Abstract—In Thailand, emergency illnesses are life-threatening conditions that constitute serious health problems and quick access to definitive care can improve the survival rate of the elderly dramatically. Currently, the pre-hospital emergency medical services have limitations which prevent the treatment from getting to the accident site on time. In this research, we proposed the A-SA SOS application, a mobile-and IoT-based pre-hospital emergency service for the elderly. The system helps the elderly to send the request to the nearest village health volunteers via a mobile application and smart device. After reaching the elderly, the village health volunteers help carry out basic life support to increase the survival rate before sending the patients directly to the Emergency Management System (EMS) agency. To evaluate the system, we tested it for three months in the Sub-district of Suthep in Chiang Mai city. Finally, the incident report showed that the average time to reach the scene (4.91±0.56) to help elderly patients was less than the standard criteria of an average 3 minutes.

Keywords—Pre–hospital emergency service; mobile healthcare; IoT-based healthcare system; elderly; healthcare volunteer

I. INTRODUCTION

Currently, Thailand has become an aging society. According to the Institute for Population and Social Research, Mahidol University [1], in 2018, there were approximately 11.7 million Thai people aged over 60, accounting for 17.6 percent of the entire nation’s population. It is extrapolated that the number of elderly will increase to 20 million in 2038. Emergency is a health problem that is common in elderly today. Apart from acute illnesses, chronic diseases, or geriatric syndromes, emergency illnesses can cause the elderly to become dependent or can lead to premature death. Based on statistical data reported during the year 2012-2015 of the Emergency Medical Institution of Thailand [1], the number of emergency illnesses increased annually from 1.1 million in 2012 to 1.3 million in 2015, 65 percent of all emergencies is caused by acute illnesses and 35 percent is caused by accidents. In addition, the deaths of the elderly who are emergency patients outside the hospital tend to increase every year [2][3]. It was found that there were elderly deaths before receiving emergency services in 1,436 cases in 2013 and it increased to 1,786 cases in 2016. Although the number of elderly patients who died before the arrival of an ambulance squad to the scene (Response Time) within 8 minutes or more than 8 minutes after receiving an incident report from an elderly patient increases every year, the number of the deaths of critical elderly patients is more related to ambulance squads that spend more than 8 minutes to arrive at a scene than the number of deaths of such cases where the ambulance squad responds within 8 minutes. The development of an emergency medical system to be effective is essential to save lives and reduce the loss, including the disability of an emergency patient. The development of a system requires planning that is ready in all aspects of knowledge, personnel and equipment, including the technology to be used cost-effectively and efficiently. Previously, the National Reform Steering Committee on Public Health and Environment, and the National Reform Steering Assembly have established the Emergency Medical Institution as the main agency for establishing a single number emergency call center, and the Ministry of Education to put contents about first aid, basic resuscitation, and road safety in the curriculum of secondary education. The National Reform Steering Assembly has also created the Organization of Local Administration to operate and manage emergency medical services outside of hospitals in the local area [6]. Besides, an Out-of-hospital emergency operations guide has been developed for all levels to guide the practice of medicine that must be under the supervision of a medical professional staff and as a guide for medical practitioners to supervise emergency operators who are not medical professionals [4][5].

Therefore, a mobile system of volunteers for the pre-hospital emergency service is developed to assist medical emergencies for the elderly in urban communities through the association of the Organization of Local Administration and to
develop the capacity of emergency volunteers in the area to be
able to provide pre-hospital treatment when an elderly person
is in an emergency situation. That can reduce the effects of a
severe illness that results in the elderly becoming dependent or
in a subsequent death. In addition, we proposed prehospital
emergency system called A-SA SOS which consisted of four
systems: the A-SA SOS Rescuer application, the A-SA SOS
erly application, the A-SA SOS Smart device and the A-SA
SOS pre-hospital data control center.

This research is organized as follows: Section I and II
covers the introduction and the related works of the pre-
hospital emergency system. In section III we propose the
system architecture of the pre-hospital emergency system.
Then, we evaluate the results of our proposed system in
section IV. Finally, in section V, VI we summarize our
research and discuss the future work.

II. RELATED WORKS

Mobile devices are present everywhere. Almost all of them
have a computing power that is similar to a personal computer
but their price is much lower. Their lightness is beneficial to
various researchers for utilizing them to improve the
effectiveness of rescue operations [7]. For instance, there is a
mobile application created to aid PEMS officials to convey to
patients with hearing loss [8]. They utilize mobile devices to
develop the system form for testing the rescue operations‘
effectiveness [9]. There is an electronic note system developed
for tablets used to record pre-hospital patient care [10].

The application called Emergency Medical Centre Locator
(EMCL) is developed to assist patients in finding the nearest
specialized emergency medical center. There are six specific
sections that the application emphasizes, including injury, eye,
cardiac, stroke, burn, and pediatric. This application is not
available for Android, only available for IOS systems. Even
even though its name and description seem like it can help the
patient find the nearest specialized emergency medical center,
the application does not work based on this method. It allows
the patient to find all the medical centers that appear and
choose the place that is nearby and appropriate for the
patient’s emergency case. Actually, this application’s function
might not be good enough to be used in an emergency
situation because of its inconvenience and because it takes too
much time for a patient who requires instant help.
Nonetheless, there is no genuine emergency help given as this
application does not offer any facilitations to a patient
emergency call for rescue and is unable to convey to physician
[13].

A model has been developed with the purpose of
supporting senior citizens’ healthcare and handicapped people.
The model is grounded on personal-centric sensing structure.
It offers the elderly and handicapped people with the service
that serves for emergency responsiveness when there is an
uncommon health condition [12].

Pre-hospital Emergency Notification System has been
developed for mobile platforms to enable the emergency
medical officials to notify a team in the hospital about
individual information of the incoming casualty and about the
seriousness of injuries of road accidents. Moreover, the system
is able to let the hospital officials learn about the information
of the incoming injuries. Pre-hospital Emergency Notification
System has been created for a mobile application, using 2
inventor apps, such as MYSQL and PHP [14].

There is a system created to assist the elderly to locate any
nearby medical place simply by using the information of a
mobile GPS locality along with access point. Furthermore,
they can observe users with a Bluetooth beacon. Hence, the
system will automatically evaluate users’ present coordinates
with the GPS or the information of a network system. This
means that the system can locate any nearby medical centers
or clinics from the database that stores the information about
the medical places‘ location [11].

III. THE PROPOSED SYSTEM

A. A-SA SOS Users

The A-SA SOS users are categorized into four types of
participants: elderly with smartphone, elderly with SOS smart
device, Village Health Volunteers (VHV), A-SA SOS officer.
In addition, the term “elderly with smartphone” refers to
elderly people who are familiar with using smartphones and
need medical emergency request for the rescue. “Participants
with SOS smart devices” refers to the elderly who are using
the SOS smart device instead of smartphone. “Village Health
Volunteers” (VHV) is a participating group who takes care of
the health of people in rural areas. A-SA SOS officer is the
person who manages the overall functioning of the system for
the elderly and the Village Health Volunteers.

B. System Architecture

The A-SA SOS application aims to improve the pre-
hospital emergency service for people living in urban cities.
The system architecture of A-SA SOS is shown in Fig 5. As
we mentioned before, there are four types of actors in the
system. For each actor, we proposed three system
architectures in order to improve the pre-hospital emergency
service, namely, A-SA SOS Rescuer application, A-SA SOS
elderly application and A-SA SOS pre-hospital data control
center. The details of each system can be described as follows:

1) A-SA SOS Rescuer application is focused on the
Village Health Volunteer user around rural areas near the
elderly people and it performs several functions as follows:
First, it receives the emergency rescue request from the A-SA
SOS elderly application via a cloud server then it uses the
elderly geo location to reach for a first aid and rescue
operation. Second, it enables to contact and point out the
elderly location and forwards it to medical equipment
transporters near the emergency site in serious cases. Third,
the application reports on the progress of the rescue situation
and transfers the elderly information to the A-SA SOS pre-
hospital center then the system contacts the hospital which is
suitable for the elderly. The A-SA SOSRescuer application is
shown in fig 1.
2) A-SA SOS elderly application is proposed to mainly focus on the elderly of traumatic and non-traumatic cases who live at home alone or are bedridden. The application consists of two types of rescuer platform.

a) A-SA SOS mobile application: This platform is designed for elderly who are familiar with using smartphone applications. The application was developed to send the rescuer request together with the geoinformation of the user, and it is designed to have only one button on the user interface. The application was developed by the Xamarin cross platform version 4.2 and it sends data to the cloud server by JSON data format via https protocol. The A-SA sos application is shown in fig 2.

b) A-SA SOS Smart device: The IoT-based platform for smart device is designed for the elderly who don’t use a smartphone. For this case, we developed a smart device based on an arduino with 4G sim card which sends data to the cloud server by MQTT protocol. The device is designed with one button on the center of the device in order to be usable in case of an accident. The A-SA SOS smart device is shown in fig 3.

c) A-SA SOS officers and the Resuscitation team: This web-based platform is to support the back-office for the A-SA SOS officers. In terms of the management system, we designed a system based on corporate management among elderly people, Village Health Volunteers and the Resuscitation team in order to manage the emergency cases of the elderly until it is confirmed that they accessed pre-hospital service.

d) A-SA SOS pre-hospital data control center: The core system of the pre-hospital support center was developed based on the cloud server consisting of three modules: First, the Broadcasting module is responsible for broadcasting the elderly information while they are in need of being rescued by Village Health Volunteers. Second, the Web-based Monitor Module is the core data center that computes the possible matches between the elderly and Village Health Volunteers and synchronizes it with the database system. Finally the A-SA SOS Management Module is responsible for querying information of all users in the system from the database. The overall system architecture of A-SA SOS is shown in Fig 4.

C. Procedure Scenario Example

In this section, we show the scenario of the procedure of how the A-SA SOS system works. The procedure consists of the steps to be followed if an accident or sudden illness occurs

1) The elderly pushes the rescue button of the application or the button of the smart device in case the user is not familiar with the smartphone, in order to call for rescue.

2) The data from the application or device used by elderly is sent to the cloud server then the Web-based Monitor Module is computed for the top ten list of Village Health Volunteers who are located near to the elderly.

3) The Web-based Monitor Module computes the distance between the geolocation of the elderly and that of all the Village Health Volunteers by the Haversine formula [15]. The equation (1) is described below.

\[ d = 2r \arcsin\left( \sqrt{\sin^2\left(\frac{\lambda_2 - \lambda_1}{2}\right) + \cos(\varphi_2) \cos(\varphi_2) \sin^2\left(\frac{\lambda_2 - \lambda_1}{2}\right)} \right) \]  

(1)
where
\[ \emptyset_1, \emptyset_2 \text{ are the latitude of point 1 and latitude of point 2 (in radians)} \]
\[ \lambda_1, \lambda_2 \text{ are the longitude of point 1 and longitude of point 2 (in radians)} \]

We filter the list of Village Health Volunteers to those not further than 1.5 kilometres and create a priority list of not more than ten volunteers. Then, the broadcast module sends the emergency case to the A-SA SOS Rescuer application.

4) In this step, the Village Health Volunteer who uses the A-SA SOS Rescuer application receives a notification of the geo-information of the elderly. Then matching between a Village Health Volunteer and the elderly is made depending on who pushed on the system first.

Please note that, in case the system is unable to make a matching to rescue the elderly within three minute two times in row then the resuscitation team or 1669 is responsible for the case.

From the procedure scenario f example, it can be seen how the elderly can benefit from our approach by using the A-SA SOS system. When an elderly person gets in an accident she can immediately contact the nearest village Health Volunteers and the resuscitation team or 1669. Also, officers can get all the information needed to rescue the elderly from the application. Most importantly, all these procedures can drastically reduce the operation time and greatly increases the survival rate of the elderly.

IV. EXPERIMENT AND RESULTS

This section shows the evaluation of our experiment and the result of the proposed A-SA SOS system. To evaluate the outcome, we carried out a pilot test of the A-SA SOS system in real situation for three months in the Sub-district of Suthep in Chiang Mai city. There were 236 participants totally, with 171 female (74.34%) and 59 male (25.65%) participants. From all the participants, there were 30 elderly who used the A-SA SOS Smart device. The statistics of the total number of time for using the emergency of our proposed system is shown in table 1.

From the usage of a medical emergency rescue system for the elderly in Suthep, Mueang, Chiang Mai, between August 1 - October 31, 2020, it was found that the emergency operations of Suthep Sub-District Municipality totally sent a medical emergency rescue for 226 times. Most of service users were under aged 60, total of 170 times, 45 times were elderly patients over 60, and 11 times were unable to specify their age. For the elderly, 62.22% were female and 77.78% lived in Suthep Sub-District Municipality. There were five causes of emergency medical services, including 1) illness, fatigue (non-specific) 22.22%, 2) Dyspnea 17.78%, 3) fall, accident, pain 15.56%, 4) cardiac arrest 11.11% and 5) unconsciousness, unresponsiveness, faint 11.11%. For the duration of the operation, it was found that the incident report time to the order time took 0.31 ± 0.09 minutes, the incident report time to departure time took 4.60 ± 0.64 minutes, and the incident report time to a scene took 4.91 ± 0.56. Minutes (Table 1).

From the results of this study, it can be concluded that the application of the medical emergency rescue system for the elderly in urban communities has been used to help the elderly report emergencies effectively and quickly and emergency rescuers could also reach the scenes faster. The medical emergency rescue system includes 1) A-SA SOS elderly application and smart devices were developed for the elderly to report emergency incidents. After reporting an emergency incident, the device sends signals via cellular wireless communication and notifies the location, and sends information to the emergency volunteer application (A-SA SOS Rescuer application) and the emergency volunteer center (A-SA SOS officers and Resuscitation team:). According to the device usage of the elderly for 3 months, it was found that the developed devices may be difficult to use for the elderly in terms of convenience, as the batteries last for approximately 15 hours, which must be recharged every day before the battery runs out. If the battery is completely discharged, the device must be turned on again. 2) The emergency volunteer application (A-SA SOS Rescuer application) is an application used for reporting and receiving emergency reports for general citizens and community emergency volunteers. This application is available only on the Android system, not on the IOS system. When evaluating the possibility of using the app, it can notify the incident time more quickly because the app will send signals to the application of a person directly and can tell the location of the emergency scene. 3) From the rehearsal of the aid system that has been developed, it was found that the incident report time to the order time was less than 1 minute, which was compatible with the standards of the National Institute of Emergency Medicine. Finally, the reported average time to arrive at a scene (4.91±0.56) when helping elderly patients was less than the standard specified criteria of 8 minutes with an average of 3 minutes.

VI. CONCLUSION AND FUTURE RESEARCH

In this research, we proposed the A-SA SOS system which consisted of a mobile and IoT-based healthcare application for the pre-hospital medical emergency rescue system for the elderly in urban communities. The main contribution of this research is to provide an effective management tool for the Village Health Volunteers to accelerate and improve the reach of elderly in order to give faster first aid during an emergency situation. In terms of evaluation of the system, we tested the A-SA SOS system for three months in the Sub-district of Sutep in Chiang Mai city. There were 226 medical emergency rescue cases in total and according to the incident report the average time to arrive at a scene was (4.91±0.56) when helping elderly patients which was 3 minutes less in average than the standard criteria.

In the future work, we first plan to improve the A-SA SOS Smart device in terms of convenience such as usability and extended battery lifetime. Second, we would like to test the system in the wider area of Chiang Mai and for a longer period than 3 months. Third, we plan to improve the application A-SA SOS Rescuer application to develop the automatic rescue request notification using a messaging platform API such as LINE, Facebook to provide health volunteers with more convenience when receiving elderly calls in emergency situations.
ACKNOWLEDGEMENT
