

Gabor Descriptor for Representation of Spatial Feature

Comparison Between the Proposed Descriptor and the Conventional Fourier Descriptor

Kohei Arai

Japan

Abstract—New spatial feature descriptor based on Gabor wavelet function is proposed. The proposed method is compared to Fourier descriptor. The experimental results with Advanced Earth Observing Satellite: ADEOS / Advanced Visible and Near-Infrared Radiometer: AVNIR image show an effectiveness of the proposed method. It is found that the restored image quality, in terms of root mean square error between the original and the restored images depends on the support length of the mother wavelet and is much better than that with the conventional Fourier descriptor method for spatial feature description.

Keywords—Spatial feature; Gabor wavelet descriptor; Fourier descriptor; wavelet transformation; ADEOS (advanced earth observing satellite); AVNIR (advanced visible and near-infrared radiometer)

I. INTRODUCTION

There are various examples of applying wavelet analysis to the processing analysis of earth observation satellite images. A method of superimposing a plurality of visible images after wavelet transform [1], a method of superimposing a plurality of SAR: Synthetic Aperture Radar images with different off-nadir angles after wavelet transform [2], and an annual fluctuation pattern of sea surface temperature estimated from satellite data. Method [3] that applies wavelet transform to extract its features, method [4] that applies wavelet transform to the extraction of surface roughness of sea ice, method [5] that extracts spatial features from images extracted from soil moisture, etc. There are [6], [7]. As a report on image processing analysis using the Gabor transform, a report on compression [8] – [11], a report on texture analysis [12] – [15], a report on reconstruction [16] – [21], and a report on feature extraction [22] – [25], there are reports on classification [26] – [28].

However, as far as the authors are aware, there is no example of applying wavelet analysis to the method of describing the geometrical features of an image. The Fourier descriptor is well known as a method of describing the geometrical features of an image [29] – [31]. The Fourier descriptor is the one that the contour line (closed curve) extracted from the image is Fourier expanded, and the closed curve is described by a finite number of Fourier expansion coefficients. The Fourier descriptor does not describe the characteristic points of the closed curve in detail but describes

all points using the sin function (cos function). Also, some proposals have already been made for the method of applying the Fourier descriptor to open curves.

On the other hand, the Gabor descriptor proposed in this paper takes advantage of the characteristics of Gabor transformation and is devised so that it is possible to describe the complicated part of the contour line in detail. The author considered that the Gabor descriptor enables the description of geometrical features with less information than the Fourier descriptor with less deterioration [32] – [34]. Furthermore, remote sensing satellite image database system allowing image portion retrievals utilizing principal component which consists spectral and spatial features extracted from imagery data is proposed recently [35].

In this paper, the author tries to extend the descriptor by Fourier expansion and opening to the descriptor by Gabor expansion. The proposed method was applied to the Visible and Near Infrared Radiometer: VNIR data of the Advanced Spaceborne Thermal Emission and Reflection Radiometer: ASTER sensor mounted on the Terra satellite to confirm that it is superior to the existing method and to change the support length in Gabor conversion. The author also confirmed the effect of the proposed method.

The next section describes theoretical background and the proposed method for spatial feature descriptor based on Gabor wavelet function. Then some experiments are described followed by conclusion together with some discussions.

II. THEORETICAL BACKGROUND AND PROPOSED METHOD

A. Fourier Expansion and Gabor Wavelet Expansion

The Fourier transform of the complex function f given the contour line (closed curve etc.) extracted from the image is defined by the equation (1).

$$F(\omega) = \int_{-\infty}^{\infty} e^{i\omega t} f(t) dt \quad (1)$$

The Gabor transform is defined by equations (2) and (3).

$$W(\omega, \sigma, k) = \int_{-\infty}^{\infty} \exp\left(-\frac{(t-k)^2}{\sigma^2}\right) e^{i\omega t} f(t) dt \quad (2)$$

$$= \int_{-\infty}^{\infty} e^{i\omega t} \exp\left(-\frac{(t-k)^2}{\sigma^2}\right) f(t) dt \quad (3)$$

However, $\overline{e^{i\omega t}}$ represents the complex conjugate of $e^{i\omega t}$ and $\exp\left(-\frac{(t-k)^2}{\sigma^2}\right)e^{i\omega t}$ expresses the complex conjugate of $\exp\left(-\frac{(t-k)^2}{\sigma^2}\right)e^{i\omega t}$. ω is a parameter in the frequency axis direction, and σ and k are parameters in the time axis direction.

The Gabor transform is a Gaussian function with a window function introduced into the Fourier transform. That is, the Gabor transform is a kind of Fourier transform with window function. In particular, when $k=0$, equation (2) becomes equation (4).

$$W(\omega, \sigma, 0) = \int_{-\infty}^{\infty} \overline{\exp\left(-\frac{(t-k)^2}{\sigma^2}\right)e^{i\omega t}} f(t) dt \quad (4)$$

When $\sigma = \infty$, equation (2) becomes equation (5).

$$W(\omega, \infty, k) = \int_{-\infty}^{\infty} \overline{e^{i\omega t}} f(t) dt \quad (5)$$

Therefore, it can be seen that it does not depend on the parameter k .

According to Eq. (2), if the value of the parameter σ is large, the influence of the parameter k on $W(\omega, \sigma, k)$ is small. If the value of the parameter σ is small, the influence of the parameter k on $W(\omega, \sigma, k)$ is large.

The Gabor transform is not restored to the original data when the inverse transform is performed because it is not an orthogonal transform. However, even in the Fourier transform which is the orthogonal transform, for example, when the inverse transform is performed through the low-pass filter, the original data is not restored. The reason why Gabor transform is not orthogonal transform is that it introduces window function into Fourier transform. In other words, it is necessary to consider the effect of the window function when performing Gabor transformation.

B. Fourier Descriptor and Gabor Wavelet Descriptor

In the Fourier descriptor, the extracted spatial feature information is Fourier expanded and the expansion coefficient is used as the descriptor. In the Gabor descriptor, the extracted spatial feature information is Gabor expanded, and the expansion coefficient is used as the descriptor. The Fourier descriptor requires operations from $-\infty$ to ∞ according to Eq. (1). The Gabor descriptor proposed in this paper does not require operations from $-\infty$ to ∞ by introducing the window function (Gaussian function) in Eq. (2). However, it is assumed that the tail of the Gaussian distribution is regarded as zero. From the viewpoint of the above calculation amount, the author thinks that the Vega ball descriptor is superior to the Fourier descriptor.

The number of non-zero Gabor expansion coefficients is called the support length. It can be seen from Eq. (2) that the support length depends on the parameter σ .

C. Gabor Descriptor for Closed Curve

Let $Z(l)=(x(l), y(l))$ be the closed curve. $Z(l)$ is a point that has advanced a distance l on the closed curve from a certain start point on the closed curve as shown in Fig. 1.

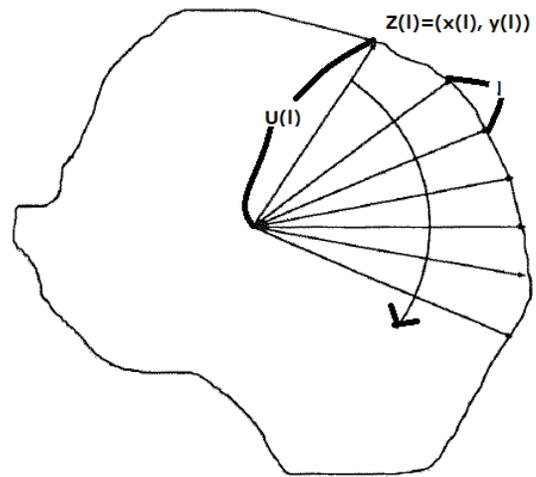

Fig. 1. Concept of the Proposed Wavelet Descriptor.

Here, if the complex function $u(l)$ is defined as follows,

$$u(l) = x(l) + iy(l), (i = \sqrt{-1}) \quad (6)$$

The complex function $u(l)$ is the total length L of the closed curve which is a periodic function. The Gabor descriptor is realized by performing Gabor expansion on the complex function $u(l)$.

D. Feature of the Proposed Gabor Wavelet Descriptor

The proposed method considers the information of the edge of the closed curve of the image as a periodic complex function and describes and saves the geometrical feature of the image using the information of the position of a certain starting point on the closed curve and the Gabor expansion coefficient. The proposed method has the following features,

- 1) When compared with the method of saving edge information as a binary image (method of saving as “face” information), it is superior in terms of the amount of saved data. That is, information of pixels that are not edges is not included.
- 2) The Fourier descriptor requires operations from $-\infty$ to ∞ , but the Gabor descriptor does not require operations from $-\infty$ to ∞ .

III. EXPERIMENTS

A. Experimental Method

The data used this time are actual observation images near Mt. Usu acquired by the sensor AVNIR onboard the ADEOS satellite. Fig. 2 shows the aerial photo of Aza-Nakanoshima island near the Mt. Usu while Fig. 3 shows the acquired Advanced Visible and Near Infrared Radiometer: AVNIR (onboard on Terra Satellite) image.

Fig. 3(a) shows an actual observation image, and Fig. 3(b) shows an image resulting from contour extraction. In this experiment, the experiment is performed using Fig. 3(b). Fig. 4 shows the distance from a certain point inside the closed curve in Fig. 3(b) to a point on the closed curve. The purpose of this experiment is to compare the effectiveness of the wavelet descriptor with that of the Fourier descriptor and to

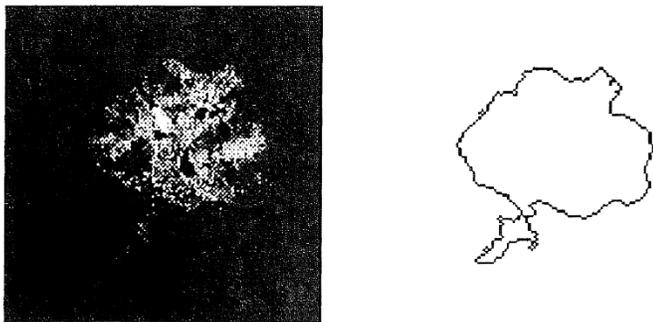

confirm it by evaluating the restoration accuracy. Therefore, the result obtained by halving the number of Fourier expansion coefficients by a low pass filter is used in the Fourier descriptor, and the result obtained by only the low frequency component is used in the wavelet descriptor. At the same time, the impact of the support length of the wavelet will be examined. In addition, equation (7) is used to evaluate the restoration accuracy.

$$J_1 = \sqrt{\frac{\sum_{s=1}^N \{(x(s)-x(s))\}^2 + \{(y(s)-y(s))\}^2}{N}} \quad (7)$$

Note that from Fig. 4, $N=256$.

Fig. 2. Google Map (Aerial Photo Image) of Aza Nakanoshima near the Mt.Usu of Intensive Study Area.

(a) Original AVNIR Image. (b) Detected Edge.
Fig. 3. Acquired AVNIR Image of Aza-Nakanoshima Island near the Mt.Usu and the Detected Edge Image.

Fig. 4 is an example of constructing a complex function $u(l)$ based on Fig. 3(b). The vertical axis in Fig. 4 is the time axis. The result of projecting the complex function $u(l)$ on the two-dimensional plane orthogonal to the time axis agrees with Fig. 3(b). Since the complex function $u(l)$ is composed of a closed curve, Fig. 4 shows one cycle of the complex function $u(l)$.

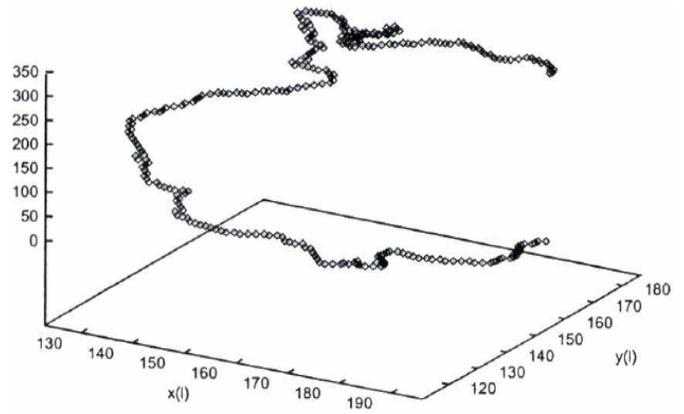

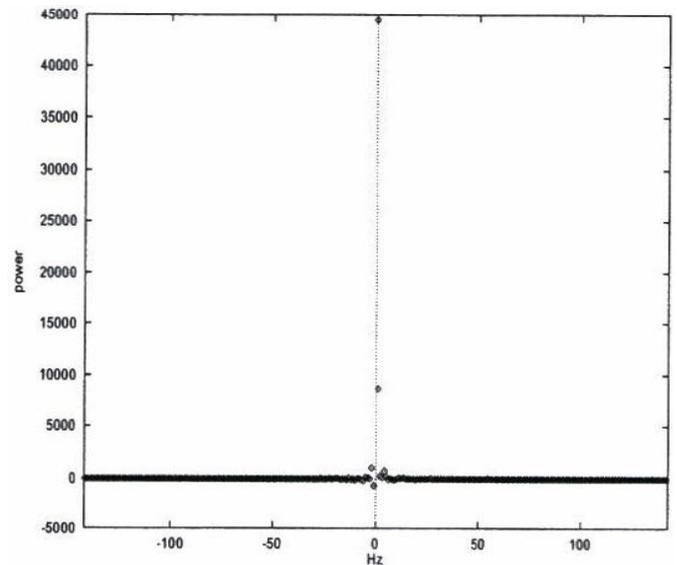

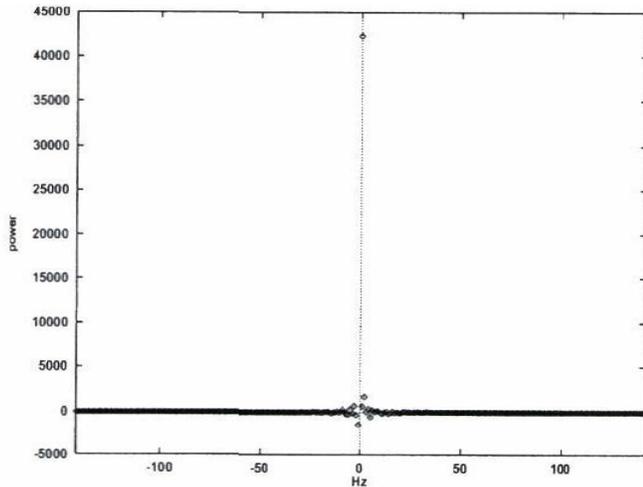

Fig. 4. The Complex Function $u(l)$.

B. Experimental Result

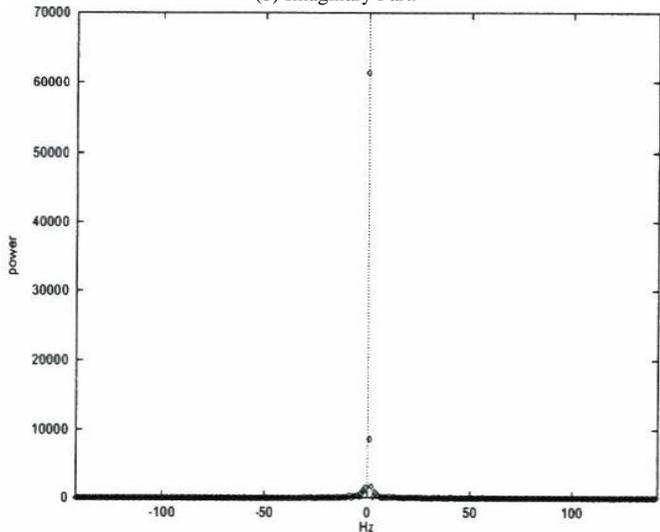

Fig. 5 shows the real and imaginary parts of Fourier spectrum and the power spectrum when the Fourier expansion is applied to the complex function $u(l)$. Fig. 6 corresponds to the result of the Gabor expansion coefficient when $\sigma=5-40$. Fig. 7 shows the number of non-zero Gabor expansion coefficients (support length) when the parameter σ is changed. Fig. 8 shows the restoration accuracy J_1 when the parameter σ is changed. Fig. 6 shows an example of a restored image when the parameters $\sigma = 10$ and 20 . Table I shows the restoration accuracy J_1 when the parameter σ is fixed and the Gabor expansion coefficient with a large parameter ω is forcibly set to zero (the restoration accuracy J_1 is shown when the number of coefficients forcibly set to zero is changed).

(a) Real Part.

(b) Imaginary Part.

(c) Power Spectrum.

Fig. 5. Real and Imaginary Parts of the Fourier as well as Power Spectrum of $u(l)$.

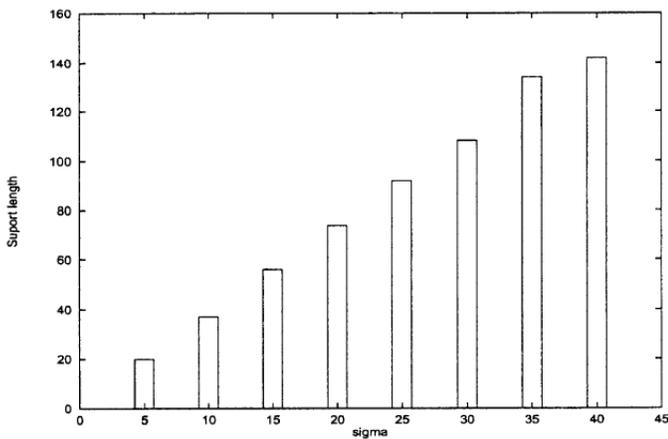

Fig. 6. Support Length for the Designated Parameter σ .

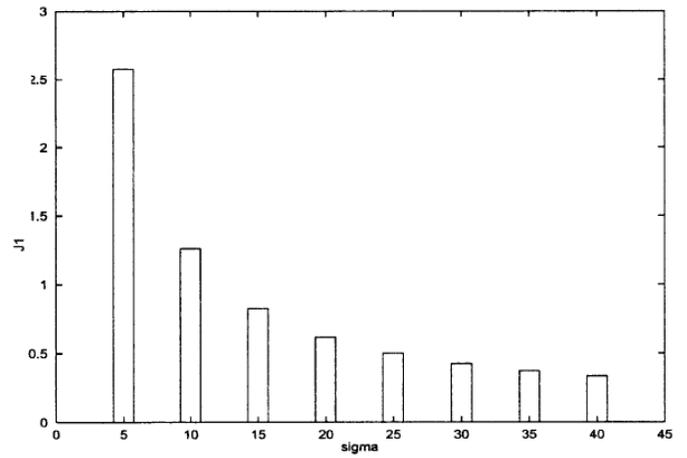

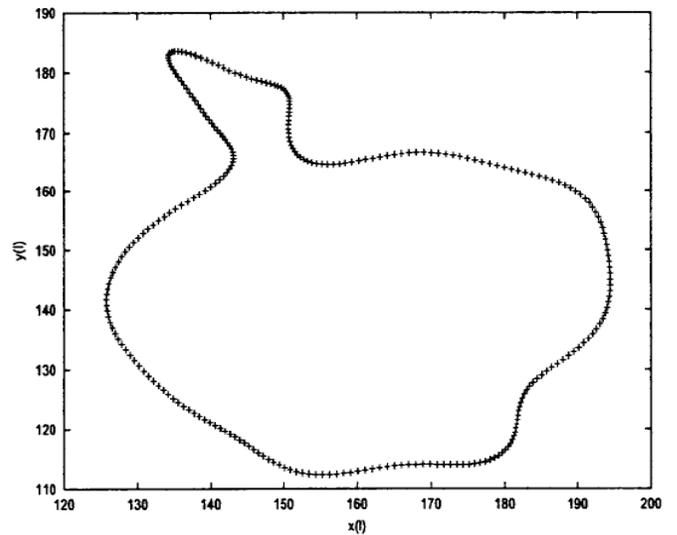

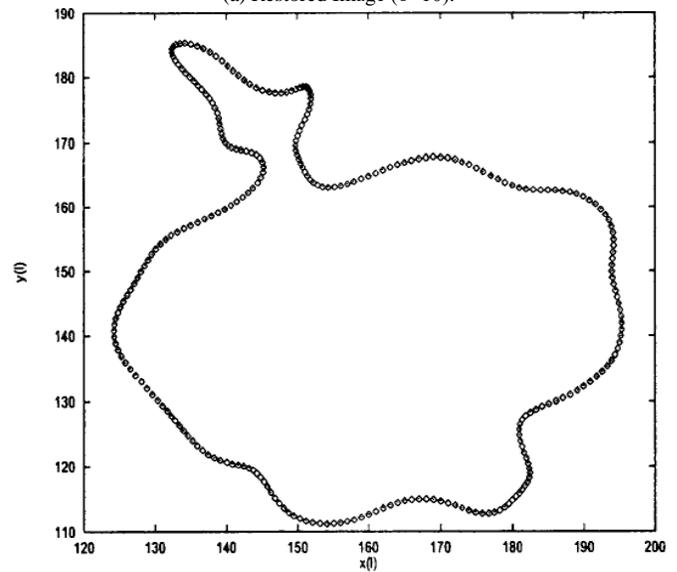

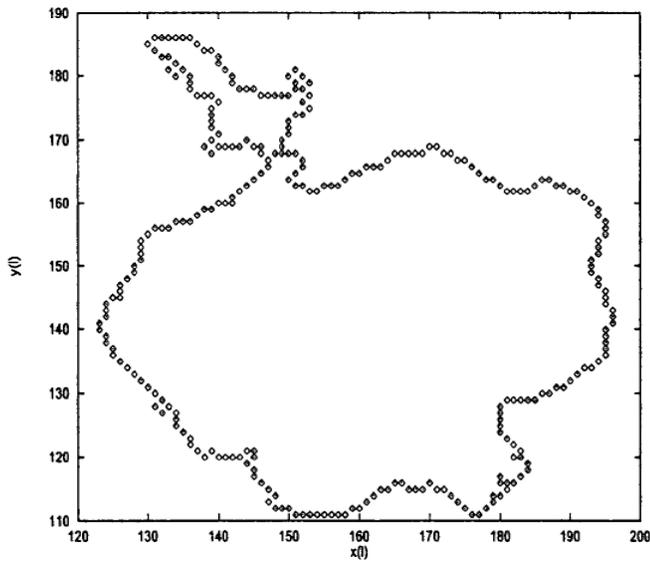

Fig. 7. Error J_1 for the Designated Parameter σ .

(a) Restored Image ($\sigma=10$).

(b) Restored Image ($\sigma=20$).

(c) True Contour (the Detected Edge).

Fig. 8. Example of Restored Image for $\sigma=10, 20$.

TABLE I. RESTORATION ACCURACY J_1 BY THE NUMBER γ OF COEFFICIENTS

$\sigma \gamma$	20	40	60	100	160
10	1.374	1.267	1.266	1.266	1.266
20	1.08	0.656	0.622	0.618	0.618
30	1.056	0.531	0.453	0.427	0.424
40	1.051	0.5	0.401	0.348	0.335
50	1.05	0.491	0.382	0.312	0.282
80	1.05	0.485	0.369	0.28	0.216
100	1.049	0.484	0.368	0.276	0.195
150	1.049	0.483	0.367	0.273	0.183

That is, the accuracy J_1 is shown which is obtained by applying the low pass filter to the result of the Gabor transform of the parameter σ and restoring it. Table I shows the restoration accuracy J_1 by the number γ of coefficients that are not forced to zero. The parameter γ is a parameter in the frequency axis direction for the low-pass filter, and the parameter σ is a parameter in the time axis direction.

C. Remarks

As for the relationship between the restoration accuracy and the parameter σ , it can be seen from Fig. 4 that the support length depends on the parameter σ . That is, the support length increases as the parameter σ increases. From Fig. 7, the restoration accuracy J_1 depends on the parameter σ . That is, the restoration accuracy J_1 improves as the parameter σ increases. From Fig. 8, the restoration accuracy of the restored image depends on the support length.

On the other hand, regarding the relationship between the restoration accuracy and the parameter ω , from Table I, the restoration accuracy J_1 , when the number of coefficients that force the Gabor expansion coefficient with a large parameter ω in each parameter σ to zero, is changed is zero. The smaller the number of coefficients to be set, the better.

IV. CONCLUSION

New spatial feature descriptor based on Gabor wavelet function is proposed. The proposed method is compared to Fourier descriptor. The experimental results with an ADEOS (Advanced Earth Observing Satellite) / AVNIR (Advanced Visible and Near-Infrared Radiometer) image show an effectiveness of the proposed method.

Through experiments with actual remote sensing satellite imagery data, it is found that the proposed description of geometric features of images based on the wavelet transform based on the Daubechies basis is more reproducible than that by existing Fourier descriptors under the condition of the same bandwidth. This is because, when the image space domain is transformed into the Fourier frequency domain and the wavelet frequency domain by the Fourier transform and the wavelet transform, respectively, if the band is halved to the maximum image frequency, the high frequency component disappears in the former case.

On the other hand, in the latter case, it can be said that the high frequency reproducibility is excellent because the high frequency component is preserved even when the latter is divided into the low frequency component. Moreover, it was found that this reproducibility depends on the support length of the basis function in the case of the wavelet descriptor, and when the support length is 2, it exceeds the Fourier descriptor in all cases of 4 or more. From the above, it can be said that the reproducibility of the geometrical description of the image by the wavelet descriptor under the same band limitation exceeds that of the Fourier descriptor.

V. FUTURE RESEARCH WORK

Further investigations are required for the validation of the proposed spatial feature extraction method with a variety of imagery data.

ACKNOWLEDGMENT

The author would like to thank Dr. Kaname Seto (former student of the Saga University) and Mr. Taroh Nakao (former student of the Saga University) for their contributions on this study. The author, also, would like to thank Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.
