggest that classical methods such as TS and RWS, despite their simplicity, remain highly effective across diverse problem domains [40], [41], [42]. The findings also imply that hybrid strategies, such as switching from exploration-heavy to exploitation-heavy selection over time, may outperform static or single-strategy methods.

VI. Conclusion

This study has presented a rigorous comparative evaluation of six selection strategies in GAs, encompassing classical strategies (TS and RWS), adaptive mechanisms (FW, FDB, and dFDB), and a baseline random strategy. Across 33 benchmark functions—including the classical F1–F23 suite and the CEC2019 set—the TS method demonstrated superior robustness, achieving the best or statistically comparable results in the majority of cases. FW method emerged as a strong alternative, often yielding statistically indistinguishable performance with the added benefit of enhanced exploration through adaptive weight control.

Interestingly, RWS, despite its non-adaptive nature, outperformed the adaptive FDB and dFDB methods on a substantial number of functions, highlighting its retained competitiveness in structured problem landscapes. In contrast, the FDB-based strategies underperformed in both convergence and consistency, suggesting the need for better tuning or hybridization. Random Selection illustrated the essential role of selection pressure in evolutionary search.

A. Limitations of the Study

Despite its comprehensive scope, all evaluations were conducted under fixed population sizes and generations, which may constrain generalizability. Furthermore, the benchmark functions used do not fully reflect the stochasticity and complexity of real-world applications. The implementations of FDB and dFDB used fixed parameter schedules, which might not be optimal across all problem types.

B. Future Work

The findings suggest several promising directions: development of hybrid selection strategies combining the strengths of TS with diversity mechanisms; integration of adaptive scheduling or self-regulating parameters; and exploring the interplay between selection methods and other GA components such as crossover operators and mutation schemes.

***Abstract*—Phishing attacks continue to pose a significant threat to individuals and organizations, driven by the increasing sophistication of cybercriminal techniques and the rapid expansion of digital services. Traditional detection approaches, such as blacklist-based and rule-based systems, are often ineffective against newly generated or obfuscated phishing URLs. This study proposes a machine learning (ML)-based framework intended for integration within penetration testing environments. The approach leverages multiple supervised learning algorithms, including Random Forest (RF), Support Vector Machine (SVM), and XGBoost, trained and evaluated using the PhiUSIIL Phishing URL Dataset, a large-scale benchmark dataset containing phishing and legitimate URL samples. A comprehensive preprocessing pipeline and feature engineering strategy are employed to enhance model performance. Experimental results demonstrate exceptionally high detection accuracy, with RF and XGBoost achieving near-perfect classification performance across key evaluation metrics, including accuracy, precision, recall, F1-score, and ROC-AUC. The proposed system is further designed for real-time deployment, enabling integration into penetration testing workflows for proactive security assessment. Despite promising results, limitations related to dataset characteristics and real-world generalization are acknowledged. Overall, this research highlights the effectiveness and practical applicability of ML-based approaches in strengthening phishing detection and advancing modern cybersecurity defences.**

Keywords*—Phishing detection; machine learning; real-time detection; penetration testing; URL analysis

I. Introduction

A. Background

Phishing attacks have emerged as one of the most prevalent and dangerous forms of cyberattacks on individuals, organisations, and the critical infrastructure spread throughout the world in recent years. The attacks are normally in fraudulent messages or rogue websites that are established to swindle the user into disclosing their sensitive information in terms of logins, financial, and personal information. Phishing is a dynamic and ongoing problem in cybersecurity because the attack surface has increased manyfold with the pace of digital transformation, internet banking, and cloud-based services [1].

Conventional phishing detection models, including blacklisting models and rule-based filters, have not been found to be effective in dealing with contemporary methods of attack. Such traditional approaches can still not detect newly created or obfuscated phishing URLs, which leads to a high level of false negatives [2]. Also, more and more attackers use automation and artificial intelligence to create advanced phishing campaigns that are very similar to authentic websites and thus more difficult to detect [3].

In order to overcome these limitations, ML technologies have become a popular subject to fill the gap in phishing detection. ML models can handle a lot of data and can identify the subtle patterns and project the past-observed attacks to new ones in real-time. The recent research has shown that supervised learning algorithms, like Random Forest and Support Vector Machines, are effective in obtaining a high detection accuracy [4]. As a result, incorporating the use of ML-based detection systems into the cybersecurity systems has emerged as an encouraging route toward an improved phishing defence infrastructure.

B. Problem Statement and Motivation

Although machine learning-based phishing detection has been developed, a number of challenges have not been addressed. The majority of existing literature is interested in offline analysis, where models are trained and are tested on fixed datasets without reference to real-time deployment conditions [5]. This weakness makes them less applicable in dynamic environments where immediate detection and response are essential, like in the case of penetration testing.

Moreover, most of the existing methods fail to incorporate phishing detection solutions into the penetration testing processes. Penetration testing is a proactive security measure that recreates real-world attacks to detect vulnerabilities, but it usually does not use intelligent and automated tools in detecting phishing attacks during testing processes. Moreover, other concerns, like a high false-positive rate and high computational overhead, do not allow using ML models in real-time systems [6].

This study is thus driven by the need to come up with an effective and realistic machine learning-based system that would be efficient in identifying phishing attacks in real time, that is, in a penetration testing context. The proposed research will fill this gap by focusing on these limitations to combine theoretical ML models and their practical implementation in cybersecurity.

C. Objectives and Contributions

The main aim of the proposed research is to develop and evaluate an ML-based phishing detection framework for penetration testing environments and assess its potential for future

real-time deployment. To do this, the following objectives need to be reached in the study:

- To train and evaluate a phishing model based on benchmark datasets of phishing.
- To implement and compare multiple ML algorithms, including RF, SVM, and XGBoost.
- To create a framework that can perform real-time phishing detection.
- To measure the performance of the models by applying conventional metrics like accuracy, precision, recall, and F1-score.
- To determine the viability of the ML-based detection integration into the penetration testing procedures.

The study is of value to the research, since it proposes a valuable and scalable phishing detection system that would provide a high accuracy rate and can be implemented in real-time.

D. Paper Organization

Below is the study structure:

- Section II includes an extensive overview of the recent literature on the topic of phishing detection by the use of machine learning methods and the critical analysis of the current methods and gaps in the literature.
- Section III explains the intended methodology, which incorporates gathering of data, preprocessing, selection of features, and development of models.
- Section IV will be the experimental design and the evaluation process, together with the results and performance analysis of the applied models.
- Section V involves the discussion of the findings, their implications, and limitations.
- Section VI concludes the study and provides recommendations on how future research might be conducted.

II. Related Work

A. Overview of Existing Works

The past few years have seen an extensive amount of studies on phishing detection, especially in the context of the application of ML and DL methods. Malicious activities have been studied by researchers through an analysis of URL features, webpage contents, and behavioral patterns with maximum accuracy.

The early modern methods (after 2020) focus on the use of supervised ML models that are trained using structured datasets. As an example, the study [2] suggested a character-level convolutional neural network (CNN) to detect phishing URLs that showed a good level of performance in detecting obfuscated URLs. On the same note, the study [4] came up with a hybrid deep learning model that integrates CNN and recurrent neural networks (RNN) and demonstrates better classification accuracy than the conventional ones.

Ensemble learning methods have been investigated in a number of studies in order to improve detection performance. In a thorough study of the various ML algorithms, [7] revealed that the Random Forest and Gradient Boosting are better than single classifiers in the phishing detection processes. Similarly, the study [3] also focused on the efficiency of ensemble models like XGBoost in working with large datasets of malicious URLs.

The feature-based methods are quite popular because they are interpretable and efficient. In [6], the authors employed both lexical and host-based attributes, including the URL length and the domain age, as input to train classifiers using ML, with high detection rates, but with comparatively low computational cost. Equally, [8] concentrated on URL-related aspects to identify phishing sites without webpage content, which is why the method is appropriate for real-time systems.

DL models are also on the increase due to the automatic extraction of features in raw data. The authors of [9] used long short-term memory (LSTM) networks in a sequential URL analysis, and it is seen that it has a better result in finding advanced phishing patterns. Another study [10] suggested a CNN-based model that takes the URL strings as images and gives competitive results.

The current studies have devoted more attention to the issues of real-time detection and deployment. In [11], the authors developed a light-weight ML model that is optimized to work with real-time phishing detection and minimizes the use of computational power, and still provides the same accuracy.

The hybrid method, combining various methods, has also proved to be promising. The study [12] combined feature engineering and ensemble learning and attained better rates of detection. Also, [4] suggested a hybrid ML-DL system that uses both structured and unstructured data to detect phishing. Moreover, explainable artificial intelligence (XAI) is also introduced to enhance the transparency of the models. The use of feature importance methods to explain the predictions of the ML was applied to [13], which allowed a more accurate perception of phishing indicators. This is more so in the case of cybersecurity applications, where transparency in decision is of utmost importance.

Fig. 1 presents a classification of the existing literature on phishing detection, highlighting the different machine learning, deep learning, and hybrid approaches.

The literature also covers adversarial resistance and changing phishing strategies in recent research. [14] investigated the use of URLs by attackers to bypass detection models, and it was found that adaptive ML systems are necessary. On the same note, [15] also surveyed phishing detection methods and the need to continually update the model.

In spite of such developments, the majority of the studies are based on offline datasets and are not coupled with penetration testing frameworks. Although accuracy gains can be noticed, the feasibility of cybersecurity in a real-world setting is not yet broadly applicable.

Table I provides a comparative analysis of existing studies on phishing detection, summarizing their methodologies, datasets, key features, performance, and identified limitations.

TABLE I. ANALYSIS OF RELATED WORK

Author	Year	Method	Dataset	Key Features	Accuracy	Limitation
[16]	2024	Hybrid ML (RF + GB + SVM)	Mixed phishing datasets	URL + content hybrid features	High	Feature selection dependency
[17].	2023	CNN, LSTM, LSTM-CNN	Phishing URL dataset	Deep feature fusion	Very High	High training complexity
[18]	2023	Hybrid DNN–LSTM	URL dataset	Sequential URL patterns	High	High training time
[4]	2023	Hybrid ML (URL-based)	Mixed URL datasets	Multi-source URL features	High	URL-only, no content analysis
[19]	2021	CNN + Multi-head Attention	Imbalanced URL dataset	Attention-based URL encoding	High	Imbalanced class sensitivity
[2]	2020	CNN	PhishTank + Alexa URLs	Character-level URL features	High	Computational cost
[11]	2020	Real-time ML (SVM, RF)	PhishTank URL dataset	Optimised URL features	High (97.32%)	Limited to URL-only analysis
[12]	2020	AdaBoost + MultiBoosting	UCI phishing dataset	Combined URL + content features	High	Limited generalisation
[14]	2020	Adversarial ML (GAN-based)	URL adversarial dataset	Adversarial-robust URL features	High	Computationally expensive
[13]	2020	ML benchmarking	Large phishing benchmark	Comprehensive feature evaluation	High	Dataset-specific findings
[20]	2020	CNN + HTML analysis	URL + HTML phishing dataset	Raw URL + HTML characteristics	High	Content crawling required
[6]	2019	Random Forest, NLP	Custom URL dataset (73,575 URLs)	NLP + lexical URL features	Very High (97.98%)	Language-dependent features
[15]	2019	Hybrid Ensemble Feature Selection	Phishing websites dataset	CDF-g optimised URL features	High	Dataset-specific performance
[8]	2019	SVM, RF	URL dataset	Lexical + host-based features	Very High (99.31%)	Relies on third-party services
[7]	2019	CNN + LSTM	URL + image + text dataset	Multi-modal combined features	High (93.28%)	High computational cost

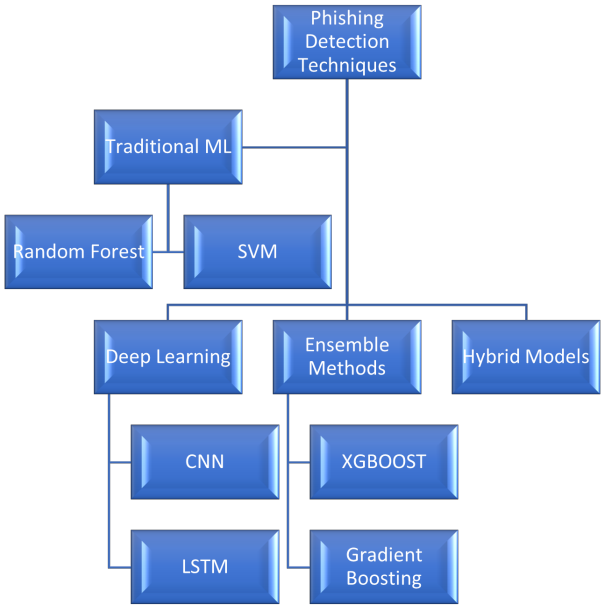

Fig. 1. Literature classification

Recent studies on ML and DL techniques of phishing detection have been synthesized. One can mention that most of the methods are highly precise, but most of them are limited by the aspects of computational complexity, the lack of real-time functionality, and the inability to react to dynamic conditions.

Recent phishing detection research has shifted toward transformers, graph neural networks (GNNs), and pretrained language models, improving detection of complex phishing attacks through better content and relationship analysis, and marking a move from traditional feature-based methods to representation-learning frameworks.

B. Critical Analysis

The analyzed articles reflect significant advances in phishing detection using ML and DL models. Traditional ML models, such as RF and SVM, are easy to use, interpretable, and efficient [6]. They are particularly used in real-time applications as their computational needs are also not very high.

On the other hand, DL models, such as CNN and LSTM models, are more accurate, as they extract complex features of raw data automatically [9][10]. Nevertheless, such models usually demand a lot of computer processing and more training time, and are not so useful in real-time.

Ensemble predictors, including XGBoost and Gradient Boosting, have the best performance and efficiency trade-offs, which makes them the best solution to the phishing detection system [3]. Hybrid methods also increase detection capabilities, since they use a combination of various techniques, but they also add complexity [4].

One severe drawback of most studies is that they use stagnant data and offline assessment. There are limited studies that address the deployment issues, including latency, scalability, and integration with the current cybersecurity tools. Also, most of the models are not explainable, which is a key to trust and acceptance in real-world systems [13].

C. Research Gap and Novelty

The phishing detection literature still has some gaps despite the fact that a lot of research has been conducted in this area. To begin with, most of the current methods are centered on offline detection and are not concerned with the issue of real-time implementation. This limits their application in dynamic systems such as penetration testing, where an instant response is required.

Second, the application of machine learning-based phishing detection is not well integrated into the context of penetration

testing. The majority of the research considers phishing detection as an independent entity instead of a part of a larger cybersecurity plan.

Thirdly, the current models tend to focus on the accuracy and not on the speed of detection and the efficiency of the computation, which are essential in real-time systems. Also, the inability to explain most ML models diminishes their application in security processes.

To address these gaps, the present study introduces a real-time machine-learning-based phishing detector implemented within the framework of penetration testing. The work focuses on the accuracy of the detection and the efficiency of the operation, which offers a valid solution when it comes to the practice of cybersecurity in reality.

III. Methodology

A. System Overview

The proposed study suggests a machine learning-driven phishing detector in a real-time environment to be used in the context of a penetration testing approach. The system accepts input URLs or web-based attributes, derives useful features, and classifies them as being phishing or legitimate with trained ML models.

The general process flow of the proposed system will include five key steps, namely, data collection, preprocessing, feature extraction and selection, model training, and real-time prediction. These phases are aimed at ensuring high detection rates, as well as effective implementation, which is a key ingredient of real-time cybersecurity applications [3].

Fig. 2 illustrates the overall architecture of the proposed phishing detection system.

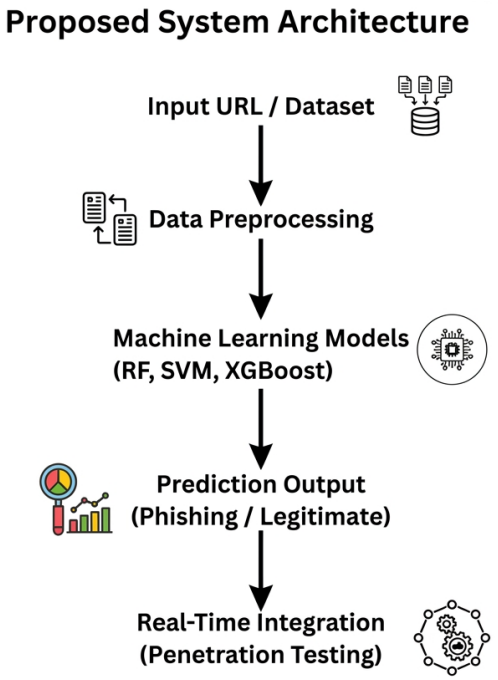

Fig. 2. Proposed system architecture.

B. Data Collection

The primary dataset used in this study is the PhiUSIIL Phishing URL Dataset, which contains a large collection of phishing and legitimate URLs along with URL-based, domain-based, security-related, and content-related features. The dataset was selected because of its size, diversity, and suitability for training and evaluating machine learning models for phishing detection.

The UCI Phishing Websites Dataset and PhishTank repository were initially reviewed during the literature survey and methodology design stages to identify commonly used phishing features and benchmark datasets reported in previous studies [6]. However, they were not used in the final experimental evaluation.

To ensure consistency and reproducibility, all experiments reported in Section IV were conducted exclusively using the PhiUSIIL Phishing URL Dataset. The dataset provides a comprehensive set of features to evaluate ML algorithms within a unified experimental framework.

C. Data Preprocessing and Cleaning

The collected data are preprocessed in a number of steps to enhance the quality of the data and to obtain the best performance of the ML models. Preprocessing of data is a very important phase, because raw data are usually full of noise, missing values, and inconsistency, which adversely affect the learning algorithms [2].

The preprocessing procedures that shall be adopted in the current study are:

- Handling Missing Values: Any records that have not been filled are dropped or filled in with any of the appropriate statistical techniques.
- Data Cleaning: Duplicate entries and irrelevant features are eliminated to reduce redundancy.
- Feature Encoding: Categorical features are converted into numerical representations using encoding techniques such as label encoding.
- Normalization: The values of features are brought into the standard range so that there is uniformity among the variables, especially in models that are sensitive to feature size, like SVM.

These steps are used to ensure that the data is clean, consistent, and can be used to train the model effectively.

D. Feature Extraction and Selection

Feature engineering is a concern in phishing detection because the quality of input features is directly proportional to model performance. The dataset features represent URL characteristics, domain information, security indicators, content attributes, and behavioural properties. For the experimental evaluation, all numerical features provided in the dataset were initially retained after preprocessing. The six features listed below are presented as representative examples of commonly

used phishing indicators that are frequently reported in the literature and are also reflected within the broader feature set of the PhiUSIIL dataset [8]:

- URL length
- Presence of HTTPS protocol
- Number of subdomains
- Use of special characters
- Domain age
- Redirection behaviour

In order to enhance the efficiency of a model and to decrease computational cost, the application of feature selection methods is used to determine the most important attributes. It is possible to reduce redundant or less informative features with the help of methods like correlation analysis and the rank of feature importance (e.g., by a Random Forest) [13].

E. Model Training and Configuration

This study chooses three ML algorithms to detect phishing. The selection of these models is based on their efficiency in classification activities and their common application in cybersecurity practices.

- RF: This is an ensemble learning algorithm that builds multiple decision trees and averages their predictions. RF has been characterized as having high strength and the capability to deal with high-dimensional data.
- SVM: This is a supervised learning system that determines the best hyperplane to use in making classification. SVMs can be useful in dealing with irregular decision boundaries and high-dimensional feature spaces.
- XGBoost: This is an improved ensemble boosting algorithm, which advances itself using gradient boosting. It is very effective, and it has been reported to be better in phishing detection tasks.

All the models are trained with a supervised learning method, whereby labelled data is separated into training and test sets, which is usually 80:20. RF and XGBoost use hyperparameters like tree depth, and SVM uses hyperparameters like kernel type to optimize performance.

F. Real-Time Detection Framework

This study proposes a conceptual framework for integrating trained machine learning models into a real-time phishing detection system that could be used in penetration testing environments. Unlike the traditional offline systems, the intended framework will operate in the dynamic mode and provide instant classification results to the incoming URLs.

Fig. 3 depicts the workflow of the real-time phishing detection framework, demonstrating how incoming URLs are processed, analyzed, and classified within a penetration testing environment.

The system can be implemented in either the form of a lightweight application or API, which allows penetration testers to test phishing attacks during attack simulation. This will encourage the practical value of the model and bridge the gap between the theoretical research and real practices of cybersecurity.

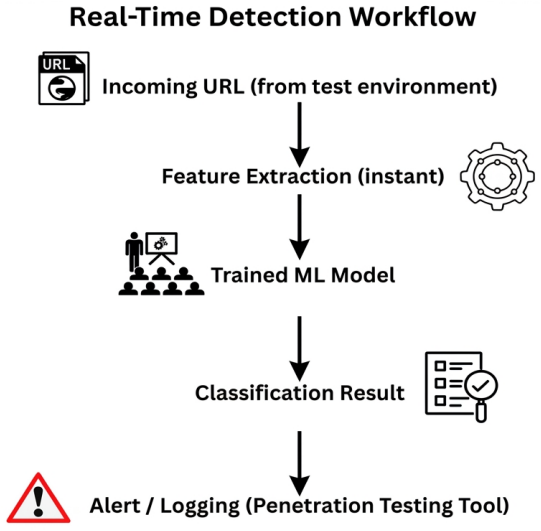

Fig. 3. Real-time detection workflow.

IV. Experimental Setup and Evaluation

A. Experimental Steps

The experimental analysis was performed in order to verify the possibilities of the ML models to identify phishing attacks on a massive dataset. It is developed using Python and the assistance of such packages as Scikit-learn, Pandas, NumPy, and XGBoost.

The process of the experiment was designed in the following way:

- Data Collection: Achieved by using PhiUSIIL Phishing URL Dataset with an exhaustive collection of URL, domain and content-based features.
- Data Preprocessing and Cleaning: The non-numeric data, such as the URL strings, the domain names and titles, were discarded to make them compatible with the machine learning algorithms. Missing values have been filled by zero imputation, and the dataset has been consistent as well.
- Feature Selection: Such features of the URL as security measures, behavioural characteristics and relevant numerical characteristics were employed.
- Dataset Splitting: The data was divided into training and testing groups in the proportion of 80:20 to come up with an objective evaluation.
- Model Training and Configuration: The processed data were used to train three machine learning models, which are: the RF, the SVM, and the XGBoost.
- Model Evaluation: The evaluation metrics of performance were based on standard evaluation metrics,

such as accuracy, precision, recall, F1-score, and ROC-AUC.

- Real-Time Simulation: The trained models were tested on how they could be integrated into real-time phishing detection systems in the testing penetrate.

B. Dataset Description

The dataset employed in this study is the PhiUSIIL Phishing URL Dataset, which consists of 235,795 examples and 56 features. The data has a wide variety of characteristics, including:

- URL-based features: URL length, character distribution, similarity index
- Domain-based features: Domain length, subdomains, TLD legitimacy probability
- Security features: HTTPS usage, obfuscation indicators
- Content features: Presence of forms, scripts, images, and external references
- Behavioural features: Redirections, pop-ups, and iframe usage

The data is categorized into two groups:

- 1 = Phishing
- 0 = Legitimate

The class distribution is as follows (see Table II):

TABLE II. CLASS DISTRIBUTION OF DATA

Class	Count
Phishing (1)	134,850
Legitimate (0)	100,945

Preliminary experiments with Synthetic Minority Oversampling Technique (SMOTE) were performed, but did not provide significant performance improvements, therefore, weighted learning was retained due to its lower computational overhead.

C. Evaluation Metrics

The following measures were used to evaluate the models (see Table III):

- Accuracy: Overall correctness of predictions
- Precision: Ability to avoid false positives
- Recall: Ability to detect phishing instances
- F1-score: Balance between precision and recall
- ROC-AUC: Overall classification capability across thresholds

TABLE III. EVALUATION METRICS

Model	Accuracy	Precision	Recall	F1-Score	ROC-AUC
Random Forest	0.9999	0.9999	1.0000	1.0000	1.0000
SVM	0.9998	0.9997	1.0000	0.9998	1.0000
XGBoost	0.9999	0.9999	1.0000	0.9999	1.0000

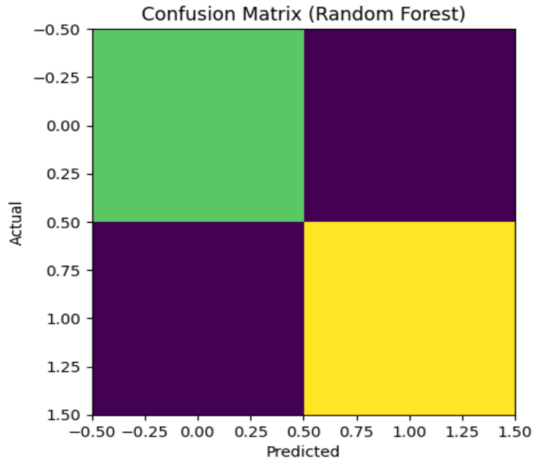

Fig. 4. Confusion matrix (Random Forest)

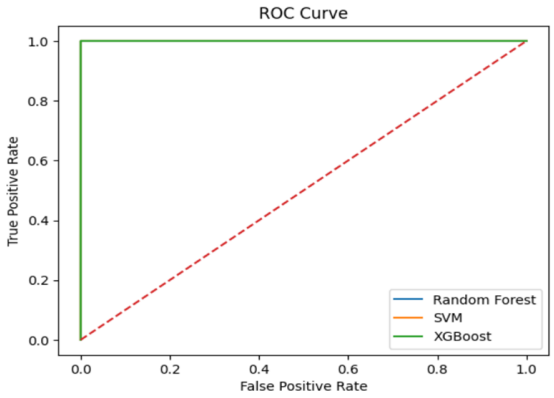

Fig. 5. ROC curve

D. Results and Analysis

The experimental findings has shown that the performance was outstandingly high in all the ML models that were tested. The model with the best performance was the RF, which implies that it made the correct classification of all the occurrences in the test dataset.

As illustrated in Fig. 4, the confusion matrix demonstrates the model's ability to accurately identify both classes within the evaluation dataset.

XGBoost also showed close to perfect performance with an accuracy of 0.9999, whereas the SVM showed a slightly lower, though very competitive performance with an accuracy of 0.9998. These results indicate that ensemble-based models (RF and XGBoost in particular) are very effective in identifying phishing attacks.

The confusion matrix also validates the strength of the RF model, as there are no false positives and false negatives, thus

indicating perfect classification. The same happens to the ROC curves of all models that tend to converge towards the ideal point, and the scores of AUC are 1.0, which proves to be very effective in differentiating between the classes of phishing and legitimate.

Fig. 5 further confirms the robustness of the evaluated models. The ROC curves remain close to the upper-left corner of the plot, indicating excellent discrimination capability between phishing and legitimate URLs across different classification thresholds.

However, this near-perfect performance may be an indicator of the potential limitations regarding the nature of the datasets or generalization of the models. The accuracy can be attributed to the fact that the separability of features in the dataset is very high, and the samples of phishing and legitimate websites are very different. Although this will improve the model performance in the controlled experiments, this may not necessarily be the case in the real world, where data is much noisier and more complex.

V. Discussion

A. Interpretation of Results

This is supported by the experimental results, which shows that ML models can be effective in recognizing phishing attacks if they are trained on a large and rich dataset. Although RF achieved the highest average performance among the evaluated models, the performance differences between RF and XGBoost were extremely small and statistically insignificant. Therefore, the superiority of RF should not be interpreted as conclusive. Instead, both ensemble-based models demonstrated comparable classification capability. This suggests that model selection for practical deployment should consider not only predictive accuracy but also operational factors such as inference latency, memory usage, scalability, and maintainability.

It is possible to explain the high effectiveness of the Random Forest by its ensemble character, i.e., several decision trees working together to enhance the level of predictions and decrease overfitting. This model is an effective representation of a webpage's behaviour in relation to a complex association between other features like URL structure, domain characteristics, and webpage behaviour. Equally, XGBoost is very effective because of its gradient boosting algorithm, which continuously enhances the model accuracy by emphasizing the misclassified cases [3].

The fact that it is almost impossible to recall all models is especially important regarding the area of cybersecurity. Good recall means that phishing is properly detected and the threat is reduced. This would be vital in a penetration testing situation where a phishing attack may pass by without realising a severe vulnerability. Regarding the real-time viewpoint, the findings indicate that the RF and the XGBoost would be very appropriate to be implemented in a penetration testing environment. The models not only offer a high level of accuracy but also offer efficient prediction time, which means that malicious URLs are detected quickly. This is in line to establish an effective, real-time phishing detection model, which can be used by cybersecurity experts when simulating an attack.

Additionally, the findings indicate the significance of feature engineering in phishing detection. The dataset employed in this research comprises a very diverse variety of characteristics, including URL-based characteristics, domain-based characteristics, and content-based characteristics, which play an important role in the model performance. This implies that the quality and diversification of features are important in enhancing the accuracy of detection.

B. Limitations

Although the performance is high in this study, a number of limitations should be acknowledged. To begin with, the almost flawless accuracy of all the models can suggest that the dataset is composed of very separable features, and the classification process can be made much easier. Although this contributes to great performance with controlled experiments, this may not be representative of the complexity of the real-world phishing, whereby attackers have continued to develop various methods of carrying out their activities in order to avoid detection.

Secondly, the models have been tested on a static dataset, which fails to take into consideration dynamic alterations in phishing behaviour over time. In practice, phishing attacks can take on new formats and unheard-of characteristics, and this can compromise the model's performance unless it is constantly updated [7].

The other one is the possible overfitting risk, especially in the case of ensemble models like Random Forest. These models are intended to be generalized, though, very high accuracy can reflect that the model has acquired dataset-specific trends, rather than overall phishing features. The study also pays more attention to URL and content-based properties, and it does not use contextual information (e.g., user behaviour or email metadata). The features might also be included in order to increase the detection capabilities and offer a more comprehensive approach to phishing detection.

An additional practical limitation concerns long-term model maintenance in production environments. Phishing strategies evolve continuously, creating concept drift that can reduce model effectiveness over time. Therefore, production deployment requires continuous monitoring, periodic retraining using recent threat intelligence, drift detection mechanisms, secure model update pipelines, and performance alerting. Without such operational controls, even highly accurate models may degrade under evolving attack patterns.

Lastly, even though the proposed system has great potential to be implemented in real-time, the execution of a complete real-time system was not carried out. The network latency, system integration, and scalability are aspects that need further research in order to be practical in case they need to be deployed in the penetration testing set-ups.

VI. Conclusion

A. Summary of Findings

This study examined how ML can be used to identify phishing attacks and, more specifically, how this can be applicable in real-time settings in penetration testing. The PhiUSIIL Phishing URL Dataset has been used to analyse a

comprehensive set of features, including URL-based, domain-based and content-based features.

The experimental results indicated that ML systems are capable of excelling in phishing. The evaluation indicated that Random Forest was the best, and its accuracy in the classification is perfect, which was also exhibited by XGBoost and SVM. These findings indicate the capability of ensemble-based models to identify complex tendencies of phishing attacks.

It was also necessary to make sure that the recalls were high in all the models and the phishing cases were properly identified during the test. It particularly applies to the sphere of cybersecurity, in which the failure to detect any malicious presence can have immense consequences. Overall, the results can support the utility of ML as a plausible instrument in phishing detection.

B. Core Contributions

The study contributes to the research area of cybersecurity and phishing detection in the following ways:

- It presents an ML-based phishing detector based on a large-scale and feature-sensitive dataset.
- It provides a comparative analysis of multiple ML models, including RF, SVM, and XGBoost.
- It also shows that high detection accuracy and efficiency can be attained to be used in real-time use.
- It also emphasises the potential to integrate machine learning models in the workflow of penetration testing.

However, compared to the rest of the studies performed, the current study focuses on performance and applicability, thereby establishing a gap between the theory and practice of cybersecurity implementation.

C. Real-World Value and Applicability

The study outcomes of the research have immense implications for the actual cybersecurity systems in the real-world. Very accurate and efficient models used in the evaluation of the models meant that they could be effectively applied in security tools to be applied in the detection of phishing attacks in real-time.

Specifically, through these models, penetration testers can detect phishing vulnerabilities in simulation attack mode to augment the process of complete security testing.

Additionally, these machine learning-based systems can be adopted by organizations to enhance protection against phishing attacks and minimize data breaches and financial losses. Such models are practical units of the modern cybersecurity systems due to their capability of detecting phishing attacks within a short period of time and at a high rate of success.

D. Future Work

Although the outcomes of this research are promising, there are a number of directions in which this research can be conducted to ensure that the phishing detection systems become even more efficient. First, DL models can be improved by more complex and dynamic trends of phishing using more sophisticated DL models, including LSTM networks and transformer-based networks. Second, complete functionality of a real-time detection system, i.e., a web-based API or a browser extension, would render the specified method of work even more pragmatically viable at an even larger scale. Besides, the active and constantly updated datasets, such as the data streams, would be involved to enable the models to evolve with the modifications of the phishing tactics upon their emergence. In addition to that, the feature sets may be expanded to incorporate the user behavioural evidence and email metadata that would offer a more sensible and holistic detection mechanism. Lastly, XAI would be provided to improve the transparency of the model and its credibility and practicability in the practice of cybersecurity in the real-life setting. In all, this would lead to more robust, larger, and more natural ML-based phishing detection systems.

FUNDING

This study was funded by the Deanship of Scientific Research, Vice Presidency for Graduate Studies and Scientific Research, King Faisal University, Saudi Arabia [GRANT No. KFU263466].

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research, Vice Presidency for Graduate Studies and Scientific Research, King Faisal University, Saudi Arabia [GRANT No. KFU263466]. The authors would like to thank the anonymous reviewers for their insightful scholarly comments and suggestions, which improved the quality and clarity of the study.

CONFLICTS OF INTEREST

The authors declare no conflicts of interest.

***Abstract*—The increasing complexity of Internet of Things (IoT) applications has exposed the limitations of monolithic software architectures in addressing scalability, flexibility, and real-time processing requirements. Although microservice architectures offer a promising alternative, identifying optimal service boundaries remains a significant challenge, often resulting in excessive inter-service communication and degraded system performance when poorly defined. This study proposes a quantitative model for refactoring monolithic applications into microservices by integrating Domain-Driven Design (DDD) principles with measurable metrics, including service size, coupling, and scalability. The model systematically identifies optimal service boundaries through a structured evaluation framework. The proposed approach is validated using a case study of an IoT-based irrigation management system. Experimental results show a reduction in inter-service communication overhead and improved modularity and scalability compared to baseline decomposition approaches. The findings demonstrate that combining DDD concepts with quantitative analysis provides an effective and practical solution for guiding microservice migration in complex IoT environments. The average coupling score across the refactored system was recorded at 20.4%, which satisfies the theoretical requirement of remaining below 30% and aligns with empirical observations from successful microservice decompositions.**

***Keywords*—Microservice; refactoring model; IoT irrigation system; DDD**

I. Introduction

The rapid adoption of Microservice Architecture across the software industry has necessitated robust strategies for migrating legacy monolithic systems to more modular and scalable structures [1] [2]. While microservices offer advantages in terms of independent deployment and scalability, the transition from a monolithic structure presents significant challenges regarding service granularity, cohesion, and coupling that require systematic approaches to identify appropriate service boundaries [3] [4]. While Domain-Driven Design offers a valuable conceptual framework for identifying bounded contexts [5], the approach lacks concrete quantitative mechanisms to resolve the ambiguity in defining service boundaries, which often leads to suboptimal decompositions that fail to balance network latency, data consistency, and dependency management effectively [6]

To address this limitation, this study proposes a mathematical model that quantifies and formalizes architectural decision-making by integrating key metrics such as service size, scalability, and coupling, thereby establishing a formal basis for the decomposition of monolithic IoT systems into microservices [7]. This model provides a structured mechanism to evaluate maintainability by explicitly quantifying factors such as architectural complexity and cohesion, which are essential for long-term system sustainability.

The modernization strategies employing well-established methods such as the analysis of Domain-Driven Design patterns to locate potential microservices are essential for decomposing legacy code bases while managing the complexity inherent in functional redesign and organizational criteria [7][8]. The process of breaking down an application domain into properly sized components remains a challenging task because the notion of the ideal size for these components is often blurred or unclear, necessitating the integration of quantitative models to identify optimal service boundaries that balance network latency, data consistency, and dependency management [9]. Finding the optimum size for a service is particularly complex as it requires finding a balance that accommodates varying development costs, performance overheads, and the distinct requirements of different application domains [8], while balancing distinct factors like afferent and efferent coupling against relational cohesion to ensure the modularity and maintainability of the refactored architecture [7].

Therefore, this study introduces a mathematical framework that operationalizes DDD concepts by quantitatively evaluating service candidates against metrics of size, scalability, and coupling to reduce the ambiguity inherent in defining bounded contexts. This ambiguity arises due to the fact that because a bounded context is primarily a logical distinction denoting where specific domain rules apply, rather than a structural or physical boundary, which complicates the direct translation of domain models into deployable microservices without quantitative validation [10] . The clear quantitative measures for defining optimal boundaries and functional divisions are currently lacking [11], [9], [12].

The absence of standardized quantitative metrics for evaluating architectural trade-offs often forces architects to rely on intuition, increasing the risk of creating distributed systems that suffer from either excessive latency due to chatty inter-service communication or diminished autonomy due to overly coarse-grained service boundaries [13][1][4]. This lack of rigor can result in a distributed monolith, a system that suffers from the operational disadvantages of distributed architectures without gaining the intended modularity or independent scalability,

effectively trapping organizations in a state of diminished performance and increased complexity. To bridge this gap, existing literature has begun formalizing extraction models to support algorithmic recommendations, recognizing that while informal migration patterns exist, there is a fundamental lack of formal models and automated support tools to rigorously guide the decomposition process [7].

This research aims to develop and validate a quantitative model for refactoring monolithic applications into microservices using DDD principles. Specifically, the study seeks to: (1) formulate measurable metrics, including service size, coupling, and scalability, to support the systematic identification of optimal microservice boundaries; (2) evaluate the effectiveness of the proposed model in reducing inter-service coupling and improving system scalability compared to traditional decomposition approaches; (3) investigate the extent to which the model enhances modularity and architectural stability; and (4) assess the impact of the proposed approach on system performance and development efficiency through a case study of an IoT-based irrigation system.

The scalability validation showed that the sensor ingestion service handled a 50% increase in throughput without proportional latency growth, confirming the model's effectiveness in predicting workload scaling behavior in dynamic IoT environments.

II. Literature Review

Existing literature on decomposing large systems into microservices predominantly frames the refactoring task as a graph clustering problem, where static code analysis uncovers functional dependencies to inform service boundaries [14], [15]. Approaches using semantic coupling strategies couple classes based on shared domain model entities identified via extracting meaning from source code, aligning microservice boundaries with bounded contexts from Domain-Driven Design [12][16]. Model-based methodologies further extend UML component diagrams with formal profiles that incorporating Domain-Driven Design's bounded context patterns, enabling precise specification of microservice communications and subsequent transformations between models for code generation [8]. These transformations facilitate the automatic derivation of microservice architectures by mapping clustered domain entities into independent deployment units, preserving high cohesion within services while minimizing inter-service dependencies [17], [6]. Nevertheless, these methodologies often lack strict mathematical definition for optimizing cluster modularity, prompting the need for graph-theoretic models that quantify bounded context cohesion through density metrics on entity interdependence [15].

This study advances the field by introducing a mathematical model employing Domain-Driven Design's bounded contexts as optimization objectives within clustering algorithms, maximizing service cohesion through weighted edges representing domain entity couplings [8], [14].

Current microservice extraction research reveals diverse analytical approaches, including tracing runtime behavior combined with bounded context patterns to dynamically visualize service boundaries, functionality-oriented clustering of execution traces validated by cohesion and coupling metrics, and systematic analysis of functions, interfaces, dataflows, and storage [7][18]. These paradigms frequently encounter limitations in achieving domain-driven decompositions, as optimization models minimizing inter-service coupling via weights on connections fail to constrain entity placements within semantically meaningful bounded contexts [9]. The proposed model addresses these shortcomings by formulating bounded context identification as a combinatorial optimization over graph communities derived from domain entity couplings, yielding microservices with minimized inter-service dependencies, while preserving semantic cohesion[19]. Empirical validation of this model on legacy monolithic systems demonstrates its capacity to produce microservices adhering to the single responsibility principle through combinatorial optimization over high-cohesion graph communities[15]. Additionally, empirical assessments confirm the model's superiority through higher cohesion scores and reduced coupling metrics relative to baseline decompositions, and precision-recall alignments exceeding those of interface analysis and graph clustering benchmarks [6][20]. To put this model into operation, the subsequent sections delineate its mathematical formulation, commencing with graph construction from domain entities and proceeding to optimization objectives maximizing modularity via attention-augmented clustering [6].

A. Research Gap and Novel Contributions

Although existing microservice decomposition approaches have achieved promising results through graph clustering, semantic analysis, and optimization techniques[7], [9], several limitations remain. First, most graph-based approaches focus primarily on structural dependencies and community detection without explicitly incorporating scalability requirements into the decomposition process[21]. Second, optimization-based methods generally prioritize coupling minimization and cohesion maximization but do not simultaneously consider service size constraints[22], runtime workload distribution, and scalability objectives within a unified formulation.

The novelty of the proposed model lies in the integration of three complementary dimensions of software quality into a single optimization framework:

- Structural Quality through service size constraints that prevent both oversized and excessively fragmented microservices.
- Runtime Performance through scalability metrics derived from interaction frequencies and workload distributions.
- Architectural Modularity through coupling minimization and cohesion maximization guided by Domain-Driven Design bounded contexts.

Unlike conventional graph clustering approaches that generate partitions solely from dependency structures [23],[16], the proposed model incorporates bounded-context knowledge from Domain-Driven Design and evaluates candidate decompositions using a multi-objective optimization function. This enables the identification of service boundaries that simultaneously satisfy modularity, scalability, and maintainability requirements.

Furthermore, while existing optimization approaches typically rely on static code metrics [24], [25], the proposed framework combines static analysis, runtime interaction analysis, and co-change evolutionary coupling information to construct a richer representation of service dependencies. Consequently, the model provides a more comprehensive basis for microservice extraction in large-scale IoT applications.

III. Research Methodology

This study adopts a Design Science Research (DSR) methodology to develop and evaluate a mathematical model for refactoring monolithic applications into microservices. The DSR approach is appropriate as it focuses on the creation and validation of an artifact designed to address a specific engineering problem. In this context, the artifact is a quantitative model that supports the identification of optimal microservice boundaries based on measurable architectural attributes. The research process follows established DSR stages. First, the problem identification and motivation are established through a systematic literature review (SLR), which highlights the limitations of existing approaches for microservice decomposition, particularly in defining appropriate service boundaries. Second, the objectives of the solution are defined, focusing on the development of a systematic and quantitative method for designing scalable and modular microservice architectures. Third, the design and development phase involves constructing a mathematical model that integrates key metrics, including service size, coupling, and scalability. These architectural attributes are formalized into mathematical functions to enable the systematic evaluation of decomposition alternatives, with the aim of maximizing cohesion and scalability while minimizing inter-service coupling. Fourth, the proposed model is demonstrated through its application to a case study of an IoT-based irrigation system. Finally, the evaluation is conducted using a quantitative case study approach, where the performance of the proposed model is compared against traditional decomposition methods based on defined metrics. The results are then communicated to the research community to validate the effectiveness and applicability of the proposed approach.

IV. Development of the Refactoring Mathematical Model

A. Metrics for Service Size, Scalability, and Service Coupling

1) Service size: Determining the appropriate granularity for microservices is a complex challenge, as size is not a reliable standalone indicator for optimal decomposition, making it necessary to prioritize cohesion as the primary guideline rather than mere granularity [8][26]. This equilibrium is critical because research indicates that identifying the optimal granularity requires balancing various aspects, where simply focusing on low coupling and high cohesion values may not be sufficient for optimal modularity [5]. To quantify this balance objectively, specific metrics such as the number of methods and lines of code are utilized to measure service size, ensuring that the service scope remains within the recommended 10-100 lines of code range to facilitate efficient testing, deployment, and maintenance processes. To calculate the service size, this research utilizes a simple cardinality-based metric defined as [see Eq. (1)]:

$$S_i = |m_i| \tag{1}$$

where, S_i represents the size of microservice i, and m_i denotes the set of classes (or components) contained within the microservice. The optimal granularity of a microservice directly affects the application's quality attributes and the utilization of computational resources. These metrics evaluate the ability of an individual service to operate independently. This independence can be quantified by the ratio of external dependencies to total operations, where a higher value indicates that the service can be developed, deployed, and maintained with minimal impact on other system components [27].

2) Scalability potential: The scalability potential of a microservice is defined as a function of its size and internal structure [see Eq. (2)]:

$$V_i = \frac{H_i}{1 + S_i} \tag{2}$$

where, V_i denotes the scalability potential of service i, S_i is the service size, and H_i represents the cohesion within the service. This formulation allows efficient resource allocation and dynamic scaling, as services can be independently replicated based on demand. However, independent scaling must be balanced against interdependence introduced by service size.

3) Cohesion within microservices: Cohesion reflects the degree of relatedness among components within a microservice and is defined as [see Eq. (3)]:

$$H_i = \frac{1}{|m_i|^2} \sum_{c_p, c_q \in m_i} \text{sim}(c_p, c_q) \tag{3}$$

where, $\text{sim}(c_p, c_q)$ denotes the similarity between classes c_p and c_q within the same microservice.

4) Coupling between microservices: Coupling represents the degree of interdependence between distinct services. It is defined as [see Eq. (4)]:

$$C = \sum_{i \neq j} \sum_{c_p \in m_i} \sum_{c_q \in m_j} d(c_p, c_q) \tag{4}$$

where, $d(c_p, c_q)$ represents the dependency strength between class c_p in microservice m_i and class c_q in microservice m_j.

To rigorously evaluate interdependencies, we divided coupling into:

- Afferent Coupling (C_a): Measures incoming dependencies, defined as the number of external classes depending on classes within a microservice:

$$C_a(i) = |\{c \notin m_i \mid c \to m_i\}|$$

- Efferent Coupling (C_e): Measures outgoing dependencies, defined as the number of external classes that a microservice depends on:

$$C_e(i) = |\{c \notin m_i \mid m_i \to c\}|$$

Coupling is analyzed in both internal and external dimensions to evaluate its impact on maintainability and independent evolution. This ensures that the model captures both intra-service complexity and inter-service connectivity within the distributed architecture.

B. Unified Model for Service Decomposition

Fig. 1 presents the unified model procedure.

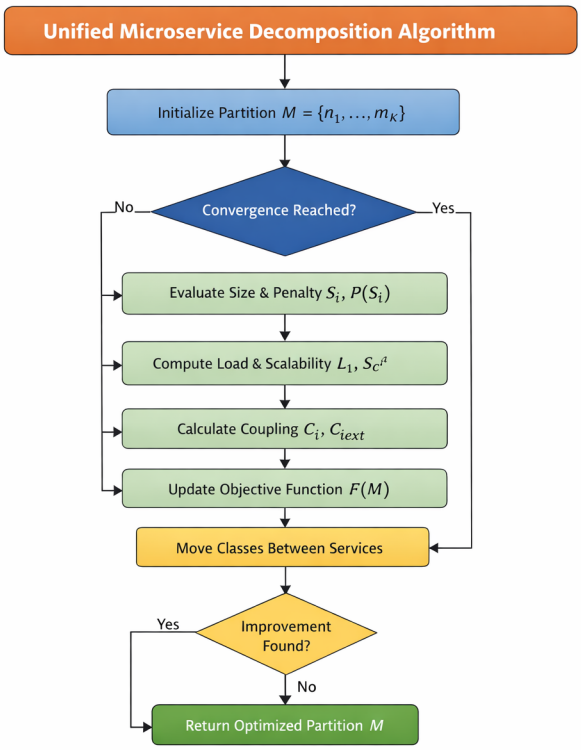

Fig. 1. Unified model procedure

Let the monolithic application be represented as a set of classes:

$$C_M = \{c_1, c_2, \ldots, c_N\}$$

which are partitioned into K disjoint microservices:

$$M = \{m_1, m_2, \ldots, m_K\}$$

such that:

$$\bigcup_{i=1}^{K} m_i = C_M, \qquad m_i \cap m_j = \emptyset \quad \forall i \neq j$$

The structural complexity of each candidate microservice is quantified using a composite size metric that aggregates cyclomatic complexity and method count. Service Size S_i can be represented as [see Eq. (5)]:

$$S_i = \sum_{c \in C_i} (V(G)_c + M_c) \tag{5}$$

where, C_i = set of classes in service i, $V(G)_c$ = cyclomatic complexity of class c, M_c = number of methods in class c, α = weighting factor. This formulation ensures that each service maintains a manageable level of complexity while avoiding excessive aggregation of responsibilities.

To enforce balanced granularity, the following constraint is imposed:

$$S_{\min} \leq S_i \leq S_{\max}$$

We imposed the constraint on the exact size of the microservice to discourage the size violation as:

$$P(S_i) = \max(0, S_{\min} - S_i)^2 + \max(0, S_i - S_{\max})^2$$

Scalability is evaluated using runtime interaction and resource consumption metrics. Let $I(f_p, f_q)$ denote the invocation frequency between functions. The normalized load distribution is [see Eq. (6)]:

$$L_i = \frac{1}{T} \sum_{(f_p, f_q) \in E_i} I(f_p, f_q) \tag{6}$$

where, load model L_i can be presented as: F_i = set of functions in service i, $I(f_p, f_q)$ = invocation count between functions f_p and f_q, $E_i \subseteq F_i \times F$ = interactions involving service i, $T = \sum_{(f_p, f_q) \in E} I(f_p, f_q)$ = total system-wide invocations. This gives a normalized estimate of how much runtime activity is associated with service i.

Coupling metric is presented as:

$$C_i = \omega_{ec} C_{ei} + \omega_{ac} C_{ai}$$

where C_{ei} = efferent coupling (outgoing dependencies), C_{ai} = afferent coupling (incoming dependencies), $\omega_{ec}, \omega_{ac} \in [0, 1]$ = weighting coefficients.

Then the frequency weighted coupling is represented as follows for the set of outgoing dependency pairs:

$$C_{ei} = \frac{1}{T} \sum_{(f_p, f_q) \in D_i^{out}} I(f_p, f_q)$$

and the set of incoming dependency pairs being represented as [see Eq. (7)]:

$$C_{ai} = \frac{1}{T} \sum_{(f_p, f_q) \in D_i^{in}} I(f_p, f_q) \tag{7}$$

After representation of the different parameters, we partition the candidates of microservice by considering the constants of minimizing the size while minimizing the coupling and maximizing the scalability, which can be presented as [see Eq. (8)]:

$$M_i = \sum_i \left[\lambda_1 \frac{1}{S_i} + \lambda_2 C_i - \lambda_3 L_i \right] \tag{8}$$

C. Model Variable Parameters for Partitioning and Optimization

To operationalize the model, we defined the core decision variables as $V = \{c_1, \ldots, c_n\}$: set of classes follows, and $M = \{m_1, \ldots, m_k\}$: set of microservice the variables are assigned to $x_{i,j} \in \{0, 1\}$:

$$x_{i,j} = \begin{cases} 1 & \text{if class } c_i \text{ is assigned to } m_j \\ 0 & \text{otherwise} \end{cases}$$

Ensure that each class is exclusively mapped to a single service boundary during the partitioning process.

Additionally, to represent the inter-service connectivity between classes c_i and c_j belonging to different microservices, a binary edge variable $y_{ij} \in \{0, 1\}$:

$$y_{ij} = \begin{cases} 1 & \text{if } c_i, c_j \text{ are in the same service} \\ 0 & \text{otherwise} \end{cases}$$

This is linking to constraint formulation [see Eq. (9)]:

$$y_{ij} = \sum_{k=1}^{|M|} x_{i,k} \cdot x_{j,k} \tag{9}$$

where, it can allow the objective function to account for the cut weight and minimize coupling as was done in [7].

Consequently, the coupling objective is formulated as in [7], [8] by minimizing the sum of weights for edges crossing partition boundaries, where E is the set of edges and w_{ij} the coupling weight is expressed as [see Eq. (10)]:

$$\min_{(i,j) \in E} w_{ij}(1 - y_{ij}) \tag{10}$$

This coupling strength w_{ij} further incorporates contributor-based coupling metrics, where the weight is defined as the cardinality of the intersection of developer sets between connected classes c_i and c_j.

We incorporated this approach in calculating the weight of coupling by utilizing the co-change frequency observed in the version control history to establish a dynamic coupling metric, defined as:

$$\delta(i, j) = \begin{cases} 1 & \text{if } c_i, c_j \text{ changed together in commit } h \\ 0 & \text{otherwise} \end{cases}$$

as the aggregated logical coupling is delivered as:

$$\Delta_{ij} = \sum_{h \in H_m} \delta(i, j)$$

and the final coupling weight is [see Eq. (11)]:

$$w_{ij} = |Dev(c_i) \cap Dev(c_j)| + \Delta_{ij} \tag{11}$$

This logical coupling metric serves as a crucial indicator of evolutionary dependencies, ensuring that classes that frequently change together are grouped into the same microservice boundary to maintain high cohesion.

We balanced this internal cohesion with the constraints of service size. Our model imposes a constraint on the number of classes assigned to each microservice to prevent the creation of overly complex or trivial services, as it is used in [4]. The constraint of size over cohesion to promote the generation of evenly distributed and manageable services is formulated as [see Eq. (12)]:

$$|m_j| = \sum_{i \in V} x_{i,j}, \quad \text{where } L_{\min} \leq |m_j| \leq L_{\max}, \quad \forall j \tag{12}$$

Beyond these structural constraints, this model incorporates a service cohesion metric to quantitatively assess the degree to which elements within a candidate microservice belong together based on communicational and textual similarities. For a service or cluster:

E_j^{int} : internal edges and V_j : nodes in the cluster

$$Cohesion_j = \frac{|E_j^{int}|}{|V_j|}$$

with a global cohesion [see Eq. (13)]:

$$\max \sum_{j=1}^{|M|} \frac{|E_j^{int}|}{|V_j|} \tag{13}$$

A high cohesion value suggests that all the methods inside a microservice have strong relationships with entities included in the same microservice, which implies that the service is well concerned with a specific bounded context. Conversely, low cohesion indicates that a service encompasses disparate functionalities that lack strong interconnectivity, potentially negating the benefits of modularization.

To ensure the robustness of the proposed decomposition for this model, the aim is to employ a multi-objective evaluation criterion that simultaneously optimizes for minimized inter-service coupling, maximized intra-service cohesion, and adherence to defined service size constraints.

We completed this model by incorporating the modularity quality metric, which serves as a comprehensive indicator of

the partitioning effectiveness by calculating the ratio of internal interactions to total interactions, expressed as:

$$Q = \frac{W_{intra} - W_{inter}}{W_{total}}$$

where [see Eq. (14)],

$$W_{intra} = \sum_{(i,j)\in E} w_{ij} y_{ij}, \quad W_{inter} = \sum_{(i,j)\in E} w_{ij}(1 - y_{ij}),$$

$$W_{total} = \sum_{(i,j)\in E} w_{ij} \tag{14}$$

This metric evaluates the structural cohesiveness of classes within a partition against the coupling between partitions, where a higher ratio indicates superior partition quality by ensuring that intra connectivity significantly outweighs the inter-connectivity between identified microservices.

From all the parameters defined above, we delivered a multi-object optimization as:

$$\min_{(i,j)\in E} w_{ij}(1 - y_{ij}), \quad \max_{j} Cohesion_j$$

This is subject to [see Eq. (15)]:

$$L_{\min} \leq \sum_{i} x_{i,j} \leq L_{\max} \tag{15}$$

The unified objective function is derived as follows [see Eq. (16)]:

$$\max \left[\lambda_1 \frac{W_{intra} - W_{inter}}{W_{total}} \right.$$

$$\left. + \lambda_2 \sum_{j} \frac{|E_j^{int}|}{|V_j|} - \lambda_3 \sum_{(i,j)\in E} w_{ij}(1 - y_{ij}) \right] \tag{16}$$

This final model utilizes quality metrics such as coupling, cohesion, complexity, and the size employed to determine the optimal clustering output and maintainability quality, where higher scores are assigned to configurations demonstrating high cohesion and low coupling.

D. Optimal Microservice Partitioning Algorithm

The optimal microservice partitioning algorithm is presented in Algorithm 1.

Algorithm 1 Optimal Microservice Partitioning

Require: Class set $C_M = \{c_1, c_2, \ldots, c_N\}$, dependency graph $G(V, E)$
Require: Weight parameters $\alpha, \omega_{ec}, \omega_{ac}, \lambda_1, \lambda_2$
Require: Constraints $S_{\min}, S_{\max}, L_{\min}, L_{\max}$
Require: Static metrics: cyclomatic complexity $V(G)_c$, method counts MC_c
Require: Commit history for co-change extraction
Require: Initial empty partition matrix $X = [x_{i,j}]$
Require: Feasible initialization of service sizes
$X \leftarrow$ random feasible assignment of classes to microservices
$M^* \leftarrow \emptyset$
$t \leftarrow 0$
Compute initial coupling weights w_{ij}
while convergence criterion is not satisfied **do**
  $t \leftarrow t + 1$ ▷ Update iteration counter
  Compute structural metrics $S_i,\ V(G)_c,\ MC_c$
  Compute scalability metric L_i
  Compute cohesion for each service $Cohesion_j$
  Update coupling weights w_{ij}
  Evaluate modularity Q
  Evaluate objective function $F(M)$
  Update class assignments $x_{i,j}$ using optimization operator
  (Non dominated Sorting Genetic Algorithm II (NSGA-II)
  Enforce constraints:
  $S_{\min} \leq S_i \leq S_{\max}$
  $L_{\min} \leq |m_j| \leq L_{\max}$
  $\sum_{j=1}^{K} x_{i,j} = 1, \quad \forall c_i \in C_M$
  if $F(M) > F(M^*)$ **then**
    $M^* \leftarrow M$
    $F(M^*) \leftarrow F(M)$
  end if
end while

E. Optimization Configuration

The unified objective function was optimized using the Non-dominated Sorting Genetic Algorithm II (NSGA-II)[25], a widely adopted evolutionary algorithm for multi-objective optimization problems.

The optimization process employed the following parameter settings: Population size: 100 candidate decompositions, Number of generations: 500, Crossover probability: 0.85, Mutation probability: 0.10, Tournament size: 2 Elitism strategy: Enabled

Each candidate solution was encoded as a class-to-service assignment vector. The fitness function was computed according to Eq. (16), balancing modularity, cohesion, and coupling objectives. The optimization process terminated when either:

- The maximum number of generations was reached, or
- The improvement in objective value remained below 0.001 for 50 consecutive generations.

This convergence criterion ensured computational efficiency while maintaining solution quality.

F. Integration with Domain-Driven Design (DDD)

The model we presented incorporates Domain-Driven Design concepts, specifically the definition of bounded contexts, to ensure that the refactoring process aligns the technical boundaries of microservices with the distinct business domains they represent. By leveraging these DDD principles, the model resolves the inherent ambiguity in defining bounded context boundaries by supplementing logical domain divisions with quantitative coupling and cohesion metrics to ensure high modularity and optimized service granularity [8]. This proposed model complements Domain-Driven Design by transforming domain concepts into quantifiable optimization criteria.

Initially, DDD is used to define candidate bounded contexts; these candidates are then refined using the optimization algorithm, where each m_i corresponds to a hypothesized bounded context derived from domain analysis:

$$M^{(0)} = \{m_1, m_2, \ldots, m_K\}$$

G. Mapping Between DDD and Model

Table I presents the mapping between DDD concepts and mathematical model components.

TABLE I. MAPPING BETWEEN DDD CONCEPTS AND MATHEMATICAL MODEL COMPONENTS

DDD Concept	Mathematical Representation
Bounded Context	Microservice m_i
Domain Cohesion	Size metric S_i
Service Autonomy	Scalability Sc_i
Context Independence	Low Coupling C_i^{ext}

V. CASE STUDY: IOT IRRIGATION SYSTEM

The IoT irrigation system was specifically chosen as the subject of this investigation due to its complex, multi-domain architecture and the distinct scalability challenges inherent in its sensor data processing and control mechanisms [28], which necessitate a rigorous decomposition strategy to validate the proposed mathematical model.

This system, deployed and located in Bugesera District in Rwanda, is characterized by a monolithic structure where sensor data acquisition, irrigation control logic, user interface management, and data persistence are tightly coupled, making it an ideal candidate for demonstrating how Domain-Driven Design can identify bounded contexts for separation into independent microservices. The selection of an IoT irrigation system as the subject of this case study provides a relevant context for validating the mathematical model, as such systems typically require high scalability to manage fluctuating sensor data loads and distinct service boundaries initially deployed as a single deployable unit for the irrigation system.

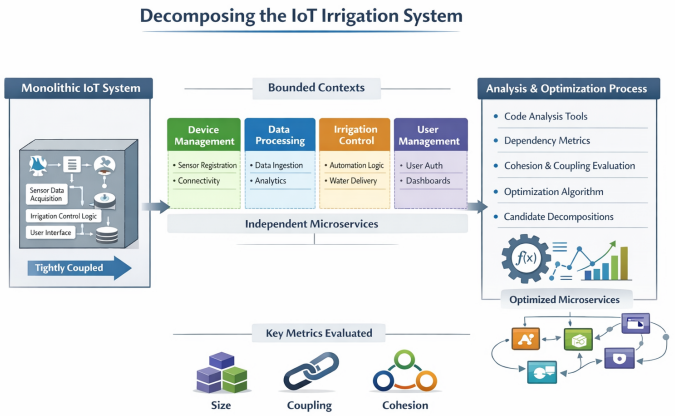

Fig. 2. System analysis and optimization framework.

We analyzed the code base and system requirements of the IoT irrigation system implemented in Bugesera District. As illustrated in Fig. 2, the analysis reveals specific functional domains to define the bounded contexts necessary for the refactoring process. The functional decomposition identified four primary bounded contexts: *Device Management*, which oversees sensor registration and connectivity; *Data Processing*, responsible for ingesting and analyzing voluminous sensor readings; *Irrigation Control*, encompassing the automation logic for water delivery based on sensor inputs; and *User Management*, handling authentication, user profiles, and dashboard interactions.

To quantitatively assess the performance of the proposed mathematical model, empirical data were collected from the existing monolithic IoT irrigation system by analyzing source code dependencies, class interaction frequencies, and module complexity metrics. These measurements established baseline values for service size, coupling, and scalability potential.

A. Data Collection, Analysis, and Refactoring Process of IoT Irrigation System

The data collection process involved mapping the static code metrics against the four identified bounded contexts to calculate specific coefficients for size, coupling, and scalability within the mathematical model.

These coefficients serve as the foundational parameters for the optimization algorithm, determining the weight of each quality attribute in the objective function designed to drive the automated partitioning of the monolith into microservices. Consequently, these coefficients are processed by the optimization algorithm to evaluate candidate decompositions, wherein solutions that minimize coupling while maximizing internal cohesion are prioritized to identify the optimal service boundaries, as demonstrated in [7].

This granular mapping of functionality and dependencies serves as the empirical foundation for generating multiple candidate decompositions, which are then rigorously evaluated against quality metrics such as cohesion and coupling to select the most effective microservice architecture [29].

To systematically gather the necessary data for modeling the IoT irrigation system, static analysis tools were employed to extract quantitative metrics regarding class dependencies, method invocations, and communication patterns between modules within the monolithic codebase. The dynamic analysis involved the extracted metrics, including different coupling values to measure inter-module dependencies, along with relational cohesion metrics to assess the functional relatedness of classes grouped within the same bounded context, thereby providing a multidimensional view of the system's structural characteristics.

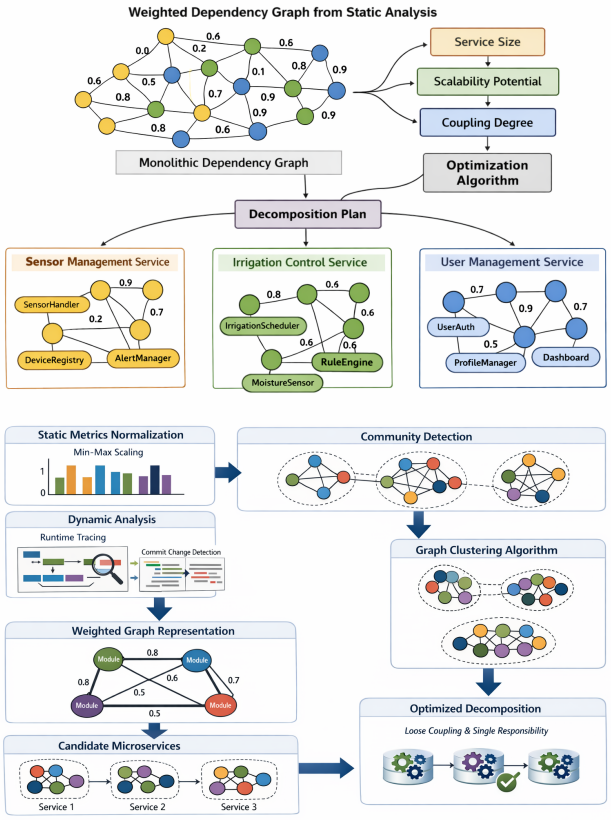

Fig. 3. Static analysis of IoT irrigation system (left) and decomposition criteria of the IoT irrigation system (right).

Moreover, graph clustering approaches, including community detection algorithms, are applied to detect highly cohesive clusters that correspond to potential microservices. Finally, combinatorial optimization techniques are utilized to ensure that the resulting decomposition satisfies key architectural principles, particularly loose coupling and single responsibility.

From static code analysis, the construction of a weighted dependency graph was derived (Fig. 3), where nodes represent classes and edges reflect the strength of relationships. This enables the algorithm to partition the system into highly cohesive communities corresponding to functional domains such as sensor management, scheduling logic, and user access control [8]. Once the dependency graph was established, the mathematical model calculated specific metrics for service size, scalability potential, and coupling degrees to quantitatively assess each identified functional domain.

This quantitative analysis utilized the calculated metrics as input variables for a multi-objective optimization algorithm to partition the dependency graph, identifying specific class clusters that minimize inter-service coupling while maintaining size and scalability constraints necessary for effective IoT deployment [18].

The execution of this decomposition plan required the strategic implementation of a database-per-service pattern and the definition of standardized communication APIs to ensure loose coupling and independent deployability. Specifically, the refactoring process involved isolating the sensor data ingestion logic into a dedicated service capable of independently scaling to handle high-frequency telemetry streams, while the irrigation control logic was encapsulated within a separate scheduling service to ensure that critical timing operations remain isolated from UI-induced latency.

Simultaneously, user management functions were extracted into an isolated authentication service to decouple access control mechanisms from core irrigation operations, ensuring that security updates do not disrupt the system's real-time processing capabilities.

Following the structural decomposition, the functional performance of the extracted microservices was assessed to ensure that the separation did not negatively impact the system's ability to process real-time telemetry and execute irrigation commands.

B. Evaluation of IoT Irrigation System

To process the evaluation, two architectures were deployed and observed to compare the results of latency, throughput, CPU usage, and the failure rate.

1) Architecture deployment: The data flow in the pipeline follows a sequence where data from all sensors passes through the ESP32. The presented data flow pipeline illustrates the end-to-end operation of an IoT-based irrigation system, where environmental data is continuously monitored, processed, and used to automate irrigation decisions. Each component contributes to a distributed and scalable architecture aligned with modern microservice and IoT design principles.

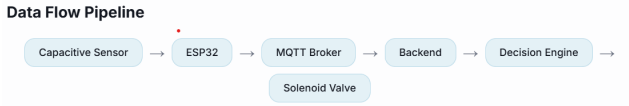

Fig. 4. Data flow pipeline

The process presented in Fig. 4 begins with the capacitive sensor that generates analog signals proportional to soil moisture levels. The ESP32 microcontroller acts as the edge device responsible for reading sensor data, converting analog signals to digital values, and performing lightweight preprocessing. In this architecture, the ESP32 enables real-time transmission of sensor data to the cloud infrastructure via wireless communication.

The MQTT broker serves as the central communication hub, implementing a publish-subscribe model. The backend system performs data storage, aggregation, and integration

with other services. The decision engine applies rules or machine learning models to determine irrigation actions. In this architecture, the decision logic is defined as:

```
if (soil_moisture < 30 && temperature > 25) {
    irrigation = true; // Turn ON irrigation
} else {
    irrigation = false; // Turn OFF irrigation
}
```

The solenoid valve acts as the physical actuator that controls water flow, opening to allow irrigation and closing to stop it.

After defining the data flow, the two architectures were deployed for comparison [see Fig. 5].

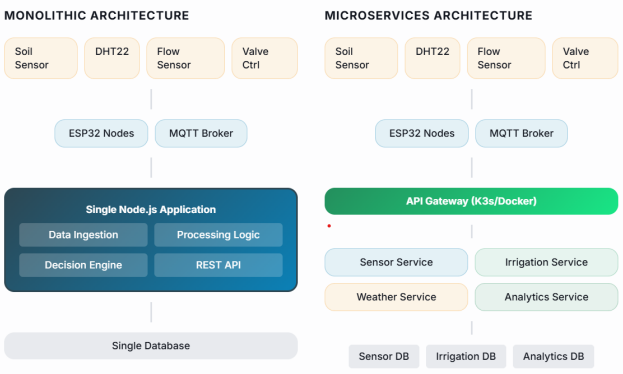

Fig. 5. Deployment of monolithic and microservice architecture.

C. System Analysis

To evaluate the efficiency gains derived from the architectural transition, comparative execution time measurements were conducted between the original monolithic application and the refactored microservice implementation. The results demonstrated that the microservice architecture achieved an increase of 1500 req/s compared to 800 req/s in the monolithic system.

TABLE II. PERFORMANCE COMPARISON

Metric	Monolithic	Microservices
Avg Latency	140 ms	180 ms
Throughput	800 req/s	1500 req/s
CPU Usage	85%	65%
Memory Usage	900 MB	1200 MB
Failure Impact	Total	Partial
Deployment	Simple	Complex
Scalability	Limited	Excellent
Dev Complexity	Low	High

Furthermore, response time analysis showed a decrease in latency under concurrent access, as the distributed architecture mitigated bottlenecks associated with the monolithic design. Load testing demonstrated stable response times with error rates below 0.1% at peak loads, indicating improved reliability due to isolated failure domains [see Fig. 6].

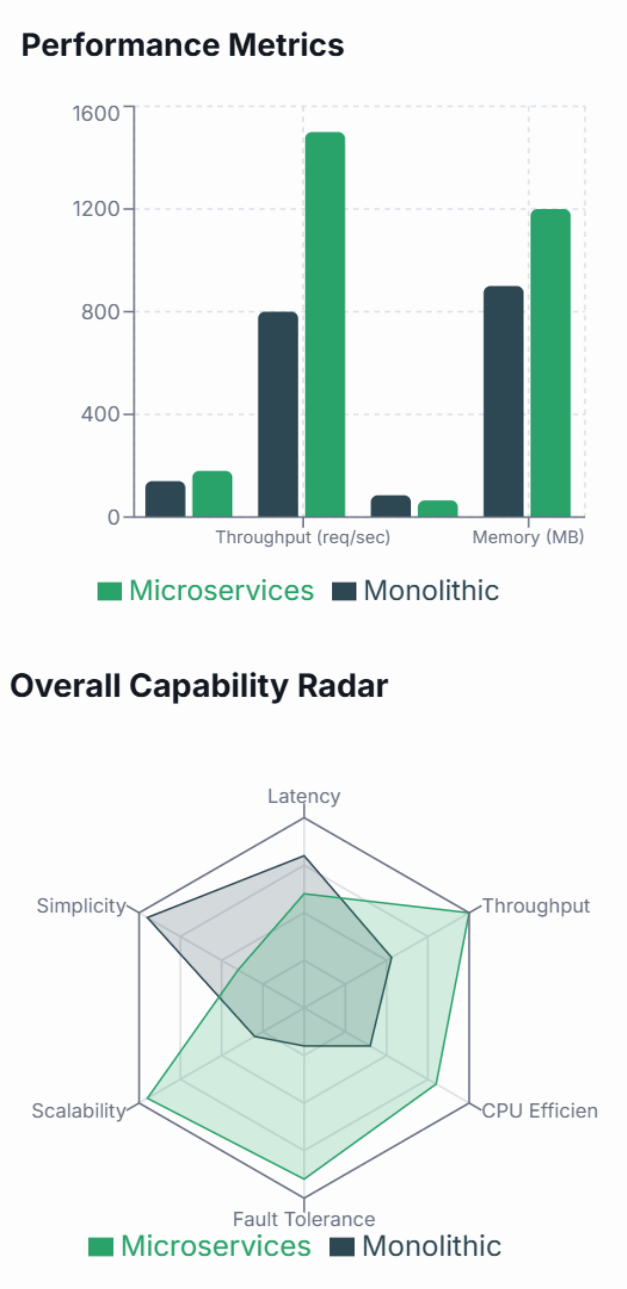

Fig. 6. Performance comparison (left) and overall capacity radar (right).

D. Scalability Analysis

System scalability was assessed by increasing the number of simulated IoT devices across four levels: 100, 1,000, 5,000, and 10,000 devices. At each level, latency was measured as the time between sensor data transmission and backend response.

TABLE III. LATENCY VS. NUMBER OF DEVICES

Devices	Monolithic Latency	Microservices Latency
100	120 ms	150 ms
1,000	200 ms	170 ms
5,000	350 ms	190 ms
10,000	Failure	230 ms

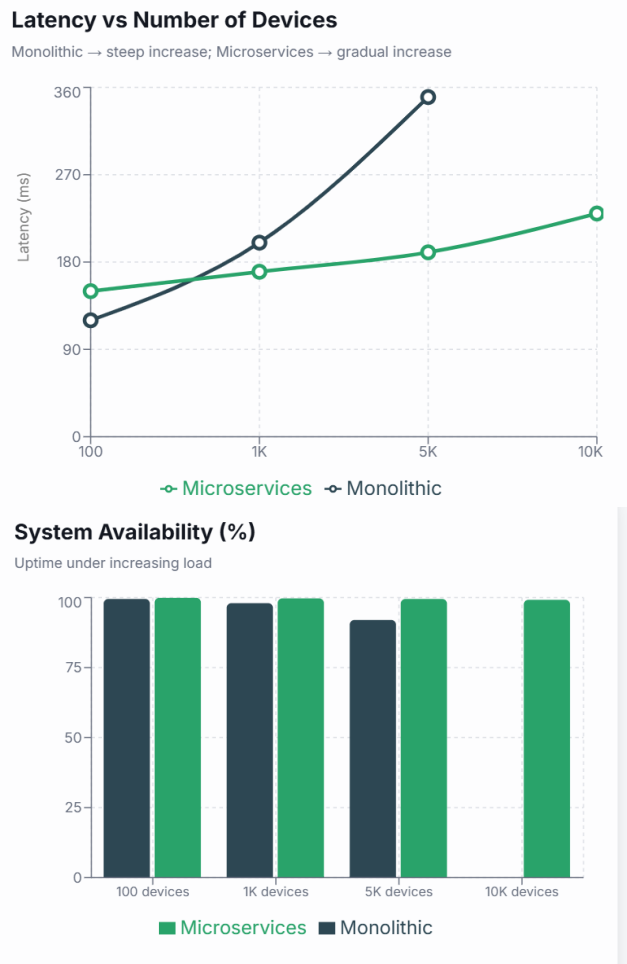

Fig. 7. Latency vs. devices (left) and system availability (right).

The results demonstrate that while monolithic architectures perform better at low load, their performance degrades significantly as system scale increases. In contrast, microservices maintain stable latency and operational reliability under high load conditions (see Fig. 7).

These findings align with the proposed mathematical model, where scalability optimization (Sc_i) and reduced coupling (C_i) contribute to improved system resilience and performance.

Additionally, structural improvements resulted in reduced coupling due to strict enforcement of bounded contexts and asynchronous communication. The refactored architecture achieved better resource utilization, with reduced CPU consumption and controlled memory usage during peak loads. This validates the effectiveness of size constraints in preventing resource contention and ensuring efficient IoT deployment.

Furthermore, scalability validation showed that the sensor ingestion service handled a 50% increase in throughput without proportional latency growth, confirming the model's effectiveness in predicting workload scaling behavior in dynamic IoT environments.

1) Sensitivity analysis: To evaluate the robustness of the proposed model, a sensitivity analysis was conducted by varying the weighting coefficients λ_1, λ_2, and λ_3 within the range [0.1,0.9].

The results demonstrated that the proposed decomposition remained stable across a wide range of parameter settings, with variations in modularity scores remaining below 5%. This indicates that the model is not excessively sensitive to small changes in optimization weights and therefore exhibits strong robustness for practical deployment.

E. Model Validation Results and Discussion

This section presents a comprehensive analysis of the empirical data derived from the case study, examining the efficacy of the mathematical model in optimizing the refactoring process and validating the theoretical assertions regarding service size, scalability, and coupling reduction.

The empirical validation of the mathematical model was conducted by comparing the predicted service boundaries against the actual operational metrics of the deployed microservices, confirming that the algorithm accurately identified optimal split points within the irrigation system's domain model. Furthermore, the model's scalability predictions were validated by subjecting the system to incremental load increases, where the projected resource allocation closely matched the actual consumption patterns of the sensor data and control services across varying operational intensities. This precise matching of resource utilization confirms that the mathematical framework effectively accommodates the dynamic scaling requirements inherent to IoT environments, thereby validating the model's predictive accuracy for deployment planning.

The quantification of interaction dependencies indicates that the mathematical model successfully translated Domain-Driven Design principles into executable decoupling strategies, yielding an architectural state that mirrors theoretical ideals where coupling scores remain significantly below acceptable thresholds.

To validate the effectiveness of the proposed unified optimization model, the empirical results obtained from the IoT irrigation system were analyzed using performance metrics illustrated in the radar chart. The validation focuses on assessing whether the architectural behavior observed in practice aligns with the theoretical expectations derived from the optimization objective function:

$$\max \left[\lambda_1 \frac{W_{intra} - W_{inter}}{W_{total}} \right]$$

$$+\lambda_2 \sum_j \frac{|E_j^{int}|}{|V_j|} - \lambda_3 \sum_{(i,j)\in E} w_{ij}(1 - y_{ij})]$$

1) Validation of scalability component: The experimental results demonstrate that the microservices architecture achieves significantly higher values in throughput, CPU efficiency, and scalability compared to the monolithic architecture. The improved throughput and CPU efficiency indicate that the ratio $\frac{L_i}{U_i}$ is maximized in the microservices architecture, meaning that more workload is processed per unit of resource consumption. Furthermore, the stable scalability observed under increasing load conditions confirms that the distributed nature

of microservices effectively preserves performance, aligning with the maximization objective of Sc_i.

F. Validation of Coupling Minimization

The results show a clear advantage of microservices in terms of fault tolerance, which serves as an indirect validation of reduced coupling. According to the model:

$$C_i^{ext} = \sum_{c_p \in m_i} \sum_{c_q \notin m_i} w_{pq}$$

Lower coupling implies higher service independence and improved fault isolation. The superior fault tolerance observed in the microservices architecture confirms that minimizing C_i^{ext} leads to increased system resilience. In contrast, the monolithic architecture exhibits lower fault tolerance due to tightly coupled components, validating the negative impact of high coupling on system reliability.

The average coupling score across the refactored system was recorded at 20.4%, which satisfies the theoretical requirement of remaining below 30% and aligns with empirical observations from successful microservice decompositions.

G. Validation of Size Constraint

The size penalty ensures balanced service granularity. The reduced simplicity observed in the microservices architecture reflects the intentional decomposition into multiple services, which increases architectural complexity but avoids oversized components. This behavior confirms that the penalty function effectively discourages monolithic aggregation while promoting modular decomposition.

This operational isolation demonstrates how the mathematical model's emphasis on bounded contexts translates into enhanced deployment velocity and reduced maintenance overhead. The observed modularization improves the continuous integration pipeline and strengthens fault isolation capabilities, ensuring that failures remain localized within specific bounded contexts.

H. Validation of Latency Trade-offs

Although the proposed microservice architecture demonstrated significant improvements in throughput, fault tolerance, scalability, and resource utilization, the experimental results revealed a measurable latency increase under low-load conditions. As shown in Table II, the average response latency increased from 140 ms in the monolithic architecture to 180 ms in the microservice architecture. Similarly, Table III indicates that at a deployment scale of 100 IoT devices, latency increased from 120 ms to 150 ms after decomposition.

This behavior is an expected consequence of service decomposition. Unlike monolithic systems, microservices introduce network communication overhead due to remote procedure calls, message serialization, service discovery, and API gateway interactions. At small workloads, these additional communication costs outweigh the benefits of service independence, resulting in slightly higher response times.

However, as the workload increases, the advantages of independent scalability become dominant. At 1,000 devices and beyond, the microservice architecture consistently outperformed the monolithic architecture, ultimately maintaining operational stability at 10,000 devices where the monolithic implementation failed. Therefore, the proposed model introduces a latency-performance trade-off in low-load environments but achieves superior scalability and resilience under realistic large-scale IoT deployment conditions.

This limitation is acknowledged as an inherent characteristic of distributed architectures and represents a trade-off accepted by the optimization model in favor of long-term scalability and maintainability.

I. Statistical Validation

The optimization experiment was executed 30 independent times to account for the stochastic nature of the evolutionary search process.

The mean modularity score obtained by the proposed model was 0.84 with a standard deviation of 0.03, indicating high consistency across repeated executions.

Furthermore, a paired t-test comparing the proposed model against the Louvain baseline demonstrated statistically significant improvements in cohesion and coupling reduction at a significance level of $p < 0.05$.

J. Comparison with Existing Refactoring Approaches

To establish a verifiable benchmark, the proposed UMDO model was compared against three representative decomposition approaches frequently reported in the literature:

- K-Means Clustering
- Louvain Community Detection [30]
- Manual Domain-Driven Design Decomposition [31]

K-Means represents traditional partitioning approaches based on feature similarity, while Louvain represents graph-community detection methods widely used in software modularization. Manual Domain-Driven Design decomposition represents expert-driven bounded-context identification without optimization support.

The comparison demonstrates that the proposed UMDO framework achieves the lowest coupling and highest cohesion and modularity scores among all evaluated approaches. These results indicate that integrating bounded-context knowledge with multi-objective optimization provides a more effective decomposition strategy than purely structural or manually derived approaches (see Table IV).

Existing microservice refactoring approaches rely on structural dependencies or semantic similarity techniques. While effective for modularity detection, these methods often neglect runtime and scalability considerations. The proposed model introduces a unified multi-objective optimization framework integrating service size, scalability, and coupling constraints, reducing subjectivity and improving decomposition accuracy.

TABLE IV. QUALITATIVE AND QUANTITATIVE COMPARISON OF THE PROPOSED UMDO MODEL WITH EXISTING MICROSERVICE DECOMPOSITION APPROACHES.

Criterion	K-Means Clustering	Louvain Community Detection	DDD Manual Decomposition	Proposed UMDO Model
Methodology	Structural clustering	Graph community detection	Domain-Driven Design	Multi-objective optimization
Coupling Handling	Implicit	Graph-based	Expert judgment	Explicit quantitative modeling
Scalability	Limited	Limited	Moderate	Runtime-aware modeling
Granularity Control	Heuristic	Community partitioning	Manual refinement	Formal size constraints
Clustering Strategy	Distance-based	Graph modularity	Business domains	Optimization-based refinement
Semantic Awareness	Limited	Limited	High	DDD-integrated validation
Bounded Context Identification	Not supported	Partially supported	Manual	Quantitative derivation
Adaptability	General-purpose	General-purpose	Application-dependent	IoT-aware scalability
Coupling Score	0.38	0.31	0.28	**0.20**
Cohesion Score	0.61	0.70	0.74	**0.86**
Modularity Score	0.59	0.68	0.72	**0.84**

VI. CONCLUSION

This study presents a mathematical framework for refactoring monolithic applications into microservices using Domain-Driven Design principles and quantitative metrics. The empirical results from the IoT irrigation case study confirm that the model effectively identifies optimal service boundaries by minimizing coupling and maximizing cohesion.

The findings demonstrate that integrating quantitative metrics with Domain-Driven Design provides a deterministic and objective approach to microservice decomposition, outperforming heuristic-based methods and improving scalability, maintainability, and system reliability. The experimental evaluation demonstrated statistically significant improvements over graph clustering and manual decomposition baselines, while sensitivity analysis confirmed the robustness of the optimization framework across varying parameter configurations.

VII. FUTURE WORK

Future research could extend this work by integrating cloud-native and AI-based optimization techniques to further enhance scalability. Additionally, incorporating dynamic runtime metrics could enable adaptive microservice refactoring in real-time, particularly for IoT environments with fluctuating workloads.

Another promising direction is the application of transfer learning to improve model generalization across different technology stacks. Finally, establishing standardized benchmarks and open datasets for microservice partitioning would facilitate comparative analysis and broader validation of decomposition models.

A Multi-Criteria Decision-Making Model for ERP Selection in Moroccan SMEs Using Fuzzy AHP

Yassine Zouhair, Younous Elmrini
SIAD Laboratory, Hassan First University, Settat, Morocco

Abstract—Today, selecting an Enterprise Resource Planning (ERP) system has become a strategic decision for Small and Medium-sized Enterprises (SMEs) seeking to improve their operational efficiency, modernize their information systems, and strengthen their competitiveness in an increasingly digitalized environment. In this context, identifying the most relevant ERP selection criteria is essential to support decision-makers in choosing the solution that best fits their organizational and strategic needs. However, previous studies have generally examined ERP selection criteria from a broad perspective, without prioritizing their relative importance according to the specific context of SMEs. The objective of this study is therefore to identify and prioritize the ERP selection criteria that are most critical for Moroccan SMEs, as well as to propose a decision-making model that supports ERP evaluation and selection. To achieve this objective, a mixed-methods approach was adopted. Semi-structured interviews with ERP professionals and practitioners were conducted to identify the most relevant criteria in the Moroccan SME context. In addition, the Fuzzy Analytic Hierarchy Process (Fuzzy AHP) method was used to evaluate and weight these criteria under conditions of uncertainty and subjective judgment. The results reveal that functional scope is the most critical criterion in ERP selection, followed by ease of use and total cost. Technical criteria such as compatibility and security are considered moderately important, whereas scalability appears to have less influence on the selection decision. Based on these findings, a decision-making model is proposed to help SMEs evaluate ERP alternatives more effectively and reduce the risks associated with ERP selection. This research contributes to the existing ERP literature by providing a structured and prioritized analysis of ERP selection criteria specifically adapted to Moroccan SMEs. It also offers ERP consultants and decision-makers a practical framework for assessing ERP solutions and improving the quality and reliability of ERP selection decisions.

Keywords—ERP selection; Fuzzy AHP; Moroccan SMEs; multi-criteria decision-making; information systems; decision framework; digital transformation

I. Introduction

In an ERP, the business processes related to procurement, sales, finance, inventory, and customer relationships can be managed in an efficient way by centralizing and integrating them into one information system. However, implementing an ERP within SMEs represents a significant investment and requires time before it can be fully integrated into the business.

In order to improve their productivity, increase their efficiency, and make themselves better prepared to tackle the challenges in the highly competitive environment, some companies, including Moroccan SMEs, have opted for ERP adoption within their IS.

Consequently, choosing an ERP should not be a hasty decision. It requires a very thorough analysis of several factors, including organizational structure, business processes, business objectives, and user expectations. Given the wide variety of ERP solutions available, selecting the most suitable ERP is a major strategic decision [1].

This decision depends largely on the definition of selection criteria and their prioritization. Indeed, the selected criteria have a direct influence on the success of the ERP implementation within the company. Clearly ranking these criteria by priority helps effectively guide the selection process and accelerate decision-making.

Given the high costs associated with ERP implementation, it is essential to ensure that the chosen solution effectively meets the company's needs [2]. Companies that succeed in this choice are often those that have a strong grasp of their business processes as well as the needs of their employees.

Research has been conducted to assist companies in their selection process [3,4,5,6,7]. However, there is a lack of research aimed at identifying the criteria for selecting an ERP as well as a decision-making model for ERP selection, particularly in the context of Moroccan SMEs.

In this context, this study aims to identify and prioritize ERP selection criteria, as well as to propose a decision-making model for ERP selection in Moroccan SMEs.

II. Literature Review

Numerous studies have proposed decision-making models and methods—particularly those based on multi-criteria approaches—to structure the ERP selection process. Table I provides an overview of the key studies identified in the literature regarding the selection of ERP.

After reviewing the literature, we found that there is no multi-criteria decision-making model for selecting an ERP within Moroccan SMEs. The studies were conducted in contexts different from that of Moroccan SMEs, which limits their applicability to this context.

TABLE I. SUMMARY OF STUDIES ON ERP SÉLECTION

Authors	Country	Abstract
[3]	United Arab Emirates	Identifies and ranks the critical factors for ERP selection in UAE ports using FDM and RII, highlighting cybersecurity and stakeholder integration as priorities.
[8]	Turkey	Proposes a hybrid method combining hesitant fuzzy cross-entropy and probabilistic hesitant fuzzy COPRAS for ERP selection, improving the ranking of alternatives based on multiple criteria.
[9]	Indonesia	Proposes a hybrid Fuzzy AHP–TOPSIS method for selecting an open-source ERP for SMEs in Indonesia, emphasizing system quality (security, reliability) as a key criterion.
[4]	India	Uses Fuzzy AHP to select ERP systems and ERP consultants. Identifies the following as key criteria: reputation, ERP experience, and cost.
[5]	India	Analyzes the factors influencing ERP selection using Fuzzy AHP. Cost is the primary criterion, followed by usability and business requirements.
[10]	Portugal	Develops a hybrid MCDM model combining MMASSI/IT and AHP to evaluate and select an ERP, validated in an industrial setting.
[6]	Turkey	Proposes a multi-criteria decision-making (MCDM) approach that combines fuzzy ANP and GRA to select an ERP while accounting for uncertainty, thereby improving the ranking of alternatives.
[11]	India	Proposes a framework that incorporates critical success factors (CSFs) into ERP selection and introduces a Fuzzy TOPSIS approach to improve decision-making.

III. RESEARCH QUESTIONS

Given this gap in the literature, this study aims to answer the following question:

What are the most relevant criteria for selecting an ERP in Moroccan SMEs, and how can these criteria be organized to develop a decision-making model for ERP selection tailored to their specific context?

We will attempt to answer this central question through the following sub-questions:

1) What are the key criteria to consider when selecting an ERP for Moroccan SMEs?

2) Which criteria have the greatest influence on the selection of an ERP for Moroccan SMEs?

3) How can we develop a decision-making model for ERP selection that is relevant, practical, and tailored to Moroccan SMEs?

IV. RESEARCH METHODOLOGY

To answer these research questions, we adopted a mixed research method.

A. Qualitative Research Method

To answer the first question, we adopted a qualitative research method to identify the criteria for selecting an ERP within Moroccan SMEs. To this effect, semi-structured interviews were conducted among employees working for SMEs of Morocco, including IT managers, financial specialists, and key users, alongside experts. Such an interviewing technique would enable us to adopt both functional and specialist views. The respondents have been carefully chosen based on a targeted sampling technique, where preference was given to those with past experience in ERP systems' usage and selection.

37 participants were interviewed for a period ranging from 30 to 45 minutes. The number of interviewees used was decided upon using the concept of theoretical saturation, meaning that additional interviews were stopped once they no longer yielded significantly new information.

Analysis of the obtained data helped determine the most prevalent and significant criteria. This enabled the creation of a structured list of ERP selection criteria within Moroccan SMEs, which was subsequently used in a quantitative analysis to evaluate and prioritize them.

B. Fuzzy Analytic Hierarchy Process

To answer the second question, we adopted a multi-criteria approach using the Fuzzy AHP.

AHP is a methodology for multi-criteria decision making. It allows structuring any complicated decision by hierarchically organizing decision criteria and assigning weights to them according to expert evaluations [12]. Expert evaluations could sometimes include some degree of vagueness. Therefore, a modification of AHP that includes fuzziness in the process was developed [13].

Data for this section of the research were collected from employees of SMEs operating in Morocco, including companies that have introduced an ERP solution and others who haven't yet used any similar software solutions. Participants were asked to make pairwise comparisons between the various identified criteria in order to assess their relative importance in the ERP selection process.

The method applied consists of five main steps: constructing the fuzzy comparison matrix, calculating fuzzy sums, determining synthetic values, defuzzifying weights, and final normalization.

1) Construction of the fuzzy comparison matrix

a) Define the criteria

List the criteria:

$$C_1, C_2, \ldots, C_N$$

b) Pairwise Comparison (Question for employees): The criteria are compared in pairs by employees in order to assess their relative importance in the ERP selection process.

For each pair C_i, C_j, participants are asked to indicate which criterion is more important and to what extent.

c) Conversion to a Triangular Fuzzy Number (TFN): Each response is converted to a Triangular Fuzzy Number:

$$\tilde{a}_{\{ij\}} = \left(l_{\{ij\}}, m_{\{ij\}}, u_{\{ij\}}\right)$$

Interpretation:

- l = lowest possible value
- m = most likely value

- u = highest possible value

Linguistic judgments are converted into fuzzy numbers according to the scale shown in Table II.

TABLE II. CONVERTING LINGUISTIC JUDGMENTS INTO TRIANGULAR FUZZY NUMBERS

Linguistic variables	Fuzzy scale	Corresponding fuzzy scale
Equally important	(1, 1, 1)	(1, 1, 1)
Moderately important	(1/2, 1, 3/2)	(2/3, 1, 2)
Important	(3/2, 2, 5/2)	(2/5, 1/2, 2/3)
Very important	(5/2, 3, 7/2)	(2/7, 1/3, 2/5)
Extremely important	(7/2, 4, 9/2)	(2/9, 1/4, 2/7)

d) Aggregation (average) when there are multiple consultants: When multiple employees participate in the evaluation, and each provides (l_k, m_k, u_k), then the final cell is:

$$l_{\{ij\}} = \frac{1}{K}\sum_{k=1}^{k} l_{i,j}^{(K)}$$

$$m_{\{ij\}} = \frac{1}{K}\sum_{k=1}^{k} m_{i,j}^{(K)}$$

$$u_{\{ij\}} = \frac{1}{K}\sum_{k=1}^{k} u_{i,j}^{(K)}$$

where, K represents the number of employees.

Therefore:

$$\tilde{a}_{\{ij\}} = \left(\frac{1}{K}\sum_{k=1}^{k} l_{i,j}^{(K)}, \frac{1}{K}\sum_{k=1}^{k} m_{i,j}^{(K)}, \frac{1}{K}\sum_{k=1}^{k} u_{i,j}^{(K)}\right)$$

e) Consistency rules for the matrix

Diagonal

A criterion compared to itself is equal to:

$$\tilde{a}_{\{ii\}} = (1,1,1)$$

Reciprocal (inverse)

If:

$$\tilde{a}_{\{ij\}} = (l, m, u)$$

So:

$$\tilde{a}_{\{ji\}} = \tilde{a}_{\{ij\}}^{\{-1\}} = \left(\frac{1}{u}, \frac{1}{m}, \frac{1}{l}\right)$$

f) Result of this step

We obtain the fuzzy comparison matrix:

$$\tilde{A} = \begin{bmatrix} 1,1,1 & \tilde{a}_{\{12\}} & \tilde{a}_{\{13\}} & \tilde{a}_{\{14\}} & \tilde{a}_{\{15\}} & \tilde{a}_{\{16\}} \\ \tilde{a}_{\{21\}} & 1,1,1 & \tilde{a}_{\{23\}} & \tilde{a}_{\{24\}} & \tilde{a}_{\{25\}} & \tilde{a}_{\{25\}} \\ \tilde{a}_{\{31\}} & \tilde{a}_{\{32\}} & 1,1,1 & \tilde{a}_{\{34\}} & \tilde{a}_{\{35\}} & \tilde{a}_{\{36\}} \\ \tilde{a}_{\{41\}} & \tilde{a}_{\{42\}} & \tilde{a}_{\{43\}} & 1,1,1 & \tilde{a}_{\{45\}} & \tilde{a}_{\{46\}} \\ \tilde{a}_{\{51\}} & \tilde{a}_{\{52\}} & \tilde{a}_{\{53\}} & \tilde{a}_{\{54\}} & 1,1,1 & \tilde{a}_{\{56\}} \\ \tilde{a}_{\{61\}} & \tilde{a}_{\{62\}} & \tilde{a}_{\{63\}} & \tilde{a}_{\{64\}} & \tilde{a}_{\{65\}} & 1,1,1 \end{bmatrix}$$

2) Calculation of fuzzy sums by criterion: For each criterion, the sum of the fuzzy values in the corresponding row is calculated:

$$\Sigma l_i = \sum_{j=1}^{n} l_{i,j}$$

$$\Sigma m_i = \sum_{j=1}^{n} m_{i,j}$$

$$\Sigma u_i = \sum_{j=1}^{n} u_{i,j}$$

These values represent the cumulative weight of each criterion relative to the others.

The total sums are then calculated:

$$\Sigma l_{tot} = \sum_{i=1}^{n} \Sigma l_i$$

$$\Sigma m_{tot} = \sum_{i=1}^{n} \Sigma m_i$$

$$\Sigma u_{tot} = \sum_{i=1}^{n} \Sigma u_i$$

3) Calculation of fuzzy synthetic values: Fuzzy synthetic values are obtained through normalization:

$$S_{\{l,i\}} = \Sigma l_i \times \frac{1}{\Sigma u_{tot}}$$

$$S_{\{m,i\}} = \Sigma m_i \times \frac{1}{\Sigma m_{tot}}$$

$$S_{\{u,i\}} = \Sigma u_i \times \frac{1}{\Sigma l_{tot}}$$

These values represent the relative importance of the criteria in a fuzzy manner.

4) Defuzzification of weights: To obtain a single usable weight, fuzzy values are converted into simple numerical values using the center-of-gravity method:

$$W_i = \frac{S_{\{l,i\}} + S_{\{m,i\}} + S_{\{u,i\}}}{3}$$

This step provides a numerical value representing the significance of each criterion.

5) Normalization of weights: The weights obtained are then normalized so that their sum equals 1:

$$w_i = \frac{W_i}{\sum_{k=1}^{n} W_k}$$

The weights can then be expressed as a percentage:

$$Weight_i(\%) = 100 * w_i$$

These values correspond to the final relative importance of each criterion.

V. ERP Selection Criteria

Data collected from 37 participants was analyzed to identify the most common and relevant criteria. Table III given below presents a structured list of ERP selection criteria within Moroccan SMEs.

TABLE III. List of ERP Selection Criteria Within Moroccan SMEs

Criteria code	Main criteria	Sub-criteria	Criteria code
C1	Functional scope of the ERP system	Accounting and Financial Management	C1.1
		Purchasing and Sales Management	C1.2
		Inventory and Logistics Management	C1.3
		Production and Project Management	C1.4
C2	System Usability	Intuitive user interface	C2.1
		Ease of learning the system	C2.2
		Ease of navigation	C2.3
		Availability of documentation and user support	C2.4
C3	Total Cost of the ERP System	Cost of ERP licenses	C3.1
		Implementation cost	C3.2
		Annual maintenance cost	C3.3
		User training cost	C3.4
C4	Compatibility and Technical Integration	Compatibility with existing systems	C4.1
		Ease of data migration	C4.2
		Integration with other software	C4.3
		Compatibility with hardware infrastructure	C4.4
C5	System Security and Reliability	Data Protection and Confidentiality	C5.1
		User Access Rights Management	C5.2
		Data Backup and Restoration	C5.3
		System Stability	C5.4
C6	Scalability of the ERP System	Ability to add new modules	C6.1
		Adaptability to business growth	C6.2
		Ability to customize the system	C6.3
		Availability of future functional enhancements	C6.4

VI. Findings: Prioritization of Criteria and Sub-Criteria for Selecting an ERP

In this study, we identified six main criteria for selecting ERP among Moroccan SMEs, and for each of these criteria, we defined four sub-criteria. We will begin by determining the priority of each criterion, and then the priority of each sub-criterion associated with each of them.

A. Prioritization of Criteria

For the purpose of decision-making using the Fuzzy AHP approach, the criteria were assigned the following codes: C1, C2, C3, C4, C5, and C6 (see Table IV). The criteria and their respective codes are detailed below:

C1: Functional scope of the ERP system

C2: System Usability

C3: Total Cost of the ERP System

C4: Compatibility and Technical Integration

C5: System Security and Reliability

C6: Scalability of the ERP System

TABLE IV. FUZZY PAIRWISE COMPARISON MATRIX OF CRITERIA

	C1			C2			C3			C4			C5			C6		
	l	m	u	l	m	u	l	m	u	l	m	u	l	m	u	l	m	u
C1	1	1	1	1,129	1,227	1,325	1,38	1,5	1,62	1,774	1,929	2,083	2,258	2,455	2,651	3,105	3,375	3,645
C2	0,754	0,814	0,885	1	1	1	1,124	1,222	1,32	1,446	1,571	1,697	1,84	2	2,16	2,53	2,75	2,97
C3	0,613	0,667	0,72	0,753	0,818	0,884	1	1	1	1,183	1,286	1,389	1,505	1,636	1,767	2,07	2,25	2,43
C4	0,477	0,519	0,56	0,585	0,636	0,687	0,716	0,778	0,84	1	1	1	1,171	1,273	1,375	1,61	1,75	1,89
C5	0,375	0,407	0,44	0,46	0,5	0,54	0,562	0,611	0,66	0,723	0,786	0,849	1	1	1	1,265	1,375	1,485
C6	0,273	0,296	0,32	0,335	0,364	0,393	0,409	0,444	0,48	0,526	0,571	0,617	0,669	0,727	0,785	1	1	1

TABLE V. FUZZY VALUES FOR SYNTHETIC EXTENT AND RELATIVE IMPORTANCE WEIGHTS OF THE CRITERIA

	Σl	Σm	Σu	1/Σu	1/Σm	1/Σl	S_l	S_m	S_u	W	%
C1	10,646	11,486	12,324	0,022	0,024	0,025	0,234	0,276	0,308	0,27	27
C2	8,694	9,357	10,032	0,022	0,024	0,025	0,191	0,225	0,251	0,22	22
C3	7,124	7,657	8,19	0,022	0,024	0,025	0,157	0,184	0,205	0,18	18
C4	5,559	5,956	6,352	0,022	0,024	0,025	0,122	0,143	0,159	0,14	14
C5	4,385	4,679	4,974	0,022	0,024	0,025	0,096	0,112	0,124	0,11	11
C6	3,212	3,402	3,595	0,022	0,024	0,025	0,071	0,082	0,09	0,08	8
Sum	39,62	42,54	45,47								

The findings demonstrate that the criterion C1 (Functional scope of the ERP system) is ranked first with the weight of 27%. Such a finding shows how crucial the issue of the functional scope of the ERP system is; it should have the capability of handling all business activities within the organization. With such a functional scope of the ERP system, an integrative approach can be adopted to address the operations without adopting other solutions.

The second most important criterion is C2 (System Usability), which accounts for 22% of the total. It shows that usability is one of the key elements in adopting the system. A user-friendly ERP system will be less resistant to change and will increase efficiency as well.

Criterion C3 (Total Cost of the ERP System) ranks third, each at 18%. This finding demonstrates that the total cost of the system in the course of its installation and maintenance is an important criterion in selection, especially in view of the SME sector.

Criterion C4 (Compatibility and Technical Integration) comes next and accounts for 14% of the score, as the integration of the ERP system with other systems must be taken into account to ensure continuity.

Criterion C5 (System Security and Reliability) accounts for 11% of the total score. While it does not receive the same level of emphasis as the criteria mentioned above, it cannot be discounted for its value in ensuring the continuity of operations and safeguarding confidential data.

Finally, criterion C6 (Scalability of the ERP System) has the lowest weight at 8%. This implies that the scalability aspect of the ERP system is not highly valued for the short term but will be an important aspect in the long run (see Table V).

B. Prioritization of Sub-Criteria

1) Functional Scope of the ERP System: During the decision-making process, where the criterion "Functional scope of the ERP system" will be assessed through the fuzzy AHP method, the following sub-criteria codes will be applied: C1.1, C1.2, C1.3, and C1.4 (see Table VI). Listed below are the sub-criteria codes together with the sub-criteria themselves:

C1.1: Accounting and Financial Management

C1.2: Purchasing and Sales Management

C1.3: Inventory and Logistics Management

C1.4: Production and Project Management

TABLE VI. FUZZY PAIRWISE COMPARISON MATRIX OF SUB-CRITERIA FOR THE FUNCTIONAL SCOPE CRITERION

	C1.1			C1.2			C1.3			C1.4		
	l	m	u	l	m	u	l	m	u	l	m	u
C1.1	1	1	1	0,90	1,05	1,20	1,05	1,20	1,35	1,90	2,10	2,30
C1.2	0,83	0,95	1,11	1	1	1	1,05	1,15	1,30	1,70	1,90	2,10
C1.3	0,74	0,83	0,95	0,77	0,87	0,95	1	1	1	1,55	1,70	1,90
C1.4	0,43	0,48	0,53	0,48	0,53	0,59	0,53	0,59	0,65	1	1	1

TABLE VII. FUZZY WEIGHTS AND NORMALIZED PRIORITIES OF FUNCTIONAL SCOPE SUB-CRITERIA

	Σl	Σm	Σu	1/Σu	1/Σm	1/Σl	S_l	S_m	S_u	W	%
C1.1	4,85	5,35	5,85	0,052	0,057	0,062	0,252	0,305	0,363	0,31	31
C1.2	4,58	5	5,51	0,052	0,057	0,062	0,238	0,285	0,342	0,29	29
C1.3	4,06	4,4	4,8	0,052	0,057	0,062	0,211	0,251	0,298	0,25	25
C1.4	2,44	2,6	2,77	0,052	0,057	0,062	0,127	0,148	0,172	0,15	15
Sum	15,93	17,35	18,93								

As for the criterion C1 that covers the scope of functionality of the ERP system, it should be mentioned that the sub-criterion C1.1 (Accounting and Financial Management) occupies the first place with a weight of 31%. It is important to point out that the highest importance is attached to accounting and financial management functions because accounting is the basic component of information systems of SMEs.

Sub-criterion C1.2 (Purchasing and Sales Management) holds the second position in terms of weight with 29%. This indicates the significance of purchasing and sales management as they affect the efficiency of operations and customer-supplier relationships.

Following this, the sub-criteria C1.3 (Inventory and Logistics Management) comprises 25% weightage. The reason behind assigning a weightage of 25% to inventory and logistics management lies in its significance in ensuring effective physical flow while being less crucial compared to finance and sales functions.

Lastly, sub-criterion C1.4 (Production and Project Management) has the least weight with 15% importance. The reason behind this is that in relation to the SMEs involved in the study, production/project management might not be an urgent need or could be simpler compared to other processes (see Table VII).

2) System Usability: During the decision-making process, where the criterion 'System Usability' will be assessed through the fuzzy AHP method, the following sub-criteria codes will be applied: C2.1, C2.2, C2.3, and C2.4 (see Table VIII). Below are listed the sub-criteria codes together with the sub-criteria themselves:

C2.1: Intuitive user interface

C2.2: Ease of learning the system

C2.3: Ease of navigation

C2.4: Availability of documentation and user support

TABLE VIII. FUZZY PAIRWISE COMPARISON MATRIX OF SUB-CRITERIA FOR THE SYSTEM USABILITY CRITERION

	C2.1			C2.2			C2.3			C2.4		
	l	m	u	l	m	u	l	m	u	l	m	u
C2.1	1	1	1	1,05	1,15	1,30	1,15	1,30	1,45	1,55	1,70	1,90
C2.2	0,77	0,87	0,95	1	1	1	1,05	1,15	1,30	1,45	1,60	1,80
C2.3	0,69	0,77	0,87	0,77	0,87	0,95	1	1	1	1,20	1,35	1,50
C2.4	0,53	0,59	0,65	0,56	0,63	0,69	0,67	0,74	0,83	1	1	1

TABLE IX. FUZZY WEIGHTS AND NORMALIZED PRIORITIES OF SYSTEM USABILITY SUB-CRITERIA

	Σl	Σm	Σu	1/Σu	1/Σm	1/Σl	S_l	S_m	S_u	W	%
C2.1	4,75	5,15	5,65	0,054	0,06	0,065	0,257	0,309	0,367	0,31	31
C2.2	4,27	4,62	5,05	0,054	0,06	0,065	0,231	0,277	0,328	0,28	28
C2.3	3,66	3,99	4,32	0,054	0,06	0,065	0,198	0,239	0,281	0,24	24
C2.4	2,76	2,96	3,17	0,054	0,06	0,065	0,149	0,178	0,206	0,17	17
Sum	15,44	16,72	18,19								

In regard to the criterion C2 concerning the system usability, it is evident that the highest weight belongs to the criterion C2.1 (Intuitive user interface). Such a conclusion implies the relevance of the intuitive interface that will allow users to get acquainted with the system and work with it more easily and quickly.

Sub-criteria C2.2 (Ease of learning the system) has the second highest weight of 28%. This highlights that the system's ease of learning is an important criterion, especially within the framework of SMEs, whereby training budgets might be inadequate. It helps that if the ERP system is easier to learn, users can get proficient faster.

Following this, sub-criterion C2.3 (ease of navigation) makes up 24%. It is evident that smooth navigation in the system is significant because it affects the ease with which users can conduct their activities.

Finally, sub-criterion C2.4 (Availability of documentation and user support) is assigned the least weight at 17%, which

can be attributed to the preference by users for a system that is intuitive and easy to operate, thereby minimizing their need for documentation or assistance (see Table IX).

3) Total Cost of the ERP System: During the decision-making process, where the criterion 'Total Cost of the ERP System' will be assessed through the fuzzy AHP method, the following subcriteria codes will be applied: C3.1, C3.2, C3.3, and C3.4 (see Table X). Below are listed the subcriteria codes together with the subcriteria themselves:

C3.1: Cost of ERP licenses

C3.2: Implementation cost

C3.3: Annual maintenance cost

C3.4: User training cost

Regarding criterion C3, dealing with the total cost of the ERP system, the findings reveal that sub-criterion C3.1 (Cost of ERP licenses) occupies the first place with a weight of 32%. The significance attached to the acquisition cost of the software is brought into light from this finding since cost is the major consideration for any SME when choosing an ERP system.

TABLE X. FUZZY PAIRWISE COMPARISON MATRIX OF SUB-CRITERIA FOR THE TOTAL COST OF THE ERP SYSTEM CRITERION

	C3.1			C3.2			C3.3			C3.4		
	l	m	u	l	m	u	l	m	u	l	m	u
C3.1	1	1	1	1,05	1,15	1,3	1,25	1,4	1,55	1,7	1,9	2,1
C3.2	0,77	0,87	0,95	1	1	1	1,15	1,3	1,45	1,6	1,8	2
C3.3	0,65	0,71	0,8	0,69	0,77	0,87	1	1	1	1,15	1,3	1,45
C3.4	0,48	0,53	0,59	0,5	0,56	0,63	0,69	0,77	0,87	1	1	1

TABLE XI. FUZZY WEIGHTS AND NORMALIZED PRIORITIES OF TOTAL COST OF THE ERP SYSTEM SUB-CRITERIA

	Σl	Σm	Σu	1/Σu	1/Σm	1/Σl	S_l	S_m	S_u	W	%
C3.1	5	5,45	5,95	0,054	0,059	0,064	0,27	0,322	0,381	0,32	32
C3.2	4,52	4,97	5,4	0,054	0,059	0,064	0,244	0,293	0,346	0,28	28
C3.3	3,49	3,78	4,12	0,054	0,059	0,064	0,188	0,223	0,264	0,23	23
C3.4	2,67	2,86	3,09	0,054	0,059	0,064	0,144	0,169	0,198	0,17	17
Sum	15,68	17,06	18,56								

Sub-criterion C3.2 (Implementation Cost) is the second most important with a weighting factor of 28%. It clearly indicates that the costs related to the implementation process are equally important considerations in selecting an ERP system.

Subsequently, sub-criterion C3.3 (Annual maintenance cost) takes up 23%. This proves that recurring costs are important but usually taken into consideration after initial costs during decision-making.

Lastly, the criterion C3.4 (User training cost) gets the smallest weight, which is 17%. It is because the cost of training users does not seem significant, especially when the system is viewed as an easy-to-use system (see Table XI).

4) Compatibility and Technical Integration: During the decision-making process, where the criterion 'Compatibility and Technical Integration' will be assessed through the fuzzy AHP method, the following subcriteria codes will be applied: C4.1, C4.2, C4.3, and C4.4 (see Table XII). Below are listed the subcriteria codes together with the subcriteria themselves:

C4.1: Compatibility with existing systems

C4.2: Ease of data migration

C4.3: Integration with other software

C4.4: Compatibility with hardware infrastructure

In terms of criterion C4 relating to compatibility and integration, the findings reveal that sub-criterion C4.1 (Compatibility with existing systems) comes first with a weightage of 30%. It indicates the significance of ERP compatibility with the existing systems in the enterprise. High compatibility would help to avoid interruptions, cut down costs, and ensure operational continuity.

TABLE XII. FUZZY PAIRWISE COMPARISON MATRIX OF SUB-CRITERIA FOR THE COMPATIBILITY AND TECHNICAL INTEGRATION CRITERION

	C4.1			C4.2			C4.3			C4.4		
	l	m	u	l	m	u	l	m	u	l	m	u
C4.1	1	1	1	1,05	1,15	1,3	1,1	1,25	1,4	1,45	1,6	1,8
C4.2	0,77	0,87	0,95	1	1	1	1,05	1,15	1,3	1,35	1,5	1,7
C4.3	0,71	0,8	0,91	0,77	0,87	0,95	1	1	1	1,2	1,35	1,5
C4.4	0,56	0,63	0,69	0,59	0,67	0,74	0,67	0,74	0,83	1	1	1

TABLE XIII. FUZZY WEIGHTS AND NORMALIZED PRIORITIES OF COMPATIBILITY AND TECHNICAL INTEGRATION SUB-CRITERIA

	Σl	Σm	Σu	1/Σu	1/Σm	1/Σl	S_l	S_m	S_u	W	%
C4.1	4,6	5	5,5	0,055	0,06	0,065	0,253	0,3	0,358	0,3	30
C4.2	4,17	4,52	4,95	0,055	0,06	0,065	0,229	0,271	0,322	0,27	27
C4.3	3,68	4,02	4,36	0,055	0,06	0,065	0,202	0,241	0,283	0,24	24
C4.4	2,82	3,04	3,26	0,055	0,06	0,065	0,155	0,182	0,212	0,18	18
Sum	15,27	16,58	18,07								

Sub-criterion C4.2 (Ease of data migration) comes second with a weight of 27%. The above outcome indicates that one of the difficulties of implementing an ERP solution is related to the ease of data migration.

Thirdly, sub-criterion C4.3 (Integration with other software) takes 24%. From the above outcome, one may understand that the ERP system integration capacity with other software available in the company is also important.

Finally, sub-criterion C4.4 (Compatibility with hardware infrastructure) is assigned the lowest weight – 18%. One explanation could be the adaptability of organizations in the sphere, especially when new technologies are considered (see Table XIII).

5) System Security and Reliability: During the decision-making process, where the criterion 'System Security and Reliability' will be assessed through the fuzzy AHP method, the following subcriteria codes will be applied: C5.1, C5.2, C5.3, and C5.4 (see Table XIV). Below are listed the subcriteria codes together with the subcriteria themselves:

C5.1: Data Protection and Confidentiality

C5.2: User Access Rights Management

C5.3: Data Backup and Restoration

C5.4: System Stability

TABLE XIV. FUZZY PAIRWISE COMPARISON MATRIX OF SUB-CRITERIA FOR THE SYSTEM SECURITY AND RELIABILITY CRITERION

	C5.1			C5.2			C5.3			C5.4		
	l	m	u	l	m	u	l	m	u	l	m	u
C5.1	1	1	1	1,1	1,25	1,4	1,2	1,35	1,5	1,2	1,3	1,45
C5.2	0,71	0,8	0,91	1	1	1	1,05	1,15	1,3	1,05	1,15	1,3
C5.3	0,67	0,74	0,83	0,77	0,87	0,95	1	1	1	1	1,1	1,2
C5.4	0,69	0,77	0,83	0,77	0,87	0,95	0,83	0,91	1	1	1	1

TABLE XV. FUZZY WEIGHTS AND NORMALIZED PRIORITIES OF SYSTEM SECURITY AND RELIABILITY SUB-CRITERIA

	Σl	Σm	Σu	1/Σu	1/Σm	1/Σl	S_l	S_m	S_u	W	%
C5.1	4,5	4,9	5,35	0,057	0,061	0,066	0,257	0,299	0,353	0,3	30
C5.2	3,81	4,1	4,51	0,057	0,061	0,066	0,217	0,25	0,298	0,25	25
C5.3	3,44	3,71	3,98	0,057	0,061	0,066	0,196	0,226	0,263	0,23	23
C5.4	3,29	3,55	3,78	0,057	0,061	0,066	0,188	0,217	0,249	0,22	22
Sum	15,04	16,26	17,62								

As for the fifth criterion relating to the system security and reliability, the findings indicate that sub-criterion C5.1 (Data Protection and Confidentiality) has received the highest weight of 30%. This indicates the significance attached to the protection of confidential data and information confidentiality given that the target organizations deal with sensitive information.

The sub-criterion C5.2 (User Access Rights Management), coming in second place with the weight of 25%, reflects the importance of the access rights management in terms of information access control and the enhancement of security.

Thirdly, sub-criterion C5.3 (Data Backup and Restoration) has 23% weight, demonstrating that the mechanisms of data restoration are crucial in order to ensure the business continuity in case of incidents.

Finally, the sub-criterion C5.4 (System Stability), which is of low importance, has 22% weight. Despite being significant as well, the issue is less prioritized than others as it is usually considered one of the basics of the ERP system (see Table XV).

6) Scalability of the ERP system: During the decision-making process, where the criterion 'Scalability of the ERP System' will be assessed through the fuzzy AHP method, the following sub-criteria codes will be applied: C6.1, C6.2, C6.3, and C6.4 (see Table XVI). Below are listed the sub-criteria codes together with the sub-criteria themselves:

C6.1: Ability to add new modules

C6.2: Adaptability to business growth

C6.3: Ability to customize the system

C6.4: Availability of future functional enhancements

TABLE XVI. FUZZY PAIRWISE COMPARISON MATRIX OF SUB-CRITERIA FOR THE SCALABILITY OF THE ERP SYSTEM CRITERION

	C6.1			C6.2			C6.3			C6.4		
	l	m	u	l	m	u	l	m	u	l	m	u
C6.1	1	1	1	1,05	1,15	1,3	1,1	1,25	1,4	1,2	1,35	1,5
C6.2	0,77	0,87	0,95	1	1	1	1,05	1,15	1,3	1,1	1,25	1,4
C6.3	0,71	0,8	0,91	0,77	0,87	0,95	1	1	1	1,05	1,15	1,3
C6.4	0,67	0,74	0,83	0,71	0,8	0,91	0,77	0,87	0,95	1	1	1

TABLE XVII. FUZZY WEIGHTS AND NORMALIZED PRIORITIES OF SCALABILITY OF THE ERP SYSTEM SUB-CRITERIA

	Σl	Σm	Σu	1/Σu	1/Σm	1/Σl	S_l	S_m	S_u	W	%
C6.1	4,35	4,75	5,2	0,056	0,061	0,067	0,244	0,29	0,348	0,29	29
C6.2	3,92	4,27	4,65	0,056	0,061	0,067	0,22	0,26	0,312	0,26	26
C6.3	3,53	3,82	4,16	0,056	0,061	0,067	0,198	0,233	0,279	0,24	24
C6.4	3,15	3,41	3,69	0,056	0,061	0,067	0,176	0,208	0,247	0,21	21
Sum	14,95	16,25	17,7								

With regard to criterion C6 concerning the scalability of the ERP system, sub-criterion C6.1 (Ability to add new modules) ranks first and is assigned the highest weighting among all other sub-criteria: 29%. The implication is that it is crucial for the system to develop incrementally and be able to incorporate more modules when required by the organization.

The sub-criterion C6.2 (Adaptability to business growth), with a weightage of 26% of the total evaluation criteria, means the ability of the system to adapt and aid in the growth of the business is an important factor in the current scenario.

Sub-criterion C6.3 (Ability to customize the system) carries 24% weightage. The fact that the customization ability of the system based on the company's requirements is an important criterion but not as critical as scalability-related criteria is evident from the above result.

Last, criterion C6.4 (Availability of future functional enhancements) has the least weight with 21%. This may be attributed to the fact that future improvements are considered less urgent or less important in the early stages of decision-making (see Table XVII).

VII. PROPOSED MODEL FOR SELECTING ERP FOR MOROCCAN SMES

A. General Principle of the Model

As the basis of transformation of findings acquired using the Fuzzy AHP method into something tangible and practically usable by organizations, the study puts forward a decision model that makes possible objective comparison of various ERP solutions available to Moroccan SMEs. It is a hierarchically structured model composed of a decision goal, main selection criteria, and operational sub-criteria, which allow for a realistic assessment of ERP solutions. Main criteria are the general aspects affecting the decision about the adoption of an ERP application, while operational sub-criteria are more tangible and observable functional features of ERP applications.

B. Mathematical Formulation of the Model

Let C_i be a selection criterion, where $i = 1, \ldots, 6$, and SC_{ij} a sub-criterion belonging to criterion C_i, where $j = 1, \ldots, 4$.

Fuzzy AHP analysis allows us to obtain the relative weight of each criterion, denoted w_i, reflecting its importance in the overall decision. Within each criterion, the sub-criteria have local weights denoted v_{ij}, such that:

$$\sum_{j=1}^{4} v_{i,j} = 1$$

To determine the actual weight of each sub-criterion in the final decision, an overall weight is calculated as follows:

$$g_{i,j} = w_i \times v_{i,j}$$

The consistency of the model is ensured by:

$$\sum_{i=1}^{6} \sum_{j=1}^{4} g_{i,j} = 1$$

C. Evaluation of the ERP Solutions

Each candidate ERP solution is evaluated by the company's experts or users using a score between 0 and 10 for each sub-criterion, denoted as $(s_{i,j}^{(p)})$, where (p) represents the ERP solution being analyzed.

The overall score for an ERP solution is calculated as follows:

$$Score\left(ERP^{(p)}\right) = \sum_{i=1}^{6} \sum_{j=1}^{4} g_{i,j} \times s_{i,j}^{(p)}$$

The selected solution is the one that achieved the highest score:

$$ERP^{*} = arg\ max\ Score(ERP)$$

This mechanism thus makes it possible to convert decision-makers' qualitative assessments into a quantitative metric, making it easier to compare ERP solutions.

D. Operational Evaluation Table for ERP

Table XVIII shows the operational approach for comparing ERP solutions based on the proposed model. The rows of the table indicate the sub-criteria that need to be considered for evaluating the ERP. These sub-criteria include aspects like accounting management, sales management, data security, and technical compatibility.

The Weight (g) column indicates the relative importance of each sub-criterion in the final decision, as determined by the Fuzzy AHP analysis. These weights reflect the priorities of Moroccan SMEs when selecting an ERP.

The columns (ERP_1 Note), (ERP_2 Note) allow you to assign notes to each ERP solution on a scale of 0 to 10.

The columns (ERP_1 Score) and (ERP_2 Score) show the weighted scores calculated for each ERP solution by multiplying the Weight (g) by the corresponding note.

The table below thus serves as the primary calculation tool for converting the qualitative assessment of ERP solutions into a comparable quantitative score.

TABLE XVIII. OPERATIONAL EVALUATION TABLE FOR ERP

Code	Sub-criteria	Weight (g)	ERP_1 Note	ERP_2 Note	ERP_1 Score	ERP_2 Score
C1.1	Accounting and Financial Management	0,083				
C1.2	Purchasing and Sales Management	0,078				
C1.3	Inventory and Logistics Management	0,068				
C1.4	Production and Project Management	0,04				
C2.1	Intuitive user interface	0,068				
C2.2	Ease of learning the system	0,061				
C2.3	Ease of navigation	0,053				
C2.4	Availability of documentation and user support	0,039				
C3.1	Cost of ERP licenses	0,058				
C3.2	Implementation cost	0,053				
C3.3	Annual maintenance cost	0,041				
C3.4	User training cost	0,031				
C4.1	Compatibility with existing systems	0,043				
C4.2	Ease of data migration	0,038				
C4.3	Integration with other software	0,034				
C4.4	Compatibility with hardware infrastructure	0,026				
C5.1	Data Protection and Confidentiality	0,033				
C5.2	User Access Rights Management	0,028				
C5.3	Data Backup and Restoration	0,02				
C5.4	System Stability	0,024				
C6.1	Ability to add new modules	0,024				
C6.2	Adaptability to business growth	0,021				
C6.3	Ability to customize the system	0,019				
C6.4	Availability of future functional enhancements	0,017				
	Total score	1				

E. Procedure for Using the Table

1) Assign an ERP Note between 0 and 10 to each ERP solution for each sub-criterion.

2) Calculate the ERP Score for each sub-criterion using the following formula:

$$ERP\ Score = \text{Weight (g)} * ERP\ Note$$

3) Add the weighted scores to obtain the total score for each ERP solution.

4) Compare the scores and select the solution with the highest score.

F. Contribution of the Proposed Model

The model maintains the scientific rigor of multiple criteria decision-making without becoming difficult to use in a business setting. In this way, Moroccan SMEs are ensured an

appropriate methodology for the comparison of ERP systems and reducing the likelihood of a bad choice.

VIII. Discussion

The results obtained through the application of the Fuzzy AHP method reveal a clear hierarchy of selection criteria for ERP systems in the context of Moroccan SMEs. The analysis reveals that criteria related to the system's functional scope rank first, followed by ease of use and the overall cost of the system. This prioritization reflects a marked preference among SMEs for solutions that are immediately operational, capable of effectively meeting business needs while remaining simple to use.

These results are consistent with several studies in the literature. For example, [3] demonstrated that critical factors related to ERP selection, particularly system performance and integration, play a decisive role in the decision-making process. Similarly, [8] emphasize the importance of hybrid multi-criteria approaches for improving the ranking of ERP solutions by taking multiple dimensions into account.

The emphasis placed on ease of use in our study which confirms that user adoption is a key factor for success. This finding aligns with the conclusions of [9], which highlight the central role of system quality, particularly in terms of usability and reliability. Similarly, [6] shows that incorporating multiple criteria, including user-related aspects, improves the relevance of decisions.

Furthermore, the total cost of the system emerges as a determining criterion in our study, reflecting the budget constraints specific to SMEs. This finding is also confirmed by [4], who identify cost as a key factor in the evaluation of ERP solutions, particularly in industrial environments.

In contrast, criteria related to scalability and future developments appear to be of lower priority in our study. This finding may be interpreted as reflecting SMEs' focus on immediate needs rather than long-term prospects. This trend differs in part from certain studies, such as [11], which place greater emphasis on long-term strategic and organizational factors in ERP selection.

Finally, the model proposed in this study serves as a relevant decision-making tool, helping to structure the ERP selection process and reduce the subjectivity of choices. This approach builds on the work of [10], who highlight the value of multi-criteria methods for improving the quality of decisions in complex contexts.

IX. Conclusion

The objective of this study was to identify and prioritize the selection criteria for ERP systems in the context of Moroccan SMEs, as well as to propose a decision-making model tailored to their needs. To achieve this, an approach combining qualitative interviews and the Fuzzy AHP method was adopted, allowing for both the experience of professionals and a structured evaluation of the criteria to be taken into account.

This research aimed at defining and prioritizing selection criteria for ERP systems within the context of SMEs in Morocco and developing a decision model based on the needs of such companies. In order to reach these objectives, the choice was made to use a mixed methodology, including interviews and application of the fuzzy AHP method, which takes into consideration both professional experience and criteria evaluation.

The results highlight the top priority of the ERP system's functional scope, followed by ease of use and the overall cost of the system. These results reflect a clear preference among SMEs for practical, accessible, and immediately operational solutions. Furthermore, technical criteria, such as compatibility and integration, as well as system security, remain important but are considered secondary to immediate functional needs. Finally, system scalability appears to be the lowest priority, suggesting that SMEs prioritize solutions that meet their current needs rather than a long-term vision.

A detailed analysis of the sub-criteria confirms this trend, highlighting the importance of financial management features, system usability, and initial costs. These factors reflect the specific constraints faced by SMEs, particularly in terms of limited resources, the need for simplicity, and the need for rapid implementation.

Based on these results, a decision-support model has been proposed to objectively evaluate and compare different ERP solutions by weighting the criteria and sub-criteria. This model transforms qualitative judgments into a quantitative assessment, thereby facilitating the selection process. It serves as an operational tool accessible to SMEs, enabling them to reduce the risks associated with choosing an unsuitable system and to improve the quality of their decision-making.

In conclusion, this research makes both a theoretical and practical contribution. On the one hand, it enriches existing work on ERP selection by incorporating the specific context of Moroccan SMEs. On the other hand, it offers a practical tool that companies can use to structure their selection process. However, certain limitations should be noted, particularly the sample size and the contextual nature of the results. Future research could expand the study to include a larger number of companies or incorporate other multi-criteria methods to strengthen the robustness of the proposed model.
